Welcome to Digital Humanities 2016

The annual "Digital Humanities" conference, first held in 1989, gives a clear proof that the field of DH is, first and foremost, very well established, even if more and more subfields emerge almost every year. Secondly, the conference confirms the fact that the discipline is constantly growing. This year is no exception. Even more: the 27th joint conference of EADH (ALLC) and ACH, and the 8th conference under the auspices of ADHO, is by far the biggest event in the field, with its almost 450 accepted submissions in different categories: panels, long papers, short papers, posters, and pre-conference workshops. The number of registered participants exceeded 850 at the time of writing these words.

The conference takes place in Kraków; this is only the second time (after Debrecen 1998) that it comes to Central/Eastern Europe. The region's rich past and its recent rapid growth has inspired the conference theme, "Digital Identities: the Past and the Future". This theme aims at stressing the very strong connections between DH and its roots in the medieval idea of a university with a prominent role of the Liberal Arts. We strongly believe that the unique relation between the origins of the humanities' scholarship and the opportunities provided by computer algorithms and the enormous amount of resources (text collections, linguistic corpora, databases, virtual libraries) can lead to a new scientific revolution.

Kraków, the venue of the conference, has been a major center of learning and culture in this part of the world: the Jagiellonian, founded in 1364, is usually ranked first among Polish universities, and the same is true of the Kraków's Pedagogical University within Poland's quite extensive community of pedagogical universities. No wonder, then, that the conference is hosted jointly by those two institutions: the Jagiellonian University and the Pedagogical University of Kraków. Their collaboration is a manifestation of the vivid digital humanities scene emerging in Poland's major centre of learning and culture.

I would like to thank all those who submitted proposals this year and all those who agreed to act as reviewers. The work load for the group of scholars who undertook the demanding task of reviewing the submissions was significantly higher than in previous years – I would like to thank them all for their great job. I would like to give my thanks to the members of the Program Committee, who this year included: Diane Jakacki (CSDH/SCHN), Michael Eberle-Sinatra (CSDH/SCHN), Jennifer Guiliano (ACH), Brett D. Hirsch (aaDH), Leif Isaksen (EADH), Asanobu Kitamoto (JADH), Inna Kizhner (centerNet), Maurizio Lana (EADH), Kiyonori Nagasaki (JADH), Roopika Risam (ACH), Glenn Roe (aaDH), Sinai Rusinek (centerNet) and Deb Verhoeven (aaDH). My special and warmest thanks go to the Program Committee Chair Manfred Thaller, whose contribution to the conference was simply outstanding. I also want to mention the Local Organizers, who were brave enough to suggest Kraków as a potential host for the DH conference, and efficient enough to make it happen.

Can CERN serve as a model for Digital Humanities?

Agnieszka Zalewska
Institute of Nuclear Physics, Polish Academy of Sciences

Nowadays CERN is perhaps the most recognized model of multinational collaboration in research. Created in 1954, it has given the international community some of the most fundamental insights into the essence of matter; and it has returned the investment in innumerable advances in technology. Its Large Hadron Collider is the world's largest particle accelerator; this is where the Higgs boson has been observed; and this is also where the Web was born to revolutionise the way we all communicate, as the DH community knows probably better than anyone.

CERN's success has always been attributed to its being a joint venture of an increasing number of nations. While it enjoys a stable status thanks to agreements between politicians, it would not have been possible without its visionaries; their vision extends from pure research to how people from all over the world and from a number of disciplines can work together and all contribute to that success.

Digital Humanities is equally and increasingly an international venture, as is evidenced, for one, by the map of past, present and future DH conferences. Here, too, people from all over the world, from various nations and ethnic groups, from very many scholarly disciplines want to work together. The lessons we have learned at CERN can help the DH community in terms of institutional organization and, more importantly, in the general approach to multinational and diverse scholarly collaboration.

Early Funding of Humanities Computing: A Personal History

Helen Agüera
National Endowment for the Humanities

From the 1970s to the 1990s, a time when funding opportunities for work in digital humanities were limited, the National Endowment for the Humanities (NEH) supported computer-based projects in several disciplines of the humanities. In this talk I review the agency's initial interest in the use of computer technology for research in the humanities. Through the lens of my experience as program officer for many of the early projects that employed computer methods, I discuss the transition from funding projects that used a computer as a tool to produce print publications, such as reference resources and scholarly editions, to supporting digital projects that published solely in electronic formats.

As digital projects became the norm in the humanities, the NEH extended its programs to support projects that address the needs of digital humanists, including development of digital standards, tools, and infrastructure. Besides describing these programs, I highlight NEH's collaboration with other funding organizations to facilitate work at the intersection of the humanities and the sciences. I conclude with some observations on the transformations that digital technology has brought to the conduct of collaborative research projects in the humanities and to the agency's evaluation process. (My presentation relates to my personal experience and does not represent the views of the NEH.)

Touching the interface: Bishop Cosin and unsolved problems in (digital) information design

Claire Warwick
Durham University

Some problems in the design of digital resources have turned out to be unexpectedly difficult to solve, for example: why is it difficult to locate ourselves and understand the extent and shape of digital information resources? Why is digital serendipity still so unusual? Why do users persist in making notes on paper rather than using digital annotation systems? Why do we like to visit and work in a library, and browse open stacks, even though we could access digital information remotely? Why do we still love printed books, but feel little affection for digital e-readers? Why are vinyl records so popular? Why is the experience of visiting a museum still relatively unaffected by digital interaction? The answer is very emphatically not because users are luddites, ill-informed, badly-trained or stupid.

I will argue that the reasons these problems persist may be due to the very complex relationship between physical and digital information, and information resources. I will discuss the importance of spatial orientation, memory, pleasure and multi-sensory input, especially touch, in making sense of, and connections between physical and digital information. I will also argue that, in this context, we have much to learn from the designers of early printed books and libraries, such John Cosin, a seventeenth-century bishop of Durham, who founded the little-known marvel that was the first public library in the North of England, and still exists, intact; one of the collections of Durham University library.

Panels

Playable Books at Electronic Literature's Interface

Katarzyna Bazarnik
k.bazarnik@uj.edu.pl
Jagellonian University, Korporacja Ha!art, Poland

Kathi Inman Berens
kathiberens@gmail.com
Portland State University, United States of America

Zenon Fajfer
zenkasi@wp.pl
Independent poet, Kraków, Poland

Susan Garfinkel
sgarfinkel@loc.gov
United States Library of Congress

For DH2016 with its theme of "Digital Identities: The Past and The Future" we propose a four-person panel in which we present the history of playable books (Garfinkel), the theory of playable books (Bazarnik), the artistic practice of playable books (Fajfer) and bookish aspects of digital literary games (Inman Berens). Together, we aim to demonstrate the procedural affinities between analog and digital modes of reading a literary interface.

This panel approaches the notion of play from the vantage of the physicality of books and what Johanna Drucker calls "performative materiality" (2013). When Espen Aarseth said in his 2015 keynote at the Electronic Literature Organization's conference that "games are the most important form of digital literature," it ruffled a few feathers. Here, we take Aarseth's provocation as a starting point from which we examine the past and future of what we call playable books. We will perform examples of digital and analog playable books, offering critical reflection toward developing a common language for methodological approaches across national languages and traditions, across analog and digital reading practices. The Digital Humanities 2016 conference is a unique opportunity to put global perspectives of ergodicity dynamically in dialog with each other. We expect, in other words, that our various types of expertise will co-mingle emergently as we "play" the works, isolate attributes, and foster conversation among the panelists and audience in this international venue. Liveness and co-presence are required to advance this form of cross-cultural communication.

All reading is situated and embodied. Throughout the history of the book, whether manuscript or mechanically reproduced, we see an ongoing tension in the moment of a reader's encounter with written work: between the abstract ideal of a text that stands on its own *sans* manifestations, and the actual instantiations of texts as books without whose affordance of interface the encounter would not be possible. Building on Aarseth (1997), Kirschenbaum (2008a; 2008b), Wardrip-Fruin (2010) and others, we note that the procedurality of playable books becomes newly and uniquely visible through the lens of computational materiality, that is, the turn to the digital. Books have always been random access portable storage devices. When Kirschenbaum argues that "new media cannot be studied apart from individual instances of inscription, object, and code as they propagate on, across, and through specific storage devices, operating systems, software environments and network protocols" (2008b: 23), we understand that such approaches prompt attention to the physicality of books. Jessica Pressman coined the term "bookishness" to describe "novels [that] exploit the power of the print page in ways that draw attention to the book as a multimedia format, one informed by and connected to digital technologies" (2009: 456). Zenon Fajfer (1999) describes "liberature" as literature which, in response to the digital media, foregrounds the shape and structure of the physical book as its semantically charged constituents. Hayles (2008) and Florian Cramer (2016) have separately written about the "post-digital" book, that is, printed books that manifest the aesthetic of Web and networked technologies, such as Mark Z. Danielewski's *House of Leaves* (2000).

As part of the first electronic literature showcase at the U.S. Library of Congress in 2013, Kathi Inman Berens and Susan Garfinkel selected sixty-nine books to contextualize the exhibit's twenty-seven featured works of electronic literature. This wide-ranging curatorial reach culled books that revealed various states of playfulness with the book's material form. While well-known examples such as *Choose Your Own Adventure* books and shaped poems ("concrete" poetry) emphasize unique aspects of playfulness and materiality, it was only through curating a set of books spanning hundreds of years and genres--and juxtaposing such books alongside the expressive interfaces of electronic literature--that a logic of playable books and electronic literature emerged. Not only did the books contextualize electronic literature, but the obverse happened as well: electronic literature's human/computer interface defamiliarized the book.

In the last years of the twentieth century, the printed book began to manifest attributes of digital art. In 1999 in the wake of "Booksday," an exhibition of unconventional books curated in Krakow by Polish writers and poets Zenon Fajfer, Katarzyna Bazarnik and Radoslaw Nowakowski, Fajfer suggested that books defying editorial conventions, whose linguistic content is inextricably bound with their material (printed) embodiments deliberately shaped by their authors, could be called "liberature." Initially juxtaposed with artists' books, liberature stresses the literary attributes of book-bound works, exploiting their semantically charged materiality. Although it began as a theory describing the codex form, liberature has strong links with electronic literature, through, for example, Fajfer's playable poems that are hybrid works combining the printed and digital interfaces, and Nowakowski's hypertextual, multimedia online narratives.

Also in 1999, N. Katherine Hayles published *How We Became Posthuman: Virtual Bodies in Cybernetics, Literature and Informatics*, a book that built the case for an interactive dynamic between seemingly disembodied information and the material substrates that convey them. These twin moves toward embodied experiences of reading suggest a parallel track between Polish and North American conceptions of reading abetted by experimentation in digital and networked environments. This is in tune with Jerome McGann's observation that "[t]he 'composition' of poetry is not completed--indeed, it has scarcely begun--when the writer scripts words on the page; and even at this initial moment of the imagination's work the scene is a social one. What kind of instrument is the writer using, what kind of paper?," which could be expanded to reflections about platforms, softwares, and mobile devices. These questions are central to understanding and interpretation of any work of verbal art, he continues, as they "are entangled with every textual network of meaning" (1993: 112). Each of the panelists will bring a specific focus to the history and future of playable books in theory and practice.

Susan Garfinkel will discuss examples from book history that display the mutability of the book as a version of Bakhtin's dialogic "world in the making" (1981). Laurence Sterne's *The Life and Opinions of Tristram Shandy, Gentleman*, for example, as early as 1759 made use of visual pastiche and typographic play along with its unusual plot, digressive presentation style, and literary borrowings. In 1804 and again in 1820, Thomas Jefferson famously cut apart and pasted up the Christian bible (Edwards, 2012). Working at the intersections of literary studies, media studies, and the digital humanities, Lisa Gitelman (2008) and Kirschenbaum (2008b), among others, have prompted media scholars to revisit the history of book materiality. Lori Emerson suggests that "by revisiting older media, we can make our current media visible once again" (2014: 130), while Kirschenbaum and Sarah Werner describe the digital within book history as "a frankly messy complex of extensions and extrusions of prior media and technologies" (2014: 408). Such awareness is enhanced by new scholarly attention to materiality, to the vibrancy of matter and the role of interpretation as mediation in the physical world (Trettien, 2013; Bennett, 2010; Appadurai, 2015). Looking back across decades and expressive genres for the precursors of electronic literature, we soon recognize an awareness of the dialogic mutability of the book itself, of its playable affordances that significantly predate the computer.

Katarzyna Bazarnik and Zenon Fajfer will focus on liberatic works and theory by exploring and expanding architecture of the codex, for example, in Oulipian *Cent Mille Milliards de Poèmes* by Raymond Queneau (1961), and their own , triple dos-à-dos of *Oka-leczenie* (2000, 2009), the book instrumental in defining the concept of "literature in the form of the book" in the central European context. However, liberature has also responded to digital technologies in various, subversive ways. In Fajfer's *ten letters* (2010), the poetic volume combining print and digital animation, it is paradoxically the material book that invites the reader to engage with the poems' visuality, to handle and manipulate the pages in a way reminiscent of Mallarméan 'espacement of reading,' ' *un espacement de la lecture*' (1998: 253). Its digital part, "Primum Mobile," accessible through the CD interface, is a piece blocked from the readers' intervention--they are only allowed to contemplate texts that infold and unfold in front of their eyes as an animated movie. In the spirit of playfulness its final section, "Spogladajac przez ozonowa dziure" ("Detect Ozone Whole Nearby") announces its further remediation as a "poem-in-the-bottle," with its text printed on a transparent plastic sheet placed in a glass container. Thereby, Fajfer's bottle-book seems to look back to the beginnings of book history, by taking on the form of the scroll. Lastly, his *Powieki* (Eyelids) (2013) is another bimedial work that seemingly, it returns to the traditional codex, yet textually is a densely linked hypertext that can be accessed via the printed or the electronic interfaces, offering readers radically different experiences of exploring the same cycle of poems.

Kathi Inman Berens will investigate the literary/ludic continuum in theories of ergodicity by Aarseth (1997), Ryan (2006), Laurel (2013) and Ensslin (2013) and examine how touch in electronic literature and playable books prompts new dimensions of liberatic engagement. Saleen and Zimmerman's *Rules of Play: Game Design Fundamentals* (2003) and the team of Robin Hunicke, Marc LeBlanc, Robert Zubek's MDA approach [Mechanics, Dynamics and Aesthetics] developed theoretical frameworks and critical language to unify conditions of play from board games to sports to computer and video games. Literary games don't figure in these discussions because they were developed before serious games initiated the hybrid literary game form. Jesper Juul's work on failure in games (2013) adds new analytic dimension to discussion of narrative, catharsis, pain, and reward systems pioneered in the work of Janet Murray (1999; 2012). Can one "lose" when playing a work of literature? Serge Bouchardon's "Loss of Grasp" (2010), winner of the 2011 New Media Writing Prize, has elicited scholarly studies among Polish literary critics applying liberatic theory and English-speaking literary critics examining literary games. A comparison of these methods could frame cross-cultural ways to analyze new works such as Inkle Studio's *80 Days* (2014), a tablet game based on Jules Verne's *Around the World in Eighty Days*, and Steve Tomasula's *TOC* (2009, 2013). *80 Days* was *Time Magazine*'s 2014 Game of the Year and also, tellingly, *The Guardian*'s 2014 Novel of the Year. This generic slippage between book and game is likely to become more common as book publishers venture into gameful environments, such as Doubleday's *Bats of the Republic* (2015), a playable novel featuring haptic elements. Berens analyzes the material book's ludic dialog with tablet-based digital stories.

Following a presentation of these varied approaches to the questions of playability and interface in books past and present, we plan a dialogue between ourselves and the audience. We conceive our conversation around the concept of playable books as a fertile starting point for thinking toward an expansively multiple understanding of agency and affordance in reading-playing, centered in acts of encounter for both the author-designer-creator and the reader-user-player. The ludic, performative materiality of all books, analog or digital, opens up inquiry across a broad range of hybrid instantiations: from children's digital literature including the Sony Wonderbook works, *The Sailor's Dream* (Simogo, 2015), and the *Mrs. Wobbles* series (Marino Family, 2013-present); to hybrid mass market haptic books like *Tree of Codes* (Foer, 2010), *Nox* (Carson, 2010) and *S.* (Abrams and Dorst, 2013); to app-based artists' books such as *Between Page and Screen* (Borsuk and Bouse, 2012), *Abra* (Borsuk, Durbin and Hatcher, 2014) and *Pry* (Tender Claws, 2013).

Administrative Challenges of a Global Collaborative Research Group

Joel Berkowitz

DYTP co-founder Joel Berkowitz will address administrative challenges facing a collaborative research group. These include the initial selection of group members, the division of labor within the group, articulating the group's mission and objectives, keeping activities moving forward in a timely fashion, managing effective communication among group members spread across a number of cities on two continents, working with partner individual organizations, and funding the consortium's work.

Data and the 'Obscurity' of Yiddish Theatre

Debra Caplan

DYTP co-founder Debra Caplan will describe the group's progress in creating a data model and database for a digital critical edition of a Yiddish theatre encyclopedia. Yiddish theatre data poses particular challenges, and our data model and database will need to accommodate relationships among individual actors, directors, and playwrights; hundreds of itinerant Yiddish theatre companies; thousands of geographical locations, often within rapidly changing national borders; a multilingual repertoire that often featured dozens of variants of a single play; literary trends in Yiddish drama; ticket prices and sale figures; cross-continental reviews; and other data related to the near-constant travels of Yiddish theatre artists across the globe. Caplan will discuss the potential of this data to document Yiddish theatre's broad impact on theatre history.

Capturing the Ephemeral: The Digitization of Yiddish Theatre

Agnieszka Legutko

Agnieszka Legutko will set the Digital Yiddish Theatre Project in a broader context of other Yiddish theatre-related digital attempts, often short-lived or only partially executed online projects created in the last decade or so. She will also discuss the unique potential of the Digital Yiddish Theatre Project resulting from its focus on specific content, collaboration of a diverse team of experts, and strategies for attaining social media presence.

Creating a Yiddish OCR

Aaron Rubinstein

Data mining, the computer analysis of large corpora, is an essential tool in contemporary textual analysis. For the humanities, Optical Character Recognition (OCR) has made this kind of analysis possible, rendering the text from printed, digitized works into a machine readable form. Though far from perfect, OCR has a high success rate recognizing roman characters but for researchers in the field of Yiddish studies, OCR engines that can recognize characters from the Jewish alphabet are still in the early stages of development. This presentation will discuss the current state of Yiddish alphabet OCR and a project that attempts to make use of existing tools and a variety of other strategies to provide machine readable access to a seminal Yiddish reference work.

Linked Ancient World Data: Relating the Past

Bringing together researchers from a wide variety of disciplinary backgrounds, this panel discusses the newly emerging ecosystem of Linked Ancient World Data projects and resources. One of the fastest growing areas of Digital Humanities, Linked Open Data (LOD) has the potential to transform traditional scholarship through its ability to promote the discovery of, and connections between, online documents of a highly varied nature (texts, maps, databases, images, etc.). Yet many barriers that are limiting its uptake and application, both technical and human, need to be addressed before this potential can be realised. This panel explores the issues relating to LOD, the semantic web and RDF technologies by focusing on three case studies drawn from the ancient world of literature, history and archaeology: the SNAP, Pelagios, and Integrating Digital Epigraphies (IDEs) projects.

Each of these three projects takes a different focus for their linking strategies: SNAP aims to connect documents through the people mentioned within them (prosopographies and onomastica); Pelagios through places (maps and gazetteers); and IDEs tackles different kinds of written material that survive from the ancient world (inscriptions and papyri). The projects are all united, however, in a concern for the use of, and access to, massive and diverse datasets that cannot be curated, aggregated or even archived in a single location. One major challenge to be addressed is the inherited scholarly infrastructure that tends to shoehorn multiple projects into a single institution's repository and data model. These projects and their participants are also concerned with issues far beyond their primary subject area: the interoperability of bibliographical references, citations of ancient sources, encoding of date and time, events and actors, material objects and their curatorial history all contribute to the study and understanding of the ancient world (and *mutatis mutandis* of any other). All also recognise that there is no firm demarcation between the cultures of the Mediterranean in the classical period, nor between the worlds and cultures bordering them in time and space. Data from the Bronze Age and Mediaeval periods can be read profitably in and against this classical focus; our sources do not exist in a vacuum that can be entirely insulated from the ancient Near and Far East, sub-Saharan Africa or pre-Columbian America, for example. The three papers in this panel will all discuss how they are deploying the formats and technologies of Linked Open Data to address the massive and multidisciplinary interoperability that these historical challenges require.

Networking Ancient Person-data: community building and user studies around the SNAP:DRGN project

Gabriel Bodard
Tom Gheldof
Faith LawrenceSimona Stoyanova
Charlotte Tupman

The Standards for Networking Ancient Prosopographies (SNAP: http://snapdrgn.net) project is using linked open data (LOD) to build a virtual authority list for ancient people through aggregation of common information from collaborating projects. A unified authority of ancient persons will serve as a convenient and powerful single resource for prosopographers, text editors and scholars to use for disambiguating person references by means of annotations that record the specific URI of a person identified by the SNAP graph.

The objective is neither to create a new universal dataset of historical persons, nor to ingest or supplant the many valuable prosopographical resources, both analogue and digital, created over the past many years. Rather, through the creation of a single entry point—and related identifier—coupled with a small subset of common fields made available both to human researchers and for automated processing, SNAP aims to facilitate interoperability and interchange, exploitation and discovery through common metadata, and the recording of both known and newly discovered relationships between person records. Users will be enabled and encouraged to (a) annotate their data with SNAP URIs to disambiguate person references, and (b) add structured commentary to the SNAP graph in the form of scholarly assertions, bibliography and apparatus.

This paper will outline our efforts to engage both the scholarly community and the wider public in the development of the SNAP model, and discuss the importance of user analysis and feedback into the design and functionality of the user interface and research tools. It is essential both for the utility of the project, and to encourage scholarly uptake in the person data and use of the virtual authority records, that we base our development on consultation with communities of our anticipated user groups, both scholarly and more widely.

In the first phase of the project, SNAP began to address the core issue of linking together large datasets containing information about persons, names and person-like entities (families, associations, deities, anthropomorphic animals) managed in heterogeneous systems and formats. Ambiguous co-referencing is a ubiquitous issue within the linked data world; how does a researcher or analyst determine whether two records refer to the same person or are related in some other way? Even more trickily, what other related information referring to one record can be said equally to apply to both people? The SNAP dataset attempts to address this issue by retaining scholarly metadata around the assertion of co-references and relationships, so that ambiguity, disagreement and academic justification can be recorded alongside all statements that can potentially lead to inference of new relationships.

SNAP models a simple structure using Web and LOD technologies to represent relationships between databases and to link from references in primary texts to authoritative lists of persons and names. The core of its source material was built around three large historical prosopographies and onomastica (databases of persons and names) from the ancient world: the *Lexicon of Greek Personal Names*, an Oxford-based corpus of some 300,000 persons mentioned in ancient Greek texts (http://www.lgpn.ox.ac.uk/); *Trismegistos*, a Leuven-run database of over half a million names and persons from Egyptian documents (http://www.trismegistos.org/); and *Prosopographia Imperii Romani*, a series of printed books listing senators and other elites from the first three centuries of the Roman Empire (http://pir.bbaw.de/). With several other more specialist databases of ancient and Mediaeval persons, museum and library catalogues, and digital editions contributing data or in the process of converting their data to the RDF format SNAP requires, the virtual authority will soon record well over a million person URIs. Due to the focus on historical datasets, we are able to address wider issues of dealing with person data without the ethical and privacy concerns raised by that gained from modern social networks. While still massive in scale, the amount of data under discussion is tractable, allowing for more academic coherence and review within the data, which, diverse as it is, is produced by a discipline with well-established working practices.

During this first phase, SNAP held a number of meetings and presentations to introduce the principles of and the preliminary work done by the project in its pilot period, and to hear from potential project partners about their datasets, practices and reactions to our proposals. These discussions led to a greater understanding of the nature of the prosopographical materials as well as helping to identify future partners. In addition, they provided the opportunity to advise participants how to present the relevant subset of their data for SNAP import in order to allow further datasets to be ingested, by demonstrating the *SNAP Cookbook* (http://snapdrgn.net/cookbook/) which sets out details of several scenarios for the encoding, publication and linking of ancient person data in RDF, and connecting them to the SNAP graph.

The second phase of the SNAP project focuses further on the ingest, creation and linking of a much wider range of person data, using a range of methodologies including named entity recognition (NER), both hand and machine-assisted curation of person references from large corpora including inscriptions and mythological sources, and the ingest of data from existing projects via prosopographical tool kits such as the Berlin-Brandenberg Academy's *Personendaten Repositorium* (http://pdr.bbaw.de/) and the Berkeley Prosopography Services (http://berkeleyprosopography.org/).

At the same time, we aim to enable a wider interchange of data and discovery of related materials as part of the larger Linked Ancient World Data community. In order to engage scholars and other interested parties in both creating and linking to SNAP identifiers, and to support and encourage the use of research tools and interfaces, we will hold a series of user analysis and engagement workshops, focusing on scholarly feedback on the SNAP web interface, API and widgets, the use of disambiguating annotation, and creation of and engagement with structured commentary. These workshops will help us assess and better understand the expectations and needs of our user communities with regards to both infrastructure and support, and sustained engagement with the project. User analysis is vital for developing an understanding of how users interact with the data and the current tools that are available for working with prosopographical data. We need to understand the goals and workflows of our user groups in order to meet their scholarly needs, and to create effective methods for attracting and maintaining engagement with the next phase of the project.

The issues being investigated by SNAP have implications beyond the bounds of this particular project: many of the issues such as variant name spellings, persons with changing or ambiguous names, uncertain identities and relationships, and tracking assertions about persons and the cascading inferences resulting from scholarly or editorial decisions, are precisely the same questions that concern both professional and amateur groups working on person-identification, including local historians, family historians, genealogists and graveyard conservationists. This has two major implications: first, as the work being done by SNAP is likely to reach far beyond its immediate subject area, this must be reflected in the way the project is conducted and disseminated to a variety of groups; and second, we must ensure that our user engagement workshops therefore include not only scholars but members of the public whose interests overlap with those of the SNAP project in these and other ways. This paper will seek audience discussion and advice about how best to ensure that the second phase of the project can meet such potentially diverse user needs.

Early Geographic Documents and the Pelagios Commons

Leif Isaksen
Rainer Simon
Elton Barker
Pau de Soto Cañamares

Pelagios is an international initiative concerned with the development of LOD methods, tools and services so as to better interconnect the vast and ever-growing range of historical resources online. Specifically, it uses the Open Annotation RDF ontology (http://www.openannotation.org/spec/core/) to associate place references within those resources to online gazetteers that offer URI-based identifiers for such places. The resulting graph is then exploited in a variety of ways to facilitate research, teaching and public engagement. The Pelagios 3 project expanded the scope of Pelagios dramatically from its original focus on classical antiquity, to encompass the early geographic documents of the pre-modern era, including early Christian, Islamic and Chinese traditions. It addressed three critical challenges for stimulating activity in these areas:

First, we developed user-friendly Web-based and Open Source software tools for the production and exploration of Pelagios LOD. Recogito (http://pelagios.org/recogito/) is a Web-based tool for the semi-automatic annotation of place references. It features several work areas, dedicated to different stages of the geo-annotation workflow: (i) a text annotation area to identify place names in digital texts or tabular documents (optionally aided by automatic Named Entity Recognition); (ii) an image annotation area to mark up and transcribe place names on high-resolution map or manuscript scans; (iii) a geo-resolution area, where identified (and transcribed) place names are mapped to a gazetteer, supported by an automated suggestion system. Recogito also provides basic features for managing documents and their metadata, as well as for viewing annotation results, usage statistics and bulk-downloading annotation data. Peripleo (http://pelagios.org/peripleo/map) is a spatio-temporal search engine for exploring the annotation data produced through Pelagios 3, as well as by the Pelagios community at large. Its user interface resembles that of Google Maps, and allows for free browsing as well as keyword & fulltext search, while offering additional filtering options based on time, data source and object type.

Second we carried out much annotation both in house and by independent contributors, so as to provide a 'critical mass' of annotated text and map documents that would attract contributions from other data curators. Over the course of the project 90 registered editors identified approximately 130,000 place references in 317 early geographic documents in 8 languages. About half of these were manually inspected for association with a gazetteer. Around 60 institutional or personal partners have contributed to Pelagios to date with a similar number expressing interest in doing so. We believe this offers substantial evidence that LOD approaches do not of necessity impose high barriers to entry, and on-ramps to semantic technologies can be offered at a varying levels of complexity.

Third, we developed a mechanism for enabling different gazetteers (each serving their particular community) to be interoperable, allowing for interlinking between data from divergent traditions. This has been achieved through the development of the Pelagios Gazetteer Interconnection Format which provides baseline requirements and optional additions for gazetteers to interoperate (https://github.com/pelagios/pelagios-cookbook/wiki/Pelagios-Gazetteer-Interconnection-Format). While such decentralized models for key infrastructure are both evolving and not without their challenges and risks, they offer significant potential for resolving conventional problems with enforcing universal standards across multiple domains and communities of practice.

Consequently, Pelagios has generated sustained and lively community interest, and has offered a pioneering model for other LOD initiatives which are semantically annotating different reference types from people to time periods, including PeriodO (http://perio.do/), SNAP (https://snapdrgn.net/), PastPlace (http://www.pastplace.org/) and al-Thurayya (http://maximromanov.github.io/projects/althurayya_02/). The success of the Pelagios approach has also attracted funding for academic research into early geographic documents through the Pelagios 4 project which is working with specialists in historical geography to identify both the advantages and limitations of semantic annotation for comparative studies and visual and statistical analyses. Topics span from the significance of hazard depictions on medieval portolan charts to the use of reliability of textual sources as proxies for the missing sections of the only extant Roman world map. In addition to this academic research, the SEA CHANGE project trialled crowdsourcing workshops for the use of semantic annotation in Higher Education in collaboration with i3 Mainz and the University of Heidelberg (http://pelagios-project.blogspot.co.uk/2014/11/bringing-about-sea-change.html).

In parallel with these developments a community of practitioners has emerged with interests in a range of related activities: the annotation of curated or third-party content; the production of specialist gazetteers; the integration of place annotations with those of people, periods and things; and the visualization and analysis of graph-based data, to name but a few. Since its early stages Pelagios has made concerted efforts to consult and support such stakeholders, but as it has grown new opportunities and challenges have emerged. In particular we have established that within a heritage context, one of LOD's key advantages is its ability to relate independently maintained projects without requiring a single centralized authority. But what are the social ramifications of such an approach? In a world in which funding criteria, academic legitimacy, intellectual property, and even conference presentations presume the authority of individuals and institutions, can LOD communities ever scale effectively? In order to do so individual stakeholders will need to shoulder responsibility for specific services within them. These may be the provision of content, real-time search aggregators, or dynamic real-time operations that offer visualization and analysis of heterogenous material. For some, reliability will be more important than complexity or innovation, while others will pioneer new strategies at the cost of longevity or broad usership. Negotiating the relationships between these stakeholders—technically, socially and legally—is perhaps the greatest task ahead for those seeking to establish Linked Open Data as a principal mechanism for drawing together, if not necessarily synthesizing, information about the past.

In addition to reviewing the outputs of Pelagios 3 and Pelagios 4, this paper will report on early developments within Pelagios Commons, a new phase of Pelagios which focuses explicitly on increasing its technical and social decentralization. This spans beyond its current pre-Modern and literary scope, in order to embrace later periods, differing scales of geography (from intra-urban to multi-regional) and the conceptual changes of dealing with arbitrary findspots and mythical, fictional and itinerant places. It will present our experiences in establishing Special Interest Groups, and the different challenges faced in devolving LOD architectures, as well as lessons learned from similar initiatives. In doing so we hope to foster discussion and critique from those planning or implementing related community-driven projects.

Acknowledgments: Pelagios 3 was funded by the Andrew W. Mellon Foundation. Pelagios 4 was funded by

the AHRC. SEA CHANGE received an Open Humanities Award from D2ME and the Open Knowledge Foundation. We thank all our financial supporters and content contributors for the collective production of this work.

Integrating Digital Epigraphies

Hugh Cayless

The Integrating Digital Epigraphies (IDEs) project aims to build on the lessons learned in the course of developing the Papyri.info project. The differences in the digital landscape between Greek Epigraphy and Papyrology are considerable, the main one being that, whereas many of the partner projects of Papyri.info were happy to permit that site to aggregate their data, IDEs will not be able to host partner data, but rather to collect citation and linking information with the goal of improving the links between the different Epigraphical sites. This paper will discuss the project, hosted athttp://ides.io and the part played in it by the Linking Ancient World Data Ontology, which may be found athttp://lawd.info.

What is a citation? It is a sequence of characters in a text that refers to something the reader may wish to consult. A citation is obviously a pointer of some sort, but what is it a pointer to? It depends: a citation like *Il 1.1* is a reference to book 1, line 1 of the *Iliad*, that is, it refers, notionally, to an ideal or composite Iliad, not to a particular expression. It is assumed that the first line of book 1 will be more or less the same in any edition. A citation like *IG I^3 40* on the other hand, is to a particular edition: number 40 in the third edition of the first volume of *Inscriptiones Graecae*. It points therefore to a particular part of a larger work. *S.C. de Bacch.*, to take a third example, is a citation of an actual inscription, not a publication of that inscription. Here, the citation refers to a physical object, and the reader is expected to be able to find a text of it if they wish to read the document.

Given all this, we must conclude that if a citation is a pointer, it is a very vague one. It may point to an abstract work, an actual (perhaps online) edition or part of it, or a real-world object with text written on it, but which the reader of the citation probably isn't expected to go and read in person. Further complicating the situation, the referring strings that comprise citations are subject to different formatting conventions: *IG I^3 40*, and *IG I[3].40* refer to the same edition, for example. Even more extreme variation is entirely possible, depending on the conventions used by the publications citing the source.

How do we model this situation then? Citations are strings that indicate resources or parts of resources, which may or may not be abstractions and may or may not have published editions, translations, etc.. The LAWD Ontology approaches this by modeling the Citation as its own RDF Class which may represent a written or conceptual work. Citations may have a value that is either a string, a URI, or both, and other properties may be attached to them as well.

In IDEs, Citations are the main component of the project. IDEs works by identifying epigraphic citations from a variety of sources, including the Packard Humanities Institute (PHI) site, the Diccionario Griego-Español's Claros project, and the Supplementum Epigraphicum Graecum (SEG). PHI contains the text of editions of Greek inscriptions, Claros collects pairs of citations where one source cites or updates another, and SEG publishes a kind of annotated bibliography of epigraphic publications. All of these manifest different citation practices, even though they deal with largely the same body of material. IDEs attempts to parse the citations from each project, match them up when that is possible, and present an interface and APIs that permit projects with epigraphic citations to retrieve related material easily. For example, if PHI wishes to find and display citations related to the inscription they assign ID number 40 to (*IG I^3 40*), they can query the URI http://ides.io/browse/ides:phi:40 which resolves to http://ides.io/browse/ides:t00003n (the IDEs ID or IDEst of the inscription itself), and from there they can retrieve machine readable data in JSON, RDF, or JSON-LD formats that could be incorporated into their own page at http://epigraphy.packhum.org/text/40. It would be possible, for example, to link to related articles in SEG, to display additional bibliography, to link to the corresponding place entry in Pleiades, and when we have incorporated data from JSTOR, to link to articles that mention *IG I^3 40*.

IDEs itself is a property graph database which uses RDF semantics without relying on an underlying RDF database implementation. This approach is intended to allow it to permit commenting on and editing relationships between the entities it tracks. RDF by itself has trouble attaching extra information to triples, requiring reification or the use of named graphs to do so. We hope that by imposing RDF semantics on a property graph structure, we can have the ability to attach additional metadata and commentary to relations without sacrificing speed or expressive capability.

Creating Feminist Infrastructure in the Digital Humanities

> Today, it is imperative that we develop an ideological infrastructure that both supports and facilitates feminist interventions within connective, networked elements of the contemporary world. [...] We want to cultivate the exercise of positive freedom – freedom-to rather than simply freedom-from – and urge feminists to equip themselves with the skills to redeploy existing technologies and invent novel cognitive and material tools in the service of common ends.
>
> (Laboria Cubonix, Xenofeminism: A Politics for Alienation)

Introduction

This panel considers how gender and digital infrastructures shape each other. Infrastructure can be described as that which creates the conditions of possibility for certain kinds of activities. In the context of digital humanities, infrastructure can refer to physical infrastructure such as servers, software infrastructure in the form of code or a software stack, organizational infrastructure such as a scholarly society, institutional infrastructure such as a DH centre, or methodological infrastructure such as a standard.

As is often observed, infrastructure tends to be transparent or invisible until broken (see Bowker and Starr), rather in the manner that ideological structures can blind us to systemic discrimination and gender bias. Rather than view infrastructure as a transparent mediation, feminist thinking invites broader questions around how we might address the social or relational aspects of infrastructure:

- How can digital infrastructure, as technologies of connection, support complex, non-binary understanding?
- How does a systemic approach to information infrastructure offer opportunities for a more systemic political critique within the digital humanities?
- How can we address the ways in which standards (such as the TEI encoding of sex [Terras]) and procedures ('organizing logic' [Posner]) embed values?
- What would an explicitly 'ideological infrastructure' look like? Is it desirable?
- To what extent can existing infrastructure be adapted for feminist ends and/or do we need to create new forms and instances of infrastructure to redress inequity?

The panel will be a hybrid of the panel- and multiple-paper session. Within each of its three sectioned themes, the panelists specified for a particular subtopic will have the responsibility to open up discussion with short statements of up to 7 minutes, followed by pithy responses from other panel members (who will have read the statements in advance) of up to 5 minutes in total, followed by an invitation to the audience to continue the discussion jointly with us. What is proposed, therefore, is not a series of 5 papers, but a set of interweaving engagements with each other and our audience that will make clear the connections between the component topics.

Training and pedagogical traditions

DH Training (Tanya Clement) Project-based research is often heralded as the site of work that defines DH. Indeed, in Willard McCarty's DH paradigm, the DH practitioner alone possesses 'an outsider's objectivity' and the 'performative ability to move in and out of disciplines, back and forth between duck and rabbit... while carrying its own intellectual load on its back' (136). Except, a feminist perspective based on situated knowledges (Haraway, 1998) teaches us that what liberates us from obstacles often blinds us to the opportunities that difficulties illuminate.

This rhetoric of 'mastery' over technology threatens an advancement of knowledge production from other perspectives, adopting what Haraway would call 'the standpoint of the Man, the One God, whose Eye produces, appropriates and orders all difference' (Haraway, 1988: 587). Further, training in project-related work arguably produces skills- rather than knowledge-based programs, and digital humanists professionals rather than researchers (Clement, 2012; Kraus, 2013; Mahony and Pierazzo, 2012). The debate about whether designing and building tools provides indispensable knowledge about information infrastructures is inflected by the concern that the ability to bridge the 'building' gap) largely reflects social privilege.

Clement will posit a contradiction between the presumed goals behind DH work, and the everyday practices of DH scholars and major DH education and training programs. In short, while scholars claim a keen desire to frame infrastructure development in the context of theories such as cultural criticism, feminist inquiry, and post-colonial critique, her investigation indicates that many training programs are not framed in these ways.

Community-based Training and Research Networks (Jacque Wernimont): FemTechNet is an activated network of scholars, artists, and students working on, with, and at the borders of technology, science, and feminism in many fields including Science and Technology Studies, Digital Humanities, Media and Visual Studies, Art, Gender, Queer, and Ethnic Studies. This networked structure works asynchronously and across local and international interventions. A major feature of our work is the series of Distributed Open Collaborative Courses (DOCCs) that recognize the complexities of the learning situation by designing platforms both locally and collectively. They represent new models from which many stakeholders will learn. The DOCCs are alternatives to the 'reform' efforts represented by the Massive Open Online Courses (MOOCs), which actually do little to change the status quo and can even be counterproductive when promoters oversimplify questions of access, underestimate investments of labor in instructional technology, deny the importance of infrastructure and its human and discursive aspects, and reinforce ideologies about technology being values-neutral.

In addition to curricular work, FemTechNet members collaborate on the design and creation of feminist technological innovations and in so doing extend our networked training into both traditional curriculum, apprenticeship, and non-hierarchical collaboration. Consequently, FemTechNet is a model of research and training infrastructure that foregrounds transparent and locally responsive structures, affords the ability to move up and back as time, expertise, and desire allow, and places feminist principles of equity, justice, and engagement at the fore. It is also a case study in understanding the labor, care, and resources necessary to maintain international cooperation and collaboration. We believe that our infrastructure is as expressive of our intellectual and ethical commitments as any content that we might produce, making the challenges of distributed online work around digital technologies not simply innovative, but also absolutely necessary.

Examples of feminist technical infrastructure

To give a sense of the array and complexity of infrastructural concerns, we will frame three quite different technical infrastructure initiatives in relation to feminism.

HuNI (Deb Verhoeven): HuNI, Humanities Networked Infrastructure, is a service that aggregates data from a broad range of humanities disciplines and institutional sources and makes them available to researchers and any members of the public with access to a browser (Verhoeven and Burrows, 2015). HuNI provides users the opportunity to build collections and propose a graph of relationships between records which in turn contribute to a HuNI network graph. As researchers themselves create the links between data, they also produce a kind of 'vernacular ontology' which, rather than providing an 'authoritative' model of the data, instead allows for diversity, complexity, interpretation and contestability. In this way, HuNI acknowledges 'difference' in the representation and organisation of knowledge and underlines the way in which gender (and other 'differences') are socially produced rather than empirical givens.

ARC (Laura Mandell): ARC, the Advanced Research Consortium, is the parent group overseeing and supporting NINES, 18thConnect, MESA, and the forthcoming ReKN and ModNets. These period-specific, online finding aids and scholarly communities work with traditional scholars to encourage digital production: they provide peer review for digital projects, and guidance along the way. ARC supports that work by hosting the web interfaces for these groups, the SOLR server feeding them metadata, providing the Lucene search engine that powers the online finding aids. ARC also coordinates with proprietary companies to import their data into these online finding aids in order to make them into comprehensive research environments. Finally, ARC is attempting to build a sustainability plan for the group by selling BigDIVA, the Big Data Infrastructure Visualization Application (http://www.bigdiva.org).

ARC is not explicitly a feminist infrastructure, but it is noteworthy that it was originally designed by a feminist, Bethany Nowviskie, and is currently directed by a feminist, Laura Mandell. It is possible, however, that the ethic of service and care is a form of stealth feminist infrastructure (Brown, 2008), channeling technological and social structures toward serving and educating the academy. Indeed, this infrastructure has a service focus: the period-specific groups attempt to serve scholars, to educate them about best practices in the peer-review procedure, to work with them in building up projects and creating metadata about those projects. ARC serves the period-specific communities so that they can focus on outreach to traditional scholars. At a recent two-day ARC meeting, including one or two directors from each period-specific group, we spent a full fifth of our meeting time discussing sexism and its impact on our work: the ARC board is made up of feminist men and women attempting to intervene in the way that the academy does its normal business.

CWRC (Susan Brown): The Canadian Writing Research Collaboratory is a feminist project in drag: built on a feminist recovery initiative (Brown et al 2006-15), it was a bid to gain infrastructure funding for several projects in women's writing, but its scope was strategically broadened and generalized to 'writing in and about Canada'. At least in 2009 in Canada, focusing on ostensibly neutral infrastructure was apparently a better strategy for gaining funding than a research grant application focused on women's writing. Hence 'drag': we weren't disguising who we were, but dressing ourselves up in infrastructural (read male) clothing, performing the 'neutral'. As a virtual research environment, CWRC tried to take on board the insights of scholars such as Lucy Suchman that we needed to design for situated, embodied, that is sexed and gendered, subjects. Nevertheless, the project struggled throughout with the divide between form and content, technical and subject expertise, that has largely characterized the division between the digital humanities and feminist scholarship, even as CWRC supports projects that investigate gender, race, nationality, and sexuality in diverse ways.

Infrastructure, collaboration, and credit

We will conclude by tackling the thorny question of credit, awkward though it is to articulate. Infrastructure development's implicit relation to service means that the development of research infrastructure is not considered research *per se* but rather is consigned to the role of research 'support' and is therefore not 'accountable' as a specific research outcome in a range of contexts. To materialize research infrastructure is a process that is clearly distinguished from the reality produced: a covert operation, not a recognized result. And yet the devising and development of new systems might equally be seen as the devising and development of their standards, measures, and meanings and the principles of their provenance in which the restless, transformative, and connective work of infrastructure can be understood as a form of inventiveness and interpretive resourcefulness too.

Collaboration is both highly prized in the digital humanities as a privileged, indeed essential (Price, 2011: 9) form of scholarly practice. Yet, we would contend on the basis of a number of stories arising from our own experience and knowledge of others', it is also fraught for women to the extent that their contributions are more prone than men's to be overlooked or misattributed. We will provide a few largely anonymized examples of having work misattributed, credit or authorship erased (or absorbed into a project identity), and contributions to fields ignored, followed by discussion of how to combat such tendencies.

The panel, we hope, will help to improve understanding of 1) the extent to which even something as apparently neutral or apolitical as infrastructure is imbued with gender and other socio-political considerations; 2) the impact of systemic gender and racial discrimination in a range of infrastructural contexts, notwithstanding the extent to which so many DH practitioners work hard to overcome the biases embedded in our cultures and our discourses; and 3) current and prospective strategies for countering those biases. We will seek to engage the audience throughout this session to include in the panel's discussions a broad range of perspectives on and positions in relation to infrastructure.

Successful infrastructure has the capacity to transform the world in which we already (co-)exist. Digital humanities infrastructure can open up new visions of the world in which we live, and invite contemplation of the different ways in which we might live, and work, in it.

This panel is devoted to two main questions: "How are the function and qualities associated with a scholarly edition changed when it is digital?" and "Is excellence in scholarly editing promoted by guidelines, articulations of best practices, enhanced peer review, or seals of approval?" The panel is intended for members of the scholarly editing community, whom it wishes to engage in dialogue about these matters, along with a wider audience of prospective scholarly editors and members of the DH community who are engaged with questions of peer review and how to foster best practices.

The immediate impetus behind the panel is "Considering the Scholarly Edition in the Digital Age: A White Paper of the Modern Language Association's Committee on Scholarly Editions" published by the MLA in Fall 2015. The primary purpose of the white paper is to define the major elements of the "digital scholarly edition" and explore their significance for the ways editions are read, used, and evaluated. Publication of the white paper, however, raised a number of related questions that we hope to explore through this panel:

- Are the following criteria fundamental to scholarly editing, regardless of school or approach: transparency, accuracy, appropriateness of method, clear and responsible documentation, and the exercise of critical judgment in representing a full account of the textual situation at stake?
- Can a communitysourced edition also be a scholarly edition?
- What is the point of scholarly editions, as we currently understand them, in an era of mass data?
- Editions can be situated within and draw upon a muchlargerscale text archive. How are such editions related to the larger archive?
- How might different traditions of editing be "networked" or brought together by digital means in relation to the same text?
- How do editions relate to largescale textual research? Must their representational precision and refined encoding be lost if aggregated through a mechanism like *HathiTrust* or *TAPAS*? How can their particular contributionthe depths of their insightsbe maintained when incorporated within a broader cultural analysis?
- How far might the criteria for exemplary digital scholarly editions actually also apply to exemplary digital scholarship?
- To the extent that the standards for digital scholarly editing are formalized and programmatic could a largescale digital scholarly corpus be produced largely algorithmically?

Peer Review

The discussion will then turn to the role of seals or hyperpeerreviews of digital scholarly editions in a range of scholarly communities and contexts as represented by the panelists.

A seal such as that awarded by the MLA Committee provides either added weight to peer review for those publishing with a press, or a potential alternative to peer review for editions that are not published by conventional scholarly presses. One would expect that with the shift towards digital editions the number of applications to the Committee would have risen. This, however, has not been the case. Panelist and members of the community of digital editors in the audience will be asked to assess the need for such seals of approval and to consider the adequacy of general guidelines such as the MLAs for editorial work.

Panelists will reflect on questions including the following:

- How do seals or peer review of digital editing projects operate in various contexts?
- Can a seal to something that doesn't reach closure in the usual way? How far along does it need to be?
- If the seal is awarded for one iteration of a project, how do we clarify what was award worthy and what later work is beyond the bounds of the award?

- Might best practices be better served by evaluating projects and their methodology at the beginning rather than the end of their lifecycles, so they have the opportunity to incorporate the results of the review to improve the project?
- If a lack of peer review has sometimes plagued digital scholarship, why have digital editors not done more to avail themselves of this kind of opportunity?
- Is the seal regarded as an additional burdenone more hoop to jump throughpotentially delaying production and unlikely to lead to increased sales of books or increased usage of a digital edition?

Panelists

- **Susan Brown**'s work focuses on borndigital scholarly production and the spectrum from regular scholarly activity to editing, particularly in relation to her leadership of the Canadian Writing Research Collaboratory virtual research environment. She recently joined the MLA CSE.
- **Hans Walter Gabler** will discuss networked editing. The native ground for the scholarly edition in our day, and for the future, is the digital medium. The scholarly edition as digital edition is to be conceived of as processual, relational, and interactive. To open it on and as a web platform is the public beginning of its life in the body of its texts and document images, their interrelation and diachronic stratification; and equally in its body of response texts (*vulgo*: commentary). Comprehensively, the digital scholarly edition should be a dynamic site for incremental enrichment through individual as well as communal research.
- **Fatiha Idmhand** or **Thomas Lebarbé,** as coordinators of CAHIER (Corpus d'Auteurs pour les Humanités Informatisation, Édition, Recherche), one of the consortia comprising TGIRHumaNum (Très Grande Infrastructure de Recherche Humanités Numériques), will address the consortium's support of digital editing projects through an initial application phase, followed by microgranta, training, and workshops. They will also address the role of CAHIER in the improvement of visibility and impact of the editions grouped under its umbrella.
- **Elena Pierazzo** will speak to the issue of standards in relation to her role as recent chair of the Text Encoding Initiative, and address the extent to which, in Europe, in general, where there are so many fragmented traditions and disciplines, the possibility of a single evaluating committee or set of guidelines is not feasible. Thus regular peer review and postpublication reviews are the norm. She will address the question of whether broad editing initiatives such as DiXiT (http://dixit.unikoeln.de) or the Nedimah research group on digital editions (which she cochairs) and the recently announced DARIAHEU initiative Living Sources might usefully contribute to formalizing certain standards.
- **Kenneth Price** will discuss the emergence of the white paper in light of the history of the MLA committee on scholarly editions. In an earlier printonly era the committee endorsed a single model of editing, the "critical edition." Now, at a time of both print and digital editions, and in a changed theoretical environment, the committee (through the white paper) endorses a diversity of additional approaches, including genetic and documentary editing. He will also discuss the challenges of awarding a seal to digital project that may well be later amended.
- **Ray Siemens**, as principal coauthor with Julia Flanders, will discuss the history of, impetus for, and basic thrust of the white paper, situating it in relation to earlier, iterative interventions by members of the CSE and our community among them Peter Shillingsburg's "General Principles of Electronic Scholarly Editions" (1993), Charles Faulhaber's "Guidelines for Electronic Scholarly Editions" (1997), the CSE/TEIC volume *Electronic Textual Editing* (2006), and its publication of guidelines and guiding questions for those preparing and evaluating editions in electronic form and more recent considerations, such as social editing.

This panel aims to stimulate a debate among the panelists and the audience about the challenges that the new requirements for the dissemination of research results and research data (often referred to as Science 2.0) is posing to researchers, information professionals and their institutions.

Digital technologies continue to reshape the way researchers do research. They are changing not only the way research is conducted, but also the way in which research results are published and disseminated. More and more legislators, funders, publishers, and scholarly research communities require that "research results" include curated and/or raw research data, methods and processes, tools and software, blogs and wikis, in addition to the "traditional" published material such as articles, monographs, conference proceedings, thesis, grey literature, etc..

In addition to that, we have seen in recent years the push (especially from the European Commission) towards the so called "Open Science", where all published material should be Open Access, i.e. freely accessible by anyone interested. The main argument in favor of Open Access is that most of research is being done with public funds, with research results and research data being produced in the public interest, and therefore they should remain publicly available. Of course, Open Access does not prevent commercial exploitation and protection of the research results and the research data, with patents and copyrights.

While there is a general agreement that Open Access is desirable and ultimately should be the main mode of publication, nevertheless its implementation still presents today a number of issues, made even more apparent by the additional requirement of publishing as Open Access also the raw material underlying the research process, generically indicated as "research data". The variety and quantity of (digital) information that needs to be processed, curated, stored, preserved, and made available in Open Access is posing new kinds of challenges to the researchers themselves (the data producers), to the information professionals dealing with that data (the data curators), and to the institutions responsible for the research activities and the data management (such as institutional repositories and libraries).

The issues range from technological issues (access to and interoperability of research data) to institutional and managerial issues (variety of institutional models and data management approaches), from financial issues (setup and maintenance of data infrastructures) to cultural and behavioral issues (reward structures as a necessary component for promoting data access and sharing practices)

Very often research in the Humanities has been done "in isolation", i.e. by a single researcher who gathers "raw data" (sometimes over many years) and based on them produces research results. More recently we often see that Digital Humanists are working in collaborative interdisciplinary team and could be willing to share the raw data, which are the basis for the research results. However, traditional evaluation criteria are an obstacle to this new behavior, as very often only traditional publication are recognized as such. In this context it is understandable the reluctance to publish also the raw data, as they could be the basis for further traditional publications, needed to get the desired recognition.

The panel will try to discuss some of the main issues related to Open Access to research data:

- Scholarly dissemination in the Humanities and in the Sciences
- The economic challenges of Open Access (Gold OA, Green OA)
- Interdisciplinary research and Open Access
- What are "research data" in the Humanities?
- Curation of research data (quality, accessibility, preservation)
- The role of university presses and academic/research libraries
- Publishing monographs or publishing in journals?
- Career issues and academic "reward system"

Each panelists will have about five minutes to present his/her views on some of the issues mentioned above, in order to stimulate a discussion among the panelists, which (hopefully) will trigger also a debate with the audience.

Atlanta might be best known around the world because it was burnt down during the Civil War. While many residents imagine that General Sherman's march to the sea is the reason we have so few historic buildings, the fact is the city has recreated itself repeatedly, knocking down the old and building the new. This trend has led many scholars interested in the city to turn to digital tools to better research and tell the stories of the city.

What started as a series of projects and platforms within the silos of departments and institutions at Georgia State University (GSU) and Emory, has turned into a broadly interdisciplinary network of Digital Humanities scholars and instructors across local institutions. This panel will explore the possibilities that arise when scholars in many disciplines from universities in the same city combine resources and begin to build projects and platforms with a local audience in mind. The panel will begin with an overview of the network, and then, one or two speakers from different institutions and disciplines will discuss each of the following sections. Each topic will be under 10 minutes to allow for discussion during and after each presentation.

Sharing collections

The first part of building our network began through dialogue between Emory and GSU scholars about digitizing archival collections, technical opportunities to produce and share spatial data and maps, and a search for ways to collaborate.

At Emory much of this process was centered on the digitization of a 1928 Atlas of Atlanta and Vicinity, which was the most comprehensive topographic mapping of the city. Over several years Emory students and staff produced a geodatabase with several thematic layers including the street networks, streetcar and rail lines, and building footprints to name a few. The digitization of map collections at Emory has opened new avenues to explore the original content and has amplified the opportunities in the area of digital heritage of Atlanta.

GSU's Planning Atlanta: A New City in the Making, 1930s – 1990s is a digital collection of material related to city planning and urban development in Atlanta. The collection consists of city planning maps and publications, demographic data, photographs depicting planning activities, oral histories, and aerial photographs. This NEH funded project sought to move beyond the traditional digital library model of simply providing digital equivalents of tangible objects. This city planning focused collection provides open access to digitally transformed, dynamic, and engaging content with the goal of enhancing this material for educational and research uses.

During the 1970s, GSU archaeologists, led by Dr. Roy Dickens, conducted excavations associated with the construction of the MARTA rail lines, a major city planning initiative. These materials, over 100,000 artifacts and all the accompanying documentation, represent the single most comprehensive archaeological collection of Atlanta's history. The new efforts to work with this legacy collection are dubbed the Phoenix Collection because, like Atlanta itself, this collection is being reborn. The collection's broader significance stems from the insight it can provide into the development of Atlanta. Because these archaeological materials have accompanying contextual data, they can more easily be connected with other datasets, such as development maps and historical texts, to create a more holistic understanding of the various processes that shaped the development of the city.

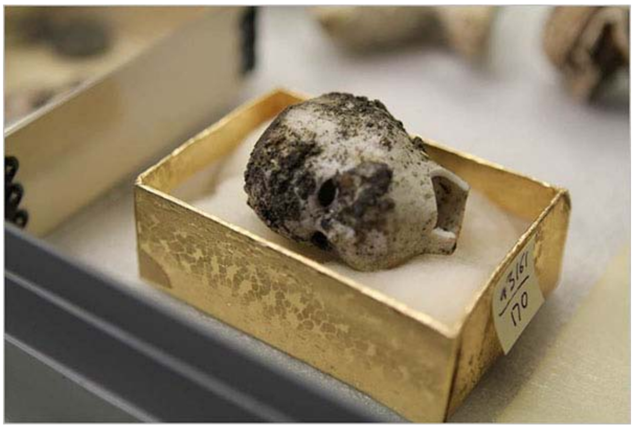

Figure 1. Doll head from Phoenix Collection.

Creating platforms

While digitizing material is crucial for research, making archives more available is only a first step. Instructors and researchers from diverse disciplines found the need to develop platforms for using, sharing, and curating data and archives from different collections.

Discussions about the projects between both institutions and the need to engage the public about Atlanta's history and contemporary scholarship led to the launch of the Atlanta Studies website, an open access, digital publication that any scholar of Atlanta can contribute to. The site hosts many of the projects that make use of the resources and platforms highlighted in this panel and provides a venue for cross-disciplinary work, collaborative institutional work, and public scholarship.

Drawing from the collections of GSU and Emory, the ATLmaps web application combines archival maps, geospatial data visualization, and user contributed multimedia location "pinpoints" to promote investigation into any number of issues about Atlanta. This innovative online platform allows users to layer an increasing number of interdisciplinary data to address the complex issues that cities pose. The project encourages knowledgeable members of the university and local communities to curate data on the site to demonstrate the possibilities for synthesizing material across projects, institutions, disciplines, and data types.

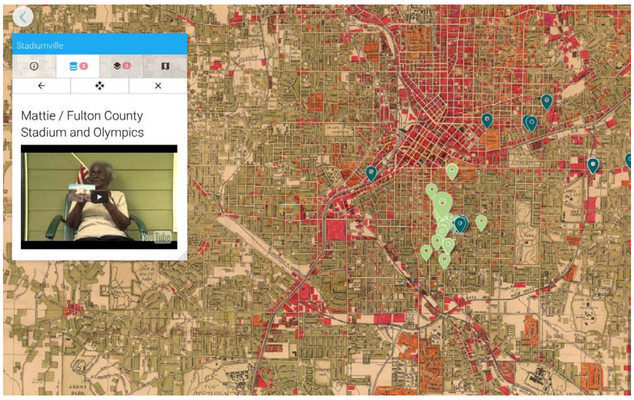

Figure 2. Screenshot of an ATLmaps project.

Emory's Atlanta 3D Explorer is an interactive virtual city circa 1930 built off the 1928 map. The application incorporates the data from the Emory produced geodatabases and historic geocoders in order to create an application that allows users to engage with the content at 3 levels, a map viewer of all atlas pages combined, a 3D city model, and an immersive 3D exploration environment. The third level provides an immersive experience that seeks to recreate street scenes around Atlanta.

In conjunction, a team of students at GSU began building an interactive and immersive 3D version of downtown Atlanta from the late 1920s. The project focuses on city blocks that GSU currently occupies and allows students to explore the history of the area using the Unity gaming engine. Classes in Archaeology, History, and English will eventually help in the research and construction of this 3D environment. Plans are currently being established as to how to integrate these two projects.

Developing a digital pedagogy community

The traditional research and communication skills generally taught in humanities disciplines are crucial to an undergraduate education, but it has become increasingly evident that digital literacy and citizenship need to be integrated into the curriculum. This need runs into the problem that in many humanities departments (where basic academic skills are often taught), digital scholarship is sometimes undervalued, underutilized, and misunderstood. Instructors experienced in or curious about using and teaching digital tools in their classes sometimes lack a community in their own departments or institutions. Atlanta Connected Learning is a collegial network of university faculty, staff, and graduate students from schools in the Atlanta area interested in digital pedagogy, scholarship, and networked collaboration. Since 2012 participants from ATLCL have been instrumental in organizing monthly digital pedagogy meetups, faculty development initiatives, and several smaller academic colloquia.

Developing a local studies pedagogy community

Students learn more if they feel the work they are doing is meaningful and has a real audience. As we have become more aware of ourselves as a network of scholars and instructors, we have begun to connect the Atlanta-based projects we are working on to classrooms. We are currently building a site to connect classes to local projects, resources, and experts that are relevant to the skills and content taught in various courses and disciplines. One example is GSU students in advanced multimodal composition courses are studying specific artifacts from the Phoenix Collection and are creating 3D digital surrogates of these objects through both laser scanning and Structure from Motion techniques. The Phoenix Project provides a visceral means of connecting with the public and bringing to life the past in a way that historical texts alone cannot.

Producing projects

The network that has organically formed over the past five years from the creation and combining of Atlanta-based platforms is now consciously developing projects based on the network that has formed across institutions and disciplines. Scholars, artists, and community leaders have started to contact and join the group understanding the possibility of developing massive projects that are only possible with a great deal of expertise, equipment, and labor.

The first project to intentionally tap into the resources of the network is Unpacking Manuel's Tavern. Students of history, political science, urban planning, sociology, film, architecture, computing and other disciplines will work independently or in the classroom to "unpack" the organic archive that has accumulated over 60 years on the walls of Manuel's Tavern, a bar that has played a significant role in the politics, culture, and history of Atlanta. Faculty and staff from local universities have created a gigapixel map of the tavern walls and a Unity-based 3D scan of the building. Students, directed by instructors from several disciplines, can then choose images they wish to research and compose content for pop-out metadata pages including text, video, interviews and links to other sources from local, national and international archives.

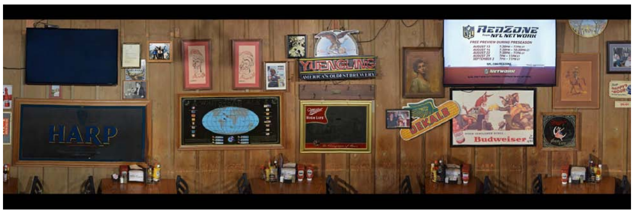

Figure 3. Screenshot of a Manuel's Tavern gigapan.

Digitally Mapping Romantic Literature and Culture

Christopher Donaldson

Lancaster University, United Kingdom

Session overview

This panel session showcases three thematically interlinked papers that report on the work of three digital mapping research projects. Each of these projects engages with specific geospatial methods and technologies to model geo-historical data. Each project, moreover, uses this data to shed new light on the literature and culture of the Romantic Period in Great Britain (c. 1780-1850). One of the projects uses a virtual globe to investigate the effect of movement on writing and authorial practice. Another combines corpus analysis and multimedia GIS to explore readerly practices of reception and spatial re-enactment. The final project engages with curating topographical and cartographic representations and extends the concern with writerly and readerly contextualisation to issues of broader diachronic relevance to literary historiography.

Collectively, these papers examine the links between the physical and discursive geographies of two of the key cultural landscapes of British Romanticism: the bustling metropolitan cityscape of London and the rural upland and coastal terrains of the English Lake District. In discussing the digital mapping of these landscapes, the papers provide new insights about these key cultural locations. In doing so, they extend the pioneering work of previous literary mapping projects, which have focused on the visualisation of authorial experience and on spatial querying of literary texts. Crucially, however, these papers move beyond previous research to explore how linking and juxtaposing different types of data can enhance the study of how places mediate the writing, reading, and critical reception of literary works. In addition, this panel conducts new explorations of the implications of creative mapping for literary criticism, engaging with issues of scale, genre, reception and the limitations and potentials of spatial analysis in humanities contexts.

The first paper, Joanna Taylor's "Path-making and Coleridge's 1802 Tour of the Lake District," uses the virtual globe environment of Google Earth to read the letters, notebooks, and verses related to the poet Samuel Taylor Coleridge's 1802 tour of the western and central Lake District. Taylor demonstrates how using the 3D environment of the virtual globe creates not only new possibilities for assessing Coleridge's journey, but also new possibilities for interpreting a number of canonical Romantic works concerned with walking and the movement of the body through space.

Building on this interest in mobility and path-making, the second paper, Dr Christopher Donaldson's "Deep Mapping the English Lake District," employs a prototype multimedia geographic information system (or "deep map") to explore the geographies underpinning the composition, publication, and reception of the poet William Wordsworth's topographical sonnet series *The River Duddon* (1820). In tracing the cultural influence of this emphatically geo-located lyric sequence, Donaldson's paper explores how digital deep mapping offers new insights about both Wordsworth's practices as a poet and about the material and geographical legacies of his writing.

Following on from this, Dr Matthew Sangster's paper, "Organising Romantic London," presents early conclusions from an ongoing online project that juxtaposes different works which sought to make sense of London by annotating Richard Horwood's "PLAN of the Cities of LONDON and WESTMINSTER the Borough of SOUTHWARK, and PARTS adjoining Shewing every HOUSE." In his paper, Sangster explores the ways in which different genres of source materials attempt to explain the nature of a city of over a million souls, contrasting often-alienated literary responses with the more positive topographical, antiquarian and visual accounts that processes of digital reclamation have brought back to light. He attends to the way that digital methods can help us both to explore the ways in which coherence can be imposed on urban spaces and to expose the limitations of such processes of ordering. In doing so, his paper reflects critically on the roles which digital media can play in preserving and making available archival materials and on the consequences of transforming old media into new digital forms.

Author biographies

Christopher Donaldson is Lecturer in Romanticism at the University of Birmingham and co-investigator on the Leverhulme Trust research project "Geospatial Innovation in the Digital Humanities: A Deep Map of the English Lake District" (2015-2018) and an associate of the European Research Council-funded "Spatial Humanities: Texts, GIS, Places" project (2012-2016). As part of these projects, he is currently completing a monograph entitled *A Literary Atlas of Victorian Lakeland* and a collection entitled *Literary Mapping in the Digital Age* (forthcoming 2016, with Ashgate's Digital Research in the Arts and Humanities series). He sits on the editorial board of the *Journal of Victorian Culture*, and is co-editor of the journal's Digital Forum.

Matthew Sangster teaches at the University of Birmingham and is currently completing the final elements of his first monograph, *Living as an Author in the Romantic Period*. He is Website Editor for the British Association for Romantic Studies and curates the association's blog (http://www.bars.ac.uk/blog/). Between 2008 and 2014, he catalogued the archive of the Royal Literary Fund at the British Library; he is currently developing the catalogue entries into a standalone database. He is working on two new and interrelated projects: one on the development of literary institutions in the eighteenth and nineteenth centuries and the other on the ways in which different genres of works represented London during the Romantic period. Early elements of this project can be seen on http://www.romanticlondon.org.

Joanna Taylor is Research Associate on the Leverhulme Trust research project "Geospatial Innovation in the Digital Humanities: A Deep Map of the English Lake District." She passed her PhD, entitled "Writing spaces: the Coleridge family's agoraphobic poetics," at Keele University in December 2015. She is the British Association of Victorian Studies Newsletter Editor and co-organiser of the ongoing digital project *Placing the Author* (https://placingtheauthor.wordpress.com).

Path-making and Coleridge's 1802 tour of the Lake District

Joanna Taylor

This paper will build on the work undertaken by three digital humanities projects: "Mapping the Lakes" (British Academy, 2007-2008), "Spatial Humanities: Texts, GIS, Places" (European Research Council, 2012-2016) and "Geospatial Innovation in the Digital Humanities" (Leverhulme Trust, 2015-2018). It will read Samuel Taylor Coleridge's (1772-1834) letters, notebooks and poems written on or about his tour of the Lake District in July and August 1802, and suggest how using digital maps to assess this journey opens out possibilities for innovative interpretations of a number of well-known Romantic texts. In particular, the paper will engage with the emergent field of walking studies to explore how physical movement – and its relationship to literary composition – can be productively emphasised using digital mapping tools.

Coleridge spent much of the summer of 1802 traversing the Lake District fells. In part, Coleridge used his pedestrian tour as an escape from his increasingly unhappy marital home, and his considerations of the Lake District landscape assisted him in analysing his personal situation. The "Mapping the Lakes" project charted Coleridge's route, as well as Thomas Gray's important 1769 Lakeland journey, and began exploring subjective elements such as the correlation between elevation and mood. The "Spatial Humanities" project developed from "Mapping the Lakes," and part of that project established a corpus of Lake District texts which now, as part of "Geospatial Innovation," are being analysed using both macro and close reading techniques in order to reveal how text and landscape mutually impacted upon each other. Coleridge's 1802 tour has remained a central text throughout these projects, and this paper will use it as a case study to demonstrate how the digital methods established by this project series can be applied to readings of texts in order to reveal hitherto concealed or unacknowledged elements.

This paper will combine these digital methodologies with approaches from the emergent field of what the cultural geographer Ceri Morgan has termed "walking studies" (2015). Walking studies consider movement through spaces, in ways that may or may not be bipedal, in order to reveal how this movement impacts upon day-to-day lived experiences. As this paper will seek to ascertain, the texts Coleridge produced during and inspired by his 1802 tour – including notebook entries, letters and "Dejection: An Ode" – deserve to be recognised as seminal texts in the walking studies canon.

Coleridge's walking tour enabled him to "command" new territory – both visually and poetically. Whilst climbing up Red Pike, Coleridge considered the relationship between movement and independence: "every man his own path-maker – skip and jump – where rushes grow, a man may go." It is well-known that Coleridge did not restrict himself to the Lake District's already established tourist trails, preferring instead to set off cross-country. As this paper will explore, the diverse terrains he covers are registered in his writing; in particular, his notebooks – which function here as pedestrian journals – indicate his attempts to replicate his walking experiences, both via the way he lays out his entries and his formation of disjointed sentences that attempt to mimic his mode of travel. The paper will aim to demonstrate how these textual embodiments of walking experiences might be recreated or reimagined digitally by interrogating the implications of the 'path' from a multi-disciplinary perspective: literary, geographic and digital.

"Path" is a slippery term. In his famous essay "Walking in the City," Michel de Certeau identifies the path – and, by extension, 'path-mak[ing]' – as one of the crucial modes of operation in constructing space (for de Certeau the imaginative conception of the physical place). He writes that the "intertwined paths" created by footsteps "give their shape to spaces" and "weave places together." Walking, then, is an act of construction in creating the pathways that define spaces. As Paul Cloke has argued, these theories might now productively be applied to non-urban spaces, too. Coleridge's path-making anticipates de Certeau's belief that constructing one's own path is an important means by which to internalise place for imaginative use. Furthermore, Coleridge's accounts of his path-making emphasise the connection de Certeau makes between walking and writing. There is a "rhetoric of walking," de Certeau writes, and this "rhetoric" is constructed through forms and figures in much the same way as a literary work. Furthermore, paths constructed by walking can – indeed, should – be "read" as a literary pursuit.

For de Certeau, the map does not allow for the necessary recognition of the importance of "intertwined paths" to place making. The map displays a set of power relations that inevitably subordinates individual experience. This paper will argue that digital maps offer a way of visualising and re-assessing the role of the path in place making. It does not seem coincidental that the structuring feature of the computer system is also the path: that is, the route to a file, folder, website or other digital destination. Furthermore, programs such as Google Earth draw attention to the connection between computer and physical pathways. Google Earth allows for the creation of "paths" which can digitally trace the physical path created by the walker, and walking websites (such as www.english-lake-district.info) have begun exploiting the potential of Google Earth in facilitating physical walking experiences. This paper will use Google Earth to map such a path of Coleridge's route in the summer of 1802. It will explore the extent to which this kind of digital path can vicariously recreate the physical act of path-making. By combining analysis of this digital path with Coleridge's written accounts of his tour, this paper will uncover a relationship between literary form, terrain and physical movement in ways made uniquely possible by combining literary study with digital techniques.

Deep mapping the English Lake District

Dr Christopher Donaldson

This paper reports on work undertaken as part of the Leverhulme Trust research project "Geospatial Innovation in the Digital Humanities: A Deep Map of the English Lake District" (2015-2018), which is answering the call for scholarship that models the implementation of deep mapping in historical and literary studies research. In this paper, I propose to use a prototype digital deep map to attend to the geographies underpinning the composition, the publication, and – in particular – the reception of William Wordsworth's topographical sonnet series *The River Duddon* (1820), which outlines a journey along one of the Lake District's most important rivers.

Deep mapping involves the accumulation and layering of different kinds of geo-locatable media within a geographic information systems (GIS) environment in order to facilitate investigations of the material, discursive, and imaginative geographies that inform our conception of a location's topography and sense of place. In helping to trace the cultural afterlife of the Duddon sonnets, in particular, the prototype deep map presented here affords insights not only about Wordsworth's reception history, but also about the sense of place communicated in his sonnet series. What is more, the deep map also enhances our understanding of how that sense of place changed and developed through creative re-appropriations during the later nineteenth century.

First published in 1820, Wordsworth's *River Duddon* sonnets have long been recognised as the first sonnet series in English to allow the course of a river to govern the entirety of its design. Wordsworth's sonnets harness the forward-flowing momentum of the lyric sequence to carry the reader on a journey down the river, from its source on the slopes of Wrynose Pass to its estuary. The note that Wordsworth uses as a preface to the sonnets sketches out the itinerary pursued by the series:

> The River Duddon rises upon Wrynose [F]ell, on the confines of Westmorland, Cumberland, and Lancashire; and, serving as a boundary to the two latter counties, for the space of about twenty-five miles, enters the Irish sea, between the isle of Walney and the lordship of Millum [sic].

Each sonnet in the *River Duddon* series moves in succession through this landscape, marking a different spot beside the river and directing the reader's attention to specific landmarks along the way. From Wrynose Pass and Cockley Beck to Seathwaite, Ulpha Kirk, and Swinside, and then finally down to the Duddon sands, Wordsworth's sequence encourages the sense of a continuous journey that carries the reader downstream, at the poet's side, along a single route.

The organic relationship thus developed between the sonnet series and its subject encourages the sense of a continuous journey that conducts the reader from the upland centre of the Lake District to its coastal periphery. Responding to this, readers and literary tourists across the nineteenth century sought to follow Wordsworth's sonnets and to map them onto the landscape of the Duddon Valley. This was accomplished with varying success, for although the *River Duddon* sonnets follow the course of the river (moving in a steady progression), many of the individual sonnets in the series are difficult to locate with precision.

In this paper I will use the deep map to explore these readerly and touristic efforts to locate the geographical sources of Wordsworth's sonnets. My main focus will be to demonstrate how the multimedia GIS environment of the deep map can help us to contextualise the accounts of these readers and tourists alongside other works of literature and visual art that Wordsworth's *River Duddon* sonnets inspired. Specific examples to be featured include the essays and photographs of the Victorian Wordsworth enthusiast Herbert Rix (now held at the Wordsworth Trust in Grasmere), Canon Richard Parkinson's 1843 novel *The Old Church-Clock*, and the sketches of the Duddon valley that R. S. Chattock completed for the Fine Arts Society's illustrated edition of the Duddon sonnets in 1884.

In implementing this approach, this paper indicates the broader ambition of the "Geospatial Innovation" project: to make a major intervention in the application of geographical technologies in the study of the creation and reception of literary works of art. Building on the work and outputs produced as part of the European Research Council-funded "Spatial Humanities: Texts, GIS, Places" project, my aim is to use deep mapping as a means of addressing challenges raised by the application of geographical methods and technologies in literary studies scholarship. A critical issue the project has set out to address is the widely perceived incongruity between the methodologies of geographic information science – with their reliance on precise, quantifiable data – and the kinds of equivocal or "slippery" information with which literary scholars typically engage.

Deep mapping presents a solution to this impediment. The concept of deep mapping emerged out of the psychogeographical experiments of the early French Situationists in the 1960s. More recently, the term has garnered popular interest through the American author William Least Heat-Moon's study *PrairyErth: A Deep Map* (1991), which employs composite, multimedia methodologies to investigate the cultural and historical geographies of Chase County, Kansas. As Least Heat-Moon's *PrairyErth* suggests, deep maps are both topological and relational. Like conventional paper maps they reveal spatial networks that tie locations together. Unlike conventional maps, however, deep maps attempt to record the artefacts, narratives, and memories that underpin those locations and, therefore, shape our understanding of them as places.

Since the appearance of *PrairyErth*, deep mapping has been applied to describe new, exploratory approaches to digital geospatial research. For example, David Bodenhamer and his team at the Virtual Center for Spatial Humanities, Indiana University—Purdue University Indiana, define deep maps as "visual, time-based, and structurally open." "They are," Bodenhamer continues:

> genuinely multi-media and multi-layered. They do not seek authority or objectivity, but involve negotiation between insiders and outsiders, experts and contributors, over what is represented and how. Framed as a conversation and not a statement, deep maps are inherently unstable[.]

Shelley Fishkin, at Stanford University, advocates for a similar conception of the practice:

> Deep maps are palimpsests in that they allow multiple versions of events, of texts, of phenomena (both primary and secondary) to be written over each other – with each version still visible under the layers. They involve mapping, since the form of display – the gateway [. . .] – would be a geographical map that links the text, artifact, phenomenon, or event to the location that produced it, that responded to it, or that is connected with it.

Fiskin's notion that "deep maps are palimpsests" is very salient. There is, after all, an analogical relationship between deep maps and GIS technology: the former is a multi-layered spatial representation; the latter is a tool for integrating layers of geographical data. Exploiting this relationship, the "Geospatial Innovation" project aims to move deep maps from the printed page into a digital environment by harnessing the power and flexibility GIS to store, organise, and visualise a wealth of visual and verbal media. Focussing on the example of Wordsworth's *River Duddon* sonnets, as outlined above, this paper will report on the progress of this research.

Organising Romantic London

Dr Matthew Sangster

In the late eighteenth and early nineteenth centuries, writers producing the kinds of works which we would now call literary were often very sceptical about London. Percy Shelley constructed a considerable part of his poem *Peter Bell the Third* around what for the city is a very unflattering comparison:

> Hell is a city much like London —
>   A populous and a smoky city;
> There are all sorts of people undone,
> And there is little or no fun done;
>   Small justice shown, and still less pity.

While earlier in the eighteenth century, poems such as John Gay's *Trivia* had been able to dwell entirely within the bounds of London, and had found a great deal that was positive to say about the city, late eighteenth and early nineteenth century literary works commonly only dipped into the metropolis, finding the task of systematising either too daunting or not to their tastes. The London poetry and the London poets of the earlier eighteenth century to a large extent fell away, and it was not really until the 1820s, with works like Pierce Egan's *Life in London* and new periodical forms like Charles Lamb's Elia essays, that writers of literary prose moved to take up the nineteenth-century city as a principal subject. Frances Burney's character Evelina circles into London twice to see two quite different sides of metropolitan life, but the city ultimately serves as a place of education through which she must pass rather than as a final destination. William Godwin's Caleb Williams flees into the city (or, more properly, into Southwark), but finds there only temporary and melancholy succour from which he is soon dragged away. William Wordsworth spends a book of the *Prelude* dealing with his residence in London, but he does so in manners which often deflect away or recoil from the city's profusion. When Samuel Taylor Coleridge imagines 'gentle-hearted Charles' from his lime tree bower, he sees him as someone who has "pined | And hunger'd after Nature, many a year, | In the great City pent, winning thy way | With sad yet patient soul, through evil and pain | And strange calamity!" London here is a blockage rather than a solution, a failure of connections rather than a place of fruitful exchange, something that must be overcome rather than a community which sustains.

However, increasingly specialised literary modes of writing were not the only sorts of works which sought to deal with the metropolis. Poetic and fictional accounts wrote back against a wave of topographical and antiquarian accounts which were increasingly seeking to glorify the city. Where poems and novels saw London's size as obstructive and its scale as almost impossible to represent, non-fictional and illustrative accounts of the city commonly perceived its vast scope to be an opportunity. The author of the advertisement to the 1804 volume *Modern London*, probably its publisher Richard Phillips, claims that his book will "exhibit the very soul of the Metropolis [...] Most of the busy haunts of the inhabitants, whether for the gratification of ambition, avarice, or pleasure, have been exactly pourtrayed [sic]; and these views convey at once correct ideas of places which interest from their celebrity, and of scenes which characterize the manners of the people." While Phillips does not claim that London's soul is by any means pure, he does contend that it is graspable – that the city can be characterised and understood, rendered down into a comprehensible and useful written form. For this reason, among others, confident sources like *Modern London* can be enormously useful for accounting for and questioning the gaps left by literary disaffection.

One of the most impressive of the many textual and visual attempts at encompassing London at the end of the eighteenth century was the "PLAN of the Cities of LONDON and WESTMINSTER the Borough of SOUTHWARK, and PARTS adjoining Shewing every HOUSE" produced at considerable financial and personal expense between 1790 and 1799 by the surveyor Richard Horwood. The physical Plan consists of thirty-two printed sheets displaying an area stretching from the middle of Hyde Park in the west to Limehouse in the east and from the southern edge of Islington in the north to the southern fringes of Kennington and Walworth in the south. When assembled, the full Plan is more than thirteen feet across and over seven feet from top to bottom. In its original form, therefore, it is like the city it represents: sprawling, unwieldy and extremely difficult to parse.

The Romantic London website (http://www.romanticlondon.org) seeks to alleviate some of these difficulties through digitally transforming the Plan. The site hosts a detailed tiled version drawn from a source copy in the British Library. This is layered over Google Maps and Open Street Map and can be annotated with text and images (this is done using a straightforward Wordpress plugin). The site makes the Plan generally available, bringing it out of the archive and allowing users dynamic control over its size and scope. It also curates the plan by bringing it into conversation with other means of ordering and organising the metropolis from the late eighteenth and early nineteenth centuries.

As Horwood's Plan and the intertexts which the site pins to it both eloquently demonstrate, London was a prospect both radically and conservatively different from any other contemporary urban or rural environment in Britain. Its quantitative scale mandated qualitative differences which encompassed systems and complexities which had not yet developed, or which were deemed unnecessary, in less extensive urban environments. At the time of writing, the Romantic London website includes a number of means by which contemporary auditors sought to understand the city: plates from Rudolph Ackermann's *Microcosm of London*; plates and text from Richard Phillips' *Modern London*; and text from *Fores's New Guide for Foreigners* and the 1788 edition of *Harris's List of Covent-Garden Ladies*. (I plan to add more curations in the coming months.) Making the geographies implied in these texts explicit through marking them on Horwood's Plan allows us to see the patterns of attention and inattention which they encode. Comparing different curations can bring to light hot and cold spots within the city and can show clearly the varying priorities of different stakeholders in its identity. When put into conversation with less geographically-specific literary works, other kinds of texts can reveal the roles that generic conventions played in shaping London, with other types of writing and visual representations both filling a gap left by literature's retreat from the city and providing key contexts for its eventual reengagement. Modern accounts of London are disproportionately shaped by privileged literary writings; neglected non-fictional accounts can therefore play key roles both in complicating negative literary views of London and recovering the occluded histories of the less fortunate.

The paper will conclude by considering the opportunities and challenges presented by digital remediation for understanding material and media histories. While a digital version of Horwood's Plan is very convenient in many respects, its creation represents an intervention that transforms the Plan's original form in ways that occlude some of its characteristics (size; physicality) and that provide new characteristics unavailable to its original users. Similarly, making texts and images into explicitly geographical systems has considerable implications for their meanings. The digital has the potential to conceal as well as to reveal, and in concluding, I will briefly discuss the ways in which informed curation can serve both to minimise the losses inherent in digital transformation and to maximise their potential for creating new tools and insights which can reify the deeper histories which previous media have encoded but concealed.

Digital humanities has been positioned as an amorphous and fluid concept (Kirschenbaum, 2014), particularized in various disciplines, national contexts and even local environments (Galina Russell, 2014; Fiormonte, 2015; Earhart, 2015; Risam, 2017). Yet intact structures that include the annual digital humanities conference, the various global organizations that form ADHO, and journals published by the various societies represent the field as a coherent body of practice. Ruptures at recent conferences reveal the deceptive constructedness of a coherent digital humanities. What we find, instead, is that digital humanities is deeply divisive and fragmented. Such ruptures were apparent at the 2013 Nebraska conference where the 2014 conference organizers announced an all male keynote lineup;[1] the 2013 conference where the awards committee admitted publicly that they made an error in the graduate student awards selection and had not considered gender, resulting in a skewed awards field;[2] the 2015 conference where the conference program featured an announcement of the all male board of the Frontiers in Digital Humanities journal; or the 2015 conference where the opening set of seven speakers were all male.[3] In light of this recurring theme, our panel examines how digital humanities, as represented by the yearly international conference, is a digital humanities that elides the borders of practice, that masks areas of dissension, and normalizes the field to a particular homogeneous form without contour.

This idea is supported by the conference programs themselves. Scott Weingart's analysis of DH2015 makes clear that "The DH conference systematically underrepresents women and people from parts of the world that are not Europe or North America" (2015). Gender representation in the digital humanities conference is a galling problem. As Weingart's analysis shows, 46% of attendees to DH 2015 were women, but only 34.6% of authors were women (2015). Weingart further notes the data collection challenges of applying quantitative analysis to race, ethnicity, or other categories of identity. Ultimately, though, whether gender, topic, language, nationality or a combination of both, the DH conference has a problem in that the public structure of digital humanities does not represent the depth of work occurring within the field nor its practitioners. The problem is compounded by the treatment of such ruptures as aberrations, temporary mistakes by individuals rather than structural to the makeup of the conference. Furthermore, the organization siloes "diversity" as a committee matter or special interest (GO::DH, MLMC, diversity committee within PC, etc.), rather than a central concern or the universal interest of an organization with global ambitions, an organization whose goals "are to promote and support digital research and teaching across arts and humanities disciplines, drawing together humanists engaged in digital and computer-assisted research, teaching, creation, dissemination, and beyond, in all areas reflected by its diverse membership" (ADHO, 2015). In part this is caused by our insistence on understanding digital humanities as a big tent or a monolithic entity or field, ignoring the ways that digital humanities is practiced in its localized and cultural environment. Whether it is the way that gender, race and ethnicity, and nation are addressed (or not), how funding works in varying countries, the permanence or impermanence of jobs, and other such structural differences, participation in the international DH conference suggests that digital humanities is, in many ways, a living term, ever evolving, ever shifting in response to particular pressures of scholarship, the academy, national and political contexts, and the individual.

A great deal of social science and psychological research has revealed that such struggles are increasingly a problem for organizational groups such as scholarly societies, and that there are productive strategies for engaging diversity questions (Fredette 2015, Plaut 2010). Further, research suggests that a "colorblind" or gender blind response to organizational structures place great strain on the organization and that ignoring issues of difference negative impacts both group dynamics and quality (Apfelbaum, 2012; Dezso and Ross, 2012; Ely, 2001; Nishii, 2013). We will be discussing such findings in relationship to positive, process oriented approaches within the digital humanities conference structure.

Our panel consists of an international group of digital humanities scholars who are invested in a broad understanding of difference and digital humanities. The panel will discuss current tensions within the field and strategies for negotiating the structural challenges to the DH conference and ADHO itself. Of particular concern will be an examination of how the digital humanities conference understands its relationship to the quality of an international scholarship that is inclusive of a broad range of research topics. Panelists will consider topics that include the challenges of negotiating a wide linguistic field, the affordances and limits of quantitative approaches to diversification, practical positive actions that can be taken as part of the work of the program committee, and other pertinent topics. In doing so, they propose an asset - not deficit- model for developing diverse programs that more accurately represent the heterogeneity of digital humanities.

Organization

The panel will open with a 5 minute statement by Amy Earhart, the chair, situating our comments within the above stated context. Each speaker will provide a ten minute statement that will address:

- Barbara Bordalejo, intersectional feminism, the challenges of the majority language and the cultural norm;
- Isabel Galina, peer review, language and perceived quality;
- Alex Gil, translation/multilingualism in the service of trans-cultural equity;
- Lorna Hughes, 'the extra academic professions': the shifting communities of practice in digital humanities, and understanding and recognizing collaboration;
- Roopika Risam, the challenges of quantifying diversity; and
- Melissa Terras, the challenges of managing gender issues in the work of the Program Committee.

After the opening statements, the panel will engage in a discussion with those in attendance. We imagine that our community has much to say about such issues and would like the panel to be a place in which to begin this discussion.

Notes

[1] Sukanta Chauduri was invited to keynote the conference, the first keynote speaker from the Indian subcontinent, and an important addition to what would have been all Global North male keynotes. At the same time, the lack of a woman keynote speaker suggests the difficulty in balancing a broad set of diversity issues.

[2] The 2013 awards committee publicly admitted their mistake and corrected the error, a highlycommendable action. However, the structural issue remains. We must consider how to develop policies and procedures to avoid replicating such oversights.

[3] The twitter stream of past dh conferences document these incidents and the digital humanities community's reactions. Introduction

The methodical discussions on *distant reading* (Moretti, 2013) or *macroanalysis* (Jockers, 2013) have contributed to the awareness of quantitative methods in literary studies, a discipline which many assumed to be the last (and impregnable) stand against the onslaught of quantitative approaches in the Humanities. But actually this late fame is built upon many years of research. Over the last decades, research has been done on style, on aspects of the fictional world like plot and character, on aspects of text groups like genre or historical discourses etc. Most of the research in these fields follows by and large an empirical paradigm. Thus the situation in literary studies is structurally similar to the situation in social science disciplines like psychology or sociology in the past. All of them were using mainly hermeneutical approaches (including some anti-hermeneutical approaches using the same basic methods) until at some point new researchers introduced empirical methods into the field. Interestingly enough, in each case the adoption of empirical methods and the restructuring of the discipline followed its own logic and produced a unique history. In psychology, non empirical methods have been marginalized, and in sociology there is mix of quantitative and qualitative research. This very rough outline does not do justice to the many negotiations and disruptions in the fields, but it is enough to substantiate a point: the adoption of empirical methods in literary studies will probably also be a rather unique story. At the moment, we are right in the middle of it. It seems that empirical methods applied to one or very few texts haven't yet yielded results interesting to larger parts of the fields – with the notable exception of stylometry – while their application to many texts opens up new research possibilities interesting to many. As far as we can see, literary studies is thus in a similar position as some other disciplines in the humanities, they also have their own history of adoption of empirical methods (like linguistics) or are now right in the middle of it.

In this situation, this panel wants to reflect on one aspect of this process: what happens to central concepts of a discipline in these negotiations and disruptions. We want to discuss questions like these:

- Do literary concepts change when DH researchers use them in their (empirical) research?
- If they change, how does this change look like? Can we see commonalities beyond the individual research problems marked by the concepts?
- Using concepts from literary studies in quantitative methods seems to foreground the aspect that many of these concepts are compound and complex notions while empirical research has a pull towards simple, clearly defined notions. If this is true, how do the results of empirical studies translate back to the hermeneutical field?
- Can DH researchers contribute to the ongoing theoretical discussions of these concepts at all and how?
- And finally: Does this tell us something new about the implications DH research has on theoretical concepts from the Humanities?
- We will discuss these question on the basis of five concepts: Genre, Translator, Text, Character and Topic. Each of these concepts has played a role in a sequence of studies using quantitative methods and thus they provide an excellent basis for the theoretical questions we raise.

Text

Maciej Eder

Text as a theoretical concept became obvious for the librarians in ancient Alexandria, who realized that various copies of the same literary work tend to differ, in terms of several textual variants introduced in various papyri (Turner, 2014). This led to the idea of the *archetype* (an ideal representation of the "original") that shines through *imperfect copies*. Since then, philology became an art of textual archeology, where the editor played the role of a demiurge and the author's advocate. In the era of electronic resources, this concept has changed substantially, not only in digital scholarly editions, but also in quantitative text analysis. Traditionally understood as a vehicle of (hypothesized) authorial intention, the text became a sequence of characters bearing some information. A careful philological attitude towards author's words was replaced by: (1) distant reading, which in fact means analysis involving *no reading* at all, (2) focusing on the most frequent words rather than on elaborated rare vocabulary, (3) distorting the original word order by applying the "bag-of-words" model of analysis, (4) high tolerance to textual errors, e.g. imperfect OCR. Such a deep redefinition, however, allows for assessing the history of literature on an unprecedented scale (Moretti, 2013; Jockers, 2013).

Genre

Karina van Dalen-Oskam

Main literary genres such as poetry, play, and novel are divided into different subgenres (mostly called "genres" in daily use). The advances in digital corpora and stylometric tools have broadened the genres that are being studied. Science fiction researchers Nichols et al. in 2014 severely criticized genre theory, stating that it has made 'little tractable progress answering the questions "what is a genre?" and "How is one genre distinguished from others?" in the previous decades'. Nichols et al. discussed the development of a methodology to test genre-related hypotheses in a verifiable and falsifiable way, focusing on science fiction and fantasy. They made use of readers' responses and text analysis to find out how subgenres can actually be distinguished. Elsewhere, Jannidis and Lauer (2014) presented a quantitative analysis in which genre played a role. Using Burrows's Delta on (amongst others) the work of Goethe, they showed that this highly successful method for authorship attribution also works well in distinguishing genres, confirming research by others in this area. This should lead to renewed attention for what a genre is and how genres can be distinguished, thus fulfilling what Willard McCarty wrote in 2010: "Computing machines and scholarly intelligence change each other, recursively".

Character

Fotis Jannidis

The concept of "character" has been intensively researched in the last 20 years. Building on (or fighting against) ideas from the 1960s and 1970s there have been proposals to conceive "character" more as sign or more as a mental model. In digital literary studies there have been attempts to apply these results directly (Zöllner-Weber, 2008), preserving the complexity of the models but basically presupposing a manual analysis of the text. Social network analysis on the other hand provides tools to analyse many and complex social networks and has been applied successfully to plays and novels offering an insight into character constellations (Elson et al., 2010; Trilcke and Fischer, 2015). In this context the question how to identify references to characters in a text, which seemed trivial to traditional literary studies, has been researched in depth emphasizing the difference to named entities in non-fictional texts like news (Elson, 2012: chap 2.4). A recent attempt to address the issue of character types (Bamman et al., 2014) also shows the widening gap between the different modes of modeling literary concepts which will make it difficult to introduce these results into the mainstream discussion on characters.

Translator

Jan Rybicki

Already some of the earliest ventures into the stylometry of translated texts focused on the balance between the translatorial and authorial voices. For a while, it seemed that Venuti's concept of translator invisibility (1995) found vindication in stylometric analysis: in machine-learning classification experiments, translated texts tended to group according to the original author rather than the translator – surprisingly so, since the results were based on translator-generated most frequent words that have little one-on-one correspondence to those in the original (Rybicki, 2012). The application of new visualization methods such as network analysis has allowed to bring out the signal of the translator. The main challenge now is to identify the mechanism of the interaction between the two. Possible directions in this respect include expansion of linguistic features used in analyses, comparison of topic models obtained for originals and their translations, application of text reuse detection tools to translations of the same text and, at the same time, further attempts to bridge the gap between empirical evidence and linguistic theory.

Topic

Christof Schöch

When topic modeling (Blei, 2003) was transferred from information retrieval in expository prose to literary studies, it brought with it the promise of a sophisticated access to the themes in large collections of literary texts. However, "theme" and "topic" are far from identical (Schmidt, 2012; Rhody, 2012): rather, the semantic relation between words grouped in a topic may concern, among others, personnel, setting, narrative motives, or metatextuality as well as (depending on preprocessing) character names, specific registers, or foreign-language terms. Usually, only a minority of topics represent abstract themes. This can partly be explained by the fact that literary texts, unlike expository prose, frequently enact rather than explicitly discuss their most important themes. It also shows that, unlike literary scholars, topic modeling does not distinguish background and foreground information. Finally, the fact that topic modeling is entirely unsupervised and data-driven challenges established hermeneutic strategies. Nevertheless, it seems that established concepts from literary studies such as motive, setting, personnel and metatextuality may help better appreciate the complexity of topic models derived from literary texts. While literary texts challenge any simple understanding of topics, literary studies appears well-equipped to deal with their complexity.

Abstract

This panel aims to address the important issue of how we as Digital Humanities scholars negotiate and present the sensitive data (textual, archival, geospatial) that constitutes the core of our analyses. The public facing nature of our work reveals significant challenges that have to do increasingly with access and ethics, and in many cases cause us to reassess how we conduct and disseminate our research. A number of topics pertinent to this issue are addressed in this panel, informed by case studies offered from the panelists' own work. Points of discussion will include, but not be limited to: the negotiation and presentation of sensitive data, access to sources and resources, collaboration, and ownership. In addition to presenting case studies, this panel will incorporate an open dialogue among attendees that addresses these issues across a broader array of research.

Research Ethics in DH

Many of us who work in the Digital Humanities are in some way negotiating, mediating, remediating, and publishing sensitive data. We use the term "sensitive" in a broad way: sensitivity has to do with data that is physically difficult to access because it is privately held, fragile under restrictive copyright, or regards peoples or places that are affected by its use. While our community is opening up new opportunities to digitize, analyze, and share archival materials, the very publicfacing nature of our work reveals significant challenges that have to do increasingly with access and ethics. In many cases, digital methods and approaches make the data upon which we rely even more sensitive. How do we take into account the possibility of risking damage to an artifact in order to digitize it? How do we negotiate rights to data and metadata that has until now been held privately and closely or that involves dozens if not more authors and artists who are still alive, or whose literary and artistic executors have established different parameters for publication? How do we act responsibly when the very publication of a personal work even one that on the surface seems not to impact upon a group of people or a place because of its historical nature may have a profound impact on the lives of those peoples' descendants or the sanctity or environmental protection of those places? The pillars of digital scholarship data visualization and markup, large corpus literary analysis, and geospatial analysis are all complicated profoundly by these questions and sometimes deter us as scholars from working with the very materials we rely on to do our research.

Case Studies

This panel's five contributors work with distinctly different types of data, utilizing a variety of approaches from across the spectrum of digital methods:

Spatial Data

Katie Faull's work with culturalhistorical spatial data in the Susquehanna river watershed has led to a role as mediator between Native American nations and Federal, State and local agencies. Her work regularly raises ethical questions about how data pertaining to sites and landscapes that are carriers of cultural identity and memory for indigenous peoples should be protected from destruction, while at the same time presented to the public as part of important negotiations about conservation. Working with present day Native American nations about the interpretation and conservation of landscapes that are deeply culturally significant, frequently demands delicate negotiations about access and protection and exemplifies the tightrope that many DH researchers must walk. For example, within the realm of Public Humanities, how do we protect indigenous knowledge systems and simultaneously educate the nonindigenous public about those knowledge systems. Her presentation will outline how she and her team of researchers have had to convince archaeologists, for example, that cultural sites can be interpreted within a broader environmental context, thus widening the focus of the cultural historical interpretive lens. At the same time she negotiates with indigenous peoples how to best represent their views of this broader environment. This paper will also discuss how the US Department of the Interior's new landscape conservation initiative (one that is garnering international recognition) may provide a bridge between access, protection and ownership of indigenous cultural memory.

Historically exploited cultural communities

Amy Earhart's work in digital critical race studies has led her to develop community collaborations. However, historical abuses of communities present formidable challenges for those who seek to develop partnerships with vulnerable populations. Earhart will address the challenges that those interested in developing equitable partnerships for collaborative projects might encounter, with particular attention to power dynamics between universities/colleges and such communities using her project The Millican "Riot," 1868 (http://millican.omeka.net) project as a lens through which to discuss how trust and protection might be built into digital projects and how decisions, from project team to technological platform, impact the equitableness of the partnership. In addition, she will discuss strategies for removing control from the academic and the academic institution and, instead, positioning the project within a community or activist site. Finally, she will discuss the use of creative commons licensing including the TK: Traditional Knowledge License and Labeling license (http://www.localcontexts.org) which ensure that historically exploited communities maintain ownership of their material and intellectual property.

Text Analysis

James O'Sullivan's work in computational analytics deals with literary datasets that, while not necessarily restricted, are difficult for peers to replicate. Literary datasets are particularly susceptible to computational approaches, and the new insights that such techniques reveal have the potential to add considerable value to our core disciplines. However, in research contexts where the subject matter is as culturally and socially sensitive as it is intriguing, scholars are presented with an ethical dilemma as far as data is concerned. Many of the works used in macroanalyses are often still under copyright, and so researchers are prohibited from sharing the texts. This restriction precludes our peers from doing two important things: validating our findings, and offering further iterations of our work. Considering the effort that is required in digitising certain datasets, our discipline is fast becoming one where much of the work that claims to be empirically valid cannot in fact be validated. Much of our field's research is conducted on datasets which take the researchers years to acquire and digitize. If datasets are not shared and oftentimes they cannot be replication requires sufficient time and institutional support, and is thus infeasible. As a result, the field has no realistic mechanism by which it can query the validity of methods and interpretations. Should scholars who create datasets hold power over digital artefacts of cultural significance? How can we validate the new insights being offered by scholars in our field? Should we, as scholars, sacrifice access in the name of exploration, or do we need to at least strive for balance between the two?

Intellectual Property

Diane Jakacki's work as a coordinator of digital humanities projects involves collaborating with researchers whose scholarship often entails significant contributions across disciplines and institutions. In addition, the digital nature of this work necessitates the longterm commitment of institutional resources. As this digital scholarship becomes public, questions about intellectual property rights become increasingly complex. Reflecting the nature of DH as a primarily collaborative mode of intellectual work, traditional models of solitary or individual production no longer work. DH collaboration requires teams of investigators, collaborators, data specialists, and research assistants; it often spans years and involves team members across institutions and international borders. The humanistic tradition honors the primacy of the scholar in terms of intellectual property. But as DH methods and forms of labor transform scholarship models, defining primacy becomes ever more complicated. Who is the scholar? Who owns the artifacts that embody DH scholarship? Who makes those determinations? As DH scholars we (rightly) resist any idea that our work is not our own; but do our institutions understand this the same way?

National Security and Public History

Micki Kaufman's work involves the text analysis, data visualization and historical interpretation of the National Security Archive's Kissinger Collection, a carefully curated set of meeting memoranda (memcons) and telephone transcripts (telcons) spanning the 9 years of former US Secretary of State and National Security Advisor Henry A. Kissinger's tenure (1968-1977). Her research into the source material and the methods she has employed to obtain and study it, confront and engage complex issues of copyright and public domain, open access and classification, legality and violence. Through a process of creative deformance of text analytics data (collocation frequency, topic models and other abstractions of text), she uses an aesthetic, visual approach to study patterns and surface complex questions of emotional motivation and behavior, intent and suppression. What ethical features apply when one asks questions about a deeply controversial historical subject's intent and behavior via statistically based text analysis methods, using declassified public domain material from a still classified correspondence, curated by a nonprofit institution and obtained from behind a corporate paywall? From the provenance of the material to the intent of the subject, and from the actions of the declassifying agencies and authorities to the research method, Micki's work examines the ethical underpinnings of the relationship between historian and narrative, setting and subject, word and byte, secret and free.

Digital Data Sharing: Opportunities and Challenges of Opening Research

Natalie Harrower
n.harrower@ria.ie
Digital Repository of Ireland, Ireland

Rebecca Grant
r.grant@ria.ie
Digital Repository of Ireland, Ireland

The data generated in the course of digital humanities research is a valuable resource, with the potential to allow collaborative research and the enhancement of researcher profiles through its publication and re-use. Researchers in the sciences have a longer standing practice of sharing research data, although the pathways to making this data open, discoverable, and interoperable are still being explored. This panel aims to introduce researchers to concepts and best practices in research data management, and to explore the specific challenges and opportunities of research data publication for digital humanities.

Research data is defined as data from any academic discipline which is the subject or product of research. This data may be qualitative or quantitative in nature, and can include documents, spreadsheets, databases, field notebooks, diaries, AV material, transcripts, digital models, algorithms, code, scripts, software applications and other formats. The impetus for research data publication is often closely linked to the principle of Open Access which states that the outputs of publicly funded research should be made openly available and accessible for interrogation by other interested parties. Researchers may be compelled to publish their research data openly due to policies driven by their institution, funder or journal publisher. Currently, the onus is on the researcher to plan their data management and data publication across the lifetime of their research.

Common practice and guidelines have been developed to support researchers in preparing their data for preservation and publication. In many research performing organisations, data curation professionals also provide guidance to support individual researchers. Digital humanities research outputs bring particular challenges, often incorporating or analysing existing copyrighted material. As international policy moves towards mandated preservation and publication of publicly funded research, it is increasingly important that researchers are assisted in identifying, curating and describing their research data, and that Humanities scholars can access training and guidelines relevant to their disciplines and data types.

Internationally, organisations, digital infrastructures and research projects exist to support research data curation activities. The Research Data Alliance (RDA) is an international organisation that draws support and funding from the EU Commission, the National Science Foundation in the United States, and the Australian Government and National Data Services. The RDA aims to accelerate and facilitate research data sharing and exchange, and its work is primarily undertaken through its working groups. Any interested party is welcome to participate in working groups and interest groups, start new working groups, and attend the twice-yearly plenary meetings. RDA Working Groups produce research and tangible outputs (see: https://rd-alliance.org/rda-outputs.html) covering areas relevant to digital humanities including Education and Training on handling of research data, Ethics and Data and Digital Practices in History and Ethnography. Current outputs include recommendations on dynamic data citation, allowing researchers to cite version of changing datasets at certain points in time.

The panel draws together a range of experts in research data management, and will give an overview of key themes in research data and research data management for digital humanities, including identifying and preparing data for deposit, repository infrastructures and the services they provide, and the potential benefits of re-using published research data. The panelists will explore how existing conceptions of research data (often built on the 'hard' sciences) fit with Humanities research, how 'data' may be understood differently depending on domain, and what challenges arise through these differences. A representative from the Research Data Alliance will provide an overview of the RDA's work and its connection to digital humanities research, providing specific examples of relevant outputs to generate discussion from the DH community. This panel will be interactive and welcome engagement from all attendees.

Panel Chair: Dr. Natalie Harrower, Acting Director, Digital Repository of Ireland (Ireland)

As chair, Dr. Harrower will provide an overview of how digital infrastructures can support researchers in preparing and publishing their data. Case studies will include the Digital Repository of Ireland, a national repository for Humanities and Social Science research data which provides services including digital preservation, education and outreach and the creation of persistent identifiers for data citation.

Speaker 2: Rebecca Grant, Digital Archivist, Digital Repository of Ireland (Ireland)

An introduction to concepts of research data in the digital humanities, including accepted definitions of what constitutes research data in a DH context. The specific challenges associated with research data management for DH will be explored.

Speaker 3: Martin Donnelly, Digital Curation Centre (UK)

This paper will present the basics of research data management practice, including the research data lifecycle and the roles and responsibilities of the researcher in managing data.

Speaker 4: Ingrid Dillo, Data Archiving and Networked Services; RDA Technical Advisory Board member (Netherlands)

An introduction to the work of the Research Data Alliance and its relevance to DH researchers. Specific outputs will be presented which have practical applications for the management and reuse of DH research data.

Speaker 5: Orla Murphy, School of English, University College Cork (Ireland)

Opportunities in research data publication for the digital humanities; how digital humanities data publication benefits the data creator, and how DH scholars can reuse research data in their work. A case study showing how published research data can be reused in a humanities context.

Recovering Shared Heritage via Spectral Imaging: Problems, Solutions, Interpretations

Introduction

This session is planned as a complement to a proposed DH2016 tutorial that will demonstrate multispectral imaging, also organized by the Lazarus Project. The Lazarus Project, based at the University of Mississippi, makes multispectral imaging available to cultural institutions at low cost.

From time to time multispectral imaging garners attention in the press for its success in recovering text and images from damaged manuscripts, maps, and printed books. Yet even among digital humanities professionals, aspects of the process of making multispectral images, from the selection of candidate objects for imaging, to practicalities of setting up for multispectral imaging, the collection of the data, the methods to combine the images to recover the feature(s) of interest, and their interpretation and display, remain obscure. The planned demonstration of multispectral imaging will allow conference attendees to become familiar with the practical aspects of the process, particularly the equipment used, its configuration, and its functioning. The talks in this session will provide a view from a higher vantage point of the practices and results of multispectral imaging. Topics to be addressed include political situations that generate an urgent need for spectral imaging projects, challenges and solutions in the organization of large imaging projects, the different purposes for which spectral images can be used, best practices in image collection, the development of new image processing algorithms to recover text from spectral images, and the use and interpretation of spectral images by scholars.

The talks will be unified by an emphasis on solutions to specific problems in spectral imaging, and it is hoped that this emphasis will facilitate projects by other spectral imaging teams, and will also help scholars in identifying manuscripts and maps that are good candidates for textual recovery through spectral imaging.

The ninety-minute session will consist of six brief papers, as follows:

From Chartres to Timbuktu: Spectral Imaging in a Time of Crisis

Gregory Heyworth

The past hundred years has witnessed greater devastation to the world's collections of ancient manuscripts than any other period since the eleventh century and the First Crusade. Between continued war and climate change, the threat is only increasing. This talk will consider the role of spectral imaging as a response to the political and environmental upheaval. Specifically it will treat various techniques of recovery from spectral and volumetric imaging to x-ray fluorescence on important war-damaged collections in Europe, as well as the logistical challenges of recovery projects on collections in politically unstable areas of the world.

The Sinai Palimpsests Project: The Recovery of Erased Texts in the World's Oldest Library

Michael B. Phelps

St. Catherine's Monastery of the Sinai, Egypt, was built to approximately its form in the mid-6th century and today maintains the world's oldest continually operating library. It holds 4,549 manuscript codices, among which are 160 known palimpsest manuscripts. The palimpsests preserve erased texts in 10 languages that date from the late 4th century to the 12th century. Only three of these 160 palimpsests have ever been the subjects of sustained scholarly study and published. Hence, the palimpsests of Sinai represent a largely unexplored source not only for new texts from antiquity but also for evidence for reconstructing the literary history of the Eastern Mediterranean.

A collaborative project of St. Catherine's Monastery and the Early Manuscripts Electronic Library (EMEL) seeks to recover the erased layers of Sinai palimpsests and make them globally accessible to researchers. Participating scientists are using state-of-the-art spectral imaging and image processing to render the erased texts legible; 23 participating scholars, scattered from Portland to Beirut, are identifying and describing the erased texts based on the image data; and EMEL and the University of California Los Angeles (UCLA) are preparing to host the images and scholarly descriptions online in service to St. Catherine's Monastery. The project represents arguably the most extensive application to date of spectral imaging to cultural heritage.

This talk will survey the methods, innovations, and discoveries of the project. The survey will explore two recurring themes of the project, one technical and the other historical. First, challenges in the implementation of large-scale spectral imaging projects in the cultural heritage arena; and second, the significance of palimpsestation in the transmission history of late antique literature and languages.

The Evolution of Spectral Imaging in the Study of Manuscripts

Adrian S. Wisnicki

The Livingstone Spectral Imaging Project (2010-) is now in its second phase. The project applies spectral imaging to study some of the most damaged surviving manuscripts of David Livingstone (1813-1873), the celebrated Victorian traveler, abolitionist, geographer, and missionary. The first phase of the project (2010-2013) targeted Livingstone's 1871 Field Diary, and sought to use spectral imaging to recover now faded and illegible text that Livingstone had written crosswise over the pages of a single newspaper. The current second phase (2013-2016) centers on Livingstone's 1870 Field Diary, which is of a much more fragmentary nature that the diary previously studied by the project and, in fact, is quite legible under natural light. As a result, in this second phase, the use of spectral imaging has shifted from recovering lost or invisible text to using the imaging technology to explore material aspects of the manuscript, such as after-the-fact-additions (sometimes in other hands) and elements of page topography that can reveal details of the manuscript's passage through time.

Broadly speaking, therefore, the Livingstone Spectral Imaging Project offers a window onto the evolving nature of using spectral imaging technology to study manuscripts during the last five-odd years. The work of the project itself has, in turn, galvanized the development of a larger, but related project, Livingstone Online. Through the collaborative, interdisciplinary nature of its methodologies, the Livingstone Spectral Imaging Project has also established a loosely affiliated network of specialists who have contributed to the development of the two project phases. This paper will reflect on the evolution of this project and give attention to the implications of this evolution, particularly in establishing a collaborative methodology that is empowered by its distributed, at times informal, international character.

Reducing a Challenging Multi-Spectral Imaging Task to Practice

Kenneth Boydston

The multispectral image data set of a cultural heritage object can have a number of uses by disparate parties, and can be in and of itself historically significant. When the object is large, largely degraded, and of significant historical value such as is the late fifteenth-century world map by Henricus Martellus at Yale, acquiring the images that will satisfy known and anticipated demands can be particularly challenging. Time constraints, budget constraints, technological limitations, logistics, handling considerations, risk assessment, personnel, and facilities are among the parameters that can affect the outcome and which should be included in project planning.

Of particular interest are the technological capabilities and limitations. The technology can impact other parameters, and other parameters can impact the technology. While technology will certainly impact the outcome of a multispectral imaging project, it is often the case that technological limitations drive the project—though this should not be the case. In this paper we will suggest that multispectral imaging projects should be driven primarily by the needs of the scholars and conservators who will use the data, and that by focusing on these needs, technological innovations can be created and appropriate technology deployed that will make the difference between mediocrity and success. Examples from the imaging of the Martellus Map demonstrate a few such innovations.

One innovation required by the combination of budget, image spatial resolution, value, size and weight of the object was a large, yet easily portable easel capable of supporting the map and precisely moving both up and down and left and right over a grid of locations. Spatial resolution required that the images be captured in an 11 x 5 grid of tiles and stitched together. Software and hardware protocols were developed to facilitate manual movements of the map. Lasers were integrated to track and maintain focus and camera alignment.

Innovative use of software (MegaVision's PhotoShoot Multispectral Imaging Capture Software) enabled a capture configuration customized for the particular needs of the map. This configuration was planned in advance, and then modified on site as the nature and needs of the map were revealed in preliminary captured samples. The magnitude of the image data set, together with the complexity of processing software (such as PCA), required innovative methods for preparing the imagery for visual appreciation.

Image Processing Techniques for Spectral Images of Historical Objects

Roger L. Easton, Jr., Ph.D.

The history of image processing of manuscripts to enhance or recover erased or damaged text goes back more than 100 years. The first work likely was that of the German physicists Ernst Pringsheim and Otto Gradenwitz in Breslau, who reported in 1895 on the development of an analog method for enhancing the visibility of the undertext of palimpsests by combining pairs of photographic transparencies that were collected under different conditions and processed differently. Their technique was improved by Fr. Raphael Kögel in the 1910s; he used ultraviolet illumination to further enhance the visibility of the undertext in one of the two images, which improved the results. These analog methods were difficult to implement, requiring careful photographic processing and accurate optical alignment to obtain good results. The first use of digital imaging algorithms to recover text from manuscripts may have been by Dr. John F. Benton at the Jet Propulsion Laboratory in the 1970s, who used contrast enhancement and image sharpening tools in the NASA image processing toolkit.

Over the last 30+ years, the capabilities for collecting and processing digital spectral images have improved to the point where it is now possible to have a complete spectral collection and processing system in a single suitcase that may be checked on an airline. The collected images may be processed using a variety of image processing tools, many of which had been developed for use in environmental remote sensing applications and are therefore not available in "general-purpose" image manipulation tools, such as Adobe Photoshop® and the GNU Image Manipulation Program ("GIMP"). Some are available as plugins in ImageJ, but we mostly use the special-purpose package ENVI that is written for remote sensing applications. This talk considers the image processing algorithms that were applied or developed for use to recover text from a wide variety of historical objects.

The algorithms may be loosely divided into two classes: deterministic methods for rendering the image data in pseudocolor, and custom methods that are based on the spectral statistics of the specific leaf. Among the methods in the latter category are principal component analysis (PCA), independent component analysis (ICA), and the minimum noise fraction transform (MNF). In all cases, preprocessing and postprocessing tools are useful. The preprocessing is applied before the deterministic and custom methods and is often necessary to calibrate the images or compensate the image data for differential fading or other problems. The postprocessing tools are used to combine processed images to improve the rendering for scholarly reading.

Examples will be shown of successful processing applied by the author and/or by collaborating team members to a wide variety of manuscripts and other objects in institutions all over the world. Among these are the Archimedes Palimpsest, the Syriac-Galen Palimpsest, the palimpsests in the "New Finds" at St. Catherine's Monastery, the Gruskovà palimpsest in Vienna, and the world map by Henricus Martellus (c. 1491) at Yale.

New Light on Henricus Martellus's World Map at Yale (c. 1491): Multispectral Imaging and Early Renaissance Cartography

Chet Van Duzer

One of the outstanding problems in the history of cartography in the last half century has been that presented by a large world map made by Henricus Martellus in about 1491, which surfaced in the late 1950s and soon came to reside in the Beinecke Library at Yale. The map has long been thought to be one of the most important of the fifteenth century; in particular, there was good evidence that it influenced the thinking of Columbus with regard to his proposed voyage west to reach Asia; it was thought to have influenced Martin Behaim's globe of 1492 and Martin Waldseemüller's famous world map of 1507. But the vast majority of the texts on the map were illegible due to fading and damage, and thus its exact place in Renaissance cartography was impossible to determine.

In this talk I will look at the results of a recent NEH-funded project to make multispectral images of Martellus's map at Yale—at the scholarly use that can be made of the images. These images have rendered almost all of the previously illegible texts on the map legible, and thus have enabled a detailed comparison with Martin Waldseemüller's world map of 1507. This comparison shows that Martellus's map was the source of most of the long descriptive texts on Waldseemüller's map. At the same time, it turns out that the later cartographer chose not to follow Martellus for many of the other details of his map, and thus the comparison generates insights into the workshop practices of an early sixteenth-century cartographer, a subject about which we have very little documentation. In effect the multispectral images enable us to watch Waldseemüller at work, choosing different sources for different categories of information on his map as part of the process of creating a new image of the world.

Diverse Digitalities: Targeted Models for Postcolonial Challenges in the Digital Discourse.

Nirmala Menon
nimmenon@gmail.com

Alex Gil
colibri.alex@gmail.com
Columbia University, NY USA

Rahul Gairola
rgairola@uw.edu
Indian Institute of Technology, Roorkee, India

The digital highway is as yet an exclusive neighborhood-let's just say that there are no traffic jams on there just yet. This disparity is of course not lost on the practitioners of digital humanities and several conversations pointing out this disparity have emerged in the last few years. Whether it is Postcolonial Digital Humanities (DHPoCo), gender algorithms experiments, the articulations of marginalizations spilling over to the digital space have all been part of this discourse. Various projects have also attempted to understand, articulate and bridge the gaps of representations. This panel too is concerned about that gap and discusses different projects that specifically address issues in countries where bandwidth and connectivity is not optimal as in the more advanced nations. How do we harness digital technology so humanities research can be innovative and access to them is not behind a pay wall or a "bandwidth" boundary?

Alex Gil's sx: Archipelagoes project sees to channel the rich and diverse theoretical engagements of the Caribbean with the Digital by providing an innovative two-tiered platform to support digital scholarship in, for and about the region and its diaspora. He proposes a minimum-computing model that can make humanities scholarship in low bandwidth countries longer lasting and easier to access. Alex will also argue for the moral imperative of DH scholars to make that access easy and useful.

Rahul Gairola's & Arnab Datta's project focuses on the theory and practice of electronic education for the under-privileged in India. With their respective humanities and engineering backgrounds, their paper will discuss the imperative of reaching digital technology to the rural population of northern India. As their paper points out, Internet access has still not reached large chunks of the population in India. However, according to Government of India statistics, nearly a billion people will have subscription to mobile phones by the end of the decade. In this context, despite the difficulty of hypertext-based learning in rural areas of India due to lack of internet availability, the solutions can be provided through portable data transfer and convenient access by means of flash memory chips readily available in mobile phones. While many digital archives to date use DVDs and CD-ROMs for archival data storage, no research to date engages alternative data storage and retrieval in rural India archives. State of the art memory technologies support novel technological trends in Postcolonial Digital Humanities – not only in terms of the resources, but also for efficient archival of them. This will make digital literacy in rural India feasible in the immediate future rather than relying on bandwidth sensitive Internet connection.

Nirmala Menon makes a similar case for the dissemination of humanities research and access to it for higher education in India. MAP (Multilingual Academic Publishing) is a new publishing project from Indian Institute of Technology (IIT), India. MAP has two specific features that address the research needs of students and established researchers of humanities in India- 1) it will be an open access platform that will allow access to students of universities across the country and 2) it will publish both original research and translations from and into different languages of India. For this, the project associates are in the process of developing translations software that will be efficient and will aid translations into multiple languages. Nirmala will also argue for the imperative of Digital Humanities to support projects in different postcolonial languages. While there are now DH initiatives in India, a lot of the discourse is still in English even if the projects themselves engage in conversations between different languages. This publishing project ambitiously aims, in the long run, to allow knowledge productions and disseminations in multiple languages.

Together, all three papers address specific problems of the global south and envisage projects that will enable a more diverse global Digital Humanities conversation. The specific examples in these papers are of places that are part of the DH conversation but the geographic locales of the discourse pose challenges that are different from those of EU or US. Each of the projects discusses ways of enabling humanities research and researchers to go from the digital driveway to the highway within the constraints of connectivity and capability.

Small Axe: Archipelagos: A minimal computing model for a digital humanities journal for Caribbean Studies

Alex Gil

The Caribbean is the site of some of the most radical and diverse theoretical and material engagements with the digital. The archipelagos project seeks to channel that activity by providing an innovative two-tiered platform to support digital scholarship in, for, and about the region and its diaspora. Each layer of sx: archipelagos will contribute something new to both Caribbean Studies and to the digital humanities, first via the creation and documentation of a new cost-efficient workflow for the production of text-based scholarly outputs; second, the production of digital humanities project reviews attached to the traditional workflow of book reviews; and third, via the creation and support of a flexible multimodal environment for the production of unique works of digital scholarship that can be ultimately preserved by integrating their components into the university repository. This paper will combine an outline of the specific technological stack needed to run the journal with low resources, and an argument for the moral and practical imperatives to adopt such a model. In brief, I will argue that a minimal computing model can make publication in the humanities longer lasting, easier to access in regions of the world with low-bandwidth and ultimately more transferable to new generations.

Democratic Digitality: Theory and Practice of Electronic Education for the Underprivileged

Rahul K. Gairola & Arnab Datta

This paper is the first co-authored study that deploys questions of gender equity and rural literacy in Literary Studies with electronic memory and communications platforms in the field of Electronics. Our goal herein is to combine our disparate fields to examine, from multiple perspectives, the haunting problems of electronic access to literary/ pedagogical tools in rural India. These problems of access are the consequence of poor infrastructure that demonstrates, as such, the complimentary relationship shared between the humanistic nature of the literary arts and the technical nature of electronics and communications platforms. We would moreover insist that research trends in our individual fields combined allow us to tackle one of South Asia's most pressing issues in the 21st century: digital literacy in rural India. By "digital literacy" here, we do not limit our definition simply to knowledge of knowing how to use digital devices. Rather, we mean the hypertexts, databases, and resources that comprise the soft materials for education and research, and also the required hardware and infrastructure needed to support them. Here, there are significant problems of electronic access to literary/ pedagogical tools in, for example, the requisite data storage and retrieval of digital archives. In principle, these have been realized through the implementation of internet-based hypertexts that facilitate a seamless exchange of knowledge.

However, in the Indian context, the Internet has not yet reached rural areas, and hypertext-based implementation of digital archives is hence not viable. According to the Government of India, nearly a billion users will be subscribing to mobile phones in the coming decade. This is in stark contrast to the growth rate of Internet subscriptions in India, which is projected to be nearly half the growth of mobile phone subscribers. In this context, despite the difficulty of hypertext-based learning in rural areas of India due to lack of internet availability, the solutions can be provided through portable data transfer and convenient access by means of flash memory chips readily available in mobile phones. While many digital archives to date use DVDs and CD-ROMs for archival data storage, no research to date engages alternative data storage and retrieval in rural India archives. State of the art memory technologies support novel technological trends in Postcolonial Digital Humanities – not only in terms of the resources, but also for efficient archival of them. This will make digital literacy in rural India feasible in the immediate future rather than relying on bandwidth sensitive Internet connection. We believe that advanced research and implementation of portable memory devices has the ability to disseminate the resources of the world to the four corners of the earth and improve digital literacy in rural populations.

Web Historiography – A New Challenge for Digital Humanities?

Jane Winters
Jane.Winters@sas.ac.uk
University of London, UK

During the last ten years the use of web archives as primary sources for historical research has attracted the attention of researchers in several different fields. From the web archiving community (Foot et al., 2003; Hockx-Yu, 2014) to Internet studies scholars (Brügger, 2009; Ankerson, 2012), from web scientists (Huurdeman et al., 2013; Hale et al., 2014) to STS researchers (Rogers, 2013; Schafer, 2013), several case studies have been presented. All these different projects have been designed to highlight the potential of born digital sources to offer a new and more complete perspective on our recent past. More recently, traditionally trained and digital historians have been directly engaged in the debate, raising both methodological and theoretical questions (Milligan, 2012; Webster, 2015). However, within Digital Humanities, the web as a source and as an object of study has not been widely debated.

For these reasons, the proposed panel brings together different researchers whose work focuses on the use of born digital materials as historical sources and who have developed, employed, criticized or refused the use of computational/quantitative methods in order to extract useful pieces of information from them.

The purpose of this panel is twofold. First, we aim to discuss how the toolkit available to new generations of historians will necessarily have to combine a vast series of new skills: from accessing and dealing with web archive objects to analyzing networks of hyperlinks, from employing text mining approaches to re-discussing the reliability of a primary source when it is born digital.

Second, our intention is to discuss with the community how this new field of study could be recognized as a relevant example of a digital humanities practice. While the number of born digital sources is increasing rapidly, a broad discussion within the Digital Humanities community is needed, in order to reflect on how to prepare the first generation of digital historians that will work with materials that do not have an analogue counterpart, of which web archives are just one.

Anat Ben-David is a lecturer in the department of Sociology, Political Science and Communication, the Open University of Israel. Her research focuses on Internet geopolitics, web historiography and digital methods for Web research. Ben-David's contribution presents her recent work on the reconstruction of portions of the Web's deleted pasts. In particular, her presentation argues that the use of the Web as a primary source for studying the history of nations is conditioned by the structural ties between sovereignty and the Internet Protocol, and by a temporal proximity between live and archived websites. The argument is illustrated with an archival reconstruction of the history of the top-level domain of former Yugoslavia, .yu, which operated on the Web since 1989 and was discontinued in 2010. The archival reconstruction of a portion of the Web's deleted past serves to assess and conceptualise the Web's limits as an appropriate source for telling its own history.

Niels Brügger is Professor and head of the Centre for Internet Studies as well as of the internet research infrastructure NetLab within the Danish Digital Humanities Lab, Aarhus University, Denmark. His research interests are web historiography, web archiving, and media theory. Within these fields he has published monographs, edited books, and book chapters at international publishers, as well as articles in international peer reviewed journals. He has participated in a number of large research projects, in Denmark and in the UK. Niels Brügger is cofounder and now coordinator of RESAW, a Research Infrastructure for the Study of Archived Web Materials (resaw.eu).

Meghan Dougherty is an assistant professor of digital communication at Loyola University Chicago. Her research focuses on methodological challenges in answering questions about how we move through networks of digital culture to create knowledge, form memory, and make history. The questions that guide her inquiry explore how knowledge production — ranging from identity formation and group membership to scholarly knowledge — is shaped by digital communication infrastructure, and vice versa. Dougherty's contribution to the panel stems from her current book project under contract at University of Toronto Press, *Virtual Digs: Excavating, preserving, archiving, and curating the Web* in which she describes a common field of Web Archaeology drawn together from experiments in Web archiving, digital preservation, and curating that are commonly found in Internet research, digital humanities, and information science. She argues that the nature of scholarly evidence and interpretation must be reconsidered in the new media ecology.

Ian Milligan, an assistant professor of digital and Canadian history at the University of Waterloo (Canada, Ontario) will talk on a specific web archiving project that he has been involved with. His contribution, "WebArchives.ca: Enabling Access to Canadian Political Party Web Archives," explores the development, deployment, and reception of http://webarchives.ca. He argues that since 1996, we have been collecting web archives – now we need to put them to good use. However, accessing and making sense of results requires computational skills. Milligan's case study, a 2005-2015 assemblage of political parties and political interest groups within Canada, should have arguably have been used far more than it had been given pivotal shifts in the Canadian political milieu during the period it studies. These collections were underused, however, due to problems of access restrictions and a lack of technical knowledge. His contribution to this roundtable will then quickly explore various access methods, from content analysis to metadata parsing, using his case study as a reference point throughout.

Federico Nanni is a PhD student in Science, Technology and Society at the Centre for the History of Universities and Science of the University of Bologna and a visiting researcher at the Data and Web Science Group of the University of Mannheim. His research is focused on understanding how to combine methodologies from different fields of study in order to face both the scarcity and the abundance of born digital sources related to the recent history of Italian universities. In particular, he employed oral histories and traditional hermeneutic practices for reconstructing the evolution of the University of Bologna website, which was excluded from the Wayback Machine of the Internet Archive. Later, he applied text mining methods in order to study the collected data. He finally focused his attention on comparing the changes in academic input and output of this institution during the last two decades by analysing the descriptions of the courses presented on the website and the dissertations abstracts available in the digital library.

Jane Winters is Professor of Digital History at the Institute of Historical Research, University of London. Her research interests include the ways in which researchers in the humanities can work with born digital big data, including the archived web. She was Principal Investigator of a big data project funded by the Arts and Humanities Research Council, 'Big UK Domain Data for the Arts and Humanities', which sought to develop a theoretical and methodological framework for the study of web archives over time. Drawing on the lessons of this project she will discuss the challenges faced by researchers wishing to work with the archive(s) of UK web space, and suggest ways in which archiving institutions and researchers can collaborate to overcome them. She will address the fractured and diverse nature of the available web archives - from the open and comprehensive UK Government Web Archive to the dataset derived from the Internet Archive for 1996-2013, from a focused institutional collection such as the Parliamentary Web Archive to the ongoing domain crawl undertaken by the British Library since 2013 - and consider the barriers for researchers in the arts and humanities who choose to use this material, whether as a key source for study or simply as one primary source among many.

Together, these six papers all point towards the growing significance of web archives within contemporary historical practice. In order to encourage the discussion, each speaker will briefly introduce his or her work (5 min), then another speaker will address a general comment (5 min) and following there will be an open discussion (5 min).[1]

The building blocks of the field are in place: what is needed is a discussion within the historical community, but also towards the broader field of digital humanities practice. Our discussion will look to find commonalities and similarities both within our work, but also within the broader DH 2016 conference.

> It is normally the case that the objects of scientific inquiry inhabit multiple social worlds, since all science requires intersectional work... The management of this diversity cannot be achieved via a simple pluralism or a laissez-faire solution. The fact that the objects originate in , and continue to inhabit, different worlds reflects the fundamental tension of science: how can findings which incorporate radically different meanings become coherent? (Star and Griesemer, 1989:392)

In the Sociology of Science, objects of scientific enquiry that are common to multiple disciplines or communities are known as "boundary objects" (Star and Griesemer, 1989). As Borgman argues, "these are objects that can facilitate communication, but that also highlight differences between groups" (Borgman, 2007: 153). They have "different meanings in different social worlds but their structure is common enough to more than one world to make them recognizable, a means of translation" (Star and Griesemer, 1989). Handled poorly, they promote "boundary work" - the effort to institutionalize difference between fields (Gieryn, 1983; Lamont and Molnár, 2002: 180); handled well, they are "important interfaces enabling communication across communities" (Lamont and Molnár, 2002: 180).

The theme of this session is the Digital Humanities as a "Boundary Land" - i.e. a locus in which such objects are common. As O'Donnell argues in his paper, this aspect is one of the defining features of contemporary Digital Humanities and an important cause of its recent rapid growth. As the field grows, DH workshops, panels, and journals see increasing work by practitioners trained in more and more traditionally distinct disciplinary traditions: textual scholars, literary critics, historians, New Media specialists, as well as theologians, computer scientists, archaeologists, Cultural Heritage specialists... and geographers, physicists, biologists, and medical professionals.

It is the contention of the speakers of this panel that interpersonal diversity (i.e. diversity along lines such as gender, ethnicity, sexual orientation, language, economic region, etc.) is as an important element of this aspect of DH. The Digital Humanities is not only a place where different disciplines work together (and at times at odds to each other): it is also a place where different people work together and at odds in developing our field. In other words, diversity initiatives in the Digital Humanities are important not only because they let more people into our field, they are important because they change the nature of our field as its practice widens.

The papers in this session each approach the issue from a different perspective. In the first paper, O'Donnell looks at the theoretical background to this understanding of diversity as a component of DH as a boundary discipline, grounding his approach in early work on interdisciplinarity and boundary work. In the second paper, Murray Ray and Bordalejo discuss the ways in which efforts to promote diversity within DH can paradoxically undermine its theoretical importance to the field, before turning to different examples of diversity's intellectual importance. In the third paper, del Rio and González-Blanco examine the institutional and social pressures that promote and hinder dialogue among researchers in developing and developed countries and across linguistic and other boundaries before proposing new approaches in Digital Humanities that go beyond lingüistic diversity focusing on theories such as Sociology of Culture and Education and other reformulations.

All along the Watchtower: an interdisciplinary approach to understanding the importance technical, disciplinary, and interpersonal diversity within the Digital Humanities

Daniel Paul O'Donnell

The increasing paradisciplinarity of Digital Humanities

Perhaps the defining feature of the Digital Humanities as a discipline is its growth (Terras, 2012). Despite some pushback and counter pushback about the precise valence of the field as a discipline (for some more famous recent examples of this growing genre, see Koh, 2015; Fish, 2012; Marche, 2013; Chun, 2013; Grusin, 2013; Jagoda, 2013; a selection of responses to these specific pieces include, among many others, Risam, 2015; Gil, 2015; Liberman, 2012; O'Donnell, 2012; Pannapacker, 2013), digitally inflected work on Humanities problems and material continues to grow.

As its popularity has grown—and, more importantly, as the potential of networked computation as applied to cultural material and questions has become more broadly apparent - it has begun to incorporate practitioners trained in more and more traditionally distinct disciplinary traditions: textual scholars, literary critics, historians, New Media specialists, as well as theologians, computer scientists, archaeologists, Cultural Heritage specialists... and geographers, physicists, biologists, and medical professionals (see Deegan and McCarty 2012 for a detailed discussion of cross disciplinary collaboration in DH).

This growth is interesting for a variety of reasons: as a demonstration of the continuing relevance of the humanities (Davidson, 2011), as a route to new approaches to traditional disciplines (e.g. Ramsay, 2011; Moretti, 2005), and as a method of improving our ability to answer old questions (e.g. Terras, 2006). It also has been interesting for the way it fed back into computer science and other non-humanities domains, for example, through the development of XML and Unicode (O'Donnell 2010).

Above all, however, this growth is interesting because it reflects the increasingly paradisciplinary nature of the domain and its methods. "Humanities Computing", the designation most commonly used before Blackwell's marketing team proposed "Digital Humanities" as an alternative in 2005 (Kirschenbaum, 2010), was far more traditional in approach: beginning with the original work of Roberto Busa in the 1940s, computation in this older form was used to work with relatively traditional objects and questions within relatively traditional humanities domains. As a glance at the tables of contents of journals from this period demonstrates, literary scholars and historians tended to use their computation to do literary and historical work: build concordances and indices, develop statistics, and, later, capture text; Gallery, Archive, Library, and Museum (GLAM) professionals, for their part, computed metadata and built catalogues; Corpus linguists built corpora; and so on. DH, on the other hand, especially in the course of the last decade, has been marked—perhaps defined (O'Donnell, 2012) - by its inter - and cross - disciplinarity: geographers study British Romantic poets' fascination with the Lake District (Cooper et al., 2015); museum curators decipher mathematical texts (Netz and Noel, 2008); literary scholars edit maps, compile archives of things, or analyse Cultural Heritage installations (Foys, 2003; Nelson, 2014; O'Donnell et al., 2012; Hobma, 2014).

Boundary objects and border lines in the sociology of science

In the Sociology of Science, such cross-disciplinary outputs are known as "boundary objects" (Star and Griesemer, 1989). As Borgman argues, "these are objects that can facilitate communication, but that also highlight differences between groups" (Borgman, 2007:153). They have "different meanings in different social worlds but their structure is common enough to more than one world to make them recognizable, a means of translation" (Star and Griesemer, 1989:393). Handled poorly, they promote "boundary work"—the effort to institutionalize difference between fields (Gieryn, 1983; Lamont and Molnár, 2002:180); handled well, they are "important interfaces enabling communication across communities" (Lamont and Molnár, 2002: 180).

The Digital Humanities as Boundaryland

As the Digital Humanities has matured technologically, the question of these Boundary Objects has become an increasingly important, if largely unrecognised, issue among practitioners, users, and critics of DH (Borgman, 2007, chap. 7). As the example of Fish and Liberman (a literary scholar and a computational linguist discussing "distance reading" and "algorithmic criticism") suggests, unacknowledged disciplinary differences about how such objects are understood can result in users talking past each other (see the debate between Fish 2012; Liberman 2012). And indeed a surprisingly large number of other debates in the field can be understood as involving such boundary constructs: complaints that the Digital Humanities are "undertheorised", for example; the "hack vs. yack" debate (i.e. about the relative importance of programming vs. cultural aspects of DH; see Nowviskie, 2014) or even "centre and the periphery" (about the definition of DH through western—or sometimes simply Anglo-American—norms; see Galina, 2013; Fiormonte, 2012).

The rest of this paper looks at the place of globalisation and diversity in light of this understanding of DH as a "boundaryland" - a place in which shared research objects or goals take on different meanings depending on the background of the participant. As the paper will show, interpersonal diversity is in this regard as important to the growth of our field as disciplinary diversity. Research objects, questions, and more importantly, solutions, look very different when lack of funds or inadequate technology prevents the proper preservation of your cultural patrimony and makes participation in collaborations next-to-impossible (see Babalola, 2013). Drawing on the author's experience in establishing and overseeing the first few years of the Special Interest Group, Global Outlook::Digital Humanities, this paper demonstrates the extent to which this openness to difference is in fact an essential feature of both interdisciplinarity and the future growth and development of the Digital Humanities as a discipline that transcends the domains it increasingly incorporates.

Conclusion

Although the concept of the "Boundary Object" is now most commonly discussed in terms of disciplinary difference, the original work on the concept involved the boundary between "Science and Nonscience" or the management of differences in the way in which professional and amateur ornithologists understood the collection of specimens for a museum (Gieryn, 1983). By failing to understand the extent to divisions within the boundaries that coincide with broader cultural, historical, economic, or regional differences amplify existing impediments to the incorporation of the full diversity of our community's experience (Fiormonte, 2012; Galina, 2013; Wernimont, 2013). As Star and Griesemer note:

> When participants in the intersecting worlds create representations together, their different commitments and perceptions are resolved into representations—in the sense that a fuzzy image is resolved by a microscope. This resolution does not mean consensus. Rather, representations, or inscriptions, contain at every stage the traces of multiple viewpoints, translations and incomplete battles... By reaching agreements about methods, different participating worlds establish protocols which go beyond mean trading across unjoined world boundaries. They begin to devise a common coin which makes possible new kinds of joint endeavour (1989, 413).

If You Think You Know the Answer, You Don't Understand the Question

Bárbara Bordalejo and Padmini Ray Murray

Digital Humanities appears to be an open and welcoming field. Indeed, conversations about diversity have been increasingly visible in the digital humanities community. It has been said that the discipline boasts "...a culture that values collaboration, openness, nonhierarchical relations, and agility" and so "might be an instrument for real resistance or reform (Kirschembaum, 59). Notably, this statement by Kirschembaum is also supported by Burdick et al., who state that "...however heterogeneous, the Digital Humanities is unified by its emphasis on making, connecting, interpreting, and collaborating" (24).

These emphases on unity are necessary and vital to ensure that the ideal of a "global" DH establishes itself as a reality in the future. But the widespread belief that these values are at the core of Digital Humanities as a discipline, and that just by virtue of such values it is open and welcoming to all, may prevent us from seeing that the discipline can also fail to meet these standards. And when we discuss the importance of diversity, we need to understand what it is we are talking about: do we mean simply the inclusion of an ever broader collection of participants? Or do we mean that diversity is in some way a crucial intellectual aspect of what we do?

The emphasis on representation and inclusivity has been a main focus of what we might describe as the initial stages in the opening of the Digital Humanities. From the early emphasis on gender balance in the selection of keynote speakers at the ALC/ALLC conference through the early years of DH, to the more recent work of formal committees within ADHO, such as the Special Interest Group Global Outlook :: Digital Humanities (GO::DH) and the the Multilingual/Multicultural Committee, the focus of work thus far has been primarily on discovering and understanding the obstacles that prevent full access to our community and developing strategies to address those obstacles.

There are two dangers to this approach, how ever well meaning and necessary it is.

The first is, of course, that "diversity" is a boundaryless category. By concentrating on one category, or even a few categories, we, almost inevitably end up ignoring others. We focus on gender, but ignore race; or emphasise language, but ignore social class, professional status, or economic/regional disparity.

Thus, when the editorial board of Frontiers in Digital Humanities was announced, it became instantly notorious because all the editors were male. What was less debated was the fact that they were, with one exception, white. Or that they all came from the usually dominant (primarily High Income) countries. Likewise, when Scott Weingart started to write about the acceptance rate of women as first author of papers to the DH conference, it had to do (at least in part) with the relative ease of identifying female and male authors.

In reality, as the example of Frontiers shows, it can be much more difficult to assess other layers of diversity which are not apparent and, therefore, cannot be easily quantified. Even if we imagine that it might be relatively simple to identify native speakers of English, we would remain ignorant of people whose day to day work is carried out in a different language from their native one. Moreover, degrees of bilingualism vary greatly from country to country and culture to culture in such way that for scholars who have English as their second language, their proficiency and ease within it, might be significantly different.

The second danger to this approach is that it trivialises the importance of the category it intends to support. If diversity involves no more than simply ensuring that a wider range of people are present at the table, then questions about the relationship of diversity to quality become, if not entirely reasonable, at least not completely beyond understanding. Perhaps it is possible to become too welcoming--or at the very least to believe that we are somehow watering down the quality of our work by allowing too many participants in simply because they belong to the right demographic.

This paper is about both aspects of the place of diversity within the Digital Humanities.

In the first section, Padmini Ray Murray examines how non-Western cultural concepts and intellectual categories might redefine the digital humanities in terms of methodological frameworks. It is particularly significant that the concept and understanding of what DH is varies in accordance to the cultural context in which it is presented. In other words: although there might be a significant conceptual overlap, one researcher's digital humanities is rarely equal to the one of another. Ray Murray's investigations look at how infrastructural and structural ramifications of working in languages other than English; how notions of the archive can be culturally fluid and how critical making as an intervention is altered by local conditions of production and economics in order to demonstrate that the digital humanities must necessarily be informed by these factors in order to be truly diverse.

In the second section, Bárbara Bordalejo looks at intersectionality and the Digital Humanities. She investigates the combination of factors that might hinder the ability of individual researchers to make themselves more widely known within the DH community. As she shows, background, race, culture, gender, language and ability are all factors whose impact we are just beginning to understand. As she argues, however, this diversity does not need to be a problem. On the contrary, it could be (and it should be) taken advantage of in such way that it challenges and enhances both our research and our community.

A final goal of both parts of this paper is to test the words of Domenico Fiormonte about the importance of social capital in the Digital Humanities: "...it's not enough to have good ideas, work in the Northern [h]emisphere and write them in English: you need good sponsors and authoritative venues." Although it is true that this is part of the problem, nothing should prevent current structures to become part of the solution. Opening authoritative venues can only bring enrichment and new understanding to the DH community.

Spanish Digital Humanities: the construction of a scientific field

Gimena del Rio Riande
Elena González-Blanco García

As Pierre Bourdieu (1975, 19) clearly stated forty years ago: "the scientific field is the locus of a competitive struggle, in which the specific issue at stake is the monopoly of scientific authority, defined inseparably as technical capacity and social power." Universities are strategic spaces for the construction of scientific competences and practices in terms of doxa and habitus (Bourdieu, 1979). The agents that are part of these academic spaces acquire there a socially recognised capacity to speak and act in an authorized and authoritative way in scientific matters. This way, these agents can define and legitimate the definitions they propose for their subjects of study. University education is also a vital experience of utmost importance: university socialization can lead to a deep identity redefinition, with the incorporation of new ways of thinking, communicating and acting. Consequently, altogether with the recognized capacity to legitimate, universities provide the social framework to interpret academic disciplines and communicate specific shared knowledge. (Bernstein, 1990:31), makes it clear when he highlights the distribution of power and principles of control that produce different communication principles unevenly distributed. In his theory, different contexts produce different codes that act selectively on the meanings and realizations.

Undoubtedly, Digital Humanities are nowadays part of the North American and European scientific field. A big offer of postgraduate courses, summer schools, Digital Humanities centers and labs, and scientific journals and websites legitimate the field and its discourse. In this sense, Defining Digital Humanities. A reader (2013), edited by Melissa Terras, Julianne Nyhan and Edward Vanhoutte, can be seen as a text that comes to serve as the last legitimated definition for Digital Humanities. The volume appeared almost ten years after A Companion to Digital Humanities

(2004), edited by Susan Schreibman, Ray Siemens and John Unsworth, and aims to collect the authoritative voices in the field. The book focuses just on voices that have defined the Digital Humanities making use of English as lingua franca and it only considers as authoritative voices a very homogenic group that legitimates the field from universities with a shared Anglo-American perspective and a set of common discourses and practices.

This landscape is very different for the Spanish speaking community. On the one side, European Spanish universities have defined Digital Humanities paying little or no attention to Latin America (González-Blanco, 2013; Spence and González-Blanco, 2014; Rojas Castro, 2013); on the other side, very few definitions have been provided in this side of the world (Galina, 2014; Rio Riande, 2014a, 2014b) or there is a preference for working on a non-defined scientific field that could lead to more open and less philological humanities, more interested in the Social Sciences or Digital Media (Piscitelli 2014). Although there may be many external social, cultural and economic issues that divide the Spanish-speaking Digital Humanities field, this work means to unveal the symbolic violence (Bourdieu, 1991) behind these facts and focus on the characteristics of the institutional spaces in which legitimated discourses and socialization occur as a set of historical and social conditions that explain their particular constitution and nature in Spain and some countries that have started regarding Digital Humanities as a possible (non actual) academic discipline. Knowledge and practices as expressed in the university curricula, but also the set of norms, values and social representations that make each space, can not be fully understood without taking into account the very specific historical, intellectual and institutional factors that have operated and operate in its constitution and legitimate in different ways their discourses.

Regarding the aforementioned, some questions arise: are there possibilities of dialogue in Digital Humanities between developed countries and others with unequal access to technology despite using the same language? Who are the agents that can be part of this dialogue? How do they become part of the scientific field? How much of that symbolic violence comes across in this dialogue? How do social, cultural and historical factors shape the knowledge built at university? The work aims to outline some possible answers to these questions at the time it claims for new approaches in Digital Humanities that go beyond lingüistic diversity focusing on theories such as Sociology of Culture and Education and other reformulations.

Introduction

This panel examines some of the many shared issues between Digital Humanities (DH) practices and theories with those in the study of Electronic Literature (E-Lit). Until recently, the fields of DH and E-Lit, though intimately related, have intersected only to a certain extent. The historical development of each of the fields––broadly speaking, DH originating from the earlier humanities computing; E-Lit work from experimental poetics and digital media––might be the reason why these two fields have not engaged in sustained communication. A few events have started to revert this tendency. Within the Alliance of Digital Humanities Organizations (ADHO), the approval of the Special Interest Group on Audiovisual Data in Digital Humanities (SIG AVinDH) is an important milestone fostering the exchange of "knowledge, expertise, methods and tools by scholars who make use of audiovisual data types that can convey a certain level of narrativity: spoken audio, video and/or (moving) images" (AVinDH SIG @DH2015 in Sydney). Similarly, constant collaboration between the Digital Humanities Summer Institute (DHSI) and the Electronic Literature Organization (ELO) in the last few years has lead to deeper collaborations between scholars bridging both fields of knowledge.

In previous ADHO conferences, though on occasion E-Lit has been part of the schedule, it remains a fact that there is room for a timely intervention not only signaling where E-Lit and DH intersect, but also pointing out where E-Lit specific insights are capable to illuminate instrumental approaches to DH theory and practice. E-Lit work has much to offer to DH. An awareness of the expressiveness and historicity of the digital medium that compliments its instrumental and innovative dimension. Dealing with multiple expressive codes besides language, and through the leadership of the ELO, E-Lit work has been at the forefront of inclusivity, diversity, and multilingualism. Issues that continue to be discussed in DH venues.

Specifically, the papers in this panel will focus on the materiality of electronic literature as it illuminates the ongoing debates of print-digital media and changing reading and writing practices; the applicability to works of E-Lit of forms of quantitative criticism that had been used exclusively for print literature in DH; and finally, the best practices for collecting and archiving electronic literature as it affects GLAM and what it can teach us about all, or most, DH work subject to obsolescence. We hope that this panel will foster further explorations and collaborations between the two fields of study.

"Print" Works of Electronic Literature and Scholarly DH Narratives

Élika Ortega

These paper starts with the question what can DH practitioners learn from material composition of electronic literature works in order to improve the outreach of DH projects? This work focuses specifically on the material architecture of "print" works of electronic literature, which I understand as those that depend or heavily hinge on print materials for their digital configuration. Drawing from this corpus, I propose to take E-Lit works as models to explore and address the effect of digital media as it has modified––and continues to propose a modification of––reading and writing practices as well as modes of abstracting, encoding, and communicating information, all of which are common in DH pedagogical and research praxis.

First, I examine a handful of creative print works of electronic literature including Stephanie Strickland's et al *Vniverse* (2011), Amaranth Borsuk and Brad Bouse's *Between Page and Screen* (2012), Nick Montfort's *#!* (2014), and Jacob Garbe and Aaron Reed's *Ice-Bound* (2015). I argue that the architecture of these works requires specific infrastructural conditions and the unfolding of several practices or protocols for their reading that pose challenges not only for preservation and archives professionals, but for the average reader as well. Strickland's , Borsuk and Brad Bouse's , Montfort's, and Garbe Reed's works are so uniquely imagined and crafted that they seem to embed within them the specific critical framework to be theorized. In that sense, they too demand a tailored reading: a look into how their text is media and how their media is text. These kinds of compositions, I argue, have much to teach DH practitioners and students about the expressiveness of the digital medium, the way electronic and print media reciprocally inform, shape, and inflect each other. Further, they allow us to study the modification of the practices and protocols associated with each of its material components: print objects are not self-sufficient and translatable outside of the digital realm, computational devices are rendered useless without input from print materials. Even when these works are highly experimental, the specific conditions of each one constitute a laboratory to investigate contemporary changing reading and writing practices.

Further, I argue that in their radical specificity, creative works like these that rely on various print or digital media for their poetic, material, or narrative construction provide models for multimodal design that is both highly desirable and commonly found in DH scholarly outputs. The organization of information––whether poetic, narrative, or scholarly––is certainly responding to the same moving-target media landscape and, thus, bringing them all together offers an opportunity to observe how material composition is approached in creative works in ways that can be extrapolated to scholarly works. To that end, I extract a handful of compositional strategies from the works mentioned above that can be translated to a scholarly realm. Among them, we can find the use of augmented reality, the design of a script that takes the reader from one medium to another, the *extension* and complementation of information through different expressive languages, and even the performance of reading as an interpretive act. Under this light, aside from being great examples of poetic and computational creativity, these works of electronic literature are capable of illuminating the ongoing debates on the future of the book, and the place of the monograph in academic careers. Crucially, these works also signal the need for training in alternative reading and writing capacities that sits at the center of DH instruction, project development, and outreach. Taken as models of composition in the media ecology in which DH work is currently carried out, these works offer avenues for communication between the two fields not only on a conceptual level, but also as a methods of argumentation and interpretation.

Quantifying the Evolution of Electronic Literature with Zeta

James O'Sullivan

Introduction

This paper seeks to determine to extent to which electronic literature (understood as born-digital literature with an inherent computational aesthetic) has evolved, by analysing the language used to describe the works included in both *Volume I* and *II* of the Electronic Literature Organization's *Electronic Literature Collection*. These anthologies include descriptions of the works by their respective editors, as well as by the contributing authors. Outlining the various technical and literary characteristics reflected in each work, these descriptions provide a unique opportunity to determine the aesthetic qualities of the canon, as depicted by some of the field's most prominent practitioners. Furthermore, the considerable time between the publication of the collections, released in 2006 and 2011 respectively, is such that they provide a useful sample when examining how the electronic literary movement has developed throughout the contemporary era. Using a method typically reserved for print literature, this paper applies a macro-analytical approach to the analysis of these descriptions in an effort to produce some quantitative evidence to support critical interpretations on the evolution of electronic literature. Research of this sort has never been conducted in this field, and thus, not only does this paper develop our understanding of the literary movement in question, but it also breaks new ground in the application of specific computational methods to born-digital artistry.

Methodology & Results

For the purposes of this study, Craig's Zeta was selected as the method best suited to identifying trends in the manner by which electronic literature is described by its creators and curators. A Zeta analysis compares two datasets, producing a set of words distinct to each. In other words, it gives a set of words most likely to occur in Set A, which are unlikely to appear in Set B. In this instance, the analysis compared the editor and author contributions from each volume, providing a list of words which indicate what topics were being prioritised across the collections. Comparing these wordlists, we can see how it is that the focus of the electronic literature community changed over the course of this particular time period. The Zeta analysis was conducted using R, with a text slice length of 2,000, text slice overlap of 1,000, an occurrence of 2, and filter threshold of 0.1. For the purposes of this abstract, the top 25 distinctive words have been displayed (see Table 1), but a more complete set of results will be addressed in the final offering.

Volume I (2006)	Volume II(2011)

Landscapes	friends
Frome	had
Day	imagery
Poetica	screens
Meditation	starts

Table 1. Top 25 distinctive words used to described the anthologised works

Interpretations

The results of the Zeta analysis provide computational evidence for many of the assumptions that one might make when speculating on this issue. For example, there is a marked shift from static "diagrams" in *Volume I*, to "video", in *Volume II*. The evolution of Web cultures is also apparent, with "dhtml" giving way to "google". Beyond these, somewhat expected, findings, other, more interesting, revelations are also present. In particular, the inclusion of herself" in the later collection would suggest a rise in feminist electronic literature, while words like "exploring" and "poetics" in *Volume I* suggests a field that, in 2006, is still ontologically uncertain. As already noted, a more robust analysis drawn from a more thorough interpretation of the entire set of findings will be offered in this paper. However, from this limited snapshot into this study, it is clear that this approach yields valuable insights into the field, and justifies the use of macro-analysis in the extrapolation of cultural contexts.

Rendering Literature: Methods for Collecting and Archiving Electronic Literature

Dene Grigar

This presentation, entitled "Rendering Literature: Methods for Collecting and Archiving Electronic Literature", focuses on methods developed to document early digital literature, 1986-1995.

This paper builds on research undertaken with *Pathfinders: Documenting the Experience of Early Digital Literature* (with Stuart Moulthrop, scalar.usc.edu/works/pathfinders), a project funded by the National Endowment for the Humanities that developed the methodology for documenting early works of electronic literature (1986-1995) and the print-based book, *Traversals* (forthcoming, The MIT Press, 2016, also with Moulthrop) that provides a critical look at the works themselves. *Rendering Literature* aims to discuss best practices for collecting and archiving electronic literature by libraries, museums and other institutions so that works retain their inherent significant properties, including its cultural context.

Electronic literature is an experimental literary art form that can include a combination of words, images, sound, video, animation, gestures, and movement but always involves code and computation. Referred to often as born digital literature, electronic literature cannot be experienced meaningfully in print and is intended, instead, to be accessed through digital devices. Early work was published on floppy disks, CDs, and DVDs, but the advent of the web made sharing it online with a global audience popular from 1995 onward. The introduction of smart mobile devices in the mid-2000s drove artists to innovate their art for the app environment. To remain accessible to a reading audience, many works of electronic literature have been updated to newer platforms and software iterations––sometimes many times––resulting in numerous versions of a work. In cases of literary art produced as apps, it is not possible to study versions of a work saved on a single device because upgrading to a new version of a work overwrites the previous version completely.

Contributing to the challenge of archiving electronic literature is that many of these works are published as a combination of digital files, accompanying documentation websites, and ephemera. Some, like John McDaid's *Uncle Buddy Phantom Funhouse* (1993) include audio cassettes that are part of the narrative. Others like Judy Malloy's *Uncle Roger Version 3* (1987-8) were packaged in hand-made artists boxes that themselves are works of visual art. Recent works like Erik Loyer's *Breathing Room* (2013) or Amaranth Borsuk and Brad Bouse's *Whispering Galleries* (2014), require additional equipment like a Leap Motion controller. Still others like Jody Zellen's *Urban Rhythms* (2011) exist only as apps. In a word, these works differ widely from traditional digital texts and yet, to date, there are no specific methods used for handling this form of literary art.

A visit in October 2015 to the David M. Rubenstein Rare Book and Manuscript Library

at Duke University to locate data in the Judy Malloy Papers for an article about her database novel, *Uncle Roger*, drove home the need to analyze methods of archiving and preservation undertaken at collections of electronic literature in the U.S. Floppy disks were separated from their artists boxes and unavailable for review, while inserts for the artists boxes were placed in separate folders in a different section of the archival containers. The six versions of the work were not readily distinguishable from one another. Discussions with the librarians and archivists revealed that they too were interested in determining how best to handle such complex problems for works that resist current preservation and archival practices.

Research Significance

Nothing lasts forever. Paper mildews. Sappho's nine books of poetry were burned, leaving but a few extant poems for us to read. Today, poetry and literary forms are increasingly produced in the electronic medium, and the danger facing them is not dampness or fire but the constant innovation of digital technology. Net poetry by artists like Jason Nelson created a mere 10 years ago, for example, is quickly becoming obsolete today because the Apple Corporation decided in 2007 not to support Flash on its iPhones. Despite this problem, digital technologies have fostered the production of so much experimental work that one of the key challenges facing the humanities today is how to transmit the heritage of a culture whose objects are multiplying not simply in mass of items but also in types of system or interface––and where the nature of those varying interfaces greatly complicates the task of identifying, collecting, and otherwise treating the object. This is an enterprise that requires traditional archival research to work in conjunction with Digital Humanities practice where computation methods figure largely (Burdick et al., 3).

Experience

For the last 25 years I have collected works of electronic literature. Driving my efforts besides a fascination with avant-garde literature was the early realization that many of the works in my collection were, over time, becoming impossible to access without computer equipment contemporary with the works themselves. In other words, it became necessary for me to collect, along with floppy disks, CDs, and DVDs holding electronic literary poetry, fiction and essays, computers for which the works were intended to be experienced. To date, I have collected a library of 200 works of electronic literature and 46 vintage computers dating to 1977. I have also found it necessary to collect versions of software for which these works were produced, such as Netscape Communicator used by many electronic literature artists for early experiments with net art and other web-based practices. My library and computer collections are now housed together in the Electronic Literature Lab (ELL, dtc-wsuv.org/wp/ell) at the Vancouver campus. ELL represents the method of digital preservation called Collecting, an approach different from Migrating and Emulating in that it seeks to retain the cultural experience of a work without moving it to a newer platform or representing it in a new setting, respectively.

Introduction

Can we find and track theory, especially literary theory, in very large collections of texts using computers? This panel discusses a pragmatic two-step approach to trying to track and then visually explore theory through its textual traces in large collections like those of the HathiTrust.

1. **Subsetting:** The first problem we will discuss is how to extract thematic subsets of texts from very large collections like those of the HathiTrust. We experimented with two methods for identifying "theoretical" subsets of texts from large collections, using keyword lists and machine learning. The first two panel presentations will look at developing two different types of theoretical keyword lists. The third presentation will discuss a machine learning approach to extracting the same sorts of subsets.

2. **Topic Modelling:** The second problem we tackled was what to do with such subsets, especially since they are likely to still be too large for conventional text analysis tools like Voyant (voyant-tools.org) and users will want to explore the results to understand what they got. The fourth panel presentation will therefore discuss how the HathiTrust Research Center (HTRC) adapted Topic Modelling tools to work on large collections to help exploring subsets. The fifth panel talk will then show an adapted visualization tool, the Galaxy Viewer, that allows one to explore the results of Topic Modelling.

The panel brings together a team of researchers who are part of the "Text Mining the Novel" (TMN) project that is funded by the Social Sciences and Humanities Research Council of Canada (SSHRC) and led by Andrew Piper at McGill University. Text Mining the Novel (novel-tm.ca) is a multi-year and multi-university cross-cultural study looking at the use of quantitative methods in the study of literature, with the HathiTrust Research Center is a project partner.

The issue of how to extract thematic subsets from very large corpora such as the HathiTrust is a problem common to many projects that want to use diachronic collections to study the history of ideas or other phenomena. To conclude the panel, a summary reflective presentation will discuss the support the HTRC offers to DH researchers and how the HTRC notion of "worksets" can help with the challenges posed by creating useful subsets. It will further show how the techniques developed in this project can be used by the HTRC to help other future scholarly investigations.

Using Word Lists to Subset

Geoffrey Rockwell (Kevin Schenk, Zachary Palmer, Robert Budac and Boris Capitanu)

How can one extract subsets from a corpus without appropriate metadata? Extracting subsets is a problem particular to very large corpora like those kept by the HathiTrust (www.hathitrust.org/). Such collections are too large to be manually curated and their metadata is of limited use in many cases. And yet, one needs ways to classify all the texts in a collection in order to extract subsets if one wants to study particular themes, genres or types of works. In our case we wanted to extract theoretical works which for the purpose of this project we defined as Philosophical works or Literary Critical works. In this first panel presentation we will discuss the use of keyword lists as a way of identifying a subset of "philosophical" texts.

Why philosophical? We choose to experiment extracting philosophical texts first as philosophy is a discipline with a long history and a vocabulary that we hypothesized would lend itself to a keyword approach. Unlike more recent theoretical traditions, philosophical words might allow us to extract works from the HathiTrust going back thousands of years.

Keywords. For the first part of this project we adapted a list of philosophical keywords from the Indiana Philosophy Ontology Project (inpho.cogs.indiana.edu/). Our adapted list has 4,437 words and names starting with "abauzit", "abbagnano", "abdolkarim", "abduction", "abduh", "abel", and so on. There are a number of ways of generating such lists of keywords or features, in our case we were able to start with a very large curated list. The second paper in this panel discusses generating a list of literary critical keywords.

Process. We used this list with a process we wrote in Python that calculates the relative frequency of each word in a text and does this over a collection. The process also calculates the sum of the relative frequencies giving us a simple measurement of the use of philosophical keywords in a text. The word frequency process generates a CSV with the titles, author, frequency sum and individual keyword frequencies which can be checked and manipulated in Excel.

Testing. We iteratively tested this keyword approach on larger and larger collections. First we gathered a collection of 20 philosophical and 20 non-philosophical texts from Project Gutenberg (www.gutenberg.org/). We found the summed frequency accurately distinguished the philosophical from the non-philosophical texts. The process was then run by the HTRC on a larger collection of some 9,000 volumes and the results returned to us. We used the results to refine our list of keywords so that a summed relative frequency of .09 gave us mostly philosophical works with a few false positives. We did this by sorting the false positives by which words contributed to their summed relative frequency and then eliminating those words from the larger list that seemed to be ambiguous.

The process was then run on the HathiTust Open Open collection of 254,000 volumes. This generated some 3230 volumes that had a summed relative frequency over .1, which seemed a safe cut-off point given how .09 had worked with a smaller collection. To assess the accuracy of this method we manually went through these 3,230 and categorized them using the titles producing a CSV that could be used with other classification methods.

The table below summarizes the categories of volumes that we found, though it should be noted that the categorization was based on the titles, which can be misleading. "Unsure" was for works which we weren't sure about. "Not-Philosophical" were those works that we were reasonably sure were not philosophical from the title. The categories like Science and Education were for works about science and philosophy or education and philosophy.

Tag (Type)	Number of Volumes	Example
Unsure	349	The coming revolution (1918)
Education	473	Education and national character (1904)
Philosophy	813	Outlines of metaphysics (1911)
Science	189	Relativity; a new view of the universe (1922)
Social	526	The study of history and sociology (1890)
Religion	722	Prolegomena to theism (1910)
Not Philosophical	158	Pennsylvania archives (1874)

One of the things that stands out is the overlap between religious titles and philosophical ones. This is not surprising given that the fields have been intertwined for centuries and often treat of the same issues. We also note how many educational works and works dealing with society can have a philosophical bent. It was gratifying to find only 4.9% of the volumes classified seemed clearly not philosophical. If one includes the Unsure category it is 15.7%, but the Unsure category is in many ways the most interesting as one reason for classifying by computer is to find unexpected texts that challenge assumptions about what is theory.

Conclusions. Using large keyword lists to classify texts is a conceptually simple method that can be understood and used by humanists. We have lists of words and names at hand in specialized dictionaries and existing classification systems. Lists can be managed to suit different purposes. Our list from InPhO had the advantage that is was large and inclusive, but also the disadvantage that included words like "being" and "affairs" that have philosophical uses but are also used in everyday prose. The same is true of the names gathered like Croce that can refer to the philosopher or the cross (in Italian). Further trimming and then weighting of words/names could improve the classification of strictly philosophical texts. We also need to look deeper into the results to find not just the false positives, but also the true negatives. In sum, this method has the virtue of simplicity and accessibility and in the case of philosophical texts can be used to extract useful, though not complete, subsets.

The Problem with Literary Theory

Laura Mandell (Boris Capitanu, Stefan Sinclair, and Susan Brown)

In this short paper, I describe adapting the word list approach developed by Geoffrey Rockwell for extracting a subset of philosophical texts from a large, undifferentiated corpus, to the task of identifying works of literary theory. The degree to which running the list of terms did in fact pull out and gather together works of literary criticism and theory is very high, despite potential problems with such an enterprise, which we discuss in this talk in detail.

1. **Developing the list of literary terms**. Susan Brown and I decided to gather lists of literary terms. Susan initiated a discussion with the MLA about using terms from the *MLA Bibliography* but upon consideration these were in fact not at all what we needed: they classified subjects of texts as opposed to listing terms that would appear in those texts. I had recently spent some time learning about JSTOR's new initiative in which sets of terms are created by what they call "SMEs"--Subject Matter Experts--and then used to locate articles all participating in an interdisciplinary subject. Their first foray is available in Beta: it gathers together all articles in no matter what field on the topic of Environmental Sustainabilty (labs.jstor.org/sustainability/). The terms collected are terms that would appear *in* the relevant texts, not in the metadata about them; the goal is to collect documents across multiple categories related to specialization, discipline, and field, since the desired result to gather together interdisciplinary texts concerning a common topic.

2. **Anachronism.** JSTOR had started a "literary terms" list, and I finished the list of terms relying on encyclopedias of literary theory. Could a list of terms significant in the late-twentieth-century theories of literature as expressed in articles gathered in JSTOR be used to extract a set of texts published much earlier that analyze literature? What about the historical inaccuracy of using twentieth-century terms to find eighteenth- and nineteenth-century literary criticism?

In fact, results show solidly that this anachronistic list of terms developed by experts do work to gather materials that preceded and fed into, served to develop, the discipline of literary theory. One of two falsely identified texts among the top relevant documents has to do with water distribution systems which had, as part of its most frequent terms, "meter" and "collection," two terms relevant to analyzing the medium and content of poetry. Other false positives are similarly explicable, and, most important, they are rare.

In this paper, we report upon the effects of running these frequent words on very large datasets using both unsupervised to supervised learning.

Machine Learning

Stefan Sinclair (and Matthew Wilkens)

The third panel presentation deals with machine learning techniques to extract subsets. Unsupervised learning techniques allow us to evaluate the relative coherence of theoretical clusters within large textual fields and to identify distinct theoretical subclasses in the absence of any firmly established anatomy of the discipline. For these reasons, we performed unsupervised classification on three corpora: (1) A large collection (c. 250,000 volumes) of mixed fiction and nonfiction published in the nineteenth and twentieth centuries. (2) A subset of that corpus identified by algorithmic and manual methods as highly philosophical. And (3) A subset similarly identified as literary-critical.

In the case of the large corpus, the goal was to identify subsets containing high proportions of philosophy and criticism. For the smaller sets, we sought to produce coherent groupings of texts that would resemble subfields or concentrations within those areas. In each case, we extracted textual features including word frequency distributions, formal and stylistic measures, and basic metadata information, then performed both *k*-means and DBSCAN clustering on the derived Euclidean distances between volumes.

As in past work on literary texts (Wilkens, 105), we found that we were able to identify highly distinct groups of texts, often those dealing with specialized and comparatively codified subdomains, and that we could subdivide larger fields with reasonable but lower accuracy. The model that emerges from this work, however, is one emphasizing continuity over clear distinction. Subfields and areas of intensely shared textual focus do exist, but a systematic view of large corpora in the philosophical and literary critical domains suggests a more fluid conception of knowledge space in the nineteenth and twentieth centuries.

In parallel with the unsupervised classification performed – an attempt to allow distinctive features to emerge without, or with less, bias – we also performed supervised classification, starting with the training set of 40 texts labelled as Philosophical and Other (mentioned in "Using Word Lists to Subset" above). We experimented with several machine learning algorithms and several parameters to determine which ones seemed most suitable for our dataset. Indeed, part of this work was to recognize and and normalize the situation of the budding digital humanist confronting a dizzying array of choices: stoplists, keywords, relative frequencies, TF-IDF values, number of terms to use, Naïve Bayes Multinomial, Linear Support Vector Classification, penalty parameter, iterations, and so on ad infinitum. Some testing is desirable; some guesswork and some craftwork are essential. We reflect on these tensions more in the iPython notebook (Sinclair et al., 2016) and we will discuss them during the presentation as well.

One of the surprises from these initial experiments in machine learning was that using an unbiased list of terms from the full corpus (with stopwords removed) was considerably more effective than attempting to classify using the constrained philosophical vocabulary. Again, this may be because the keywords list was overly greedy.

Just as we experimented with ever-larger corpora for the "Using Lists to Subset" sub-project, the supervised learning subproject broadened its scope gradually in an attempt to identify theoretical texts unknown to us while examining the efficacy of the methodologies along the way. Indeed, the overarching purpose of adopting all three approaches (keyword-based, unsupervised classification, machine learning) was to compare and contrast different ways of studying theory in a large-scale corpus.

Working with HTRC datasets

Boris Capitanu

The fourth panel presentation focuses on working with the HathiTrust and the particular format of HathiTrust texts. Researchers may obtain datasets directly from HathiTrust [1] by making a special request, after having fulfilled appropriate security and licensing requirements. Datasets in HathiTrust and HTRC are available in two different ways:

- via rsync in Pairtree format
- via Data API

According to "Pairtrees for Object Storage (V0.1)" [2], the Pairtree is "a filesystem hierarchy for holding objects that are located within that hierarchy by mapping identifier strings to object directory (or folder) paths, two characters at a time". In the HathiTrust, the objects consist of the individual volume and associated metadata. Volumes are stored as ZIP files containing text files, one text file for each page, where the text file is named by the page number. A volume ZIP file may contain additional non-page text files, whose purpose can be identified from the file name. The metadata for the volume is encoded in METS XML [3] and lives in a file next to the volume ZIP file. For example, a volume with id "loc.ark:/13960/t8pc38p4b" is stored in Pairtree as:

loc/pairtree_root/ar/k+/=1/39/60/=t/8p/c3/8p/4b/ark+=13960=t8pc38p4b/ark+=13960=t8pc38p4b.zip
loc/pairtree_root/ar/k+/=1/39/60/=t/8p/c3/8p/4b/ark+=13960=t8pc38p4b/ark+=13960=t8pc38p4b.mets.xml

where "loc" represents the 3-letter code of the library of origin (in this case Library of Congress). As mentioned, the volume ZIP files contain text files named for the page number. For example, here are the first few entries when listing the contents of the above ZIP file:

ark+=13960=t8pc38p4b/
ark+=13960=t8pc38p4b/00000001.txt
ark+=13960=t8pc38p4b/00000002.txt
ark+=13960=t8pc38p4b/00000003.txt
…

Note that the strings that encode the volume id and the ZIP filename are different. Before a volume id can be encoded as a file name, it goes through a "cleaning" process that converts any character that is not a valid character to be used in a filename into one that is (for example ":" was converted to "+" and "/" to "="), also dropping the 3-letter library code. The specific conversion rules are obscure, but library code already exists [4][5] for multiple languages that is able to perform this conversion both ways.

The pairtree is an efficient structure for storing a large number of files. However, working with this structure can pose certain challenges. One of the issues is that this deeply nested folder hierarchy is slow to traverse. Applications needing to recursively process the volumes in a particular dataset stored in pairtree will have to traverse a large number of folders to "discover" every volume. A second inconvenience stems from the use of ZIP to store the content of a volume. While efficient in terms of disk space usage, it's inconvenient when applications need to process the text data of the volume as they would need to uncompress the ZIP file and read its contents, in the proper order, concatenating all pages, in order to obtain the entire volume text content. A further complication is due to the fact that the exact ordering and naming of the page text files in the ZIP file is only provided as part of the METS XML metadata file. So, if the goal is to create a large blob of text containing all the pages of a volume (and only the pages, in the proper order, without any additional non-page data), the most correct way of doing so is to first parse the METS XML to determine the page sequence and file names, and then uncompress the ZIP file concatenating the pages in the exact sequence specified. This, of course, has a large performance penalty if it needs to be done on a large dataset every time this dataset is used to address some research question.

An alternative way to obtain a particular dataset is to use the Data API [6]. Currently, access to Data API is limited, and is allowed only from the Data Capsule [7] while in Secure Mode. Using the Data API a researcher can retrieve multiple volumes, pages of volumes, token counts, and METS metadata documents. Authentication via the OAuth protocol is required when making requests to the Data API. The advantage of using the Data API in place of the pairtree (other than disk storage savings) is that one can request already-concatenated text blobs for volumes, and make more granular requests for token counts or page ranges without having to traverse deeply-nested folder structures or parse METS metadata.

In this panel presentation we will show how the tools developed for the Trace of Theory project were adapted to work with the Pairtree format. The goal is to help others be able to work with the HathiTrust data format.

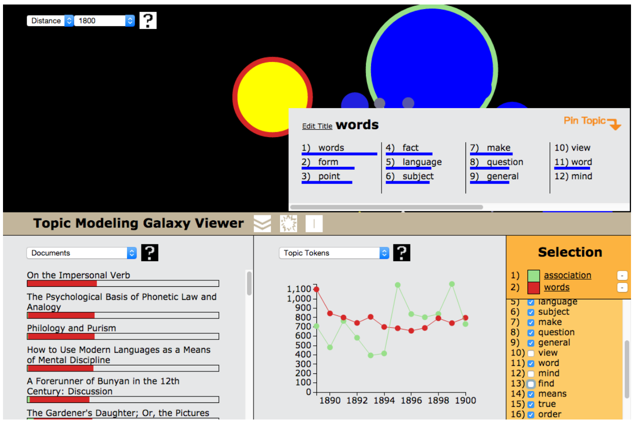
Topic Modelling and Visualization for Exploration

Susan Brown (Geoffrey Rockwell, Boris Capitanu, Ryan Chartier, and John Montague)

When working with very large collections even subsets can be too large to manage with conventional text analysis tools. Further, one needs ways of exploring the results of extraction techniques to figure out if you got what you were expecting or something surprising in an interesting way. In the fifth panel presentation we will discuss the adaptation of a tool called the Galaxy Viewer for visualizing the results of Topic Modelling (Montague et al., 2015). Topic modeling is an automated text mining technique that has proven popular in the humanities that tries to identify groups of words with a tendency to occur together within the same documents in a corpus. Chaney and Blei explain that, “One of the main applications of topic models is for exploratory data analysis, that is, to help browse, understand, and summarize otherwise unstructured collections.” (Chaney et al., 2012)



On the Impersonal Verb

The Gardener's Daughter; Or, the Pictures

The Galaxy Viewer prototype was developed to explore the results of topic modelling over large collections. It combines different views so that one can select topics, compare topics, explore the words in topics, follow topic tokens over time, and see the document titles associated with topics. In this presentation we will demonstrate the Galaxy Viewer and then discuss how it was scaled to handle much larger collections.

The prototype Galaxy Viewer backend code uses Mallet (McCallum, 2002) to infer the set of topics, topic distributions per document, and word probabilities per topic. Unfortunately, Mallet is meant to be used on small- to medium-sized corpora as it requires that the entire dataset be loaded into RAM during training. An additional constraint with Mallet is the fact that although Mallet can fully utilize all the CPU cores on a single machine, it’s not designed to work in a distributed-computing fashion across a number of machines, to speed up execution. As such, processing very large datasets (if even possible) might take a very long time (as the algorithm makes multiple passes over the entire dataset). Many implementations of LDA exist, which primarily fall into one of two categories: Batch LDA, or Online LDA. The core difference between batch and online LDA stems from what happens during each iteration of the algorithm. In batch mode, as mentioned earlier, each iteration of the algorithm makes a full pass over all the documents in the dataset in order to re-estimate the parameters, checking each time for convergence. In contrast, online LDA only makes a single sweep over the dataset, analyzing a subset of the documents each iteration. The memory requirement for online LDA depends on the chosen batch size only, not on the size of the dataset - as is the case with batch LDA.

We are currently in the process of researching/comparing the available implementations of LDA to establish which one would be best suited to use for the Galaxy Viewer. We are also considering the option of not fixing the LDA implementation, but instead make the backend flexible so that any LDA implementation can be used (as long as it provides the appropriate results that are needed). In the latter case we’d have to create specific result interpreters that can translate the output from the specific implementation of LDA to the appropriate format to be used to store in the database (to be served by the web service).

Given that Topic Modeling results do not expose the textual content of the documents analyzed, and cannot be used to reconstruct the original text, they are safe to be publicly shared without fear of violating copyright law. This is great news for researchers working with collections like those of the HathiTrust as they should be able to gain insight into datasets which are still currently in-copyright and would, otherwise, not be available to be inspected freely.

In the prototype Galaxy Viewer implementation, the output of the topic modeling step is processed through a set of R functions that reshape the data and augment it with additional calculated metrics that are used by the web frontend to construct the visualization. These post-processing results are saved to the filesystem as a set of five CSV files. One of these CSV files is quite large as it contains the topic modeling state data from Mallet (containing topic assignments for each document and word, and associated frequency count). The visual web frontend code loads this set of five files into memory when the interface is accessed the first time, which can take several minutes. For the prototype this approach was tolerated, but it has serious scalability and performance issue that needs to be addressed before the tool can be truly usable by other researchers.

Scaling the Galaxy Viewer therefore consists of creating a web service backed with a (NoSQL) database which will service AJAX requests from the front-end for the data needed to construct the topic visualization and related graphs. We are developing the set of service calls that need to be implemented/exposed by the web service to fulfill the needs of the front-end web-app. The backend service will query the database to retrieve the necessary data to service the requests. The database will be created based on the output of the Topic Modeling process, after required post-processing of the results is completed (to calculate the topic trends, topic distances, and other metrics used in the display). Relevant metadata at the volume and dataset level will also be stored to be made available to the front-end upon request. This work will be completed by the end of December 2015 so that it can be demonstrated in the new year. The scaled Galaxy Viewer will then provide a non-consumptive way of allowing users of the HathiTrust to explore the copyrighted collections. Extraction of subsets and Topic Modelling can take place under the supervision of the HTRC and the results database can then be exposed to visualization tools like the Galaxy Viewer (and others) for exploration.

Closing reflections: How "Trace of Theory" will improve the HTRC

J. Stephen Downie

The HathiTrust Research Center exists to give the Digital Humanities community analytic access to the HathiTrust's 13.7 million volumes. The HT volumes comprise over 4.8 billion pages each in turn represented by a high-resolution image file and two OCR files yielding some 14.4 billion data files! Thus, as the earlier papers have highlighted, the sheer size of the collection, along with the idiosyncratic nature of the HT data, together create several hurdles that impede meaningful analytic research. The HTRC is engaged in two ongoing endeavours designed to assist DH researchers in overcoming these obstacles: The Advance Collaborative Support (ACS) program [1]; and, the Workset Creation for Scholarly Analysis (WCSA) project [2].

The ACS program at HTRC provides no-cost senior developer time, data wrangling assistance, computation time and analytic consultations to DH researchers who are prototyping new research ideas using the HT data resources. The ACS program is an integral part of the HTRC's operation mission and was part of its value-added proposition when the HTRC launched its recent four-year operations plan (2014-2018). It is a fundamental component of the HTRC's outreach activities and as such, has staff dedicated to its planning, management and day-to-delivery. The ACS team was responsible for creating, and then reviewing, the competitive ACS Request for Proposals (RFP) that ask interested DH researchers outline their intellectual goals, describe their data needs, and estimate their computational requirements. The ACS team is generally looking for new projects that could benefit from some kickstarting help from HTRC. HTRC welcomes proposals from researchers with a wide range of experience and skills. Projects run 6 to 12 months.

Originally funded by the Andrew W. Mellon Foundation (2013-2015), the current WCSA program is building upon, extending and implementing the development made during the funding period. The HTRC project team, along with subaward collaborators at University of Oxford, University of Maryland, Texas Agriculture and Marine University and University of Waikato, developed a group of prototype techniques for empowering scholars who want to do computational analyses of the HT materials to more efficiently and effectively create user-specific analytic subsets (called "worksets"). A formal model has been designed to describe the items in a workset along with necessary bibliographic and provenance metadata that is now being incorporated into the HTRC infrastructure (Jett, 2015).

The Trace of Theory project was selected from the first round of ACS proposals. This concluding panel presentation will discuss in what ways the Trace of Theory project has been both a representative and a unique exemplar of the ACS program. It will present some emergent themes that evolved from the HTRC-Trace of Theory interactions that we believe will have an important influence on the delivery of future ACS projects. In the same manner, it will reflect upon the problems the team of researchers had in subsetting the data to build their necessary worksets along with the solutions that the HRTC-Trace of Theory collaboration developed to surmount those difficulties. The panel will finish with a summary of how HTRC intends to incorporate the lessons learned into its day-to-day operations as well as future ACS projects.

Panel Topic

Folkloric communication is a specific mode of social interaction that uses existing knowledge and creatively adapts it to particular situations, audience, and intent. It always includes some repetition and some innovation or, in other words, as Michel de Certeau (1984) expresses it in his study of everyday practices, the main attribute of cultural transmission is the changing nature of everything that is being passed on.

The questions of authorship, stylistics and variation in time and space have been discussed and problematized in folklore studies for over a hundred years. Digital era has brought along mass digitization of cultural heritage documents and the compilation of folklore databases and text corpora (see e.g. Schmitt, 2014). However, the use of computational methods in researching folklore and its specifics has thus far been modest. The intention of this panel is to discuss the possibilities that computational methods have to offer in revealing the inherent qualities of folkloric communication in various text collections and research corpora. The participants of the panel deal with different source data including archival records and publications as well as contemporary social media. They discuss different aspects of folkloric communication and variation, contributing together to a general insight into these processes.

The Panel: speakers and contributions

In this panel, the participants will introduce their projects, data, methods and research results to contextualize and elicit a discussion on the state-of-the-art in digital folkloristics, and on possible ways forward.

Mari Sarv and **Risto Järv** (Estonian Literary Museum) analyse the essence of **folkloric variation** relying on the text corpora from the collections of Estonian Folklore Archives. The Estonian Runic Songs' database (1996-2015) contains ca. 100,000 poetic texts, and the database of folk tales consists of 11,000 tales (both together with metadata). Previous studies of folksongs have shown that the statistical analysis of poetical features of songs as well as their content allows us to locate their geographical origin (i.e. tracing the belonging of songs to the tradition of a local community) quite precisely. At the same time there are clear differences in the geographical distribution of linguistic-poetical features, especially compared to the elements of content. The stylistic analysis of folklore texts enables us to find out how much the personal style of performer is revealed in folkloric recordings of traditional plots ('types' in the folkloristic discourse). The potential of computational methods to tackle the dichotomy of stability and variation in the folkloric communication poses a most intriguing challenge.

Kati Kallio (Finnish Literary Society) will discuss **the characteristics of oral poetry**, including complex patterns of variation and tricky definitions of authorship, and concentrate on the challenges posed by of the SKVR-corpus of Finnic oral poetry (see also Digital Archive of Finnish Folk Tunes). The corpus represents various languages and dialects, orthographies, personal writing styles and traces of different modes of performance, but is held together by similar poetic registers. For this kind of specific poetic register in several related small languages and across a wide variety of genres, no ready-made tools for computational linguistic analysis exists. On the other hand, the corpus already includes a detailed thematic index, and the researchers have applied various manual methods to the corpus for hundred years. What kinds of new questions could be answered with computational methods? The author will present some test analyses and discuss the future possibilities of digital folkloristics on oral poetry.

Greta Franzini and **Emily Franzini** (Göttingen Centre for Digital Humanities) will elaborate on two research projects focusing on the computational interrogation of folktale collections and corpora. Using the Brothers Grimm's Kinder- und Hausmärchen as a case study and base reference, one project addresses the popularization of fairy tale motifs triggered by the Brothers, and seeks to algorithmically crawl web corpora to study the global network of motifs. Motifs form the significant set of "key words" of a tale. In order to systematically crawl for parallel texts, we prepare a digital, machine-readable and -citable index in different languages. TRACER as a text reuse framework is used to check if a document contains similar keywords or describes the same tale. It implements a seven-layer approach combining segmentation, preprocessing, featuring, selection, linking, scoring, and postprocessing steps. The other project examines the textual evolution of the Kinder- und Hausmärchen, starting with the first edition published in 1812 to the seventh and last in 1857. The number of fairy tales grew with every edition, and the numerous changes the Brothers made over the decades in terms of both style and content were symptomatic of societal interest and development. These seven editions represent an ideal testbed not only to computationally verify existing research about this progression but also to identify and distinguish the authorial and stylistic fingerprints of Jacob and Wilhelm Grimm. The discussion will demonstrate the possibilities afforded by the Digital Humanities to conduct **web-scale** and **Big Data** research.

Liisi Laineste (Estonian Literary Museum) is applying the methodologies of Digital Humanities to the folkloric aspect of **social media** content in combination with theories of global information flow, participatory journalism and humour theory. Internet has become central in contemporary cultural communication – most of online communication can be treated as folklore, in which shared norms and values are constructed through cultural artifacts. Forums, commentary boards of news sites, blogs, Twitter and other social media applications have become commonplace during the last fifteen years. In the Internet, news, ideas and opinions travel fast. Social media spreads folklore in unforeseen volumes across national and cultural boundaries. Above all, the focus is on producing and consuming texts, images and multimedia. The presentation will attempt to trace such cultural texts as they move across and between cultures. Besides, as social media is often perceived as a catalyst and accelerator of public discussion and citizen movements, cultural texts as valuable agents in citizen engagement will be discussed in the light of the 2015 refugee crisis in Europe.

APIs in Digital Humanities: The Infrastructural Turn

As a community of practice, digital humanists deal with data and metadata not as static artifacts, but rather as complex, multi-dimensional and multi-layered datasets that can be analyzed, annotated and manipulated in order to produce new knowledge. One of the most important challenges facing DH today is how to consolidate and repurpose available tools; how to create reusable but flexible workflows; and, ultimately, how to integrate and disseminate knowledge, instead of merely capturing it and encapsulating it. This technical and intellectual shift can be seen as the "infrastructural turn" in digital humanities (Tasovac et al. 2015).

Application Programming Interfaces (APIs) have the potential to be powerful, practical building blocks of digital humanities infrastructures. On the technical level, they let heterogeneous agents dynamically access and reuse the same sets of data and standardized workflows. On the social level, they help overcome the problem of "shy data", i.e. data you can "meet in public places but you can't take home with you" (Cooper 2010). Some 10 years ago, Dan Cohen started the conversation about APIs in DH by pointing out that, despite their potential, Andreas few humanities projects — in contrast to those in the sciences and commercial realms — were developing APIs for their resources and tools (Cohen 2005). In the decade since, API development in the digital humanities has certainly increased: today, both large-scale, national and international initiatives, such as HathiTrust, DPLA or Europeana, as well as individual projects, such as Canonical Text Services (CTS), Open Siddur, Folger Digital Texts, correspSearch etc., are focusing their attention and resources on developing APIs. It is now time to reflect on this development: have standards or best-practices evolved? What workflows are most effective and efficient for creating APIs? What are the challenges or stumbling blocks for creating or using APIs? Are APIs being used by DH researchers? What is the future of API development and use in the humanities community?

This panel will cover both the theory and practice of APIs in the digital humanities today. It will bring together researchers working on major European and North American projects, who will discuss APIs from the perspectives of design, implementation, and use, as well as technical and social challenges. Each group will have 10 minutes for their statement, and 40 minutes will remain for group discussion and questions from the audience. One of the panel members will serve as the moderator. All speakers have confirmed their intention to participate in the panel.

Toma Tasovac (Belgrade Centre for Digital Humanities) will discuss an API-centric approach to designing and implementing digital editions. Starting with the notion of text-as-service and textual resources as dynamic components in a virtual knowledge space, Tasovac will show how two recent projects — *Raskovnik: A Serbian Dictionary Platform* and *Izdanak: A Platform for Digital Editions of Serbian Texts* — were implemented using API-focused data modeling at the core of the project design process. The API-first approach to creating TEI-encoded digital editions offers tangible interfaces to textual data that can be used in tailor-made workflows by humanities researchers and other users, well-suited to distant reading techniques, statistical analysis and computer-assisted semantic annotation. The "infrastructural turn" in Digital Humanities does not only have practical implications for the way we build tools and create resources, but also has theoretical ramifications for the way we distinguish highly from loosely structured data: if text is not an object, but a service; and not a static entity, but an interactive method with clearly and uniquely addressable components, a formal distinction between a dictionary and, say, a novel or a poem, is more difficult to maintain.

Clifford Wulfman and **Natalia Ermolaev** (Center for Digital Humanities, Princeton) will discuss the design and implementation of Blue Mountain Springs, the API for the Blue Mountain Project's collection of historic avant-garde periodicals. By modeling magazine data using the FRBRoo ontology and its periodical-oriented extension PRESSoo (PRESSoo, 2014), this RESTful API exposes the Blue Mountain resource in a variety of data formats (structured metadata, full-text, image, linked data). The authors will provide several examples of how Blue Mountain Springs has been used by researchers, drawing especially from the results of the hackathon they will host at Princeton in February 2016, which will bring together approximately twenty periodical studies scholars, technologists, and librarians to work with the API. Creating APIs is part of a trend in DH to move into a post-digital-library phase, when the traditional library functions of discovery and access are no longer sufficient to support research in the humanities. This trend also suggests that DH researchers must reconceptualize their own engagement with material, to think less in terms of monographs and more in terms of resources, and consequently to promulgate their work not as web sites but as web services.

Thibault Clérice (University of Leipzig) will discuss the design of the Canonical Text Services (CTS) and its URN scheme, which make the traditional citation system used by classicists machine-actionable (Blackwell and Smith 2014)[1]. The Homer Multitext (HMT) implementation of CTS requires textual data to be extracted out of its original digital representation into RDF triples in order to be served. The Perseus Digital Library (PDL) implementation, on the other hand, uses extended transformations to slice XML files into multiple records, each representing a passage at a certain level. While relational and RDF database approaches have had some success in scalability and speed (Tiepmar 2015), they also have to deal with maintenance and evolution capacity. There is a real need for this type of DH projects to scale not only in terms of data retrieval speeds, but also in terms of allowing researchers to correct and enhance their data. In addition, projects need to be able to propose other narratives: sliced data doesn't easily provide access to the full data model. Clérice will discuss why and how, using both a native XML-based system such as eXist and a Python-based implementation, one can achieve scalability while guaranteeing maintenance and evolution.

Adrien Barbaresi from the Austrian Academy of Sciences (ICLTT) will discuss the use of APIs in building resources for linguistic studies. The first case deals with lesser-known social networks (Barbaresi 2013) while the second tackles the role of the Twitter API in building the ICLTT's "tweets made in Austria" corpus[2]. For computational linguists, short messages published on social networks constitute a "frontier" area due to their dissimilarity with existing corpora (Lui & Baldwin 2014), most notably with reference corpora of written language. Since data are mainly accessed and collected through APIs and not in the form of web pages, Barbaresi argues that social networks are a frontier area for (web) corpus construction. He will point out the challenges of using Twitter's API, for example how to reveal the implicit decisions and methodology used by API designers, as well as concrete implementation issues, such as the assessment and optimization of data returned by the API. Free APIs may come at no cost, but they also offer no guarantee, so that the use of commercial APIs for research purposes has to be seen with a critical eye in order to turn a data collection process into a proper corpus.

Finally, **Jennifer Edmond** and **Vicky Garnett** (Trinity College Dublin), will provide reflections on the place of APIs within European research infrastructures for the humanities. Their contribution to the panel builds on their recent study on the Europeana Cloud project, which found that while access to data is a real and growing area of interest, very few humanities researchers seem to actively and directly use APIs.[3] They will describe two initiatives, one technical, one social, aiming to better harness the potential of the API to meet researcher's implicit needs. The first is the Collaborative European Digital Archival Research Infrastructure (CENDARI) project, whose platform is structured around an internal API that will allow multiple data sources (local repository, triple store, metasearch engine) to be aligned, enhanced and then served out to a number of environments and tools, including the project's native note-taking environment. The second example is the genesis and development of the concept of the 'inside-out' archive. This framework, which has arisen out of a collaborative venture between several European humanities research infrastructure projects, seeks to encourage collection holding institutions to look beyond their own digitization programs and platforms and recognize the rising importance of machines-as-users (requiring specific access points and formats) rather than the somewhat outdated model of individual institutional web presence serving individual human resource seekers.

The five speakers on this panel will address some of the most pressing issues related to the ongoing development and future of APIs on the DH research infrastructure landscape. The discussion will cover both micro- and macro levels, ranging from methodological implications and technical scalability to the ways in which API-based data access to collections challenges traditional norms of institutional identity and independence. As such, the panel will offer a timely platform for a multifaceted debate on the potentials and pitfalls of building and using APIs in the digital humanities.

Notes

[1] Infrastructures are installations and services that function as "mediating interfaces" or "structures 'in between' that allow things, people and signs to travel across space by means of more or less standardized paths and protocols for conversion or translation" (Badenoch and Fickers 2010, 11). Digital research infrastructures are no different: they are a mediating set of technologies for research and resource discovery, collaboration, sharing and dissemination of scholarly output.

[2] http://bluemountain.princeton.edu

[3] Traditional scholars have been citing texts the same way for centuries : for example, "Hom. Il. 1.1", which corresponds to Homer's Iliad, Book 1 Line 1. However, although the passage identifier does not change from one scholar to another in most cases, the abbreviation used for the author and the work title will diverge among authors, countries, and publications.

[4] http://www.oeaw.ac.at/icltt/node/193

[5] This is a result of the confluence of several factors: that the research data most humanists want to access is seldom available via an API; that many sources that do offer relevant data lack the structure or metadata to make the API useful; and that humanistic researcher generally lack the skill set to experiment directly with APIs. At the same time, however, one of the key desires expressed by researchers in the current landscape is the federation of high-quality data (Edmond and Garnett 2015).

MEDEA (Modeling Semantically Enriched Digital Editions of Accounts)

Most human communities have produced accounts of various sorts, and scholars have long used accounts as primary sources for economic and social history. MEDEA is a collaborative project that involves participants from three continents and includes projects using primary sources that span several centuries across multiple geographical regions. We recommend that digital editions of accounts—business, governmental, personal—use XML/TEI, the widely accepted stable archival format for digital scholarly editions, as a first step. XML/TEI-based editions of accounts should be further encoded using RDFs/OWL to take advantage of the affordances of the Semantic Web and Linked Open Data. Producing semantically enhanced digital scholarly editions of accounts on this general model will create opportunities to ask new questions about the social and economic lives of people in the past. The session features participants from MEDEA's first year; we expect the project to continue for several more years, depending on resources.

Accounts: abstract models of human interactions

Account books share with printed and manuscript texts in prose, poetic, or dramatic forms a problem in data modeling because they are already abstract representations of human interactions. In the case of accounts, although these representations have taken different forms in different times and places, they have an apparent uniformity in that they often consist of lists of people, goods, and services accompanied by numerical values that represent amounts of currency, credit, or in-kind benefits exchanged. Often but not always, these values are totaled or balanced in some way (Tomasek and Bauman, 2013). The development of printed ledgers and spreadsheets illustrates the apparent uniformity of the structure of account books. Contemporary spreadsheet software fails to recognize the conceptual abstractions embedded in the physical format, but these unmarked abstractions are carried into the representations of spreadsheet information in digital form.

Accounts contain both numerical and semantic information (Thaller, 2012; Vogeler, 2014). Various types of accounts lend insight into business dealings, institutional, municipal, and state activities as well as personal uses of goods, property, and currency. The numerical information might include prices, wages, payments of customs duties or taxes as well as quantities of time worked and goods exchanged. In its simplest form, such information can be input as comma separated values (csv), and spreadsheet software can be used to perform calculations on the data. Through the emphasis on calculation, spreadsheets privilege the numerical information found in accounts.

But financial records include information of historical interest in addition to data expressed in numerical form. Account books often include the names of people with whom an individual or organization exchanged goods and services. Goods, services, and currencies have historically significant values in addition to the numerical data expressed as prices, wages, and quantities of time or goods, and such values have associations that are of historical interest. For example, different grains were staples for bread making in different regions (Allen, 2001).

Indeed, the semantic information contained in accounts can provide a rich picture of a community at the local level as well as that community's relationships to others across space and time. In combination with other kinds of community records well known to social and economic historians—tax lists, church memberships, probate inventories, manuscript census returns—the semantic information embedded in accounts can reveal insights that the pure numerical representation might obscure. And such information might open up new avenues of inquiry or facilitate new insights into the operations of past networks of human relationships.

Historical accounts on the Semantic Web

If the semantic information is marked in standardized machine-readable ways, digital editions of accounts can be combined with Semantic Web technologies to produce much richer comparative information about the human relationships they represent than has been possible with earlier iterations of social and economic history. In fact, accounts are an example of a problem space in which insights of

Digital Humanities can improve longstanding practices in social scientific uses of computers to produce data about past human practices and relationships.

Since the Semantic Web offers opportunities to collect and compare data from multiple digital projects, the MEDEA project looks to the potential of developing broad standards for producing semantically enriched digital editions of accounts. Because the Guidelines of the Text Encoding Initiative (TEI) offer a method for creating stable humanities-oriented data from textual sources, MEDEA explores models for building on them to test ways to publish data on commodities, wages, and prices susceptible to comparative analysis.

While the TEI Guidelines provide a standard for markup of manuscript and print sources, some of the elements and attributes most useful for accounts fail to model machine-readable values adequate to the goal of comparability of accounts originally created across broad ranges of time and space. Thus the MEDEA project looks also to CIDOC-CRM and RDF/OWL as sites to begin consideration of the kinds of taxonomies and ontologies that will produce standard machine-readable values to express some of the semantic values found in accounts--especially information about commodities and currencies--that are relevant to humanities scholars. This includes conversion of local measures (Vogeler, 2014).

At present, the MEDEA leadership team imagines semantically enriched digital editions as networks of references between several digital representations of original archival account books. Such editions will allow scholars with varied interests to use the data from the accounts in different ways according to their fields and scholarly interests. We consider RDF a good solution to publish the data extracted from accounts in machine-readable format as it facilitates explicit references to other (possible) representations of the accounts. If spreadsheets are employed, their use should be restricted to data input and calculations.

Presentations

This multi-speaker session reports on results from the first stage of a joint project of historians at the University of Regensburg, the Centre for Information Modeling - Austrian Centre for Digital Humanities at the University of Graz, and Wheaton College in Massachusetts. Short presentations from participants will highlight historical and technical features central to MEDEA.

Kathryn Tomasek will act as chair for the session and offer some brief observations about the advantages of international and cross-institutional collaborations for developing standards for semantically enhanced digital editions of accounts. In North America, the greatest support for producing digital editions of accounts tends to come from a small number of well-established documentary projects and from librarians and archivists who seek to encourage use of their sources. Resistance continues in the form of familiar objections emphasizing the labor-intensive nature of TEI and transcription generally. Both using transcription and markup in undergraduate classrooms and exploring opportunities for carefully curated crowdsourcing offer possible solutions. Graduate advisors in Asia and Europe seem to be more open to encouraging their doctoral students to explore digital edition of accounts than do those in the United States. Developing an international community of practice increases the likelihood that existing projects will seek ways to optimize their own data for the Semantic Web.

Kathrin Pindl and **Anna Paulina Orlowska** offer examples of ongoing interest in accounts as primary sources for historical study at the graduate level. Influenced by the work of British economic historian Richard C. Allen, Pindl hopes to develop better serial data through digital edition of accounts (Allen, 2001). Pindl will discuss her MEDEA working groups' experiences with beginning a digital scholarly edition of granary accounts from the St. Katharinenspitalarchiv in Regensburg. Orlowska will describe challenges to producing a digital edition of the accounts of Hanseatic merchant Johan Pyre, who was active in Danzig from 1421 to 1455. Since Pyre's bookkeeping methods developed through eight clear stages during those twenty-four years and contained unreliable temporal data, they demand a careful search for proper algorithms for their translation into digital media.

Oyvind Eide, **Cliff Anderson**, and **Georg Vogeler** will speak to some of the technical questions involved with data modeling for the Semantic Web. Eide will describe advantages of event-based modeling like that used in the CIDOC-CRM. Anderson will present observations based on his comparison of XML/TEI and the contemporary business tool XBRL-GL using information extracted from the Dutch periodicals *De Heraut* (*The Herald*) and *De Standaard* (*The Standard*), which were edited by the scholar, pastor, and prime minister Abraham Kuyper in the late nineteenth century.

Vogeler will close the presentations with a brief discussion of the value of Semantic Web technologies for historians interested in the "content" layer of accounts. RDFs/OWL allows modeling and encoding of the basic economic facts recorded in historical accounts and economic records. SKOS allows describing taxonomies of commodities, services, and monetary values recorded. They can be aligned into a common vocabulary. SPARQL allows aggregate querying of resources on these common facts together with individual data recorded. Digital editions of registers and accounts that not only publish text but try to express their interpretation of the text in a "content" layer and that publish this interpretation online with the help of semantic web technologies do what scholarly edition is meant to do: publish the critical analysis of the document by a competent scholar.

Funding

The MEDEA project is supported by an award from the Bilateral Digital Humanities program of the National Endowment for the Humanities and the German Research Foundation [grant numbers HG-229349-15]. Any views, findings, conclusions, or recommendations expressed in this session do not necessarily reflect those of the National Endowment for the Humanities or the Deutsche Forschungsgemeinschaft.

Pedagogy and Emblematica Online: Humanities Students in DH Projects

Mara R. Wade

Why DH a Pedagogy?

As Burdick, Drucker, Lunenfeld, Posner, and Schnapp state: "A new kind of digital humanist is emerging who combines in-depth training in a single humanistic subfield with a mix of skills drawn from design, computer science, media work, curatorial training, and library science" (Burdick et al, 166). Researchers with Emblematica Online took this challenge seriously, and determined ways to incorporate student researchers into our federally funded project as a means of investing in our shared DH future. Tier-one research institutions present particularly rich opportunities to advance the rapidly changing field of undergraduate research. Faculty members in the humanities at these universities have excellent opportunities to advance undergraduate research, and strong obligations do so. With graduate students, we can scaffold our mentoring to offer creative and productive experiences for DH pedagogy across all areas of the academic landscape. DH pedagogy involves experiential learning within a framework that emphasizes peer learning as well as more formal modes of instruction. Because DH pedagogy involves learning by doing, it emphasizes approaches in university teaching including both a vertical to a horizontal pedagogy.

The Emblem Scholars

This paper presents the research initiative with bachelor students at the University of Illinois, analyzes their research results, outlines the challenges, and makes suggestions for future efforts in DH pedagogy. "Digital Humanities: Emblematica Online" was a course for undergraduate researchers with no experience whatsoever in DH. Our goal was the long-term intellectual development of students with respect to the disciplines, concepts, workflows, and methodologies. This project also incorporated international research exchange and modeled experiential learning beyond the narrow confines of an undergraduate major.

The undergraduate research opportunity was a hybrid course, introducing students to early modern books and book history directly in the rich collections of the University Library, to literary criticism of texts and images with a tight focus on the European emblem, and to digital humanities concepts such as consistent vocabularies, multilingual thesaurus, best practices and standards for transcriptions of texts, and the importance of linked open data and semantic web technologies. The class integrated "a holistic learning by project approach" (Rehbein and Fritze).

The "Emblem Scholars" with six undergraduates was launched in spring semester 2013. The project PI organized the course as "Digital Humanities: Emblematica Online" and met twice per week. Project researchers introduced the virtual collection Emblematica Online and the workings of the Portal; they developed spreadsheets for motto transcriptions and the "stitching" program to collocate individual emblems with their metadata and create a URI from a handle server. The PI, together with a senior project consultant and a graduate assistant, directed these students. Students were also paired with faculty mentors from early modern studies who checked the students' transcriptions of emblem mottos from various early modern versions of European vernacular languages and Latin. These mentors also met with them once or twice during the semester about their research papers. The Emblem Scholars transcribed emblem mottos, associated this data with the emblems within their books, and wrote scholarly papers. Together they also presented two posters at the Undergraduate Research Symposium 2013 (see ill. 1). This pedagogy was largely student driven, and three students continued their research with Emblematica Online for several additional semesters. The continuing students created the website Emblem Scholars: Emblematica Online as an extension of their course work (see ill 2)

Student Outcomes and Next Steps

The student research associated with Emblematica Online is vital to training the next generation of DH scholars and users. All three continuing undergraduate students now plan graduate study in the humanities with DH integrated into their studies. Their research for Emblematica Online positions them ideally as users, and perhaps even creators, of future digital resources. There are further multipliers for positive outcomes. One student presented new aspects of her research at the Undergraduate Research Symposium 2014, while the two others studied abroad, in Ireland and France, respectively. During her semester abroad, the one student volunteered in the library, digitizing a photo album. She considers her research as an Emblem Scholar key to her acceptance to the highly competitive 2014 Andrew W. Mellon Summer Academy and Undergraduate Curatorial Fellowship Program at the Art Institute Chicago. One has an internship at a museum in the Chicago area, another has entered Library School.

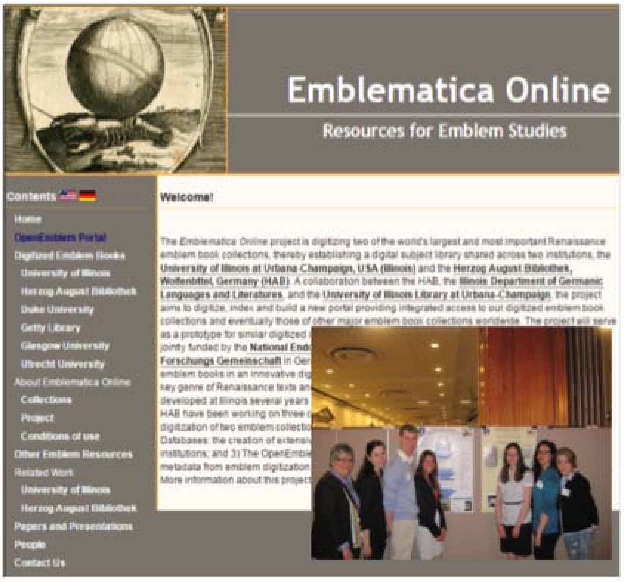
Challenges in Undergraduate Research

The first semester was time intensive to bring the students up to speed in all areas: DH, early modern literature and culture, working with rare books, and training in accurate transcription of foreign languages. (The six students came from Spanish, Communications, Mathematics, Psychology, English, and Art History.) Taking ownership of their work, responsibility for accuracy in all workflows, and dependability in meeting deadlines were habits they quickly developed. These students were smart and eager to work; they developed the necessary skills rapidly. We received a competitively awarded start-up fund of $1,500 for a new initiative in undergraduate research. That contributed to the purchase of materials (a book, a large-capacity flash drive, some computer hardware) and to printing posters. All teaching was done as an overload to the normal courses assignments. Regularizing funding and integrating the teaching of such courses into the normal operations of an academic department are clear desiderata. Owing to generous consortium and renewed SLCL funding, the three students will participate in a DFG funded event at the Newberry Library, Chicago, "Emblematica Online Workshop: Link Open Data – Developing an Ontology for Annotating Emblems."

DH and Critical Digital Pedagogy

We posit that investment in undergraduate (bachelor) education is well worth the time and resources spent. The "Emblem Scholars" participated in aggregated, distributed, collaborative, and open learning techniques (Gold, 2012a) within the framework of a federally funded project, Emblematica Online, that offers an ideal test bed for new knowledge, best practices, and emerging standards for all researchers involved in the project. Significantly, it has introduced students at all level of study in the humanities and library science to humanistic digital research. The researchers at Emblematica Online invested in their long-term trajectory of scholarly and intellectual development. We also developed a kind of "critical digital pedagogy" that educates for the long run through intensive mentoring and experiential learning. As Sean Michael Morris and Jesse Strommel define it: "Critical Pedagogy is an approach to teaching and learning predicated on fostering agency and empowering learners… ." The experience of Emblematica Online suggests that DH pedagogy is praxis-oriented teaching that positions students to learn experientially in a hybrid setting. While the usual project "tasks" are certainly part of the experience, the focus is on the development of a theoretical and conceptual understanding of the intersection of traditional and digital humanities. By situating learning directly in the research experience, students acquired a broad range of skills and concepts that exceeds a narrow academic focus. These students see DH as an integral part of the way we do humanities (McCarty, 24). Emblematica Online is a scholar driven project, and this synergy is reflected in the pedagogical outcomes.

In her blog post, "Commit to DH people, not DH Projects," Miriam Posner, University of California, Los Angeles, makes the case for investing in the human resources clustered around projects, such as Emblematica Online. Posner raises the questions: "What if you saw that training period as an investment in healthy, long-lasting relationships? What if we saw digital humanities as a long-term investment in scholarly growth, not a short-term investment in projects?" The student researchers with Emblematica Online learned a range of critical thinking, technical, intellectual, and administrative skills that are the most transferrable and will serve them well in the future. They are well prepared to be DH citizens.



Welcome!

The *Emblematica Online* project is digitizing two of the world's largest and most important Renaissance emblem book collections, thereby establishing a digital subject library shared across two institutions, the **University of Illinois at Urbana-Champaign, USA (Illinois)** and the **Herzog August Bibliothek, Wolfenbüttel, Germany (HAB)**. A collaboration between the HAB, the **Illinois Department of Germanic Languages and Literatures**, and the **University of Illinois Library at Urbana-Champaign**, the project aims to digitize, index and build a new portal providing integrated access to our digitized emblem book collections and eventually those of other major emblem book collections worldwide. The project will serve as a prototype for similar digitized

Transforming SPINE metadata to Linked Open Data

Myung-Ja K. Han
Timothy W. Cole
Maria Janina Sarol
Patricia Lampron

Background

Emblem books flourished in Europe as a popular literary genre from 1531, the publication date of the first emblem book, through the mid-18th century. The form of the emblem book is compound, integrating text and graphics, and highly contextual, often influenced by cotemporaneous events. Remaining copies of printed emblem books are widely dispersed in libraries across Europe and North America today. To facilitate access and better support Emblem Studies, a large segment of the corpus has now been digitized and made discoverable through the Emblematica Online Portal (http://emblematica.library.illinois.edu/). Because the individual emblems within emblem books are themselves of scholarly interest, emblem books pose interesting descriptive challenges for libraries. A domain-specific, XML-based metadata schema was developed and implemented to address these challenges and support a measure of interoperability within the Emblem Studies community (http://diglib.hab.de/rules/schema/emblem/emblem-1-2.xsd). However, emblems are of interest to scholars in additional disciplines, e.g., art historians, historians of Renaissance and Baroque cultures, comparative literary scholars, etc. To maximize utility it is crucial to integrate digitized emblem resources with other kinds of resources used by scholars in multiple domains. As a step towards this vision, this presentation will report on work done to transform our emblem-specific XML metadata into Linked Open Data in order to support broader discovery and access and to better integrate digitized emblem resources with other resources on the Web.

The SPINE Metadata Schema and Discovery Services

Discovery and browse services provided through the Emblematica Online Portal are possible because of the emblem-specific SPINE metadata schema. The genesis of the SPINE schema was an international workshop on the digitization of emblems held in 2001 at the Centre for Emblem Studies at the University of Glasgow. The participants in the workshop, drawn from widely dispersed institutions, recognized the need for a shared metadata vocabulary to support interoperability across emblem collections. The classes and properties of the SPINE schema were subsequently documented by Stephen Rawles of the University of Glasgow (2004). Thomas Stäcker at the Herzog August Bibliothek Wolfenbüttel implemented the schema proposed by Rawles in XML. To express most book-level properties, Stäcker integrated the Metadata Object Description Schema (MODS) into SPINE. He supplemented MODS classes and properties with emblem-level descriptive classes and properties and added a few additional book-level properties to record the provenance of digitized emblem volumes, i.e., to link digitized items back to the print item from which they are derived. SPINE is now available as an XML based metadata schema, currently in version 1.2 (Stäcker, 2012).

As implemented in the Emblematica Online Portal, the SPINE metadata schema, designed for describing emblem books, the emblems contained in those books, and copy-specific information about the book, allows digital humanities scholars access to digitized emblem resources at any of three different levels granularity, an entire emblem book, an individual emblem, and an individual pictura, while providing detailed descriptive information at each level (Cole et al. 2012). Iconclass, a multilingual, extensible classification system for visual cultural content containing more than 28,000 hierarchically ordered descriptors, has been used extensively by scholars and curators to describe emblem picturae. Most recently, the team has exploited Iconclass.org linked open data services ("Iconclass as Linked Data" 2015) to facilitate emblem discovery. By using the available Iconclass Web services, the Emblematica Online Portal can now support multilingual search and browsing services for Iconclass headings as well as browsing broader and narrower Iconclass headings, demonstrating the benefits of being a linked open data consumer (Cole et al. 2013).

Exposing SPINE Metadata to the Web

As a next step, the Emblematica Online project team has been exploring ways to become a linked open data producer by publishing SPINE metadata as linked open data. To accomplish this, the Emblematica Online project team takes a rather unique approach. Instead of creating a new ontology for the SPINE metadata schema, the project team is focusing on discovery and visibility of digitized emblem resources on the web, in other words, using linked data as a vehicle that brings the emblem resource information contained in the SPINE metadata to the web. To make SPINE metadata more web friendly, i.e., indexed and searchable by web search engines including Google, and compliant with current linked open data work being conducted across cultural heritage institutions, the Emblematica Online project team has developed a workflow that transforms SPINE metadata to Resource Description Framework in Attributes (RDFa) based web pages for the presentation of both emblem books and emblems. As an extension to HTML5, RDFa allows web search engines to generate better search results through the attributes embedded in the web pages, ultimately improving the visibility of these resources on the web. The RDFa attributes are being populated relying on schema.org semantics, since these semantics are recognized and used by major web search engines as a de facto linked data markup standard, whenever schema.org semantic meanings aligned well with the SPINE metadata elements. When there are no corresponding semantics in schema.org, or it is necessary to keep the semantic meanings of the SPINE schema, schema.org extensions (2015) are employed to represent emblem specific information, such as Pictura, Iconclass, subscriptio, motiv, emblemParts, and so on. The figure below shows how the SPINE XML description of an emblem pictura that includes an Iconclass descriptor (figure 1-a) can be transformed to RDFa with semantics from schema.org (figure 1-b).

Conclusion

Early experimentations with linked data undertaken by the Emblematica Online Portal have allowed emblem scholars to access related resources available in the Virtual Printroom (Virtuelle Kupferstichkabinett, VKK), jointly managed by the Herzog August Bibliothek and the Herzog Anton Ulrich Museum in Germany, and Festkultur Online, developed and maintained at the Herzog August Bibliothek, since all three sites use Iconclass as a descriptive vocabulary for their resources. Additionally, exposing SPINE metadata in RDFa based HTML pages would expand relationships between information resources in SPINE and other contextual information available on the web that is represented with the same schema.org semantics, such as information about the author or historical or cultural events related to emblem books and emblems, ultimately enabling emblem scholars to access additional information in conjunction with emblem resources available at the Emblematica Online Portal. This presentation will discuss why Emblematica Online experimented with linked open data, describe details of the workflow, challenges, and lessons learned from this SPINE to linked open data transformation work, and enumerate future plans for using additional linked open data sources to improve user experiences.

Linked Open Data for Emblem Research

Dr. Thomas Stäcker

This paper presents a project carried out in close collaboration with the current research of Emblematica Online, University of Illinois (Prof. Mara Wade, PI). It aims to strengthen international co-operation in the field of emblem studies, to jointly develop and apply technical models, and to make use of synergies to establish transnational digital collections and data pools that can be freely used by the international emblem community. The new project at the Herzog August Bibliothek, Wolfenbüttel, proposes to develop and integrate concepts and models that can be applied to and employed by other areas within the burgeoning field of Digital Humanities. It is divided into four distinct but interconnected areas of activity. First, the data in the collection itself will be enlarged; secondly, emblem books will be transcribed and made available as full text; thirdly, and that is the most innovative part of the project, data and metadata will be modeled and designed in such a way that they can be used in the semantic web; and finally, interfaces and web services will be enhanced or established to facilitate the harvesting and retrieval of emblem data.

A central feature of this project is the development of an ontology that allow scholars to analyze emblems by offering a vocabulary that is apt to ascertain identities, resemblances, or significant differences of emblems digitized at various places on the web. Supported by suitable tools scholars will ideally be able to encode in RDF (see example, Ill. 1) that there is an identity with respect to meaning by relating a helmet with bees to a camel walking through the eye of a needle (both of them allude to the topic peace, see Ill. 2), or they will be able to assemble identical emblems from various books or will characterize instances where the same motto is used for various picturae. The project draws on a comprehensive corpus of emblems that were digitized in several larger projects within the last decade. It is meant to move a step forward in that it no longer intends to make source material merely available, but attempts to offer means and methods for practical research by applying semantic web techniques and standards such as the Open Annotation Collaboration and Iconclass' RDF representation.

When DH Meets Law: Problems, Solutions, Perspectives

Andreas Witt
witt@ids-mannheim.de

Paweł Kamocki
pawel.kamocki@gmail.com
IDS Mannheim, Germany; Université Paris Descartes, France;
Westfälische Wilhelms-Universität Münster, Germany

Digital data is fuel for data-intensive science. Access, re-use and sharing of this data, however, while required by academic ethos and good practice, are often highly restricted by legal frameworks. In particular, the areas of law that can affect research data are: intellectual property (copyright and database rights) and personal data protection. These issues are particularly relevant in the field of Digital Humanities, which study various aspects of human activities in general, and their creative and social aspects in particular. In fact, most of the research data in digital humanities are within the scope of either intellectual property or data protection law, which means that they cannot be freely accessed, re-used and shared without a permission of the right holder or the data subject's consent.

Moreover, research funding agencies require more and more often that the results (and underlying data) of research projects that they fund be made available in Open Access. Open sharing of research data and outcomes is often perceived nowadays as an ethical obligation in contemporary science, but it cannot be done in a satisfactory way without addressing legal concerns (such as appropriate licensing and rights clearance).

Legal issues are increasingly being taken into account in the preparation phases of many research projects. Scientists who do not consider legal issues in their research activities may be exposed to certain legal risks. Existing statutory exceptions for research rarely provide for enough relief (even though lobbying efforts are being made to extend their scope). In short, modern science in general, and Digital Humanities in particular, are more concerned with legal issues than ever before.

The purpose of the multiple paper session we propose is to emphasize the problem, discuss various technological and organizational solutions, as well as future legal challenges that DH researches will have to face.

Three papers by authors with both legal training and hands-on experience with D-SSH research data management will be presented. The first one compares organizational and technical solutions adopted in the field of DH and Social Sciences. The second discusses research data licensing, and presents existing tools that help researchers in the process. The third paper examines legal and ethical aspects of stylometry and authorship attribution research.

"One Does Not Simply Share Data". Organisational and Technical Remedies to Legal Constraints in Research Data Sharing – building bridges between Digital Humanities and the Social Sciences

Pawel Kamocki
Katharina Kinder-Kurlanda
Marc Kupietz

Within the Social Sciences there exists a long tradition of data sharing, which is facilitated by infrastructure institutions such as the GESIS Data Archive that has been providing survey data to researchers since the 1960s. More recently various technical solutions aiming to grant secure and user-friendly access to data requiring special protection have been emerging in the field.

The DH also have a well-established tradition of research data sharing. In linguistics, for example, digital text collections have also been published since the 60s (e.g. the Brown Corpus or the Mannheimer Korpus). First software solutions to share the data and to make it accessible to other researchers emerged in the late 1980s and started to boom with the appearance of the WWW in the early 1990s.

Legal barriers to data sharing

Legal issues have long been identified as barriers to research data sharing. They can be divided into two categories: those related to intellectual property rights and those related to privacy laws.

Intellectual property rights — such as copyright and the database right — grant the rights holders certain exclusive rights (monopolies), i.e., rights to exclude others from the use of their property. For example, in order to copy and distribute a copyright-protected work or a database, one normally has to obtain permission from the rights holder, usually in an agreement known as a license. This highly affects DH — disciplines fueled by digital data issued from human creative activities, which normally qualify for copyright protection.

It is essential to understand that intellectual property is similar to "traditional" (i.e. corporeal) property. Therefore, it can be said that most research data in DH in fact belong to a third party (author or publisher). The right to property is a fundamental freedom, which overrides freedom of research. As a consequence, statutory research exceptions are rarely enough to allow use of copyright-protected data in research projects.

Researchers in DH therefore need to obtain licenses for the use of data, which is not an easy task. The negotiations may be time-consuming, and the result is not always satisfactory. In practice, licenses signed with e.g. publishers are often very restrictive and non-transferable.

Another legal framework that affects researchers in areas such as medicine or the social sciences, but also in the DH, is personal data protection. In principle, personal data (i.e. any information related to an identifiable person) can only be processed if the data subject has validly consented to the processing. While it is true that anonymised data can be freely processed, anonymisation may strip a dataset from most (if not all) of its informational and scientific value. The obligation to obtain consent is particularly burdensome when it comes to older data that has been collected without consent, or that has been collected for a different purpose (re-purposing normally necessitates a new consent). Also, in practice, consent rarely covers transfer and sharing of data with other researchers.

Social Science approach

In the Social Sciences quantitative survey data is particularly interesting for sharing. The highly controlled and well-documented ways of gathering data in large-scale survey programmes make the data highly reusable in a methodologically sound way. The GESIS Data Archive for the Social Sciences in Germany provides survey data for secondary use and thus allows researchers to share collected data in a user-friendly, searchable and standardised manner. Due to data protection legislation participants of survey data provided by the archive must not be re-identifiable, or only with a disproportionate amount of time, expense and labour. Anonymization challenges usually occur once detailed geographical as well as demographical information has been collected.

To improve data sharing several solutions have been found for the Social Sciences. For example, most data at the GESIS archive is anonymised and thus can be provided for download via the online data catalogue. Some datasets containing more detailed information are provided employing secure data access solutions. A combination of contractual, organizational and technical safeguards is employed to ensure that individuals' rights to anonymity are protected. For example, for particularly disclosive data, researchers must visit a safe room where a completely encapsulated virtual research environment is provided via a thin client. They cannot download any data or access the internet. They are also not allowed to bring mobile phones or other electronic devices. Any analysis output they produce is intellectually assessed for its level of disclosiveness and only handed to researchers once the output criteria are fulfilled. Only users whose signed usage agreements (detailing the research topic and the methods applied) have been approved can use the safe room.

Secure remote solutions either provide researchers with a secure connection to an encapsulated work environment as described above or allow the submission of code and syntax to be run on the data by the data provider. All remote solutions need to be secured from threats posed by using the internet.

DH approach

To cope with legal challenges, to make research data as openly accessible as possible, and to enable traceability and replicability without interfering with legitimate interests of rights holders, the disciplines that deal with language as their primary research data, particularly linguistics, have developed several strategies.

As already discussed above, usually the only way to acquire text for research purposes is to obtain licenses from copyright holders. The copyright holders can sometimes be convinced to provide scientific licenses for free or for comparatively low fees as long as they do not interfere with the company's business model. Given that some institute is willing to conclude partially transferable license agreements with rights holders and license agreements with end-users, thus acting as an intermediary between both parties, and to provide software that enforces the license restrictions and provides all retrieval and analysis functions that researchers need, every group's interests can be satisfied. Indeed, this model has worked successfully at the Institute of German Language (IDS) since the beginning of the 90s and also for most other providers of national and reference corpora.

The problem with the intermediary model alone is that it requires the intermediary to provide all functions that are required for any researcher. While, for example, the requirements for more traditional linguists could be satisfied, this was not possible for researchers in the field of text mining and computational linguistics where the methods of analysis themselves are in the center of research and therefore subject to rapid change.

To meet the needs of such user groups, another idea, recently described for linguistics but traditionally used in data-intensive disciplines such as climate research, has to be put into action. Extending Gray's (2003) famous claim "put the computation near the data" to situations where the data cannot be moved due to license restrictions, data providers also provide mechanisms that allow end-users to run their analysis software on the data located at the provider, making sure that the software does not violate any license restrictions.

Another remedy that is often applied in the context of corpora that are based solely on texts from the WWW, is not to share the research data itself, as this could be a copyright violation, but rather to share the software that retrieves the texts from the Web. Depending on the the application scenario and the local legislation, this technique can enable end-users to benefit from statutory exceptions. An unwanted side-effect of this approach is that the identity of the corpus data retrieved by different runs of the retrieval software cannot be guaranteed. However, there is some consensus in the research community that the sights with respect to demands on replicability and persistency of research data necessarily have to be lowered to a realistic standard that takes into account legal restrictions. This aspect has also recently entered the best-practice guidelines of the German Research Foundation.

Conclusions

D-SSH are dealing with data surrounded by legal issues. Traditionally, Social Science researchers process more privacy-sensitive information, whereas DH researchers work with data protected by intellectual property rights, usually belonging to third parties; the division, however, is not clear-cut. Some disciplines in DH (such as linguistics) also have to deal with privacy-sensitive material, and the Social Sciences are concerned if not by copyright, then by other branches of intellectual property (such as database right). Increasingly commercial data owners such as social media companies are becoming important.

Institutes in both disciplines have developed idiosyncratic ways of coping with legal restrictions which provide satisfactory results. This shows us that some legal issues may be resolved by appropriate organisational, technical and infrastructural solutions; the comparison between DH and Social Sciences, however, demonstrates that both disciplines still have room for improvement and that there is a lot that they can learn from each other.

«Trust me. I'm a License Selector». Licensing for Digital Humanities

Paweł Kamocki & Pavel Stranak

Lack of legal interoperability (i.e. a situation in which a dataset cannot be used due to incompatible licensing restrictions on its various parts) has been identified as one of the major obstacles for data access, sharing and re-use. This is particularly relevant in the field of Digital Humanities, where data are often protected by copyright (i.e., they are created by human authors). While it is true that some data (e.g. those obtained from press editors) are only available to researchers under very restrictive license agreements, in fact quite often legal interoperability problems can be solved by proper licensing of research outcomes. Indeed, despite the fact that openness and reproducibility of results have long been identified as cornerstones of the scientific community, in practice many digital datasets and tools are being shared under licenses that are unnecessarily restrictive or not fit for the purpose, or even without any licenses at all. This is probably due to the fact that the task of choosing an appropriate license may seem difficult for an average researcher with a limited access to legal advice. As a response to that problem, attempts have been made to build tools (referred to as License Choosers, License Selectors or even License Wizards) that would guide the users through the jungle of available public licenses and allow him to choose one that is the most suitable for his needs.

Before these License Selectors can be presented and assessed, it is essential to define the notion of a public license. A public license is a license that grants certain rights not to an individual user, but to the general public (every potential user). Public licenses for software has been known since 1980s (when software licenses such as BSDL, MIT or GNU GPL emerged). However, public licenses for other categories of works (including datasets) only appeared in the 21st century, mostly due to the creation of the Creative Commons foundation. The latest version of the CC license suit (including six licenses, a waiver and a public domain mark), CC 4.0, is well adapted for datasets, as it covers not only copyright, but also the sui generis database right, but older versions are still in use. While choosing a license, one has to keep in mind that the licenses which are appropriate for software are not appropriate for data and vice versa. Moreover, not all public licenses are 'open', i.e. not all of them meet the requirements for Open Access/Open Data/Open Source label. In our paper, we would like to briefly demonstrate three online tools made specifically for licensing of research material.

The Licentia tool (http://licentia.inria.fr/visualize) has been developed in 2014 by Cardellino for INRIA (French Institute for Research in Computer Science and Automation) is in fact a conglomerate of three tools: a License Search Engine (which allows to identify licenses that meet a set of requirements defined by the user), a License Compatibility Checker (which assesses whether two licenses are compatible, i.e. whether material licensed under those two licenses can be 'mixed') and a License Visualiser (an interesting extra feature which produces graph-based visualisations of licenses expressed in ODRL - Open Digital Rights Language Deontology).

The ELRA (European Language Resources Association) License Wizard (http:// wizard.elda.org), released in April 2015, allows users to define a set of features and browse corresponding licenses. For now, the tool only includes CC, META-SHARE and ELRA licenses, so it is particularly useful for language resources.

Finaly, the Public License Selector (http://ufal.github.io/public-license-selector/) developed by Kamocki, Stranak and Sedlak in 2014 as a cooperation between two CLARIN centres (IDS Mannheim and Charles University in Prague) uses an algorithm (a series of yes/ no questions) to assist the user in the licensing process. It allows to choose licenses for both data and software, and features a built-in License Interoperability Tool. Licenses that meet the 'open' requirement are clearly marked. Finally, unlike the two other tools, it is made available under Open Software/Open Data conditions.

All of these tools have both advantages and disadvantages; their biggest disadvantage is that they use (to a different degree) a very specific language, which in fact requires basic knowledge of Intellectual Property Law from the user. They also necessarily involve a certain degree of over- or undergeneralization, especially when it comes to assessing license interoperability. Nevertheless, they remain very useful for the research community and may indeed help facilitate re-use and sharing of tools and data in Digital Humanities.

Legal and Ethical Aspects of Authorship Attribution Using Stylometry - EU and US Perspectives

Erik Ketzan & Paweł Kamocki

Introduction

Authors have written anonymously since the invention of writing, and the growing digital humanities field known variously as stylometry / computational stylistics / authorship attribution often aims to discover the identify (or rule out the identity) of anonymous authors.

Depending on whether such authors are living, whether the works in question are protected by copyright, and what the aims of the digital humanities research is, vastly different legal frameworks govern such research in the European Union and United States. The strong data protection laws of the EU seem to prohibit certain types of authorship attribution research, while researchers in the US have vastly fewer restrictions regarding data protection regulations. In addition to data protection, the acts of copying and analyzing texts for the purposes of stylometry raise copyright concerns. In the US, these acts seem to be largely allowed by the fair use doctrine. In the EU, these fall into more questionable legal territory, although new laws regarding text and data mining offer improved guidance to researchers.

As laws concerning research in the digital age are being revisited in both the US and EU, it is important to see where stylometry falls under current legal frameworks, and how, and whether, researchers should advocate for changes to law. Finally, we argue that a parallel debate regarding the ethics of stylometric research should be begun. As stylometric research and technology continues to improve, with promises of improved reliability of authorship attribution, researchers should begin to debate which questions researchers should ethically tackle, not only which questions they can.

Stylometry of anonymous authors under EU law

In the EU, where the memory of totalitarian governments is still present, Member States value privacy very highly. This is translated in the legislation, where the right to be and remain anonymous is not only protected by rules on the processing of personal data, but sometimes also to an extent guaranteed by copyright laws.

The Data Protection Directive is the primary source of laws governing the processing of personal data, and guides Member States in protecting "the fundamental rights and freedoms of natural persons, and in particular their right to privacy with respect to the processing of personal data." The Directive defines personal data as, "any information relating to an identified or identifiable natural person ('data subject'); an identifiable person is one who can be identified, directly or indirectly, in particular by reference to an identification number or to one or more factors specific to his physical, physiological, mental, economic, cultural or social identity." Processing of personal data is defined as, "any operation or set of operations which is performed upon personal data, whether or not by automatic means, such as collection, recording, organization, storage, adaptation or alteration, retrieval, consultation, use," etc.

In general, processing of personal data can only be done if the data subject (i.e. the person that the data refer to) has unambiguously given his consent. Moreover, the Data Protection Working Party (a body composed of representatives of National Data Protection Authorities from each Member State and whose purpose is to give expert advice on the interpretation of the Data Protection Directive) clearly stated that information that does not relate to an identified person, but is collected for the purpose of identification, shall also be regarded as personal data.

European researchers engaging in stylometric research for the purpose of identifying a living author therefore engage in the processing of personal data, and are subject to the rules and restrictions of the Data Protection Directive and related Member State data protection laws. Alternatively, consent could be obtained to process the personal data, but this leads to the absurd suggestion that researchers obtain permission from an anonymous author so that they can guess at his/her identity.

While the current framework allows for alternative grounds for lawfulness of processing (other than consent), such as e.g. pursuit of legitimate interests, these provisions remain vague and do not guarantee the necessary legal security for researchers. Exceptions from the rules set up by the Directive exist, but only cover very special cases such as freedom of journalistic and artistic expression, public security or (to a limited extent) historical, statistical and scientific research.

An inevitable conclusion, however, is that Personal Data Protection law in the EU protects anonymous authors from being identified against their will, at least when they are still alive.

Anonymity of authors is also addressed by many national laws on copyright. Although anonymous works benefit from a significantly shorter term of protection (70 years after publication, and not 70 years after the death of the author), the anonymity of the author is nevertheless protected; his rights can be exercised by a proxy (usually an agent or publisher). Moreover, in some jurisdictions (i.e., in France), inaccurate attribution of authorship can be regarded as violation of moral rights (i.e., a form of copyright infringement) of both the real author and the falsely attributed one.

Stylometry of anonymous authors under US law

The legal framework of the United States governing stylometry of anonymous authors is vastly different from the EU. The United States has no single general data protection law. The First Amendment of the United States Constitution guarantees the right to free speech, and a broad right to privacy has been inferred from the Constitution by the United States Supreme Court. A number of state constitutions, such as California, explicitly mention privacy as well.

Courts in the US have recognized certain rights to anonymity, most notably in McIntyre v. Ohio Elections Commission, 514 U.S. 334 (1995), where the Supreme Court held that the freedom to publish anonymously is protected by the First Amendment, and extends beyond the literary realm to the advocacy of political causes. Whether such a right extends to a researcher attempting to remove that anonymity is an open question.

Regarding copyright, there are strong arguments that the acts of copying and data mining text for research purposes are covered by the fair use doctrine, especially after the landmark Google Books case, which held that the scanning of books and making snippets available in search engines is a fair use. As a typical stylometric analysis involves the copying of texts and analysis on a single computer, without distribution of snippets (in other words, infringing less upon exclusive rights than the facts in Google Books), the acts seem to be covered by the fair use framework.

De Facto

Regardless of the letter of the law, the fact remains that many writers write anonymously and academics are increasingly asked to identify them.

In courts of law, researchers with expertise in linguistics, computer science, and stylometry have acted as expert witnesses for decades now in criminal and civil disputes.

Outside of courts, academics have published or given pronouncements to journalists in most news-worthy instances involving high-profile anonymously written works, including Primary Colors (a 1996 novel satirizing the Clinton Presidential campaign), The Cuckoo's Calling (a 2013 novel revealed to be the work of J.K Rowling), the Wanda Tinasky letters (dozens of eccentric and creative letters mailed to local California newspapers from 1984-88, which academics proved were not the work of Thomas Pynchon), and many more. In all of these instances, journalists and academics have not discussed the moral or legal right to make such analysis; they have simply done it.

Ethics and stylometry

The purpose of the proposed paper is, through an analysis of different legal frameworks, to highlight the different norms and assumptions that surround the "un-masking" of anonymous authors. The radical difference in EU and US legal approaches proves that opinions can differ, and that serious debate needs to be begun among researchers. As the technology and approaches to stylometry yield increasingly accurate results, it is time for the digital humanities community to begin to discuss ethical standards.

Introduction

If, as Ta-Nehisi Coates has suggested, the most lasting traumas of United States history can be traced back to Americans' "need ... to think that they are white" (2015), what might digital literary studies be able to tell us about this self-inflicted delusion? Specifically, how might quantitative textual analysis help us reconstruct the process by which ethnicities, nationalities, religious groups, and other identity categories became dominated by the all-encompassing category of race? One might expect literature to present a complex field of racial discourse, one in which what sociologist Matthew Snipp calls "administrative definitions of race" (2010) coexist with self-identifications and ethnic stereotypes, colonialist fantasies and half-forgotten family trees. Literary scholars specializing in race and ethnicity have established a rich tradition of close readings that attempt to disentangle this discourse within particular texts, generating information about how individual writers navigate race in the United States. How would this understanding change, however, if we expanded our scope to hundreds of writers and two centuries of American history? What discontinuities or consistencies might we find in the language associated with different ethnicities? Would historical changes in civil rights, immigration, and territorial expansion be visible on the level of fictional discourse?

Corpus and Methods

To approach these questions, we have assembled a corpus of 193 works of American fiction across a range of genres. Our selection begins in 1789: the year of Washington's election and the establishment of the Constitution, it also saw the publication of William Hill Brown's *The Power of Sympathy*, considered the first American novel. 1964, on the other hand, marked the beginning of President Lyndon Johnson's systematic immigration policy reforms, culminating in the Immigration and Nationality Act of 1965, which finally erased the restrictive quotas that had limited entry into the U.S. for non-white, non-western European populations. Within this extended period, major changes in government policy toward various racial and ethnic groups -- the Indian Removal Act, Emancipation, the Chinese Exclusion Act, the Immigration Act of 1917, the internment of Japanese citizens -- provide cardinal points that guide our analysis and raise fundamental issues about the relationship between fiction and the world it represents. What kinds of socio-political shifts make a difference in literary characterization? Can literature change the direction or accelerate the pace of social change, as in Abraham Lincoln's oft-quoted but probably apocryphal claim that Harriet Beecher Stowe's *Uncle Tom's Cabin* incited the Civil War?

To probe our assumptions about the language of identification in the novel, we combine methods that both investigate the formal features of the novels as a whole and extract racialized discourse as it attaches to particular characters. We suggest that the semantics of identity, whether racial, cultural, ethnic or national, operate at two discrete levels: 1) embedded within discourse such that it acts as a background to the particular worldview of the text; 2) at the level of character, where the lexemes of identity become a self-aware system of description, whether leveraged by the narrator, in the reactions of other characters or internally as part of a character's self-articulation. We argue through this project that characters embody a set of racialized identifiers that operate against a set background understanding of the meaning of identity within the text -- a dialectic between intratextual characterization and intertextual stereotyping that has its origins in, but expands significantly upon, the model of marginalized characters articulated in Alex Woloch's *The One vs. the Many* (2003). The goal of our project is to tease apart these two levels of discursive identity in order to reassemble a new history of the discourse of race in American fiction as it evolves against the backdrop of history and a changing set of aesthetic principles in novel writing.

Phase One: The Racial Unconscious

The first stage of this investigation examines the discourse of identity categories as they propagate throughout our corpus. We begin with a set list of various racial determinants that include national origins (German, Italian), ethnic identifiers (Jew, Arab) and racialized categories (Negro, Indian) and identity the pattern of language that attaches to these descriptors over time. In our first pass, we extract the collocates of each of our terms and identify which, if any, are significantly distinctive of that term.[1] For example, the term "foreign" appears significantly often as a collocate of the names of European countries, but never within the vicinity of racial descriptors, or ethnic identifiers. We then extend the process and trace a new set of second order distinctive collocates from the terms we have identified, to see which trace back to our initial set of identifiers and which introduce new discourses into the semantics of race. By visualizing our results as a dynamic network of interconnected language we trace the connections between our primary identifiers, as well as how these relationships change over time. To extend the above example, in the nineteenth century, a language of "foreignness" is connected with European nationalities, while "America/n" is distinctively used as a descriptor of African Americans. By the mid-twentieth century, the terms describing African Americans shift away from the emphasis on their "Americanness" and instead incorporate a set of terms, such as "descent" and "blood" borrowed from the foreign discourse of immigration. Such analyses can help us to identify in precise historical detail both the moment at which particular national or ethnic groups became American and the related but not the identical moment at which they, in Noel Ignatiev's phrase, "became white" (1995) -- that is, when the language surrounding those groups became unmarked. At the same time, finding consistencies in the language applied to different racial or ethnic groups at different historical moments grants support for Theodore Allen's claim that the concept of race names "a pattern of oppression (subordination, subjugation, exploitation) of one set of human beings by another," where the "phenotypical" identity of those sets is less important than the structure of their relationship (2012). This work builds upon the previous work of the members of the Literary Lab on the language of human identification in Anthropology, presented at the 2015 Digital Humanities conference and forthcoming in *Current Anthropology*, although it represents a substantial methodological extension over this early project, as well as shifting the emphasis from scholarly writing to literary representations of identity.

Phase 2: Identity as Cultural Construction

The second phase of our project examines the construction of individual characters against this backdrop. This not only allows us to observe which characters actively resist the discourse of the period in which they were created, but also how the evolution of this terminology as applied to individuals differs from the cultural construction of identity as a historically contingent socio-cultural phenomenon. That is, does a character described as "black" inherit the descriptors of identity from the language of the period or is discourse radically more individuated on a character by character basis? To test this assumption, we adopt a similar approach to the "BookNLP" developed by Bamman, Underwood and Smith (2014), using Named Entity Recognition to extract characters coupled with a set of scripts to perform co-reference resolution. We then tag the corpus for part-of-speech and extract the distinctive adjectives that appear in dependent positions within 50 words of each mention of the character. This allows us to identify, with reasonable precision, a descriptive terminology for each character. We then tag each character for the racial, ethnic or national identity that is given in the novels and compare our descriptive discourse for characters who embody similar identities across texts, using a set of semantic network diagrams that allow us to trace the contiguities of identity both across genre and across time.

Conclusion

By combining these methods, we are able to see, for the first time, not only how the distinctive language of identity alters over the history of the American novel, but how the discourse of characterization functions as both a vehicle for the standard tropes and stereotypes for identity, as well as a point of resistance to the dominant representational language of a given period. It also provides new insights into the process of characterization, especially in regard to the representation of immigrant or minority identities.

Triggered by an article by Lev Manovich *How to compare one million images?* (Manovich, 2012: 249-78) we were intrigued to find out "how to compare and analyse thousands of architectural floor plans"? The reason for this interest was the availability of the archive of the *Bureau Wederopbouw Boerderijen* (Office for Farm Reconstruction, 1940-1955) with data of 7700 farmhouses that were destroyed during World War II and were subsequently rebuilt – reconstructed or redeveloped in a new form – between 1940 and 1955 (Elpers, 2008).

Since it seemed impossible to analyse almost 8000 drawings by hand we decided to study the possibility of automatic identification and categorization of these floor plans. For this paper, we explored several strategies and digital tools to find out more about their usefulness in art and architectural history in general to answer questions about change, distribution of spaces, typology, genre, etc.

Automation of architectural floor plans

By examining the differences between and changes of the floor plans of the reconstructed farms from the period between 1940 and 1955 and by comparing them with reconstruction sketches of the old destroyed farms, we hope to be able to answer questions such as: how was the struggle about tradition and modernization which determined the debate about farm construction in the middle of the twentieth century (Elpers, 2013) resolved in practice? This question focuses on the maintenance or abandoning of the so-called 'streekeigen bouwen' (traditional regional building)(Lambert, 2007) and related planning principles. Which traditional elements were retained and which were not? Which new elements were added? Can any general structural patterns be recognized?

For this aim we would like to be able to automatically categorize and recognize elements in the architectural drawings. Following the visualization method and software (ImagePlot) by Manovich we would also like to create clusters of images of farms ordered by morphological structure, type, architect, region and timelines as output.

As architectural historians with limited programming knowledge, we started looking for existing software to find answers. Search engines usually use databases with (meta) data about objects. In our case we would rather be able to study the drawings directly on its visual content. We hoped that a combination of image processing software, techniques for pattern recognition, OCR and vectorization would bring us closer to our goals. Following information about conventions of farmhouses e.g. specific rooms, and workspaces like sheds could be labelled and found. This method, that we use in our study, has been, amongst others, described by Hansson (1998).

Preprocessing

A test-set of about 1000 images was scanned in 300 dpi TIFF: 400 reconstruction drawings and 600 new floor plans. For each farm we have two sets of scans available: drawings of the old, destroyed farms and plans of the new farms. Further, we have built a repository with the TIFF-images in relation to a simple database.

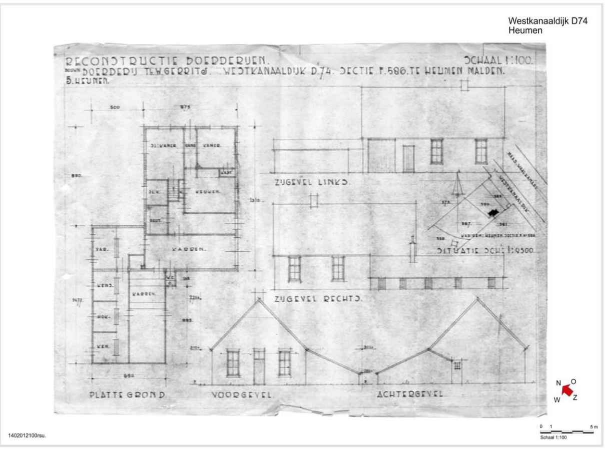

Illustration 1. Image of original architectural drawing Westkanaaldijk D74, showing plan, views and situation plan

The architectural or engineering drawings show not just one floor plan of a farm but also plans of other floors, sheds and outbuildings, cross sections and several views, a drawing of the lay-out of the premises etc. Often several details are depicted, sometimes added in a separate drawing. Although the human eye can instantly distinguish which element is the main floor plan, one has to teach the computer how to find it. In order to isolate the floor plan from all the other parts of information, the white empty spaces surrounding the different elements in a drawing could be taken as a division space, separating the individual elements. First, we had to isolate the floor plan in the drawing and deconstruct its information. Unfortunately we could not find software that could ingest the drawings and produce the isolated floor plans, without programming.

As a consequence, since it appeared too complicated to automatically find the position of the floor plan on the drawing, we skipped this part for the moment and prepared manually a new set of cut-out images of the floor plans.

With a simple image-processing program it appeared possible to manually deconstruct the contents of a drawing. In this way we could find out what steps were needed to automate the process. A drawing of Westkanaaldijk D74 in the village of Heumen (middle east of the Netherlands) was selected as a random example for the first test that shows the following manipulations:

- OCR-text
- Vectorize the floor plan
- Floor plan with text labels
- Walls (thick, medium, without openigs)
- Walls (thick, medium, with openings and numbers)

Although most techniques could be carried out with simple imaging software, such as CorelDraw – and we tried some other free online programs such as Inkscape, VectorMagic, Gimp, etc – the number of actions or manipulations just for one drawing appeared quite high. Although it works reasonably well for one drawing, this is exactly the process that we want to automate and connect with a search system.

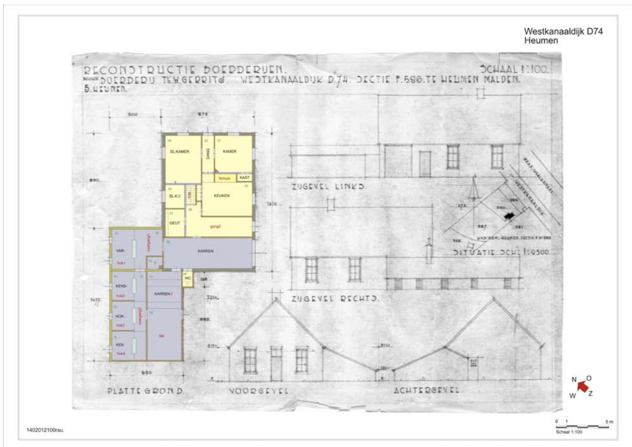

Illustration 2. Architectural drawing of Westkanaaldijk with vectorized plan and labelled spaces.

To scale up the process a bit, in a test with 10 floor plans of farms in the city of Groesbeek (middle east of the Netherlands) the following manipulations were carried out:

- the plan of ground floor and first floor were manually cut out
- images were converted from heavy tiff to the lighter jpg
- reconstruction drawings were converted from 1:200 to 1:100
- resolution of new plans were converted from 300 dpi to 150 dpi
- x/y axes were calibrated
- a central axis was determined
- it was noted that the drawings were not always on the right scale, while the inscribed measurements were noted correctly
- rooms are taken to be rectangles (which can be corrected later, but in most cases will not affect the results)
- the main spaces of farmhouses are accurate, while the interior spaces should be estimated on sight

It appeared that most walls have static measurements that can be brought into a library: the thickness of the walls depends very much on the type of bricks they are built with. These bricks have common measurements such as the *Waalformaat* (210 x 100 x 50 mm). The thickness of a wall therefore varies from 27 cm to 6 cm. The different sizes could then be coded by colour and compared.

Deconstructing drawings, isolating elements and detecting symbols

In order to deconstruct each drawing (see e.g.: Henderson, 2014; Dosch, 2000) the following steps were determined and carried out:

- Building a repository with images and database (same scale, direction)
- Finding the position of the floor plan on the drawing
- Determine (outlines of) spaces / rooms
- OCR all text information
- Recognizing walls (determining and labelling exterior and interior)
- Recognizing specific rooms (determining and labelling livingroom, kitchen, bathroom, hall, bedroom, stables etc.)

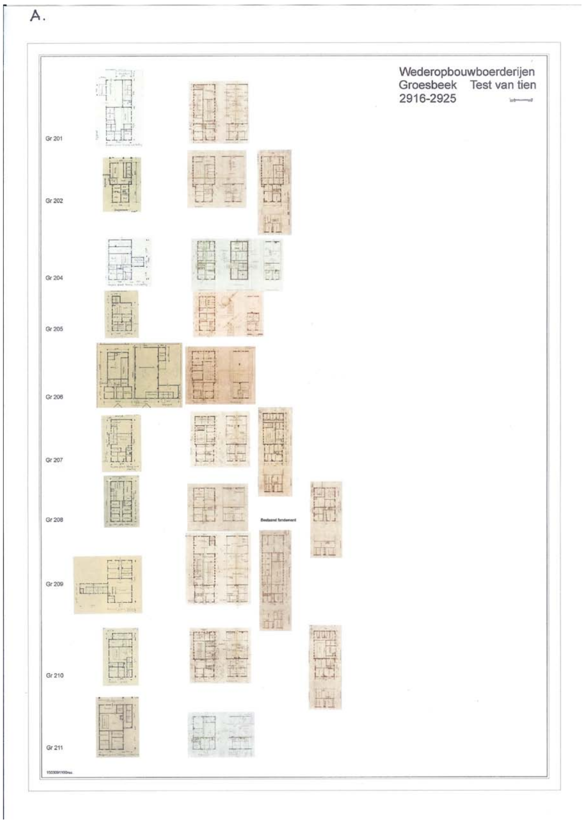

Illustration 3. Cut-out plans showing ground floor and other floors

- Determining difference between reconstruction drawing (original state) and new plan and difference between reconstruction drawings from different years

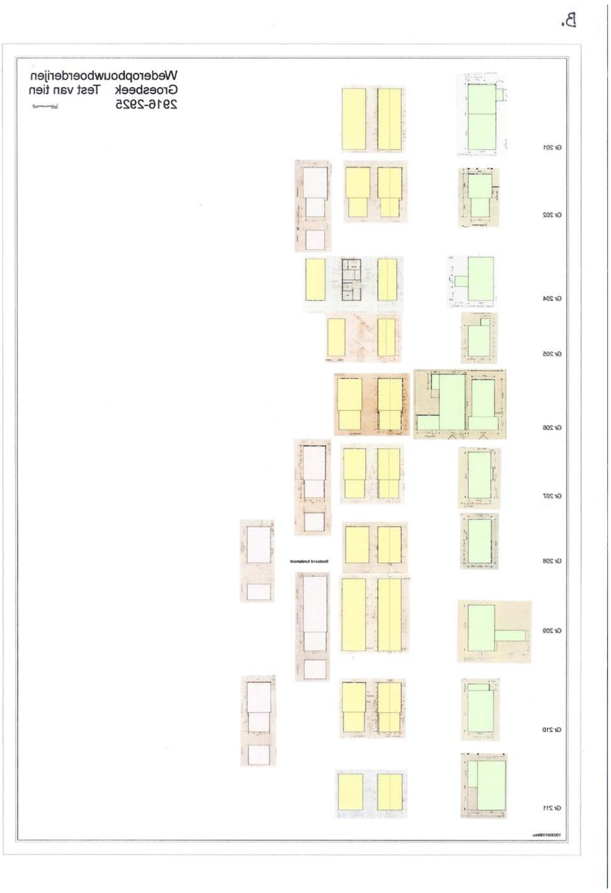

Illustration 4. Cut-out floor plans, vectorized showing the volumes of spaces.

To carry out the recognition part such as wall detection, text recognition and labelling, and making comparisons of old and new, the approach of Ahmed and Liwicki (Ahmed et al. (2011; 2014) appears promising for solving some of our problems. Although they focus on using sketches to be recognized and compared with floor plan drawings in a repository, we would like to see how their system works for us with our repository of cut-out floor plans.

Timelines can relatively easy be visualized using the metadata - with the tag "year" - in the database example (Borner, 2010; Alkhoven, 1998; 2008). Other tests with visualization software such as ImagePlot produced interesting and beautiful views of the drawings but could not yet provide the required results for analysis. More experimentation and possible adaptation of the software is needed.

Next steps

We set out to find answers on how we could compare thousands of drawings of floor plans, what digital tools and best practices are currently available to analyse them and how we could visualize differences in sets of floor plans. In this first stage of the process we have gathered information about the preprocessing stages and we were able to perform some experiments with the scanned architectural drawings.

We discovered many – free–tools but it turned out difficult to distinguish among them and to choose the best ones that could solve each part of the problem. We have tested several apps but since it was not our objective to deal with coding, we could not adapt the software and we were therefore limited in doing our research. As a consequence much had to be done manually in a computer-assisted way.

Since our overall problem appeared a bit too ambitious to carry out within the given boundaries of time and budget, we have limited ourselves to producing a list of ingredients and a well-argumented recipe formulating the next sequence of steps to take. These form the basis for a new research proposal for the Digital Humanities' call in The Netherlands. A long article with more detailed information about the process, experiments, and results, will be ready later this year.

Geocoding Thousands of Fiscal Records: Methodological Approach for a Study on Urban Retail Trade in the Belle Époque

Daniel Alves
alves.r.daniel@gmail.com
IHC, FCSH, New University of Lisbon, Portugal

In August 1902 the British newspaper The Times inserted an article announcing "The passing of the grocer" as a result of a crisis in the small retail trade that apparently had bankrupted more than 900 stores (Winstanley, 1983). Across the Atlantic, Canada's shopkeepers faced a crisis equally significant, with overabundance of shops and a lot of bankruptcies (Monod, 1996). The same happened in continental European cities like Paris or Milan, in the final decades of the nineteenth century (Nord, 1986; Morris, 1993). Much of what happened this time was the result of an demographic growth in the cities in the nineteenth century that almost everywhere would have important consequences in the reorganization of urban space, leading to changes in their economic and social geography. Lisbon was no exception and the city's retail trade, after a phase of growth in the 1880s, faced a crisis in the last ten years of the century (Alves 2012). This occurred while the city was transformed, witnessing an expansion into new urban areas to accommodate an increasing volume of inhabitants.

Through the analysis of the geographical distribution of Lisbon's retail trade, between 1890 and 1910, it is possible to verify the impact of this crisis on the way small businessmen apprehended the urban space, as well as the opportunities and risks that those changes could represent to them. The study is based on a very detailed information about the localization and characteristics of every single shop in the city streets, gathered from fiscal sources in the municipal archives (around sixteenth thousand records for each of the three years, 1890, 1900 and 1910) and analyzed through the use of spatial statistical analysis tools. This volume of information and the potential introduced by a Digital Humanities / Spatial Humanities approach, brings in methodological challenges regarding the digitization and geocoding process of several thousands of records, as well as opens new research possibilities and new research questions, namely: about the role of women in the retail trade business, since previous work based on smaller sets of data analyzed with traditional qualitative methods had misrepresented or even ignored gender issues in the retail business (Alves, 2012); or about the influence of the dwelling rents in determining changes in the social space of a city in the Belle Époque, only possible by the digital analysis of a very large, temporal and geographical encompassing amount of data for all the city.

In terms of the methodology two were the challenges we faced in two distinct stages of research, data collection and its georeferencing. The first challenge relates to the difficulty in scanning a volume of data of this nature, only available on archive, with no available funding to carry out a project of mass digitization of the original tax records. This was associated with the fact that all sources are handwritten, drawn up by several employees, with equally different handwritings, which would make it impossible, given the current state of handwritten character recognition technology (Beatty, 2010; Brumfield, 2014), for an automatic or even semiautomatic data treatment. The solution followed a close approach to crowdsourcing projects (Causer et al., 2012), using shared databases and collaborative work, a method already developed with excelent results in previous studies (Alves and Queiroz, 2013; Alves and Queiroz, 2015). The second challenge went through georeference about fifty thousand addresses obtained in this documentation, using essentially the computer's processing power. It is recognized that there are advantages and disadvantages in using several geocoding methods (Zandbergen, 2008). Its application to Lisbon is made difficult due to the fact that the city have gone through a deep urban morphology transformation and experienced significant changes in its street names throughout the twentieth century (Alves, 2005; Oliveira and Pinho, 2006). Nevertheless, it remains one of the best methods for automatic assignment of geographic coordinates. The challenge was to think of a process that could overcome the difficulties listed, without having to go through the full reconstitution of the urban network. Not least because the available sources do not made possible the recreation of all the buildings and their functional classification in a GIS environment, as was achieved in other projects (Dunae et al., 2013). The option went through reconstruction of the existing streets network of the time, based on geo-referenced digital cartography. Thus an addresses' database was created, with slight adaptations on the geocoding algorithm of the GIS platform used, allowed for a success rate of around 90%.

As for georeferencing, the first and greatest of all the problems is related to the urban changes that the city has undergone over the last 120 years. On the one hand, strong population growth led to the expansion or changes in the corresponding urban area, even If we take into account just the three years analyzed. The city of 1890 is very different from the one in 1910, in the layout of the streets, in the expansion into new areas, construction or renovation of its buildings. On the other hand, Lisbon had the particularity to overcome, between 1890 and the present, four very different political regimes that have left a peculiar and deeply transformative mark in the city's toponomy. Even if the urban area was stable, only the change of street names over more than a century of profound political changes, would pose great challenges to an automated geocoding process.

For this there was first the need to rebuild the streets network of the time, trying to recreate the map of Lisbon of the Belle Epoque. This map was fixed for 1890 and then it was possible to apply the normal geocoding techniques, adapting either the collected data source, or the software algorithm used, in order to overcome difficulties so small, but so significant in the final results, such as the fact that the software was incapable to deal with some Portuguese names and characters or to recognize certain types of streets that were used at the time but ignored or underused today. Or the fact that the names of some streets are identical or very similar in different areas of the city. This is an iterative process of trial and error so as to refine the best model data that maximizes the results obtained.

However, there was still the issue of street names changing over time. For the period in question this problem is not very complicated, since only at the end of 1910 took place the first regime change, the Republican Revolution, with the consequent wave of place names changed. But there was almost annually, specific changes in street names. These changes were incorporated in the database, maintaining the address structure already georeferenced for 1890, allowing to incorporate the data for the same streets that appeared in the sources with different names.

These two ways to overcome the problems with georeferencing were only possible due to the existence of sources, either cartography or streets itineraries, which allowed to go adapting the original map so as to incorporate, with a similar success rate, the 1900 and 1910 data.

As for the quality or accuracy of georeferencing, it is obvious that the ideal would be to have the possibility to rebuild not only the network of city streets, but also the actual location of the various housing/trade blocs. Unfortunately no sources for this level of detail are available. In the original shapefile map, which represented the actual city streets, in 2012, the streets were targeted with the actually existing building numbers in each block. Since we have no way of saying, at this stage of the research, how many buildings existed on every block in 1890, it was decided to distribute all points along the entire length of the street, according to the geocoding algorithm. Obviously, this option can cause some significant deviation in less consolidated urban areas of the city, but it is also true that the areas where the overwhelming majority of small businesses traditionally where implemented account for already established streets. So that problem here is much lower, and the geocoding accuracy is much higher.

I did not use crowdsourcing primarily due to the available time for the collection of data and to poor accessibility to the original sources. Seems odd to state this because apparently these are precisely justifications for using crowdsourcing. However, it is known, also through the literature already cited in the abstract, that the use of crowdsourcing can be a lengthy process and not always easy to check on the quality of final results. Furthermore, it requires easier access to sources through digital copies because not all potential participants have availability or even competence for archive work. In our case, the sources correspond to thick volumes of bound sheets, deposited in a municipal archive without major conditions for local consultation and without the financial ability to carry out its full or partial scan. There was also the problem of the quality of the data, given that we are talking about handwritten information sometimes difficult to read. In this sense, the use of a collaborative work, through volunteer history students with availability and sensitivity to archival work was decisive. This data collection was made via a PostgreSQL database, shared with all students through ODBC, so that all data collected by one of the students become available for subsequent use by others. This process, already tested in other project with very good results (Alves and Queiroz, 2013; Alves and Queiroz, 2015) , saved up a lot of time in data collection and redundancies were avoided, because a new address o r a new commercial activity detected by one of the students in the sources once registered in the database, was automatically available and could be used/selected by all the others. Even if the original record contained an error, since it was registered only once in the database, because the data model prevented duplicates, the validation task was also facilitated.

The reconstruction of the 1890 street map, base of all subsequent work, was made through a current map in shapefile format, provided by the Municipality. This map was superimposed on a digital copy of an old city map properly georeferenced. The mere overlap of the two maps identified a broad set of streets that did not exist at the time (eliminated from the shapefile) and others that changed their layout (fixed in the shapefile). Using streets itineraries, namely one for 1890, very complete, mentioning the name, location and building numbers of all city's streets, it was possible to correct the shapefile street names that had gone through changes over these 120 years. The link between this corrected shapefile and the shops' addresses collected in the shared database allowed for geocoding, with minor adjustments to the software algorithm.

Overcoming these issues, it was possible to get a far more dynamic source, more accessible and manageable, able to respond quickly to old research questions or to introduce new perspectives about Lisbon and its retail trade in the Belle Époque. Just to mention one possibility, in the Lisbon municipal archive there are many available data that could be crossed with the information collected on shops and shopkeepers. In particular, it has data on electoral census and elections, with voters lists organized by parishes and addresses, for several years of the nineteenth and twentieth century and this data can also be mapped and analyzed using the methodology now developed. The same can happen with data on primary education, for example, because this fund has information on the addresses of the students also. Given that the addresses of the shops are being collected in a separate table and that it allows to be connected to either the GIS or to other tables with different data, whether on small businesses, on elections or on education, the use of this methodology will allow for results in other projects or to add new information relevant to the history of the city without the need to start everything from scratch.

In this sense, while recognizing the limitations of GIS (Boonstra, 2009; Bodenhamer et al., 2010; Silveira, 2014), it must be highlighted the capabilities of its spatial analysis, processing and data visualization tools, that has been particular useful in the context of urban history (Hillier, 2010; DeBats and Gregory, 2011). In recent years, the use of GIS for the study of cities and their retail trade (Beascoechea Gangoiti, 2003; Mirás Araujo, 2008; Bassols and Oyón Bañales, 2010; Novak and Gilliland, 2011; Ünlü, 2012) has enhanced the theoretical framework and the possibility of international comparative studies, which represented a definitive stimulus to the application of these methodologies to this case study. To this matter it is useful to mention that a session comparing four case studies for Iberian port cities will occur in the ESSHC in Valencia, this year, putting together comparative analysis about Barcelona, Bilbao, Coruña and Lisbon, in the first decades of the twentieth century (https://esshc.socialhistory.org/esshc-user/programme?day=55&time=145&session=3003).

Unlocking The Mayan Script With Unicode

Deborah Anderson
dwanders@sonic.net
UC Berkeley, United States of America

Carlos Pallán Gayol
pallan.carlos@gmail.com
University of Bonn, Germany

Problem

At present, three hieroglyphic scripts are encoded in the Unicode Standard: Egyptian, Anatolian, and Meroitic. The historic Mayan hieroglyphic script is not yet in Unicode, in part because its complex clustering poses special encoding problems.

Besides the difficulties inherent in the Mayan script, writing a Unicode proposal for Mayan involves additional challenges, requiring significant time commitment and travel. Early meetings between with Unicode experts are a desideratum in order to identify the best technical approaches to handle Mayan text issues. Then the proposal needs to be written – complete with all the required details for the entire character repertoire. When the proposal goes before the two standards committees, the authors need respond to any questions, and make revisions to the proposal as needed. In addition, proposers need to commit to seeing the process through to the end, which can take between two to five years, or longer.

In short, the twin challenges of representing and displaying Mayan clusters on computers and writing a Unicode proposal (especially for anyone new to the process) present a huge hurdle.

Background on Mayan clustering

Mayan signs appear in clustered glyph-blocks or "collocations," which could be modified by the masterful Mayan scribes with advanced "tools," such as ligatures, conflation, infixation, superimposition, pars pro toto and full-figure variants (see Fig s. 1 and 2). The visual complexity of Mayan requires mechanisms that go beyond standard script encoding approaches.

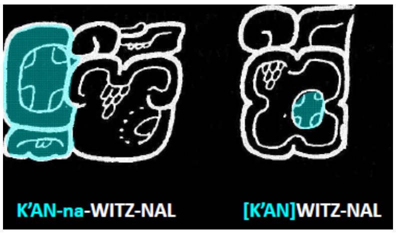

Fig. 1 Infixation of the highlighted logogram K'AN (shown on left, infixed as a circle on the right)

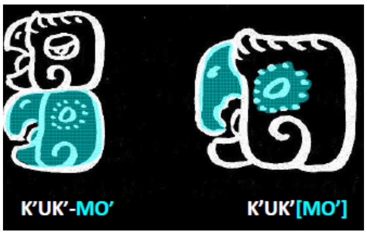

Fig. 2 Conflation of the highlighted logogram MO' (shown on the left, conflated on the right)

Solution

A recent multidisciplinary collaboration established between UC Berkeley's Script Encoding Initiative (SEI) and the MAAYA Project aims to employ new methods combining linguistics, Mayan epigraphy, digital palaeography and computer vision to overcome some of the major challenges preventing the encoding of Mayan hieroglyphs in the Unicode Standard. Some of the strategies envisioned rely on already existing MAAYA-Project resources. Such resources include datasets with annotated database records for all individual glyphs and possible sign-combinations attested in Mayan hieroglyphic books and an advanced concordance functionality, that cross-references Mayan signs across existing glyph-catalogues (Gatica-Perez et al., 2014 and Hu et al., 2015).

In addition, SEI's experience in overseeing the encoding over 70 of the world script systems means Mayan experts will have a front-line guide to help the proposal through the entire encoding process – providing Unicode expertise, assisting on the authoring and review of a proposal, and presenting the proposal at standards meetings. Having direct involvement of Unicode specialists means the proposal can draw on Unicode experience to identify successful methods that can adapted and expanded to account for the extraordinary variability of Mayan signs clustered in glyph blocks.

Specific encoding issues: Egyptian format characters

In Unicode 8.0, the default display for the three encoded hieroglyphic scripts (Egyptian, Anatolian and Meroitic Hieroglyphs) is a linear listing of the characters, as shown by the example in Fig. 3.

Fig. 3 Current default display of Egyptian hieroglyphs in Unicode (Richmond, 2015)

According to the Unicode Standard, display of the characters in a non-linear manner (i.e., in clusters) should be handled by a higher-level protocol (Unicode Consortium

2015: 430-31, 437), and is outside the scope of Unicode. However, clustering is more typical of the layout for most hieroglyphic scripts.

Although Egyptian hieroglyphs were encoded in Unicode in 2009, Egyptologists are currently prevented from interchanging data easily, because they have had to rely on non-standard software to handle character grouping. According to Richmond 2015, hieroglyphs need to be capable of being grouped together in plain-text - without proprietary software - in order to be truly useful.

In 2015, a new proposal was put forward for three format characters that allows basic clustering (Richmond, 2015, see Fig. 4). The characters indicate placement of a character, either above another character or alongside it, or, for the third character, identify it as forming a ligature with the following character. The three characters are based upon the conventions of the Manual de Codage, which uses ASCII characters to indicate the placement of the hieroglyphs. (Note: Since the mirroring of glyphs is handled by line direction, as specified by markup or bidirectional characters, no format characters are not proposed for that.)

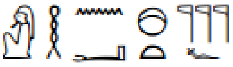

Fig. 4 Example showing the same characters as in Fig. 3, but with expected clustering, made possible with the format characters (Richmond, 2015)

The three Egyptian format characters were approved by one of the two standards committees in January 2016 (Unicode Consortium, 2016). The characters have been tested and shown to display as expected in the Universal Shaping Engine, a rendering engine in Windows 10 and recent versions of Android, Chrome, LibreOffice and Firefox.

If the characters successfully complete the approval process, simple clustering in Egyptian hieroglyphs should be capable of plain-text representation in the future, meaning that scholars would not have to rely on an ad hoc, non-standard solution. At this point, Egyptian hieroglyphs appear to only require the three format control characters for clustering, and need no other mechanisms.

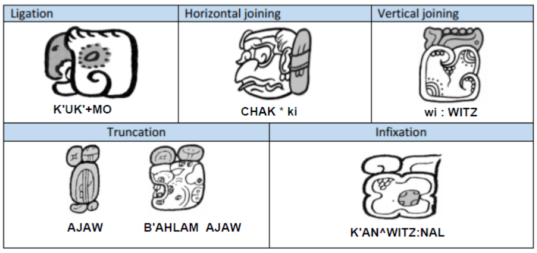

Fig. 5 Expected clustering of Mayan hieroglyphs (adapted from Richmond and Glass, 2016)

Evidence from the MAAYA project suggests that Mayan will require three script-specific format characters that serve the same functions as Egyptian, and at least two additional characters: one for truncation and another for infixation (see Fig. 5).

Hence, it appears that Egyptian and Mayan can share a common model, using format characters for clustering (with at least two additional ones needed for Mayan). In addition, advances in text display of Egyptian hieroglyphs, which have been tested successfully on the Universal Shaping Engine, may well be applicable to Mayan.

Specific encoding issues: Ideographic Description Characters

Unicode contains a mechanism to describe Chinese-Japanese-Korean (CJK) ideographs, called Ideographic Description Characters (IDCs). These characters are used to describe the layout of CJK characters, but is not used for rendering. The IDCs have been defined as capable of being extended to other scripts (Unicode Consortium 2015, pp. 679-80). (See Fig. 6.)

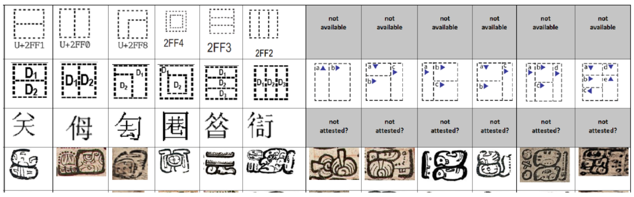

Fig. 6 Examples of Ideographic Description Characters (extended to Mayan hieroglyphs). Top row: Unicode Ideographic Description Characters (IDC); second row: Chinese IDCs (left) and Mayan descriptors (right); third row: Chinese examples; fourth row: Mayan script examples

In April 2015, Unicode experts met with the co-author, Mayan expert Carlos Pallán Gayol, and recommended the MAAYA project identify the structural patterns of Mayan characters, and use Ideographic Description Characters (IDCs) to describe them. Such a mechanism will help in defining Mayan characters (in Unicode terms), and help "unlock" the script.

Next steps

At a meeting in January 2016 with the co-author Pallán Gayol, unicode experts noted progress on the encoding model issues and suggested the MAAYA project continue to define the base set of characters, identify the structural patterns of IDCs, and verify the number of format characters needed.

Expected results

Encoding the Mayan hieroglyphs in the Unicode format will allow creation of vast open-access Mayan hieroglyphic text repositories and libraries, upon which advanced search and query functionalities relying i.e. on Optical Character

Recognition (OCR) and text-mining could be applied. (Once a script is in Unicode, an OCR engine can be trained to read the script, though the text needs to be consistent).

Thus, we argue that the ability to render any Mayan hieroglyphic text in an encoded digital format could impact on the overall accessibility, reproduction, visualization and long-term preservation of the sum of ancient knowledge recorded by the Mayan scribes on thousands of texts and inscriptions produced between ca. 250 B.C. and 1520 AD in Central America. It could also act as a model for the encoding of other hieroglyphic scripts of the Americas, including Aztec.

Developing Competencies in Digital Scholarship Among Humanities Scholars

Smiljana Antonijevic Ubois
smiljana@smiljana.org
Penn State University, United States of America

Introduction

This paper draws on results of a three-year ethnographic study funded by the Andrew W. Mellon Foundation and the Royal Netherlands Academy of Arts and Sciences, which explored research practices, challenges, and directions in contemporary digital humanities (DH). Within this broader set of questions and results, the current paper focuses on findings related to humanists' strategies for developing competencies in digital scholarship. The study was conducted from 2010 to 2013 at twenty-three educational, research and funding institutions in the United States and Europe, and it included case studies, surveys, in-depth interviews, and observations. The study involved 258 participants, including researchers, faculty, students, university administrators, librarians, software developers, policy makers, and funders. For more information about the methodological design and results of the study see *Amongst Digital Humanists: An Ethnographic Study of Digital Knowledge Production* (Antonijević, 2015).

Results

The majority of humanists consulted in this study reported awareness of methodological and epistemological benefits of digital research tools and methods, but also a lack of opportunity to acquire skills and knowledge that would enable them to reach beyond the "search and access" level of digital scholarship. As one assistant professor of art history put it, "I haven't used technology in my research in a pervasive way to really, really think about epistemological issues. I'm not opposed to using technology to analyze, but I haven't had a chance to learn it."

Humanists commonly identify lack of time as one of the main impediments to developing digital research skills. One aspect of this is the learning curve, and a perception that the time needed to learn new tools and methods slows down their established research process. Another root of researchers' lack of time for developing computational skills stems from the structure of disciplinary incentives and rewards in humanities disciplines. Respondents underscored that when training sessions on digital research tools and methods were organized at their universities, hardly any of the tenure-track faculty attended them: "We are not rewarded for doing that. What we are rewarded for is publishing, and going to one of those sessions takes away

[time] from our publishing. So, there's a lot of resistance" explained an assistant professor of linguistics.

With digital skills still having an unrecognized status in their disciplines and departments, interviewees said the only organized educational initiatives at their disposal were training sessions at university libraries, to which they had mixed reactions. While some found the library sessions "eye-opening" the majority did not regard them as helpful. Commonly, respondents pointed that the librarians focused on digital tools and resources, while field-specific research questions exceeded their scope. The respondents held that only their peers understand epistemological and methodological complexity of particular research problems, so they considered working with colleagues as a more effective way to develop digital skills than attending library workshops or instruction sessions. In the same way, respondents identified as the preferred type of instruction the one that does not profess to teaching about digital technologies, but about a specific humanities subject area, introducing digital tools and methods along the way. Attending library and similar workshops was thus seen as less effective then attending academic conferences where peers present results achieved through digital methods and tools. Learning by example inspires humanists to discover new tools and methods, and to apply them in their own work. As a professor of Romance languages and literature put it, "in an ideal world, I would like to see humanists teaching other humanists how to conduct research using the enhancements of digital tools; I guess that's as opposed to we bring the IT people in to teach us. I think that it should happen the way that we teach other things in the humanities, through collaboration with one another."

Dissatisfaction with existing educational initiatives might be the reason that the majority of humanities scholars consulted in this study reported not having any formal technology-related instruction, which is consistent with Siemens' (2013) findings. Instead, the respondents reported that they predominantly relay on informal channels, such as word of mouth, to learn about digital research tools and methods: "I do everything on my own, I ask around. It feels serendipitous, I sort of bump into it, or I hear a friend talk about it, or a colleague will shoot me an e-mail. It's not organized or strategic at all" related an associate professor of philosophy.

This informal learning path is linked to immediate and specific research problems scholars are facing, which makes it preferred over workshops and similar efforts where learning is often decontextualized from practice. This method also successfully makes use of one of the scholars' most scarce recourses—their time. It enables them to direct learning efforts towards tools, methods, and subjects of particular interest to them.

Informal learning also often takes place through engagement with students. The respondents explained that teaching prompts them to expand knowledge of digital tools and methods, and students challenge them to be up-to-date with technology. Even those respondents who described themselves as "technological dinosaurs" identified the need to take up digital technologies in the classroom.

In addition to class interaction, more formal initiatives where students teach faculty take place in digital humanities centers, where graduate students often work as tutors. Students consulted in this study believed that this reversal of instructional roles facilitated their understanding of the didactic principles, motivating them to develop their own pedagogic strategies:

"You're doing work with people who are the smartest people on the earth in their particular discipline. On average, they don't like to admit that they don't know something. So, it's not trying to force things upon them, but it's trying to present things in the same way that you would pedagogically teach a difficult concept. If I can present it it in such a way that leads them to discovering on their own, they have a sense of ownership of the idea, so that's "teaching the old dog new tricks" if I can say that." [A graduate student]

Conclusion

Findings of this study indicate that library initiatives and units should not remain the main locus of digital scholarship in the humanities. Instead, digital scholarship needs to be part of humanities departments and wider university initiatives, since "digital humanities will ultimately matter, or not at all, *inside* the department" (Liu, 2009: 21; italics in the original). As long as humanists' interaction with digital tools, methods, and resources is treated merely as a technical skill that can be taught by non-expert personnel, it will be difficult to achieve more substantial transformations and to motivate academics about digital scholarship. As Raley (2014) points out, "academic service staff providing skills-based training [...] and performing service work for "clueless arts and humanities scholars" can tell us something about both the field and the university" (p. 7).

Instead of skilled-based training, humanities education in digital scholarship needs a comprehensive framework encompassing epistemological, methodological, technical, and sociocultural aspects of digital knowledge production. These include developing understanding of digital and other types of data, fostering critical reflection on digital objects of inquiry, comprehending the influence of algorithmic processes on humanities investigations, and so on. Similarly, digital methods training should include systematic deliberation on methodological decisions influencing research process and results, epistemological and ethical challenges of digital scholarship, as well as making choice of digital tools and methods as best suited for specific research questions.

This study reveals that humanists favor and best learn in practice, when instruction is closely related to their area of study and when it unfolds organically, through collaboration with colleagues and students. Therefore, initiatives for developing competencies in digital scholarship among senior scholars should use a variety of collaborative learning strategies. Furthermore, these educational activities should not restrain the generative potential of digital scholarship in the humanities through the exclusive focus on research themes, methods, and skills recognized in the DH field. Humanities scholars do not necessarily need or want to be digital humanists; they do, however, need and overwhelmingly want to be scholars competent at teaching and conducting research in the digital age. As a program officer in a major humanities foundation consulted in this study pointed out, the goal should be "to fund training for scholars even if they don't want to be a digital humanist in the sense that they're building their own tools and their programming, but more along the lines of users of digital technology within their own research." This kind of funders' support to digital scholarship in the humanities is vital. Equally vital is the need that education in digital scholarship becomes administratively recognized as part of scholars' professional development included in their paid time and activity, as well as in their promotion dossiers.

Introduction

Starting from Manovich's (2007) statement that "a prototype is a theory", Galey and Ruecker (2010: 406-07) argue that design can become "a process of critical enquiry itself", a "thinking through making" pursuit allowing the combination of digital prototyping with critical analysis. Furthermore, Pierazzo (2011: 466) brings into discussion the theoretical assumptions that may underpin the decision making process in building an edition as an "interpretative scholarly product" based on the "selection of features transcribed from a specific primary source".

The present proposal focuses on the construction of a visualisation framework allowing transformation and visualisation in the browser of XML-TEI encoded documents on European integration history. The tool developed for this purpose, the Transviewer, uses a combination of XML, HTML, XSLT, CSS and JavaScript technologies. The addressed research questions are related to the analysis of this prototyping case, viewed as a dynamic and iterative process of evaluation, adjustment, decision making, adaptation and in-house development. Our standpoint, inspired by the above mentioned studies, is that such type of analysis can shed light on the theoretical and practical questions, at the crossroad of tradition and new ground, involved in the creation of scholarly digital tools.

The Transviewer prototype

The Transviewer concept consists of building a framework for the publication of European history documents on the CVCE's Website, from treaties, official declarations and meeting reports to letters and interview transcriptions. In a first phase, a pilot testing set for the prototype (Figure 1) has been encoded in XML-TEI P5, including a selection of 55 documents on armament issues within Western European Union (WEU), from 1950's to 1980's.

19 mars 1955

COMITE D'EXPERTS
OPPORTUNITE DE STANDARDISER

Note du Secrétaire Général

Le Secrétaire Général communique ci-joint un document soumis conjointement par les Délégations belge et française sur l'opportunité de standardiser.

Une première version de ce document a été examinée par le Comité de Rédaction à sa séance du 17 mars 1955.

Le Comité d'Experts étudiera la nouvelle version ci-annexée lors d'une de ses prochaines séances.

- 1 -

PWG/E/24

OPPORTUNITE DE STANDARDISER

1. La décision sur l'opportunité d'adopter un nouveau matériel est influencée par un certain nombre de circonstances, dont les principales sont :

(a) le programme déjà arrêté par chaque nation pour le renouvellement de son matériel et pour l'équipement de nouvelles forces,

(b) l'urgence des besoins,

(c) les disponibilités financières espérées,

(d) l'âge et la vie probable du matériel en service (dans chaque nation),

Figure 1. Transviewer. Side-by-side view digital facsimile (left) and transcription (right) (WEU sample)

In line with Booth et al. (2008), Galey and Ruecker (2010: 412-13) consider that a prototype can be the embodiment of an argument (or more), with all the key components of a "good thesis topic": to be "contestable", "defensible", and "substantive". This refers to how a prototype includes old affordances in a new way or proposes something new, to its potential of convincing people to accept it, or finally, to its intellectual and practical value.

Our idea in designing the Transviewer has been based on the following "arguments":

1. The historians or researchers in European integration studies (the CVCE's main category of readers) are always interested in comparing a transcription with the original (when available).

2. The architecture of the visualisation framework should be multi-project-oriented and support multiple types of historical documents (primary/secondary sources – text/image/audio/video).

A number of features to be encoded and rendered via the interface have been considered after consultations with the users (CVCE's researchers):

Transcription		
Feature type	**Encoded**	**Ignored**
Documentary	Ink colour of stamps (red, black)	Ink colour of handwritten text
Topology	Document layout (position and alignment of headers/footers/headings)	
Writing	Capitalisation and punctuation	Empty lines and exact vertical spacing on the page
Handwriting	Handwritten elements from header/headings	Handwritten fragments, sometimes not legible, from the body of the text
Textuality	Paragraphs and structural divisions	
Semantics	Named entities (e.g. names of persons/organisations/places/functions/events/products, dates)	

Table 1. "Grid of features" (Pierazzo, 2011: 467) encoded in the transcription (WEU sample)

The current version of the prototype supports functionalities such as side-by-side view of digital facsimile and transcription, page-by-page navigation, zoom-in/out, vertical scrolling, search (by names of persons/places/organisations, dates).

Figure 2. EVT. Fragment (Vercelli Book)

Although the direct adaptation of EVT was considered from the beginning, different requirements for EVT and Transviewer project have been identified.

Characteristics	EVT	Transviewer
General architecture	Project-oriented (Vercelli Book manuscript)	Multi-project-oriented (documents/collections in European integration history)
XML-HTML transformation granularity	Page-oriented (one HTML file per page/manuscript image)	Document-oriented (one HTML file per XML document)

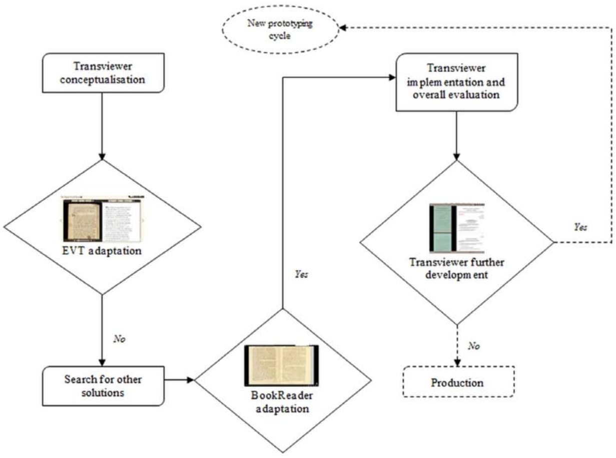
XML-HTML transformation process	HTML generation	XML transformation on the fly, in the browser, and XHTML generation
Transcription	Line-oriented	Structure-oriented (divisions, paragraphs) with semantic annotations (named entities).
Navigation	Page-by-page (supported by a single HTML file per page implementation)	Page-by-page and vertical scrolling (applied to a whole document)
Image management/loading	One by one	Images for a whole document

Table 2. EVT/Transviewer differences

Therefore, the EVT concept of side-by-side view of digital facsimile/transcription has been combined with the integration of third-party libraries (BookReader, Saxon-CE) and in-house development. The first one has been chosen for enabling on the fly loading of images, the second for supporting XSLT 2.0 transformations in the browser.

The in-house development mainly comprised modules for the implementation of a core/project specific architecture including elements of configuration, frames and buttons layout/actions, XSLT transformation and transcription rendering.

A simplified diagram of the decisions points in the first development cycle of the Transviewer is shown in Figure 4.



New prototyping cycle
Transviewer conceptualisation
Transviewer implementation and overall evaluation
EVT adaptation
Transviewer further development
Yes
Yes
No
No
Search for other solutions
BookReader adaptation
Production

Figure 4. Transviewer. Decision points (diamonds) in the first prototyping cycle

As illustrated, the prototyping process can imply multiple iterations. Once a functional prototype is built, the decisions on further development may reiterate similar phases of conceptualisation, search for solutions, implementation, evaluation and decision making. In this respect, our theoretical approach could be framed at the crossroad of "iterative prototyping" (Buxton and Sniderman, 1980; Buchenau and Suri, 2000; Lucena and Astua, 2012), "user-centered design" (Shneiderman and Plaisant, 2009; Warwick et al., 2009; Gibbs and Owens, 2012), and scholarly digital editions (Pierazzo, 2011; Rosselli Del Turco, 2011).

iv *The* TRANSLATOR'*s* PREFACE.

But what if *Cervantes* made this ſeeming ſlip on purpoſe for a bait to tempt the minor criticks; in the ſame manner as, in another place, he makes the princeſs of *Micomicon* land at *Oſſuna*, which is no ſea-port? As by that he introduced a fine piece of ſatire on an eminent *Spaniſh* hiſtorian of his time, who had deſcribed it as ſuch in his hiſtory; ſo by this he might only take occaſion to reflect on a parallel incident in *Arioſto*, where *Brunelo*, at the ſiege of *Albraca*, ſteals the horſe from between the legs of *Sacripante* king of *Circaſſia*. It is the very defence he makes for it, in the fourth chapter of the ſecond part, where, by the way, both the *Italian* and old *Engliſh* tranſlators have preſerved the excuſe, though by their altering the text they had taken away the occaſion of it.

The edition by *John Stevens* is but a bare attempt to correct ſome paſſages of *Shelton*, and, though the grammar be a little mended by the connecting particles, the antique ſtile of the old one is entirely broken. This is therefore ſo much the worſe by altering the ridiculous of the old diction, without coming nearer to the ſenſe or ſpirit of the original. *Stevens* alſo has made the ſame wiſe amendments with his predeceſſors.

That of *Motteux* is done by ſeveral hands, and is a kind of looſe paraphraſe, rather than a tranſlation; and has quite another caſt, being taken wholly from the *French*, which, by the way, was alſo from the *Italian*. It is full of what is called the *Faux brillant*, and openly carries throughout it a kind of low comic or burleſque vein. *Motteux* is ſo injudicious as to value his verſion upon this very air of comedy, than which nothing can be more foreign to the deſign of the author, whoſe principal and diſtinguiſhing character is, to preſerve the face of gravity, generally conſiſtent through his whole work, ſuited to the ſolemnity of a *Spaniard*, and wherein without doubt is placed the true ſpirit of its ridicule.

For

The TRANSLATOR'*s* PREFACE. v

For the three principal points, which a ſtaunch *Spaniard* lays down to his ſon, are ranked in the following order; *Gravedad, lealdad, y el témor de Dios*, i. e. "In the firſt place *gravity*, in "the ſecond *loyalty*, and in the third *the fear of God*." The firſt is to manifeſt itſelf in a punctilious zeal for the ſervice of his miſtreſs; the ſecond in an unreſerved ſubmiſſion to his prince; and the third in a blind obedience to the church. The firſt of theſe makes the chief ſubject of the preſent ſatire.

Upon the whole, I think it manifeſt this author has not been tranſlated into our language in ſuch a manner as to give any tolerable ſatisfaction; though it is evident from the two attempts made by *Motteux* and *Stevens*, and the ſucceſs they met with upon the firſt publication, that there was an univerſal demand for ſuch a work. However, in a ſhort time, all thoſe, who had any taſte of the author, finding themſelves diſappointed, choſe rather to have recourſe back again to the old one, which, as it was nearer the words, was ſo much nearer the ſenſe of the original.

There are three circumſtances, wherein the excellencies of this author appear in the ſtrongeſt light. The firſt is, that the genius of knight-errantry having been ſo long expired all over *Europe*, excepting in *Spain*, yet this book has been tranſlated into moſt languages, and every where read with univerſal applauſe; though the humour was long ago ſpent, and the ſatire affected none but the *Spaniards*. Secondly, that, although it requires a good judgment to diſcover all the nicer beauties in this writer, yet there remain enough ſufficiently obvious to pleaſe people of all capacities whatſoever. The third (which I confine wholly to *England*) is, that, though we have already had ſo many tranſlations and editions, all abundantly defective, yet the wit and genius of the author has been able to ſhine through all diſadvantages, ſo as to make every one of them as entertaining as any we have among us.

The

Figure 3. BookReader. Fragment (Don Quixote de la Mancha)

Evaluation

Although partial evaluation had been carried out throughout the prototyping cycle, a more formal testing and evaluation phase has been conducted on the first functional version of the Transviewer. Several facets of assessment have been taken into account:

Facet	Short description	User group/ stakeholders
Technology	Technical issues have been identified and worked upon (e.g. non-uniform support for Saxon-CE in different browsers and the use in BookReader of an older version of the jQuery library). Another evaluation aspect, related to argument 2, consisted of proving the scalability of the framework by testing it with different projects samples.	CVCE's development team
User	The prototype functionalities and argument 1 have been evaluated via usability tests (Nielsen, 2000; Lund, 2001) mainly enquiring on the ease of use, ease of learning, usefulness and user satisfaction (on a scale from 1 to 5), and on suggestions for potential improvement.	Internal/external researchers as end-users of the Transviewer
Impact	Beside the impact on the final product (e.g. how many/in what proportion the functionalities/features/arguments of the prototype are reflected in the final product), another point of interest concerns its impact on other products, in particular, the initial models having inspired it.	Cooperation partners, research infrastructures

Table 3. Transviewer evaluation facets

Discussion

As an outcome of the analysis on the first prototype cycle, a new iteration and development reassessment is currently ongoing. The analysis helped us to: (1) identify and amend technical (see Table 3) and design issues (e.g. functionalities not quickly accessible or requiring extra-effort, unclear terminology or functionalities hierarchy, simplification); (2) adapt the encoding to support a larger variety of objects to be visualised (e.g. transcription only, facsimile only, transcription and audio/video); (3) better understand the needs of the users while dealing with historical documents (e.g. "trust" and "contextualisation" seem to play an important role).

Moreover, the development of new technical tools poses not only challenges to the process itself and the methods it introduces or refines but it also raises the question of sustainability: project based funding stimulates the development of new tools between different entities but far too often, this development stops once funding runs out. In the context of the informal and not project-funded cooperation between the CVCE and the EVT team, we therefore want to explore the trials and tribulations of building and maintaining a shared codebase that would be beneficial for both entities even though our specific use cases differ. As a result of the experiences made in this ongoing process of building the new version of the EVT framework, we will take the opportunity to discuss the practical challenges, opportunities and limitations of open-source development models for digital humanities projects as an approach to achieve sustainability.

In other words, we are not just testing an application but a development framework which implies considering complex theoretical-practical elements: Human-Computer Interaction (HCI) aspects, Information Technology (IT) methods and tools, specific types of documents to be published, projected audience, collaborative strategies and sustainability, etc.

Conclusion

The article proposes an analytical approach to the prototyping of a visualisation framework for historical documents. Its main assumption is that a critical perspective can be applied not only to a finished digital artefact but also to the process of its creation. In line with more traditional methods of criticism from the Humanities, a "thinking through making" viewpoint may bring into light theoretical and practical aspects related to the construction of digital tools and to the mechanisms of the "laboratory". A prospect that, by its nature, positions itself at the crossroad of the old and the new, of the past and the future.

Combining Corpora and Statistics using Geographical Technologies: New Evidence on Nineteenth Century Infant Mortality Decline in England and Wales

The division between quantitative and qualitative approaches is fundamental to the study of the past. Quantitative approaches are predominantly used to study statistical sources in fields such as historical demography and economic history where large numerical databases are available. These approaches are well suited to situations where large volumes of digital statistics are available and are very good at finding relationships between variables. They can be criticised on two levels: firstly, while good at identifying relationships they are poor at establishing the causal mechanisms that cause them. Secondly, and more fundamentally, most information about the past is not in numerical form and thus cannot form part of a traditional quantitative analysis, thus many relevant factors cannot be included within the analysis. Qualitative sources, particularly texts, are richer in both the range of material available and in the amount of detail it provides about the conditions in which people lived. They are however much more complex to work with and traditionally required close reading which is slow and selective. Digital technologies offer the potential to overcome this divide and make use of the combined advantages of both types of source, making use of statistical sources to identify patterns and relationships, and textual sources to help explain the patterns found. This paper presents an example of this based on infant mortality in Victorian and Edwardian England and Wales.

Infant mortality refers to deaths before the age of one, usually expressed as an infant mortality rate (IMR) of infant deaths per thousand births. An orthodox story is that infant mortality decline was brought about by government action on sanitation (Szreter, 1991; Woods et al., 1988; Woods and Shelton, 1997). More recently Gregory (2008) used a GIS database and demonstrated that infant mortality decline actually started before the Public Health Acts, that decline was earlier and steeper in rural areas of the south and east of England than anywhere else, and that rural parts of the north, Wales and the West Country had among the lowest rates of improvement. He was, however, unable to explain this variation with the data available. This paper uses a combination of statistical and textual sources to attempt to provide explanations for infant mortality decline with an emphasis on rural areas.

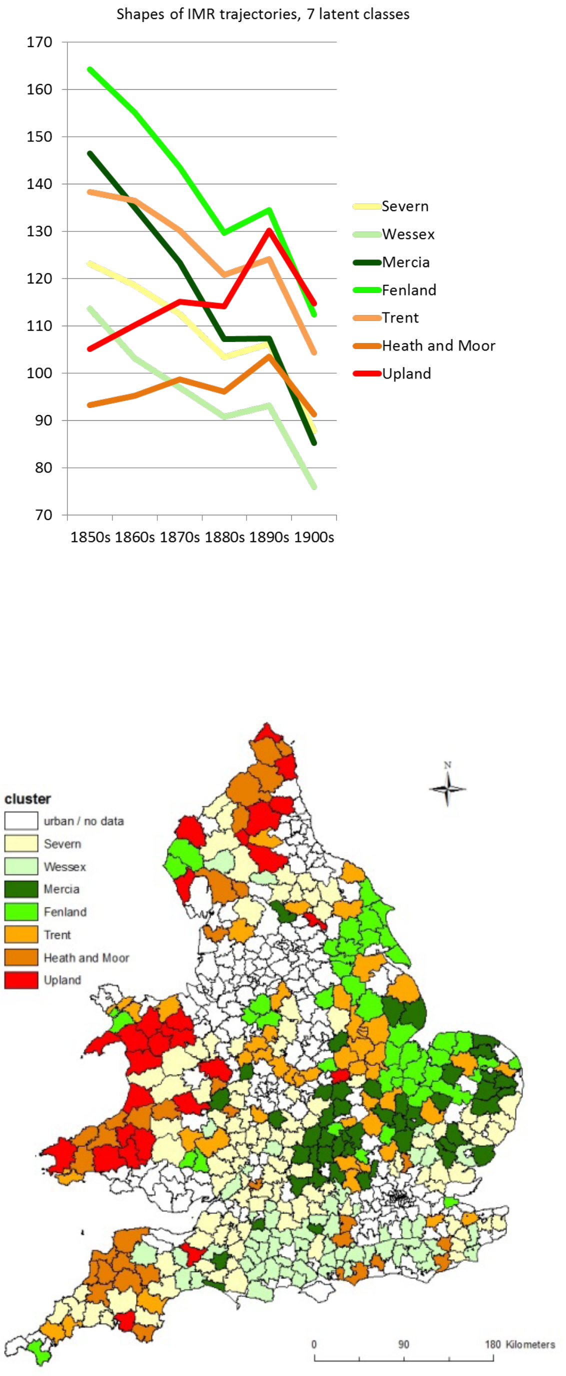

Figure 1: Temporal trajectories and geographical locations of the seven latent classes

In the quantitative stage, as many geographically disaggregate independent variables as possible were assembled to explore what other factors seemed to be associated with infant mortality decline. Analysing change over time and space for multiple variables is difficult. A technique called Latent Trajectory Analysis to do this but combine it with the use of GIS (Nagin, 1999). Figure 1 shows how this techniques was used to group districts into seven clusters based on their temporal characteristics, and then map where rural districts with similar trajectories are found. This confirms that there was a clear geography to infant mortality decline. The biggest improvements occurred in rural areas in the south and east in the clusters described as 'Fenland' and 'Mercia.' Areas showing the lowest declines, which in some cases actually got worse, were in the north and west in the clusters described as 'Upland' and 'Heath and Moor.'

Further analysis reveals statistically significant relationships between infant mortality change and rates of female TB and a less strong relationship with female literacy. These relationships have been shown elsewhere in the literature, however our findings show that these factors were important in rural areas as well as in urban ones. Interestingly convincing relationships could not be found with population density or fertility, these would be expected from the literature. The other striking finding was that the most important independent variable in every model was 'decade', in other words, change over time that none of our other variables could account for. Fundamentally this tells us three things: first that there are some very interesting geographical patterns to infant mortality decline, second that this is related to some other factors, particularly female health and education, and third that even though we have assembled what we believe to be as many quantitative independent variables as it is practical to use, these are unable to account for much of the change in infant mortality over this period.

The relative lack of explanatory ability by the quantitative analysis is hardly surprising given the lack of variables on a whole range of topics that may be associated with improving infant health, including: sanitary conditions, access to midwives and healthcare, attitudes towards breastfeeding, access to safe cows' milk, and so on which have never been captured in statistical form. Thus, if we are going to improve our understanding we need to explore non-quantitative sources. Of particular interest here is the British Library's Nineteenth Century Newspapers collection, a corpus of over 50 newspapers, most of which are available for series that cover most of the century. The corpus is at least 30 billion words although, to date we have been working with individual newspaper series which are usually hundreds of millions of words.

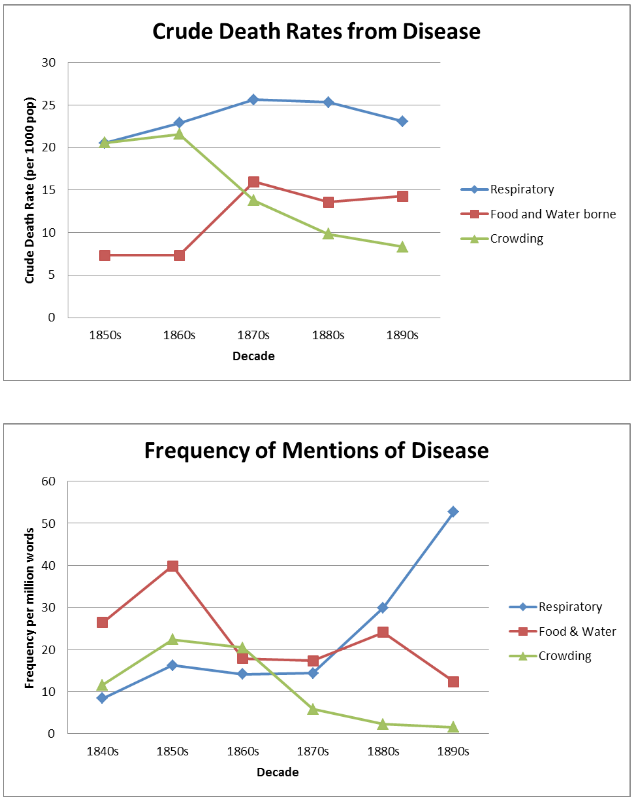

Figure 2: Crude death rates from disease classes and frequency of instances of these diseases in the Era

Figure 2 shows the use of one newspaper, the Era, to explore the relationship between interest in a variety of diseases associated with the young, classed according to whether they are respiratory diseases, food and water-bourn diseases, and diseases associated with crowding (Woods, 2000). The frequency with which these diseases are mentioned in the corpus is compared with the death rates from the diseases. Different disease types show quite different results. Interest in diseases of crowding follows the decline in these diseases, particularly associated with the decline of scarlet fever and typhus. Food and water death rates rise overall while interest in them seems to fall, while deaths from respiratory diseases are broadly flat but there is a major increase in interest in them in the 1880s and 1890s. We can then explore the collocates to these terms, the words that are found close to them. This shows four major classes of collocates: first, other words associated with disease, included other disease names, and words such as 'died', 'attack' and 'epidemic.' Second there are symptoms of disease, third are brand names of medicines typically found in advertisements, and fourth there are military terms which are found in the 1850s and are related to the Crimean War.

To allow us to explore the geographies within themes within the newspapers we have developed a technique we call concordance geoparsing (Rupp et. al., 2014). This involves firstly extracting concordance lines around the search-term. These concordance lines are then geo-parsed using the Edinburgh Geoparser (Grover et. al., 2010) which identifies place-names and matches them to a gazetteer to allocate them to a grid reference. The results are then explored to check for errors which are corrected with the corrections added to an updates file. In this way we can cumulatively remove geoparsing errors and have confidence in its results.

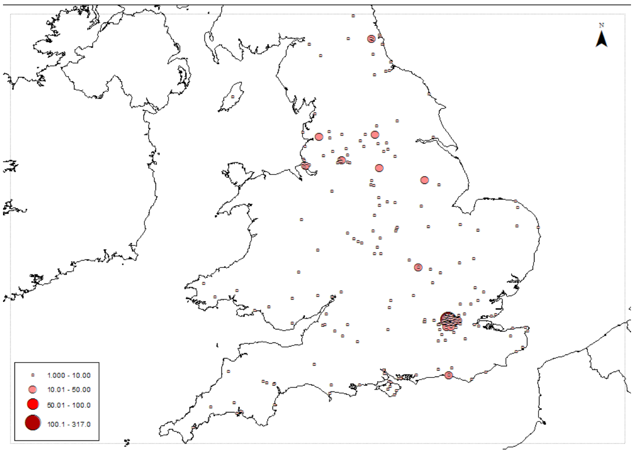

Figure 3: Locations associated with disease instances from the Era

Figure 3 shows the place-names associated with the diseases in the Era. It is noticeable that these are concentrated in urban areas but there are exceptions to this. We will present comparisons between the number of references to a disease and the number of deaths from it in a district, showing how media interest was not related to disease severity.

Taking this work further, we will take regional newspapers from rural areas that experienced the highest and lowest declines and explore these for collocates and places that are associated with diseases themselves and a wide range of potential causal factors that may be related to them. In this way we will be combining the descriptive strengths of statistical data with the explanatory power of textual sources, using text to work around insufficiencies of data and making use of the temporal and geographical detail in both.

Acknowledgement

The research leading to these results has received funding from the European Research Council (ERC) under the European Union's Seventh Framework Programme (FP7/2007-2013) / ERC grant "Spatial Humanities: Texts, GIS, places" (agreement number 283850).

vWise: Visual Workspace for Information Seeking and Exploration

Introduction

Increasingly, scholars have access to large, heterogeneous collections of information such as those provided by the Digital Public Library of America, Europeana, or Canadiana as well as more targeted thematic research collections like the Whitman Archive. In additions to purpose-built humanities projects, scholars commonly make use of general-purpose resources such as Flickr, Google Search, HathiTrust Digital Library and many other services.

Traditional search interfaces allow scholars to rapidly search for specific items and to explore a collection via facetted search interfaces and other techniques. Search, however, is only one part of a complex ecosystem of behaviors associated with information seeking (Toms and O'Brien, 2008; Buchanan et al., 2005). In practice, scholarly information seeking is not characterized by a single search event or interaction with a single system. Rather, it is a process that takes place over an extended period of time and involves searching different sources for potentially relevant material. As material is found, scholars organize, annotate and make notes about the retrieved material; activities that lead to more questions and more seeking.

These tasks serve a dual purpose of cataloging material for re-discovery, use and interpretation as well as engaging the participant in a process of sensemaking and internalization. The fundamental purpose of this work is not merely the discovery, consumption or indexing of information or even the production of a concrete research output such as a paper. Instead, scholarly information seeking serves to hel

p the seeker develop an internalized, systematic understanding of a body of knowledge and cultivate a distinctive interpretive voice (Audenaert and Furuta, 2010).

We are developing the Visual Workspace for Information Seeking and Exploration (vWise[1]) to support these tasks. This paper introduces the key features and capabilities of the vWise platform and discusses how those features and capabilities reflect and build on a theoretical framework for designing systems to support open-ended information seeking and exploration.

System Overview

vWise is an extensible Web-based application framework that allows scholars to search for content from different data providers and bring the resulting information together into a single display. Once resources have been added to the workspace, they can then organize and reframe that information, for example by culling unwanted results or juxtaposing digital surrogates for newly discovered relationships.

Panels are the primary way people interact with content in the vWise interface. They are used to display different types of information drawn from different sources in a single workspace. Users can organize this information by rearranging panels within the workspace and add visual annotations by setting properties such as background color, border style, font properties and drop shadows. The panels themselves support user interactions tailored to the types of content they display. For instance, users could read a book from HathiTrust, watch a video from YouTube, explore metadata from DPLA or manipulate manuscript page images to improve readability.

Users have several options for adding content panels to a workspace. A basic search service allows them to execute searches using pluggable content providers. Alternatively, custom panel implementations may provide advanced searching capabilities or allow users to drag composite content such as pages from a manuscript onto the workspace to create new panels.

Workspaces provide a site for both individual and collaborative work. To enable collaboration, a user can share a workspace with others. Modifications to this shared workspace are reflected on all users' display simultaneously. This allows both synchronous and asynchronous collaboration.

As a framework, vWise is designed to be customized and configured by an application developer prior to being deployed. This customization allows the basic application to be extended in four major ways:

Integration with external data sources. vWise provides a pluggable architecture for defining interfaces to external data sources such as a digital library or search service. For instance, we provide data sources that allow users to load videos from YouTube videos, search Wikipedia and display web-pages.

Custom panels for working with data objects. Individual units of content are displayed using panels that provide basic support for moving, resizing and styling. Extensions support rich interactions tailored to specific types of content. For example, an image annotation tool could allow the creation and storage of annotations.

Ad hoc panels for interacting with underlying search services. The core use-case for panels is to display and organize individual content elements. Panels can also be used to implement other application services. For example, we envision implementing a search service panel that will display basic and advanced search options, display facets from the currently active search, maintain a history of recent search and display search results as panels in the main workspace.

Integration with server-side workspace persistence. vWise runs in a browser and stores workspaces and workspace configuration information via a well-defined RESTful interface. Application developers can use the default implementation that comes with vWise or provide a custom implementation. For instance, we developed a custom data storage implementation to connect the vWise interface with a proprietary system used to train emergency responders.

Supporting Information Seeking and Exploration

Information seeking and exploration in scholarly research is an intensive, creative activity. Supporting these activities require tools that go beyond merely helping scholars find resources to provide environments that reflect and facilitate the creative process. vWise is based on ideas that have emerged from the literature in hypermedia systems, digital libraries and creativity research, including the following core concepts:

Information Triage: The process of information seeking requires people to rapidly assess the utility of various information resources, discard those that aren't relevant and prioritize those that show promise (Marshall and Shipman, 1997). vWise goes beyond traditional search interfaces by allowing users to remove individual results, prioritize the remaining objects and combine the results from multiple searches in a single workspace.

Incremental Formalization: One aspect of open-ended information seeking tasks is sense-making—the process of gaining a broad understanding of the structure of ideas within a domain. During sense-making, the emerging organizational framework is partial, provisional and implicit (Shipman and Marshall, 1999). vWise facilitates incremental formalization of knowledge by allowing users to express an emerging organization framework implicitly via the spatial arrangement and visual properties of the panels displayed on the workspace. Within this environment, user can rapidly form and reform organizational structures by manipulating the visual characteristics of the display.

Representational Talkback: The visually expressed knowledge structure serves as an externalized representation of a user's internal, evolving mental models. Creating and interacting with this content supports representational talkback (Schön, 1983; Nakakoji et al., 2000). Representational talkback occurs when material externalizations of an internal mental model initiate a "reflective conversation" in which they talk back to their creator to inform subsequent stages of the sense making process.

Heterogeneous Sources and Material: Complex information seeking tasks rarely involve one-stop shopping. vWise allows people to integrate, analyze and synthesize information from different sources, by bringing content into a unified information organization space. Manipulation of spatial and visual properties (border color, drop-shadows, backgrounds, etc.) provides a lightweight and open-ended interface manipulating this content. Domain-specific panel implementations allow users to engage in content-specific interactions.

Summary

vWise provides support for the complex information seeking needs of scholars and other professionals that goes beyond the capability of traditional search systems. It allows people to gather information from multiple sources and to work either independently or collaboratively to organize and analyze that material using a workspace metaphor.

To date, we have demonstrated prototype implementations of vWise in two different settings. While initially conceived and designed to support the needs of scholars in the humanities, we have integrated a version of vWise into the Emergency Management*Exercise System (EM*ES). EM*ES is a simulation tool used by Texas A&M Engineering Extension Service (TEEX) to train incident managers, supervisors, and jurisdiction officials in the management of a large-scale crisis (TEEX, 2016). We have added vWise as a component to support the training of communication and coordination between emergency managers and cyber response teams. vWise is currently in use in a series of training exercises starting in January of 2016 and running through September 2017. During this period we will investigate options for more widespread use within the EM*ES application.

Our second deployment of vWise was a demonstration prototype for use in wall-sized display of the Humanities Visualization Space (HVS) at Texas A&M University's Initiative for Digital Humanities, Media and Culture (IDHMC). While vWise is envisioned primarily for desktop-oriented use, when working on knowledge organization tasks, bigger is often better. The HVS provides just such a space and opens intriguing possibilities for scholars to work with this class of interfaces both as individuals and in collaborative settings.

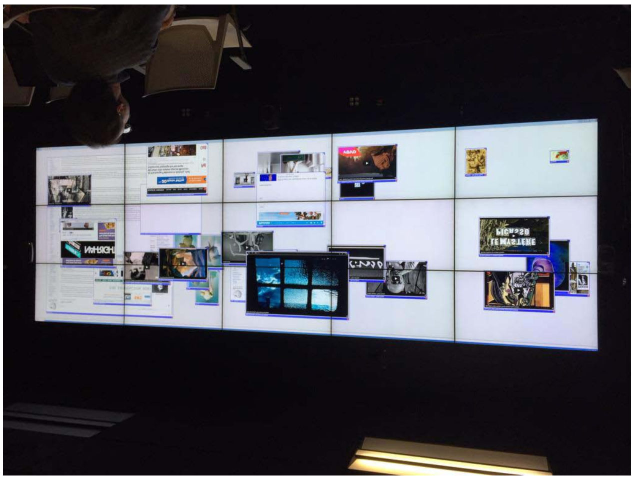

Figure 1: vWise demonstration at the IDHMC Humanities Visualization Space

Moving forward, we continue to develop the core implementation of vWise framework and to add additional content provider connections and panel implementations for displays. We are specifically interested in developing integrations with major content providers for humanities and cultural heritage scholars and are working to pursue such collaborations.

From Index Cards to a Digital Information System: Teaching Data Modeling to Master's Students in History

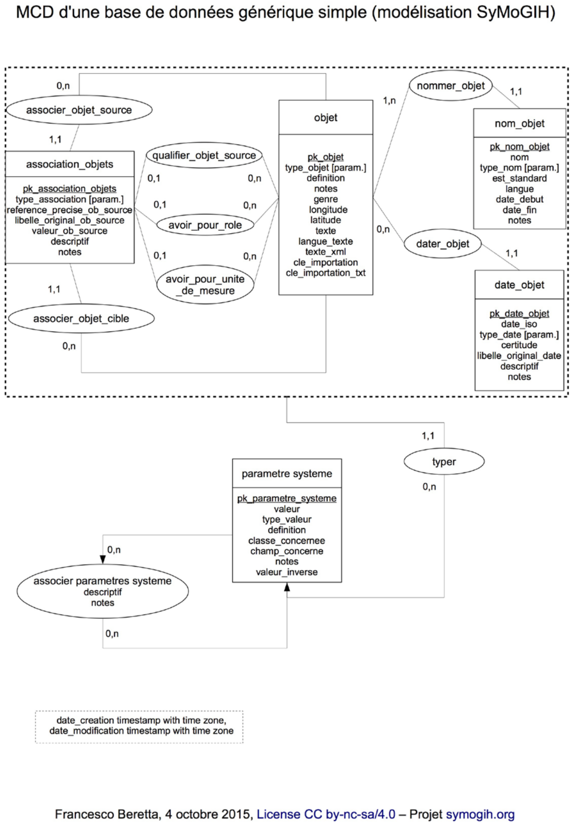
Francesco Beretta
francesco.beretta@ish-lyon.cnrs.fr
CNRS - Université de Lyon, France

For the last five years I've taught a course on "computer science for historians" at University Lyon3 Jean Moulin. The course includes 20 hours in ten sessions and has attracted twenty to forty students each year. It addresses history students during the first semester of their master studies: they start at this stage with information collection in archival sources and bibliography, which they can later exploit to write their master's thesis. Thus, the aim is to provide them with methods and digital tools for modeling and storing information, and then for subjecting it to interrogation, visualization and analysis. This is a great challenge because many students still use paper for taking notes when they analyze historical sources and are not used to working with software that is not completely self-installing. Furthermore, students will receive from their tutors all kinds of research subjects, from Ancient to Modern history, and they often want to analyze quite complex information which one cannot store in a simple spreadsheet. For this reason, the pedagogical challenge is also a challenge for the digital humanist: how can the students be provided with a generic and flexible information system of ready use for their research but sophisticated enough to store any sort of data?

In this paper I will treat some theoretical and practical aspects of the digital information system I devised to cope with this problem, and will present some issues raised by recourse to the information system that concern both students and teacher. The manuscript of the course is publicly available on a dedicated website[1]: anyone interested can download the tools I developed and test the methods proposed to the students, or employ them for their own teaching. As I teach in French the documentation, interfaces, etc. are written in this language. The information system I propose in the course combines the experience acquired in developing the symogih.org project[2], a collaborative platform for storing and sharing structured historical data, with the method of semantic annotation of texts adopted in our platform for digital editions[3] in accordance to the *Text encoding initiative*'s

guidelines (TEI). These data production practices, both as structured data and encoded texts, must be radically simplified to cope with the pedagogical need exposed above and this requires working on a high level of abstraction.

The first component of the information system provided to the students is a relational database designed using a generic data model[4]. In the center of the model (Figure 1), the object class, having the same sense as the “Endurant” class in DOLCE[5], or the “Persistent Item (E77)” class in CIDOC-CRM[6], comprises individual actors, institutions, places, concepts, etc. about which students will be collecting information. The function of this class is to provide an identifier for each individual, in turn characterized by one or more names, a time span of existence, a type and an accurate textual definition. The database also allows treatment of some basic associations between objects defined in a class “system parameter” – a typical component of a generic data model – whose instances are predefined by the teacher. This simplifies the use of the database by students and guides them in their first steps of data production, but if needed parameters can be extended to other kinds of relationships. A simple PHP interface is added to facilitate data capture.



MCD d'une base de données générique simple (modélisation SyMoGIH)

Francesco Beretta, 4 octobre 2015, License CC by-nc-sa/4.0 – Projet symogih.org

Figure 1

The database is implemented using PostgreSQL because this open-source database provides extended features in datatype treatment (namely XML) and comes along with a procedural language (PL/pgSQL) allowing data treatment in a SQL context without having to learn a different programming language[7]. The teacher can thus write predefined functions to help the student prepare, transform and code the data before further treatment. A spatial extension is also available (PostGIS) which permits working with geo-referenced data if needed[8]. PostgreSQL is therefore a kind of "Swiss Army knife" for historical data storage and treatment.

If the "Objects" ("Endurants" or "Persistent items") are identified in the database, where then is collected information about them? According to the *symogih.org* semantic data model[9], a "Knowledge Unit" is an atomized portion of information that expresses a relationship among objects situated in space and time, established on critical analysis of documents. The class "Knowledge Unit" is therefore equivalent to the "Temporal entity (E2)" class in CIDOC-CRM or "Perdurant" class in DOLCE: “An endurant lives in time by *participating* in some perdurant(s). For exemple, a person, which is an endurant, may participate in a discussion, which is a perdurant”[10].

In former years, "knowledge units" were also stored in the database, as the "objects" are presently[11]. Pedagogical experience has shown that the degree of abstraction required for modeling information in form of structured data is generally too steep for training digital historians, although some students used this method with ease. The newly proposed information system comprises therefore a second component which consists in a text encoding method using some specific TEI tags and attributes. These allow semantic text encoding: "knowledge units" can be directly annotated into the text, thus marking up named entities with the database identifiers of the related objects and then encoding their properties and relationships in the text with specific tags and attributes[12].

But this method raises the question of the XML editor to adopt for text semantic encoding, meaning the addition of a further software component to the workflow of data production providing XML schema validation and also tools for querying the encoded text. XML text encoding is more suitable and I prefer it for PhD student and researcher training, but this demands a supplementary specific instruction that it impossible to provide in the limited master's course time. I therefore conceived a way of semantically tagging the text in a simple text editor or word processing program using curly brackets instead of angle brackets and replacing XML-attributes by predefined codes. This method is described on the course wiki that also furnishes instructions for using regular expressions for proper encoding[13]. Regular expressions are then used in a PL/pgSQL script in the database to transform the curly brackets and their content into real XML tags and attributes: the encoded tag “{en2ai_10}Johannes Kepler{/en}” becomes “<en type=“ai” ref=“2” ana=“10”>Johannes Kepler</en>” (belonging to a course-specific namespace). This transformation allows storage of the encoded text in a PostgreSQL XML field and consequently benefit of the full power of the XPath and SQL queries, and programming capabilities of PL/pgSQL, to extract information from the texts.

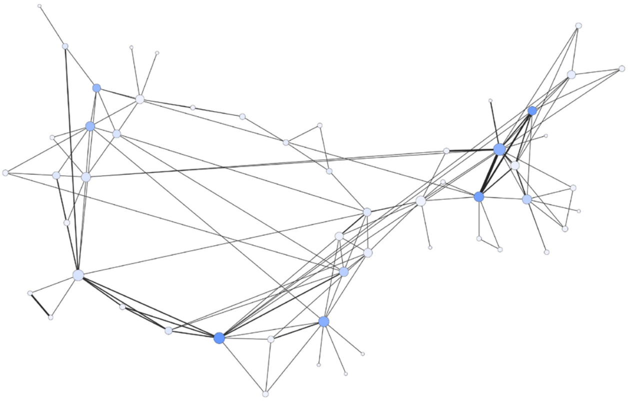


Figure 2

The workflow of data production and treatment ends with the phase of data analysis and visualization. For this purpose I adopted the R software that can be directly connected to a PostgreSQL database and provides many useful libraries. For instance, a former student produced data about relationship between persons attested by medieval charters that can be used for network analysis (Figure 2).

The students can send the teacher a dump of their database and formulate the research questions that the latter will transcribe into SQL, XPath or procedure language queries for extracting data, before sending this back to the students. Building upon these examples the students can themselves adapt the queries and scripts to new research questions. A wiki dedicated to each student's project can be created to document the specific workflow of each research project: it is not public but it is accessible to all other students participating in the process of data production and analysis. The students can use the results of data analysis and visualization to formulate new research hypotheses or they can integrate them into their master's thesis.

In this paper I will present the essential conceptual and technical aspects of the whole workflow and consider three major advantages of this pedagogical approach for the disciplinary domain of digital history. First, students gain the experience of managing a workflow going from installation and personal practice on a solid community maintained open-source software, to reflection on data modeling concerning their own research agenda, to collaborative data and project management through a wiki, to an introduction in data mining and visualization techniques. Secondly, the abstraction level of the data model and text encoding practice proposed to the students implicitly introduces them to knowledge management and data production according to present-day standards like CIDOC-CRM and *Text encoding initiative*: from this perspective historical knowledge is modeled as a graph of objects situated in time and space and linked to the texts from which they derive. Thus —and this is the third advantage— the course acquaints students with the basic principles of linked data and of semantic text encoding, introducing them to the concepts and practice of resource sharing and data curation: the datasets I use for the exercises come from the French national library (BNF) SPARQL endpoint and DBPedia, and the texts from Wikipedia. In a final part, I will discuss the issues that this pedagogical approach raises for master's students in history.

Modelling Taxonomies of Text Reuse in the Deipnosophists of Athenaeus of Naucratis: Declarative Digital Scholarship

This paper presents work on documenting text reuse of fragmentary authors and of extant works. By **fragmentary** we mean authors whose texts are lost and known through quotations and references by other authors. Within ancient Greek literature 60% of authors is preserved only in fragments, showing the challenge of working with innumerable pieces of reuse scattered in our textual heritage (Berti et al., 2009). This work is necessarily prior to any specific research questions. We cannot inquire into, e.g., the historical works of Istrus the Callimachean until we can comprehensively and precisely catalogue the surviving fragments of Istrus; nor can we ask "how did intellectuals in the 3rd century CE read epic poetry?", until we can comprehensively identify instances of Homeric text reuse and work with them in their context.

The term **fragment** is the result of print editorial practices, where chunks of text preserving traces of lost authors and works are extracted from their contexts and reprinted in separate collections. Even if such editorial workflow has produced invaluable results for reconstructing lost authors, the concept of **textual fragment** is problematic: It includes different kinds of text reuse and implies a certain degree of originality, which is difficult to assess and represent because the original text from which the reuse derives is hidden by the **cover text**, i.e., by the intention of the quoting author and the characteristics of the preserving context (Most, 1997; Schepens, 2000; Berti, 2013).

Our data model defines taxonomies of text reuse for representing references to authors and works not as separate chunks of text but as contextualized annotations, expressing their nature of reuse of textual evidence. These annotations include not only the portion of text classifiable as a reuse, but also biographical and bibliographical data preserved in the source text.

Text reuse of fragmentary authors presents the challenge of documenting text aligned with no extant exemplar. Text reuse of extant works presents additional challenges of aligning as precisely as possible (but no more precisely than is possible) two or more extant passages of text that may differ in small ways or large. Our data model documents uniquely instances of text reuse and it is developed on the Canonical Text Services (CTS), which is a protocol for identifying and retrieving passages of text based on concise, machine-actionable canonical citation. It is founded on the assumption that a "text" can be modelled as "an ordered hierarchy of citation objects" (Smith and Weaver, 2009). CTS URNs can identify passages more grossly or more finely; they can identify a range of passages at various levels of specificity; by the addition of an indexed substring, a CTS URN can identify a particular string within a passage of text (Blackwell and Smith, 2012). CTS is one component of a larger digital library architecture, developed for the **Homer Multitext** project and called CITE (Collections, Indices, Texts, and Extensions): http://www.homermultitext.org/hmt-doc/cite/.

In order to produce citable analyses of text reuse in their context, we have been working with the *Deipnosophists* of Athenaeus of Naucratis, which is the account of a banquet where learned men quote authors and works of Greek literature concerning a wide range of topics related to dining and food. The *Deipnosophists* is significant because it is a very rich collection of many different kinds of text reuse of fragmentary authors and of extant works (Braund and Wilkins, 2000; Lenfant, 2007; Jacob, 2013).

Our data model specifies four subjects of analyses:

1. **Authors**: enumerate and identify authors reused by Athenaeus;

2. **Works**: enumerate and identify works reused by Athenaeus;

3. **Mentions**: catalog every mention of authors and works in the text of Athenaeus, including his vocabulary for identifying them. For example, Athenaeus may mention that a work by Archestratus of Syracuse was known by four different names (i.e., *Gastronomy*, *Life of Pleasure*, *Science of Dining*, or *Art of Cooking*); this would generate five entries in this list: one mention of Archestratus, and four mentions of the same work.

4. **Reuses**: uniquely identify instances of text-reuse in the text of Athenaeus.

A fifth analysis will also include the twenty-two learned men who take part in the banquet described by Athenaeus and who are actually the **characters** who quote and reuse a huge amount of authors and works.

We need seven records to produce citable analyses of the above mentioned subjects:

1. **Analysis Record URN**. Every documented instance of text reuse (authors, works, mentions, reuses) has a CITE URN uniquely identifying this instance in a CITE collection.

2. **Sequence Number**. The collection of instances of text reuse is an **ordered collection**; each item has a sequence number, reflecting the item's sequence in the text of Athenaeus. This value is programmatically generated by a CTS-aware script before publishing the collection.

3. **Analyzed Text**. A CTS URN defining, as precisely or imprecisely as necessary, the span of text in the *Deipnosophists* that is the subject of this analysis of text reuse. The scope of the **Analyzed Text** is determined by the nature of the text reuse. In the case of authors and works, this CTS URN identifies a passage in the *Deipnosophists* that serves to justify the inclusion in the respective list. When an author or a work is reused often, the passage should be a clear, unambiguous reference (e.g., "Homer says …").

4. **Reused Text**. While the **Analyzed Text** identifies a coherent and contiguous span of text, as it appears in the edition being analyzed, the **Reused Text** is a string identifying only the text being reused. The **Analyzed Text** provides context and a basis for alignment, while the **Reused Text** gives us the flexibility to call out non-contiguous text, to normalize text, or even to promote morphological forms determined by indirected statement to those appropriate for direct speech, without doing violence to our source-edition. The **Reused Text** record allows us to represent different intepretations of the same text reuse, especially in the case of non-verbatim quotations.

5. **Alignment URN**. This collection documents reuse of extant authors and works, for which we have extant editions with canonical citation. The **Alignment URN** is a CTS URN pointing to the quoted extant author (identified with a CtsGroupUrn) or to one specific edition of the reused work (identified with a CtsWorkUrn) that (a) justifies our claim of text reuse, and (b) is the basis for attaching a citation of a still extant work to this analysis.

6. **Analytical Edition URN**. The collected instances of text reuse of extant work in the *Deipnosophists* represent a new edition of these works, whose text-content is based on our analysis of our project's edition of Athenaeus. The **Analytical Edition URN** is a CTS URN to an **Athenaeus Edition** of these works; the citation-value is based on that of the **Alignment URN**; the text-content of this edition is the **Reused Text** in Athenaeus. The **Analytical Edition** gives us an orthogonal view of the text reuse of extant authors in Athenaeus.

7. **CITE Collection of Lost Works**. For text reuse of lost authors and works, there is no citation scheme, nor any inherent order to the text. For these, we produce a collection of text-reuse. This Collection can be cited by CITE URNs.

Initial work on documenting text reuse has been focused on references to Homer's *Iliad* in the *Deipnosophists* (data available at http://digitalathenaeus.github.io/). The aim is to extend our data model including the categorization of different kinds of text reuse and further concrete examples of references to fragmentary authors and extant works in the *Deipnosophists* of Athenaeus of Naucratis.

Two Centuries of Russian Roads – Diachronic Study of Polysemy in the Context of Cultural Change

Anastasia Bonch-Osmolovskaya
abonch@gmail.com
National Research Unversity Higher School of Economics
Moscow, Russian Federation

Preamble

The goal of the study is to show links between lexical and social diachronic change. The study is conducted in the culturomics framework (Michel et al., 2011). In contrast to the Big data approach the study promotes the idea of medium data, i.e. amount of data which allows both to make quantitative and qualitative analysis (Bonch-Osmolovskaya, 2015). The main characteristics of the medium data are:

- The reliability of sources, which metadata can be filtered manually
- The sufficiency of the data amount for reliable statistical measures
- The possibility of additional semantic mark-up

The research is based on the data from Russian National Corpus (ruscorpora.ru) (see Plungian, Sitchinava, 2003). The study pursues changes of context frequencies for the lexeme road in the period from 1800 till 2000, and correlates the observations with social and economic progress as well as change in conceptual language space

Choice of concept

Russia is a big country, so transportation has been traditionally a critical problem. The choice of the word *road* for culturomics study is based on our expectations of the concept's centrality for the economy, society and culture in Russia of the 19th–20th centuries. *Road* appears to be a productive sign in terms of semiotics of art (Tchepanskaya, 2003,), that's why I expected to collect numerous relevant contexts both in fiction and nonfiction. At the same time *road* in Russian has several meanings, the nature of its polysemy has been treated a lot in previous works (Arutiunova, 1999). We can distinguish three basic meanings which are contrasted by the position of Observer (Paducheva, 2006) – the one that percepts the *road*. The first meaning is *road* as a physical object, a line on the ground the observer sees while standing on it. It can be characterized by the quality of its surface or surrounding landscapes (i.e. dirty road). The second meaning is *road* as a vector, a line on a map, that connects two points (i.e central road). The observer operates in this case with the abstract idea of the road's topology. The third meaning is metonymical and it stands for the travel-event the Observer experiences while moving along the road (i.e. tedious road). Finally due to semiotic abundance *road* is frequently used in metaphorical sense (i.e. life path = "road of life"). At the same time, the first three meanings present the most important parameters that determine mobility of population: quality of roads, connectedness between localities and time and quality of journey. Therefore, it seems insufficient to track frequency change of *road* occurrences in the corpus in general, but it is important to distinguish how the frequency of different meanings has been changing.

Method

Different meanings of *road* can be captured by attributive constructions as adjectives usually refer to only one sense. The corpus has been divided into 7 time periods from 1800 to 2000. To make the sub-corpora comparable the 19th century has been divided into two periods of 50 years and the 20th century into five periods of 20 years. The contexts, containing constructions of adjective plus *road* has been extracted from every sub-corpus. The noisy entries has been removed, the data has been lemmatized and normalized as ipm. As a result, I obtained a database with 15000 constructions, containing more than 1500 unique adjectives.

On the next step, all the adjectives have been categorized by 20 semantic domains. The domains correlate with four basic meanings of *road* defined below but render more specific characteristics of different *road* parameters. The most frequent construction "zheleznaya doroga" (literary *metal road*, meaning railroad) has been selected in a separate category.

Then I applied hierarchical clusterization to the data of 20 categories, see Figure 1

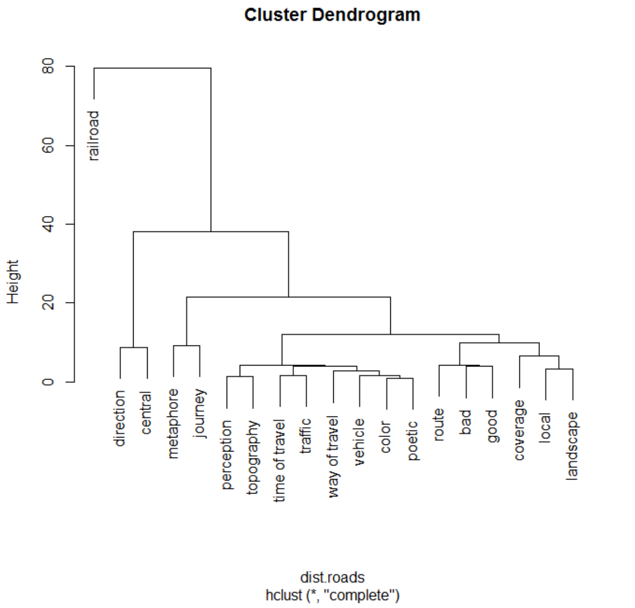

Figure 1: Clusterization of semantic categories for adjectives describing road

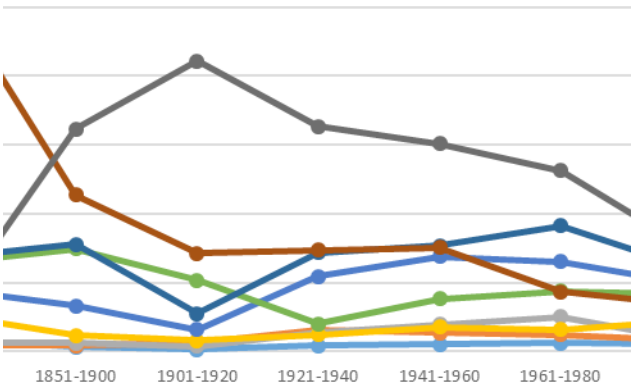
The data of the categories in one cluster has been summarized and then plotted on the graph (see Figure 2)



Analysis

The data allows plenty of research scenarios, comparing different domains, such as, for example:

- sources of domain contents and diachronic change of the distribution of sources (for example, fiction or nonfiction)
- widening or narrowing of the category through time (how many adjectives are in the category), as a well as persistence of the content to time and economical or social changes
- substitution of one adjective to another (for example, all the changes connected with replacement of horses to cars) and its time frame
- migration of an adjective from one adjective to another

In this abstract, I will focus on the most prominent changes of cluster graphs. As Fig 2 shows the railroad (RR) cluster and the direction and centrality(D and C) cluster are the most distinctive in their behavior. In the beginning of the 19th century, the existence of big central roads from one town to another completely determined mobility opportunities of Russian population. We see that more than 50% of all the occurrences of *road* are associated with D and C attributes (Warsaw road, big road – as a specific term of central road). In the 1851, the railroad between Moscow and St.Peterburg has been open and this fact nicely correlates with the crossing of the RR and D and C graph in the period of the 1850s. The intensive growth of the RR cluster in the second half of the 19th century reflects not only the growth of railroad communications in Russia but also great conceptual influence of the railroad innovation, which can be also traced in numerous literary pieces of this period such as Tolstoy's Anna Karenina or Dostoevsky's Idiot. The intriguing fact about RR cluster is its consistent fall in the 20th century that may of course correlate with developing automobile transportation. The sharp fall of

RR cluster in the 1960s corresponds to the growth of civil airlines; see Figure 3 that demonstrates quite the opposite trend for air transportations starting from the 60s

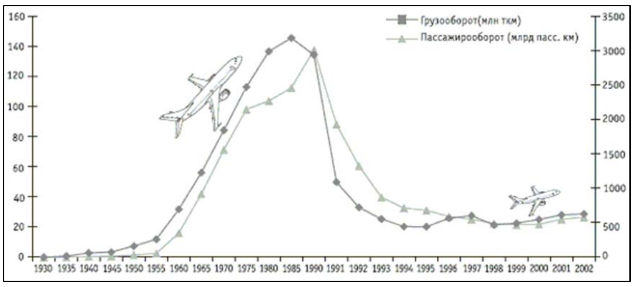


Figure 3: Graph of air transportation, line with triangles marking passenger traffic

The most important generalization that arises from the observations above is that in the 20th century the topological (vector) meaning of *road* is consistently fading while the reference to a road as a physical object on the contrary increases in frequency. In other words, while economic and industrial growth results in diversity of mobility means, *road* as a concept in lexical space has changed the balance of its meanings reducing the *connection* idea. At the same time the metonymic usage of *road* as a journey has been increased in the 20th century as a well as the metaphorical usage, the both categories are very similar in their data values so they have formed one common cluster. In 1960s, the *connection* idea is transferred from direct usages of D and C cluster to figurative usage of Journey and Metaphor cluster. This means that we can document the moment when the idea of *connection* is separated from the physical movement along the road. The tedious road now is sitting in the airport for many hours waiting for your flight.

Introduction

The ancient Maya civilization flourished from around 2000 BC to 1600 AD and left a great amount of cultural heritage materials, in the shape of stone monument inscriptions, folded codex pages, or personal ceramic items. All these materials contain hieroglyphs (in short glyphs) written on them. The Maya writing system is visually complex (Fig. 1) and new glyphs are still being discovered. This brings the necessity of better digital preservation systems. Interpretation of a small amount of glyphs is still open to discussion due to both visual differences and semantic analysis. Some glyphs are damaged, or have many variations due to artistic reasons and the evolving nature of language.

Signs following ancient Mesoamerican representational conventions end up being classified according to their appearance, which leads to potential confusions as the iconic origin of many signs and their transformations through time are not well-understood. For instance, a sign thought to fall within the category of 'body-part' can later be proven to actually correspond to a vegetable element (a different semantic domain). Similarly, several signs classified as 'abstract', 'square' or 'round' could actually be pars-pro-toto representations of a larger whole.

Category T1
Category T25
Category T229
Twin glyph (duplicated)
Impersonated glyph (designed as animal or human head)
Category T110, T102, T103 (left to right)
Category T116 and T117 (left to right)

Figure 2. Maya glyph samples from several categories (according to Thompson's catalog) that illustrate the within-class variety and between-class similarity

Fig. 2 illustrates the challenges to analyse Maya glyphs visually. Adding functionalities that take context (i.e., co-occurrence statistics, characteristics of the data) and part-whole relations (i.e., highlighting diagnostic parts) into account would bring guidance during decipherment tasks. The tools we envision are different from existing almanac-by-almanac visualization systems (Vail and Hernandez, 2013). They are also more engaging for users (i.e. visitors in museums), and offer promising perspectives for scholars.

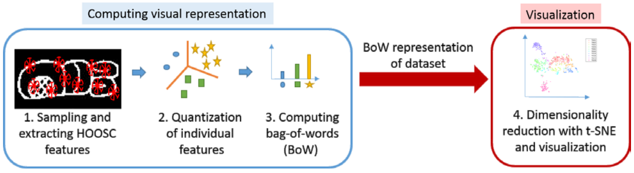
This motivates the study of data visualization. In this paper, we built a prototype for visualization of glyphs based on visual features. We introduce (1) an approach to analyse Maya glyphs combining a state-of-the-art visual shape descriptor, and (2) a non-linear method to visualize high-dimensional data. For the first component, we use the histogram of orientation shape context (HOOSC) (Roman-Rangel et. al., 2011a; Roman-Rangel et. al., 2011b; Roman-Rangel et. al., 2013) which has similarities to other descriptors of the recognition literature (Belongie et. al., 2002; Dalal and Triggs, 2005; Lowe, 2004), but is adapted to shape analysis (Franken and van Gemert, 2013).

For the second component, we use the t-distributed Stochastic Neighbourhood Embedding (t-SNE) (Van der Maaten and Hinton, 2008), which is a dimensionality reduction method from the machine learning literature that has value for Digital Humanities (DH), as it can highlight the structure of high-dimensional data, i.e., multiple viewpoints among samples.

As analysis of DH data is often based on attributes like authorship, produced time, and place, observing these variations as smooth transitions with t-SNE becomes a relevant feature.

We show that the proposed methodology is useful to analyse the extent of spatial support used in the shape descriptor and to reveal new connections in the corpus through inspection of glyphs from stone monuments and glyph variants from catalogue sources. In particular, we hope that the presentation of our use of t-SNE can motivate further work in DH for other related problems.

Methodology



Computing visual representation
1. Sampling and extracting HOOSC features
2. Quantization of individual features
3. Computing bag-of-words (BoW)
BoW representation of dataset
Visualization
4. Dimensionality reduction with t-SNE and visualization

Figure 3. Overall flow for visualization with t-SNE

The analysis process is illustrated in Fig. 3. First, for each glyph, a standard visual bag-of-words representation (BoW) is computed from the HOOSC descriptors. Second, dimensionality reduction is performed on the BoW representation of a glyph collection to generate the visualization. The main steps are described below.

Datasets

We analyse our visualization pipeline on two individual Maya glyph datasets.

Monument data

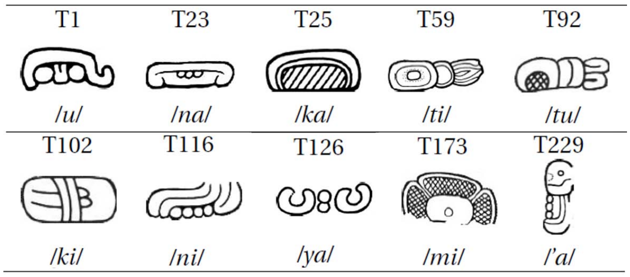


Figure 4. Sample glyph images, corresponding Thompson annotations, and syllabic values (sounds) of selected 10 classes from the syllabic monument glyph dataset

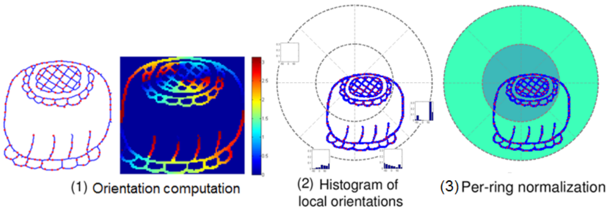
We use a subset (630 samples from 10 classes, Fig. 4) of hand-drawings (Roman-Rangel et. al., 2011), corresponding to syllabic glyphs inscribed in monuments. These samples are collected by archaeologists (as part of Mexico's AJIMAYA project) from stone inscriptions spread over four regions (Peten, Usumacinta, Motagua, and Yucatan). As an additional source, around 300 glyph samples are taken from existing catalogues (Thompson and Eric, 1962; Macri and Looper, 2003).

Thompson catalogue

Secondly, we use 1487 glyph variants cropped from the Thompson's catalogue. These variants belong to 814 categories and divided as main sign and prefix/suffix groups in the catalogue.

Visual feature representation



(1) Orientation computation
(2) Histogram of local orientations
(3) Per-ring normalization

Figure 5. HOOSC computation at a sample position of the shape

The HOOSC is a shape descriptor proposed in our research group for Maya glyphs (Roman-Rangel, 2011b). It is computed in two main steps (Fig. 5). First, the orientations of a set of sampled points are computed. Secondly, for a given sampled position, the histogram of local orientations are computed using a small number *Na* of angle bins forming a circular grid partition centred at each point. The HOOSC descriptor is obtained by concatenating all histograms, and applying per-ring normalization. Basic parameters are the spatial context *sc* defining the extent of the spatial partition; the number of rings *Nr*; and the number *Ns* of slices in a ring. With *Na* =8, *Nr* =2, *Ns*=8, HOOSC has 128 dimensions. We have used HOOSC for usual retrieval and categorization tasks (Hu et. al., 2015).

Dimensionality reduction: t-SNE

Proposed in (Hinton and Roweis, 2002), SNE is a non-linear dimensionality reduction method. It relates the Euclidean distances of samples in high-dimensional space to the conditional probability for each point selecting one of the neighbours. In t-SNE (Van der Maaten and Hinton, 2008), these distributions are modelled as heavy-tailed t-distributions. t-SNE aims to find for each data point, a lower-dimensional projection such that the conditional probabilities in the projected space are as close as possible to those of the original space (measured with KL divergence (Kullback and Leibler, 1951)).

In our application, first, we project the BoW representation to a 30-dimensional space using PCA, then applied t-SNE to these projections to get 2-dimension mapping. t-SNE keeps track of the local structure of the data as it optimizes the clusters globally.

Results and discussion

The full-scale visualization of the glyphs are available at https://www.idiap.ch/project/maaya/demos/t-sne.

Glyph monument corpus structure

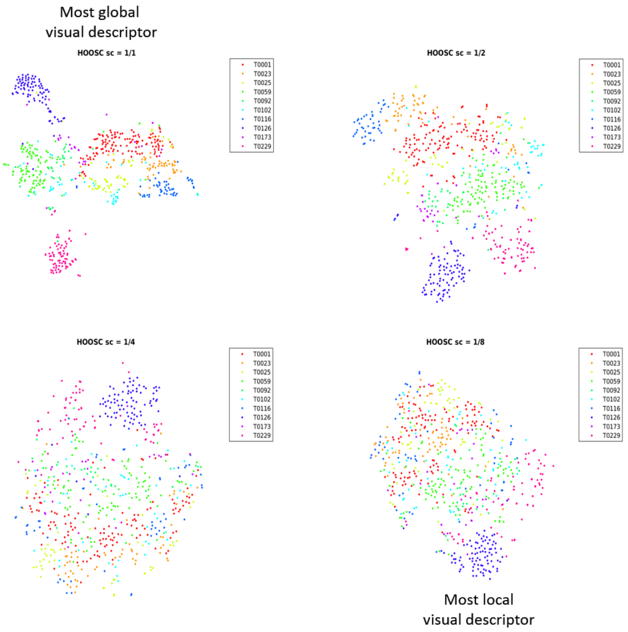


Figure 6. Monument data: t-SNE plots with visual representations obtained at four different spatial context levels

Fig. 6 shows the monument corpus. The region encoded in the visual descriptor varies from almost whole glyph (sc=1/1) to small local parts (sc=1/8). One question is how spatial context influences visualization of the representation. Regarding the visual clusters, with the most global representation (sc=1/1), our method extracts more distinct clusters, e.g. T229 and T126 in Fig. 7 (navy and magenta in Fig. 6 and 9). Please see Fig. 9 for roughly-coloured clusters of the glyphs. As the descriptor gets more local, the categories with common patterns mix up (Fig. 6). Yet, our method is able to capture meaningful common local parts and maps the samples based on these elements, i.e. parallel lines, hatches, and circles.

For Maya epigraphers in our team, a more neatly differentiated grouping of signs, e.g. obtained by HOOSC with sc=1/1 is preferable. However, work on the effects of parameter choice is required to obtain groupings that make more epigraphic sense. Clearer 'borderlines', less 'outliers,' and less 'intrusive' signs (e.g. T25 and T1) within each cluster would be desirable. Our results in this regard are preliminary, but they open promising research questions.

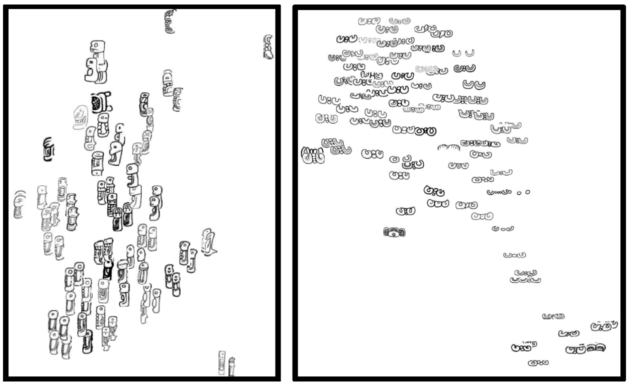

Figure 7. Monument data: Close-up of two clusters (T229 on the left and T126 on the right), corresponding to navy and magenta clusters in Fig. 6 with the most global HOOSC descriptor (sc=1/1)

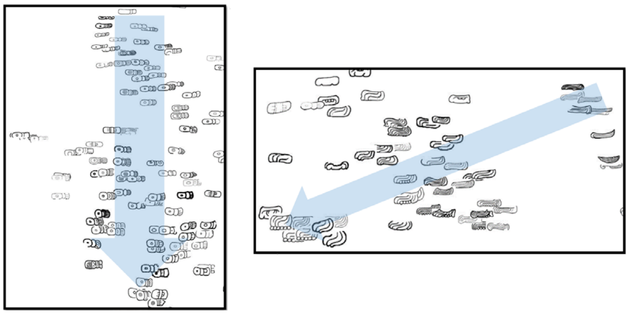

Figure 8. Monument data: Close-up of two clusters (T59 on the left and T116 on the right), which exhibit smooth transition between samples corresponding to place or temporal variations

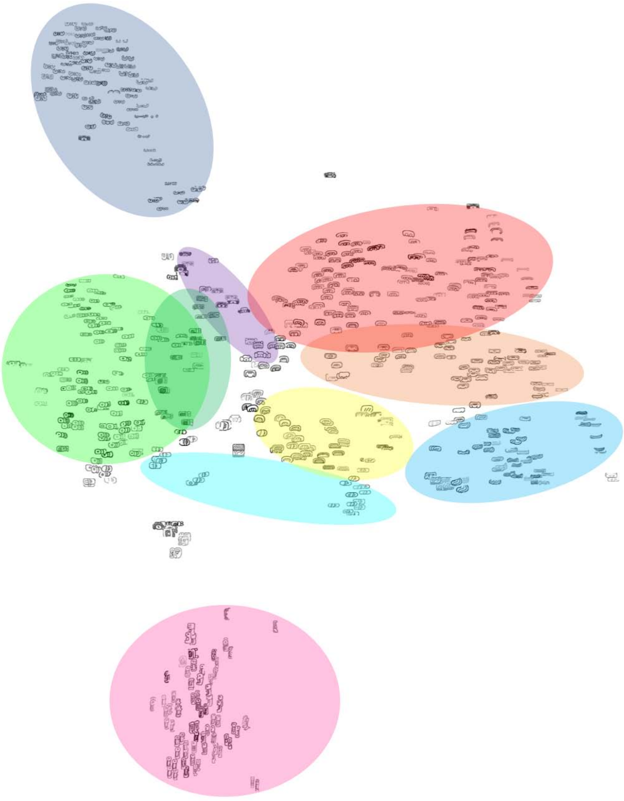

Figure 9. Monument data: Visualization of all class samples with the most global HOOSC descriptor (sc=1/1)

Another important epigraphic point is that we observe interesting visual transitions between samples of the categories. Fig. 8 shows examples from category T59 and T116, which illustrate a smooth dilation of samples in one direction. These kind of observations are interesting for archaeologists, since they might correspond to modification of the glyph signs over time or place.

Glyph variants from Thompson catalogue

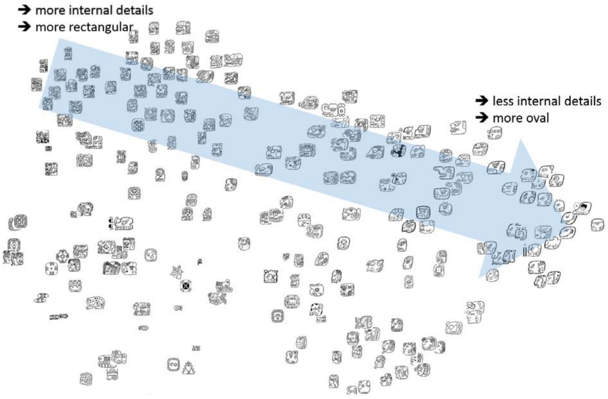

Figure 10. Catalogue data: A visual cluster of main signs from the Thompson's catalogue, with the most global HOOSC descriptor (sc=1/1). Many of them are impersonated main signs that corresponds to gods or animals. In this part of the visualization, the upper left part has more visually complex variants than the rightmost samples

From the visualization of glyph variants in Thompson's catalogue with the largest spatial context level (sc=1/1), we observe that visually similar categories are grouped together, while exhibiting smooth transitions. These transitions may correspond to some characteristics of the data. Fig. 10 shows a cluster of personified main signs in which degree of visual internal detail decreases in the indicated direction. We also observe separate visual clusters for hatched, horizontal and vertical glyphs.

Conclusion

Our goal in this study is to help DH scholars to visualize data collections not as isolated elements, but in context (visually and semantically). Even though early catalogues are built based on visual similarities, i.e., (Thompson and Eric, 1962) or (Zimmermann, 1956) relied on graphic cards to study similar patterns, the categorization methods were poorly understood and were not easy to reconfigure.

Furthermore, due to the limited knowledge at the time about semantics and sign variants, these catalogues turned out to be inaccurate or outdated. Similarly, Gardiner's list (Gardiner, 1957) is insufficient to elucidate sign variability in the 'Book of The Dead' (Budge, 1901).

With the proposed tool, however, considering details at different scales as semantic/diagnostic regions in the visualization can help archaeologists to discover semantic relations. In this way, overlapping notions such as 'colours', 'cardinal directions' and specific toponyms from earthly, heavenly or underworld realms can be studied in greater detail.

Finally, illustrating all variations with different visual focus in a fast and quantitative manner brings out the characteristics of signs. This also helps experts match samples from various sources (i.e. monuments, codices, and ceramic surfaces) to corpus data more efficiently; and trigger the decipherment of less frequent and damaged signs. Hence, our work is a step towards producing a more accurate and state-of-the-art sign catalogue.

The Evolution of Virtual Harlem: Bringing the Jazz Age to Life

Bryan Wilson Carter
bryancarter@email.arizona.edu
University of Arizona, United States of America

Imagine being faced with the choice of remaining in your hometown, living in what you have known all of your life in harshly oppressive conditions, or leaving, along with a number of your family and neighbors, headed North or West toward a land of promise and opportunity. This was the basic choice that many African Americans had in increasing numbers after 1865 when the emancipation proclamation was signed and a flurry of legislation passed in an attempt to equal the playing field for recently emancipated African Americans. By the early 20th Century, the Great Negro Migration was well underway, as African Americans were being driven off the land by the violence and intimidation of the Ku Klux Klan, natural disasters, and increasing levels of legal and extra-legal oppression and inequality in all sectors of life. They were also being pulled to the North and West by the perceived promise of increased opportunities in many aspects of life, the receipt of letters and communication from friends and relatives who had already made the move, and the perception of less racism in the North and West.

By the end of World War I, The Great Migration had reached flood proportions with hundreds of thousands of African Americans moving to urban centers in the north such as Chicago, Il, Harlem, NY, the steel belt and the auto industry in the midwest, as well as out towards the great promise of the West. Those who left the south for the urban North knowingly or sometimes unknowingly became a part of the New Negro Movement , known later as The Harlem Renaissance, of the 1920s, and The Chicago Renaissance of the 1930s and 40s. Understanding the cultural, intellectual and political output of African Americans during this period is key to understanding American history and our contemporary society. But what was it like in the big city of the 20s? How did that change, if at all, from the big city of the 40s and 50s?Artistic production was huge during both these periods, how might similar issues of artistic production be discussed from within this virtual environment?

There are a variety of ways to introduce our current generation of students to this vibrant aspect of African American culture that encompass both traditional and avant garde approaches. This project builds on two existing projects to engage today's learners and teachers in ways not previously possible, and also intertwines modern technology and advanced visualization with traditional practices to create a learning experience like no other that is focused on *The Great Migration, and Beyond*. Additionally, this paper explores, through the discussion and demonstration of the aforementioned project, ideas related to digital preservation, lack of diversity in Digital Humanities and introduces Digital Africana Studies as an engaging pedagogy.

The Great Migration and Beyond represents the first time that two major virtual environments focused on African American history and culture will be connected through both technology and theme. We recognize that there will be a number of challenges as we create rich historic landscapes and experiences while simultaneously creating a non-linear, visually and technologically unified journey through time and place related to African American life and culture.

The technology enabling this virtual world development is based on the Unity 3D game engine. Unity 3D is a platform for creating virtual worlds and games that accepts 3D assets or models using Open Standards format, meaning that assets can originate in nearly any 3D modeling tool and those entities can then be imported into Unity. The platform then enables us to distribute the final project to the spectrum of media devices (e.g. PC, Tablet, Game Console, Mobile, and full VR environments such as the CAVE, CAVE2, or a Data Wall. Additionally, we plan to address how the environment can be experienced through the increasing number of peripheral devices such as the Oculus Rift, HTC Vive, Samsung Gear or even Google Cardboard.

Key to the verisimilitude and distinctive look/feel of the Harlem/Bronzeville environment is the use of motion capture-based animation of the characters that the visitor encounters. While exploring the environment, visitors will encounter scenes depicting significant historic events of the time and place or common everyday occurrences where, those occurrences actually become a part of the evolving experience, in essence, a living part of a Theater of the Surround.

The Starting Point

The Virtual Harlem Project is a representation of Harlem, New York, as it existed during the 1920s Jazz Age, in 3D space, where objects such as buildings, interiors, automobiles and more are constructed using 3D modeling applications. This project is one of the earliest full virtual reality environments created for use in the humanities and certainly one of the first for use in an African American literature course. Virtual Harlem was originally conceived by Dr. Bryan Carter as part of his graduate work at the University of Missouri-Columbia in 1996, and developed by the Advanced Technology Center there who assisted him in designing it as a collaborative Virtual Reality (VR) environment and learning simulation in which participants learned about and experienced the Harlem Renaissance to supplement real world courses about the subject. The Harlem Renaissance/New Negro Movement was a unique period in American history that occurred in the 1920's, just after the end of World War I.

It was a time when Langston Hughes, Eubie Blake, Marcus-Garvey, Zora Neale Hurston, Paul Robeson, and countless other African Americans made their indelible mark on the landscape of American and international culture. This is a time when African Americans made their first appearances on Broadway; chic supper clubs opened on Harlem streets; riotous rent parties kept economic realities at bay while the rich and famous, both white and black, attempted to outdo each other with elegant, integrated soirees (Lewis)., and African American artists and entertainers were the toast of European Cafe Society.

Time Machine: Bronzeville has been in-development as a multi-modal recreation and immersive experience of the vanished and historically significant Bronzeville section of Chicago's South Side, during The Chicago Renaissance period (1930–1950). Components of this project include a computer game treatment, online immersive web destination, and augmented reality gallery installation.

Through the use of digital 3D image creation and animation, game and web technologies, the visitor can explore the history, lore, and legends of Bronzeville during the defining events of the 20th century: The Great Migration, The Great Depression, The Chicago Renaissance, Jim Crow Segregation (American Apartheid), World War II, and the emergence of The Black Metropolis.

Intuitively navigating the avenues, alleys and interior spaces of Bronzeville, and interacting with its residents, the visitor discovers the genius, ingenuity, and invention in all the arts and humanities, from painters' studios and recital halls, juke joints and storefront churches, to lecture halls, theater stages and street corner soapboxes that distinguishes the vibrant and creative period of The Chicago Renaissance.

The Vision: An Expanded Harlem/Bronzeville World

The immersive cityscapes of *Virtual Harlem* and *Time Machine: Bronzeville* are historical simulations and interpretations of the vanished Harlem and Bronzeville of the 1920s, 1930s and 1940s, recreated from extensive research of the photo and graphic records, the African American press archives, personal memoirs, oral histories and statistics.

The richly detailed environments will be deeply embedded with informing and contextual media. The visitor's movements and interactions with animated characters and objects will trigger radio broadcasts, phonograph recordings, ambient soundscapes, and links to other resources. The visitor will be able to interact with and manipulate objects in the environment to access the archive of historical photos, print documents and media clips that illuminate the events, persons, and significance of the creative, cultural, social and commercial engines that were Harlem and Bronzeville in these periods. Extensive use is made of documentation gleaned from African American press, radio and film archives.

The projected Harlem/Bronzeville complex will enable the visitor to explore 3D simulations of the vanished Harlem and Bronzeville communities. With a click/touch, select locations can be viewed through decades of change, allowing the visitor to witness the evolution of the neighborhoods, and to compare the historical views with the contemporary cityscape. 3D animated scenes and tableaux depict historical events, persons and places significant in understanding this period and its arts movement. In-world interactive maps and guides aid the visitor in navigating the terrains and times.

Featured historical figures, locations, and significant events of Harlem and Bronzeville include: artists' profiles and portfolios for Langston Hughes, Richard Wright, Arna Bontemps, Margaret Walker, Gwendolyn Brooks, Inez Cunningham Stark, William Edouard Scott, Charles White, Archibald John Motley, Jr., Eldzier Cortor, William MacBride, Elizabeth Catlett, Gordon Parks, Horace Cayton, John Johnson, the Jones Brothers (Policy Kings), The Apollo Theater, the Cotton Club, Connie's Inn, The Theresa Hotel, The Dark Tower, The South Side Community Art Center, Parkway Community House, South Side Writers' Group, the American Negro Exposition, Louis Armstrong and Chicago Jazz, Thomas Dorsey, the "Father of Gospel Music", blues artists, Contralto Mahalia Jackson, Katherine Dunham and Ballets Negres, the Beaux Arts Ball, The Skyloft Players, The Bud Billiken Parade, Artists' and Models' Ball, Savoy Ballroom, Regal Theater, Rhumboogie, Club DeLisa, among many others.

Timeline, Maps, and Infographics

Through the Graphical User Interface Unity3d overlay (GUI), the visitor will be able to access a Timeline, maps and other infographics, presenting a multimedia chronology of The Great Migration, The Harlem Renaissance, and The Chicago Renaissance. Images and text, media clips and animations pop up as the cursor rolls over key points on the graph. Hot spots on the graph link to other components of the environment, enabling visitors to travel quickly around the space. The Timeline, maps and infographics also present contextual information about national and international events, as documented in the African American press and other media sources. This prototype GUI will also enable users to save information, take snapshots and submit suggestions for integration of their own research for approval or suggestions to improve the experience.

Community-Of-Interest

Another of our challenges will be to create a forum for a community-of-interest, encouraging inquiry and making connections, and a host site/server for live presentations, teaching/learning experiences, performances and discussions. We envision an expanding archive and repository for Humanities research and scholarship (Implementation Phase). The start-up phase will include the design and samples of supplemental materials and guides to aid educators, and researchers in making full use of the evolving technology components and capabilities of this multi-modal compendium of reference materials, image archive, bibliography, repository for and curation of visitor contributions, and library of, and portal to, essays and lectures by scholars.

The immersive Harlem/Bronzeville complex presents an unprecedented contribution to the historical representation and interpretation of African Americans, uniquely enabled by current and emerging technologies. The design of the content and interactive engagement will make the Harlem/Bronzeville destination attractive to a wide spectrum of visitors, with international reach.

Enhancing the Humanities

The evolution of video games, the excitement surrounding virtual reality with the launch of a number of VR headsets, the increased graphic and processing power of currently available personal computers and gaming consoles, the rise of low cost and accessible virtual environment and game development tools, and the focus on increased engagement in the classroom makes this a perfect time to consider ways that both these projects might focus on a much larger and unifying aspect of African American culture and transformative period of American history, *The Great Migration*. The nationwide observance of the centennial of The Great Migration begins in 2016, and our project is intended to contribute to this multi-year observance.

The Larger Discussions

This project, in addition to it representing an innovative use of emerging technologies to teach Africana content, also introduces three parallel discussions; digital preservation, lack of diversity in Digital Humanities and the pedagogy of Digital Africana Studies.

Lack of Diversity in Digital Humanities

So what exactly is the Virtual Harlem/Bronzeville project? Since its inception, the Virtual Harlem Project has been called a variety of things to include a virtual learning platform, a collaborative learning network and a digital humanities project. Although it is most likely one of the oldest VR environments focused on African American life and culture, more specifically, that of the 1920s Jazz Age/ Harlem Renaissance, until recently, Virtual Harlem has rarely been discussed as an example of diversity in Digital Humanities. This is rather odd given that the project is particularly focused on African American life and culture, that it was conceived by an African American scholar and that it was initially intended to be used in an African American literature course. Yet, discussions of Virtual Harlem tend to center on the project as a good example of advanced visualization, technology in the classroom, or even a digital humanities project, without much mention of it having an emphasis on diversity. There are a variety of reasons why this may be the case. One is that there are so few VR projects that deal with diverse topics that those that are tend to be discussed with regards to the technologies used, not necessarily the nature or content of the project. Virtual Harlem also represents the use of interactive technologies where students are encouraged to become active contributors to a much larger landscape that is accessible by other members of the class and by limited numbers who are not enrolled. Contributions to the environment are done in non-traditional ways, to include performance, 3D body scanning and motion capture. It is just this sort of non-traditional teaching, learning and use of advanced technologies that some, particularly within the Africana Studies scholarly community, sometimes tend to view with a level of scepticism. Possible reasons for this are complex and may in part be related to how traditionally, scholarly respect for the discipline has been connected to knowledge and experience of its scholars. When the focus is shifted towards the technology used, there may be a fear of losing part of that respect. Tara McPherson suggests that "politically committed academics ...engage technology and its production not simply as an object of our scorn, critique or fascination but as a productive and generative space that is always emergent and never fully determined" (McPherson 155). Virtual Harlem represents one of the myriad of technologies that are and can be used in the humanities to address the learning styles of this generation of students, to encourage students to make use of the variety of tools they have at their disposal to express their understanding of humanities content, and to help us all deal with increasing amounts of data and information directly and indirectly related to the humanities. There are, however, a number of exciting projects by a diverse set of scholars that are flying under the radar simply because these scholars tend not to publish their work in digital humanities journals, many are dealing with tenure and promotion and focusing their publishing efforts on that which those evaluating their dossiers are more familiar instead of pushing projects that some fear may call their scholarship into question simply because evaluating digital humanities projects is not always fairly done in every discipline. These scholars are caught in a catch 22. Their projects are an amazing example of the use of technology in the classroom, yet evaluators have a fundamental lack of understanding of what digital humanities is or how to deal with it for tenure and promotion. So underrepresented scholars typically have to publish in traditional venues while working on their digital humanities projects as side projects until tenure and promotion are earned. Funding for digital humanities projects dealing with diverse topics is also difficult. Statistics are difficult to come by, but judging from the articles published in the most difficult popular digital humanities journals and books, there are very few pieces published that document projects dealing with diverse topics, created by underrepresented scholars. That is a problem. So what can be done to diversify the field? What can be done to encourage young minority scholars to contribute their ideas to the growing body of digital humanities scholarship in an effort to strengthen the field? Answers to these questions are not easy, nor will they be addressed in the very near future. However, there are efforts being made to introduce underrepresented scholars to digital tools and projects that, in time, may filter into the classroom and eventually into scholarship of these groups. These activities include workshops funded by the National Endowment for the Humanities and the Mellon Foundation along with pedagogies being developed that inherently incorporate technology as a part of the teaching and learning process.

Digital Africana Studies

Digital Africana Studies closely parallels Digital Humanities in that it encourages scholars to use a variety of technologies to teach and research within their fields and seek connections to the outside world in an effort to understand the human condition. Furthermore, Digital Africana Studies, also encourages students to use a variety of digital tools to express their understanding of course content and find relationships between what they are learning, their lives and the world around them. Digital Africana Studies is a direct outgrowth of Afrofuturism, which is a theory that explores how people of African descent are represented in conversations of the future, whether that future be depicted through science fiction, the entertainment industry, popular culture or education, as well as a way of looking at the world, a canopy for thinking about black diasporic artistic production, a way of considering the presence of people of African descent within past, present and future Western society, as well as an epistemology that is thinking about the future, the subject position of black people, and about how that is both alienating and about alienation. So when I am asked, "what *is* Virtual Harlem?", I find it simultaneously strange, curious and sometimes insulting that some would try to categorize, label and subsequently only *see* it through a relatively narrow lens, thus missing the larger, experiential aspect of the project. Digital Africana Studies is the pedagogical and practical application of Afrofuturism in that it seeks to explore how advanced technologies may be used in the classroom to support a more experiential environment, one that creates memorable encounters with the culture and content of the course.

Jonathan Edwards (1703-1758) is generally considered the most eminent and versatile thinker in early American history. His impact on the shaping of the theological thought and the preaching tradition of the colonial period was profound and long-lasting. Today he remains one of the best studied figures of the American past and different elements of his impressive output are continually reprinted by both academic and commercial publishing houses. Over his life Edwards authored more than a thousand sermons, hundreds of letters and a number of theological treatises. The Jonathan Edwards Research Center at Yale University edited and published most of these texts in their complete form as *The Works of Jonathan Edwards*, led by Harry Stout as general editor and Kenneth Minkema as executive editor. The series of almost thirty volumes is described by Phillip Gura, a former editor of *Early American Literature,* as the "most important editorial project in American cultural history in the past 50 years" (2004, 149). Edwards' life is so well documented that there are hardly any stones unturned in the life of the Northampton divine. Especially, his relevance for the events of the Great Awakening, a powerful social-religious movement of colonial America, underwent close scrutiny and the most notorious sermon of America, "Sinners in the Hands of an Angry God" which he authored, has been the studied linguistically, rhetorically and stylistically.

Like most people of his age, Edwards was a diligent diary-keeper and an avid letter-writer. His private texts offer a comprehensive insight into his daily struggles and ambitions – in consequence, the very writing and publishing process of his texts is relatively well documented. Yet, surprisingly – in spite of such extensive research conducted upon Edwards – the relationship between him and Thomas Foxcroft (1697-1769), his editor and literary agent has not been extensively studied.

Foxcroft was a minister at First Church in Boston, Massachusetts and Jonathan Edwards's ally in the pro-revival debate. Their collaboration began most probably in 1849; Edwards had great trust in his erudition and skill to carry out the authorial intent expressed point-by-point in his commentaries to the suggestions of corrections. Foxcroft sometimes included Edwards's correction verbatim, exactly as indicated by the author, at other times, he paraphrased them, while preserving the author's thought. Edwards entrusted Foxcroft with the editing, the correction and the publication process – as he writes in a letter sent from Stockbridge – a small mission he was sent to after the dismissal from his own parish of Northampton: "I should be glad that you would endeavor that this book may be printed in a pretty good paper and character, and may be printed correctly, and that particular care may be taken that the printer don't skip over a whole line as they sometimes do. And if the bookseller can be agreed with to let me have a number for the copy, it would be pleasing". (30 June, 1752). Edwards also consulted Foxcroft about the correctness of his interpretation of other authors: "(…) it is very difficult, and almost impossible, for another to enter into all the views of a writer, or to know everything he has in view in all that he says; and therefore a little variation of sentiment, may much thwart and disappoint his design, insensibly to another. But this I should take as a very friendly part and much desire, that if you observe, that in any instances I have mistaken Mr. Williams' meaning, and misrepresented him, or in any respect injured him (…)" (30 June, 1752). The extent to which the style of the editor (whose idiosyncratic style can be described on the basis of numerous publications he himself authored) permeated the author's writings in this case has not been determined. The influence of Foxcroft's thought and style in Edwards's writings seems to be potentially very strong and demands close investigation and the stylometric approach seems a most fitting tool to be employed for such a study.

The analysis was performed with two quantitative methods: frequencies of most frequent words were compared between the texts using the Delta procedure (Burrows 2002); then, an analogous procedure (this time using Support Vector Machines) was used to look for traces of the editor's signal in consecutive segments of several treatises by Edwards ("rolling.classify," Eder 2015a). The analyses were performed with *stylo* (Eder et al. 2013), a package for R, the statistical programming environment (R Core Team 2014), postprocessed with Gephi network analysis software (Bastian et al. 2009).

A general view of stylometric similarities and differences between the writings of Edwards and Foxcroft is presented in the network diagram in Fig. 1. It shows, above all, a good separation of the signal of the two preachers, especially when Edwards's spiritual texts; sermons, treatises and Biblical comments are concerned, these, in turn, exhibit a degree of separation by subgenre – as opposed to Foxcroft's generally more uniform stylometry.

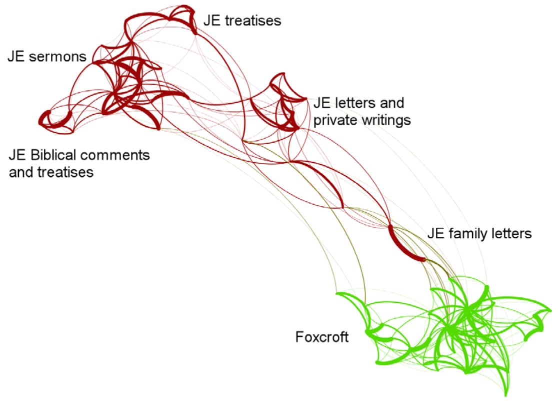

Figure 1. Network analysis of texts by Edwards (red) and Foxcroft (green).

In the more detailed search for the editor's signal with the "rolling.classify" method, longer texts by Edwards, i.e. his treatises, were compared against his own signal averaged over the rest of his *oeuvre* and against that of Foxcroft, bearing in mind the suggested caesura of 1749. Sure enough, consecutive segments of Edwards's works written before that date exhibited no traces of the editor (as exemplified by Fig. 2), and then surfaced in a series of works (as visible in Fig. 3). Interestingly, the editor's signal disappears again in 1758, the year of Edwards's (not Foxcroft's) death.

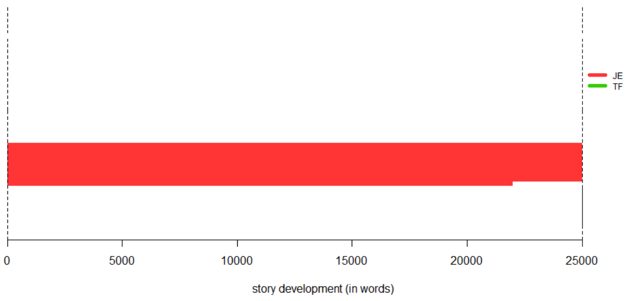

Figure 2. Consecutive segments of Edwards's *Mind* (1723); throughout the work, Edward's signal (red) dominates over the (absent) signal of Foxcroft.

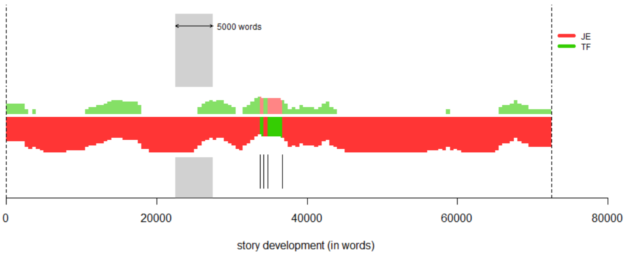

Figure 3. Consecutive segments of Edwards's Humble Inquiry (1749); in many other fragments, dominated by Edwards (red), Foxcroft's impact is still visible. The lower band shows the strongest signal; the upper, the second strongest.

These results have two significant consequences. The first is that we have now produced a quantitative confirmation of the extent of collaboration between two major colonial authors. But the fact that the quantitative agrees so well with the qualitative (or historical) evidence also shows that editorial traces can indeed be found with stylometry, perhaps to a greater degree than we might have anticipated.

What's in a Topic ModelI fondamenti del text mining negli studi letterari

Fabio Ciotti
fabio.ciotti@uniroma2.it
Università di Roma Tor Vergata, Italy

Introduzione

Nel 1975 William A. Wood, ricercatore alla Bolt Beranek and Newman (una delle culle di Internet), pubblicò un articolo dal titolo "What's in a link" . Il lavoro, che determinò una svolta nella storia dell'Intelligenza Artificiale e in particolare della Knowledge Representation, consisteva in una serrata e argomentata critica della nozione di rete semantica (in tutte le sue varie accezioni, dal primo modello proposto da Ross Quillian alla più avanzata nozione di *conceptual dependencies* di Roger Shank), il concetto centrale di gran parte delle teorie di semantica computazionale. Il problema secondo Wood era che quella nozione non era fondata teoricamente (Wood, 1975): "there is currently no 'theory' of semantic networks. The notion of semantic networks is for the most part an attractive notion which has yet to be proven. Even the question of what networks have to do with semantics is one which takes some answering."

Nel suo titolo questo paper allude, immodestamente, al lavoro di Wood poiché si propone di affrontare, con lo stesso atteggiamento critico, i fondamenti teorici di una nozione e di un metodo che sono oggi molto diffusi negli studi letterari computazionali: quella di topic modeling, ovvero l'individuazione statistico/probabilistica dei cluster lessicali che caratterizzano un insieme di testi, e l'analisi delle loro distribuzioni (Underwood, 2012a; Blei, 2013). Occorre chiarire che quando parliamo di fondamenti teorici ci riferiamo al ruolo che tale nozione può giocare nel contesto di una teoria del testo e di una metodologia della critica letteraria, e non ai suoi aspetti puramente matematici, che sono ovviamente saldamente basati sulla statistica e sulla teoria della probabilità bayesiana (Blei, 2012).

Il distant reading e l'interpretazione

Come noto le tecniche di topic modeling rientrano nell'insieme più generale di metodi e approcci all'analisi computazionale dei testi letterari che Mario Moretti, con una formula di notevole successo coniata in antinomia con il metodo critico tradizionale, ha definito "distant reading" (Moretti 2013b: 48):

> what we really need is a little pact with the devil: we know how to read texts, now let's learn how not to read them. Distant reading: where distance, let me repeat it, is a condition of knowledge: it allows you to focus on units that are much smaller or much larger than the text: devices, themes, tropes— or genres and systems.

Tra i numerosi ricercatori che, con interesse se non addirittura con entusiasmo, hanno adottato questi metodi si nota talvolta una specie di atteggiamento riduzionista secondo cui i fenomeni letterari possono essere ridotti senza residui a fenomeni quantitativi misurabili e analizzabili in virtù di metodi puramente numerici e statistici (Jockers, 2013):

> Close reading is not only impractical as a means of evidence gathering in the digital library, but big data render it totally inappropriate as a method of studying literary history [...] massive digital corpora offer us unprecedented access to the literary record and invite, even demand, a new type of evidence gathering and meaning making.

A questo atteggiamento ovviamente si oppone una posizione che rivendica la radicale irriducibilità della letterarietà e/o dell'ermeneutica letteraria, la loro natura qualitativa. La tesi che intendo difendere in questo paper è la seguente: un metodo quantitativo o computazionale riveste interesse come strumento critico letterario nella misura in cui fornisce dati osservativi che possono essere correlati a termini o nozioni teoriche rilevanti per la teoria e la critica letteraria. In particolare, ritengo che le teorie semiotiche del testo letterario rappresentino una fonte di modelli e teorie di enorme utilità in ambito computazionale.

L'interpretazione di un testo letterario consiste nella creazione ed elaborazione di una serie di nozioni intenzionali adottate per spiegarne il funzionamento: nozioni come quella di storia, personaggio, eroe, autore e lettore, descrizione. Possiamo dire che la scuola semiotica nella teoria e nella critica letteraria ha adottato verso queste nozioni la stessa strategia che la corrente funzionalista nella teoria della mente ha avuto verso i termini della psicologia del senso comune: ne ha fornito una spiegazione in termini di concetti (come quella di attante, funzione narrativa, fabula, intreccio, isotopia) e modelli formali più rigorosi. Questi concetti non negano la natura intenzionale dell'interpretazione, ma non la intendono come un fenomeno irriducibile, bensì ne tentano una spiegazione al livello del progetto, per usare i termini del filosofo Daniel

Dennet (Dennet, 1990). Lo stesso Eco ha descritto questo doppio livello esplicativo introducendo la distinzione tra interpretazione semantica e interpretazione critico/semiotica (Eco, 1990: 29):

> L'interpretazione semantica o semiosica è il risultato del processo per cui il destinatario, di fronte alla manifestazione lineare del testo, la riempie del significato. L'interpretazione critica o semiotica è invece quella per cui si cerca di spiegare per quali ragioni strutturali il testo possa produrre quelle (o altre alternative) interpretazioni semantiche.

D'altronde è lo stesso Moretti (che in questo mostra una accortezza teorica e una conoscenza del campo letterario non riscontrabile in altri autori) a suggerire questa via in uno dei suoi migliori saggi teorici adottando la nozione epistemologica di "operazionalizzazione" come processo di traduzione di un termine teorico in una procedura sperimentale (Moretti, 2013a):

> Operationalizing means building a bridge from concepts to measurement, and then to the world. In our case: from the concepts of literary theory, through some form of quantification, to literary texts.

Topic model e loro possibili interpretazioni

Accettando il suggerimento metodologico di Moretti, quale nozione teorica della teoria letteraria viene operazionalizzata dal concetto statistico di *topic model*? O per usare un linguaggio più caro ai praticanti delle tecniche di *text mining*, di quale fenomeno letterario funge da "proxy" un topic model?

Dal punto di vista tecnico il *topic modeling* è una tecnica di text mining non supervisionata. Esistono diversi algoritmi di topic modeling, ma ad oggi il più diffuso è quello noto come Latent Dirichlet Allocation (LDA), fondato su un approccio probabilistico bayesiano. In modo intuitivo possiamo dire che alla base di LDA vi è un semplicistico modello generativo del testo: quando un autore scrive un testo in prima battuta sceglie l'insieme degli argomenti (topic) di cui vuole parlare e poi determina la proporzione con cui ciascun argomento sarà presente. Ammettiamo ora che ogni possibile topic possa essere caratterizzato come un insieme di parole con una data distribuzione: una specie di sacchetto di parole dove le parole possono essere ripetute in ragione diversa a seconda delle loro rilevanza rispetto all'argomento. Il nostro autore dunque potrà "pescare" in modo casuale dai vari sacchetti che corrispondo agli argomenti di cui intende scrivere ed estrarre da ciascuno un numero di parole proporzionale al peso che intende assegnare a ciascun argomento. Alla fine non dovrà fa altro che mettere in sequenza il suo mucchietto di parole ed ecco che avrà ottenuto il suo testo, in cui ovviamente le parole avranno una distribuzione determinata dalla rilevanza degli argomenti/sacchetti da cui sono state estratte. In termini tecnici si dice che in LDA un testo è una distribuzione di probabilità su un insieme di topic e un topic una distribuzione di probabilità su un insieme di parole. La cosa interessante di questo semplice metodo modello generativo è che può essere invertito: otteniamo in questo modo un algoritmo che è in grado di estrapolare i topic prevalenti in un insieme di documenti, ovvero la lista delle parole che co-occorrono con frequenza notevole e la loro distribuzione di probabilità.

I problemi tecnici dell'applicazione immediata di questo metodo (come di altri simili) in ambito letterario, sono diversi (Sculley and Pasanek, 2008). Ma qui ci interessa soprattutto il fatto che la nozione di topic non ha un chiaro statuto in ambito letterario: che cosa è quella lista di parole che costituisce un topic? E che cosa è la lista di topic (il topic model) nel suo insieme?

Le risposte possibili a questo quesito sono diverse: Ted Underwood ha proposto di interpretare i topic prodotti dal algoritmi come LDA come "discorsi", ovvero "kinds of language that tend to occur in the same discursive contexts" (2012a). Ma questa proposta da un lato richiede che lo statuto del concetto di discorso sia meglio definito; dall'altro nella formulazione di Underwood sembra dare adito a circolarità, poiché è proprio la natura e la funzione letteraria di quel particolare insieme di parole che va spiegata. Altri possibili candidati come correlati teorici della nozione di topic sono le nozioni di tema e motivo, che hanno avuto una lunga storia teorica nella teoria letteraria del secolo scorso; ma anche in questo le varie accezioni che possiamo assegnare ai concetti di tema e motivo paiono avere poco a che fare con i risultati di un algoritmo come LDA. Temi e motivi sono entità di contenuto che possono manifestarsi linguisticamente in specifici sintagmi o enunciati, ma che possono altresì essere manifestate da vaste porzioni di testo (a limite un testo nella sua interezza) senza avere nessun correlato linguistico immediato (Segre, 1985) . Si identificano in quanto temi e non generici contenuti concettuali in virtù della loro natura di stereotipi culturali che risiedono nella memoria culturale collettiva a cui autori e lettori attingono, pur mutandone nel tempo e nello spazio i valori semantici connotativi. Altrettanto problematica la interpretazione di un topic model come *isotopia* nel senso definito da Greimas (1985), intesa come classe paradigmatica di caratteristiche testuali discorsive che presentano una omogeneità semantica: infatti l'isotopia non è un fenomeno lessicale e soprattutto è il prodotto della cooperazione interpretativa del lettore, come la nozione di *topic discorsivo* adottata da Eco in nel suo *Lector in Fabula* (1979).

Conclusion

La discussione delle possibili interpretazioni semiotico letterarie della nozione di topic modeling e la constatazione della difficoltà teoriche che esse presentano ci porta ad affermare che in effetti non è possibile trovare un unico e soddisfacente correlato teorico- letterario dei risultati di questi metodi di analisi quantitativa. La conseguenza di questa difficoltà nella definizione teorica, ovviamente, non deve essere il rifiuto di queste tecniche di analisi come metodi utili alla conoscenza dei testi letterari. Occorre tuttavia essere consapevoli che di volta in volta il ricercatore dovrà individuare, sulla base dei testi che ha sottoposto ad analisi, quale siano i fenomeni letterari che i risultati intendono spiegare. Ne consegue inoltre la fallacia dell'idea di adottare nella ricerca letteraria le strategie di analisi esplorativa tipiche dei metodi della *Big Data analytics*. La natura intenzionale degli oggetti letterari rende impossibile individuare fenomeni rilevanti senza avere un modello o una ipotesi critica che orienti e regoli l'indagine.

Introduction

This paper presents the results of an effort that our research team has done in order to develop an OWL 2 ontology to formally define the semantics of the Text Encoding Initiative markup language. The preliminary steps of this research project have already been presented at the TEI Conference in 2014 and 2015 (Ciotti and Tomasi 2014, Ciotti et al., 2015). We believe that our work has reached a satisfactory level of development, both on the theoretical side and in the practical implementation.

Why an ontology for TEI

The reasons to have a formal and machine-readable semantics for TEI are manifold. In the first place we can set forth a list of pragmatic and technical benefits that have been already pointed out in many previous works dedicate to this topic, that dates back to the mid-90s (Di Iorio, Peroni and Vitali, 2009; Ciotti and Tomasi, 2014). Here is a brief summary of those arguments:

- enabling parsers to perform both syntactic and semantic validation of document markup;
- inferring facts from documents automatically by means of inference systems and reasoners;
- simplifying the federation, conversion and translation of documents marked up with different markup vocabularies;
- allowing users to query upon the structure of the document considering its semantics.

The advantages envisioned in this list are not specific to the TEI or aim to facilitate the relationships between different markup languages; but some of the issues have special relevance for TEI and for the usage of TEI inside its reference community.

Take for instance the query issue: we all know that there are many ways of expressing one and the same textual feature in TEI markup, so that it is very difficult to query heterogeneous TEI corpora and text archives. Having a set of ontological definitions of the conceptual level behind markup, that is, a set of shared formal definitions of the textual features to which any single encoding project could bind idiosyncratic markup usage, could help solve this problem. The same argument could be made for a far more adequate management of interoperability of TEI text collections between different repositories or applications.

But we believe there is also a deeper theoretical and foundational advantage in the idea of an ontological semantic model for TEI. It is a commonly acknowledged notion that the very core of digital methods application in humanities research is the notion of model/modeling. The pair of terms "model/modeling" is deplorably understood in many different ways in the community. We think that, as far as we are using Turing machine like device for computation, the only workable notion of modeling is a formal one: model we should be interested in are formal models. Where formalization is to be understood as a series of semiotic processes that generates an algorithmically computable representation of one (or more) phenomenon/object.

It is widely recognized that the TEI is not only a markup facility but first and foremost a conceptual model of textuality. In fact, the Guidelines (TEI Consortium, 2015, chap. 23) explicitly introduce the notion of a TEI Abstract Model. The fact is that the notion of an abstract model is used in many formal procedures but this very notion is not formally defined. This ends up in a lot of problems and circularities. We think that we need to have a formalized account of the quasi-formal notion of TEI abstract model, if it has to be of any use other than a sort of regulatory principle.

We do not advocate going back to a monist theory of textuality. Our suggestion to adopt contemporary Semantic Web formalisms to build this abstract conceptual model give us the possibility to have a "foundation" of TEI in a well-defined data model that is not dependent on the notion of a single hierarchical "ordered hierarchy of content object" (OHCO, DeRose et al., 1997), and that can accommodate, at least to some extent, the "pluralities" of textuality.

Structure of the ontology

TEI as a whole is very complex, and its usage is governed by pragmatics and contextual requirements. We acknowledge that it is impossible to reduce to a unique formal semantic definition this fuzzy cloud. Though, we can identify a subset of shared assumptions, a common ground of notions about the meaning of TEI markup and the nature of documents like object: we think that this subset can be the object of an ontological formalization. For various reasons we have adopted the TEI Simple customization (Cummings et al., 2014) as an acceptable approximation of this common ontology. This is not an opportunistic ad hoc choice, as it may seem. TEI Simple in fact has been defined by a group of domain expert that have analyzed the actual usage of TEI markup in some big textual repositories and have selected and organized a set of one hundred or so elements that can describe all the textual features represented by the markup in those documents. This fits perfectly in the definition of a formal ontology development process.

The main design requirements for building our ontology have been the following:

- the ontology must express at the same time an abstract characterization of TEI Simple elements' semantics and an ontological definition of their structural role;
- the ontology must define a precise semantics of the elements having a clear characterization in the official TEI documentation (e.g., the element <p>), while it should relax the semantic constraints if the elements in consideration can be used with different semantic connotations depending on the context (e.g., the element <seg>);
- it must be possible to extend the ontology, reuse it and define alternative characterizations of elements semantics without compromising the consistency of the ontology itself;
- where possible existing ontologies or meta-ontologies must be reused

In accordance with these overall principles we have decided to implement a complex architecture using some pre-existing meta-ontology frameworks to express the meaning of TEI element set by the way of the classes and properties they define. In particular we have adopted:

1) LA-Earmark (Di Iorio, Peroni, Poggi, Vitali, 2011; Peroni, Gangemi, Vitali, 2011), a markup metalanguage, that can express both the syntax and the semantics of markup as OWL assertions, and an ontology of markup that make explicit the implicit assumptions of markup languages. LA-EARMARK is an extension of EARMARK with the Linguistic Act module of the Linguistic Meta-Model that allows one to express and assess facts, constraints and rules about the markup structure as well as about the inherent semantics of the markup elements themselves.

2) Structural Pattern Ontology (Di Iorio, Peroni, Poggi, Vitali, 2014), whose goal is to identify a small number of patterns that are sufficient to express how the structure of digital documents can be segmented into atomic components.

The specification of markup semantics for the various TEI Simple elements is done by means of LA-EARMARK class and properties. The general Earmark class for any markup element is earmark:Element. The <abbr> element is defined as follows:

```
Prefix earmark: <http://www.essepuntato.it/2008/12/earmark#>
Prefix co: <http://purl.org/co/>
Prefix tei: <http://www.tei-c.org/ns/1.0/>
Class: tei:abbr a
 earmark:Element that
 earmark:hasGeneralIdentifier "abbr" and
 earmark:hasNamespace "http://www.tei-c.org/ns/1.0"
```

LA-EARMARK allows us to link particular class of elements with the actual semantics they express. From our point of view there are at least two semantic levels that we explicitly define:

- one concerning the structural behavior of markup that is described by means of the Pattern Ontology (PO);
- the other regarding the intended semantics of an element (e.g., the fact that an element is a paragraph rather than a section, a personal name reference rather than a geographical reference), that is described by TEI Semantics Ontology or by a combination of already existing ontologies.

TEI Semantics Ontology is the core component that gives the actual semantics of TEI elements. Its definition is based on a categorization of the elements of the TEI Simple, based on a refactoring of the TEI model Classes.

The link between the class describing kinds of elements and their related semantic characterization is possible by means of the property "semiotics:expresses". The associations of semantics to markup elements can be contextualized according to a particular agent's point of view, in order to provide provenance data pointing to the entity that was responsible for such specification. This is possible by means of the Linguistic Act Ontology included in LA-EARMARK that allows one to consider all these markup-to-semantics links as proper linguistic acts done by someone.

Conclusions

The work we have done so far is limited to the Simple subset of TEI. We envision some further development:

- Refine the TEI Semantics Ontology component.
- Extend to some other areas of TEI that are suitable for formalization.

We think that in the long term this ontological formalization could become the primary formalization of the TEI encoding schema, independently of any serialization format. Today XML is still the better strategy to encode digital texts in real word projects for many practical reasons. But there is no reason for the TEI to be strictly based on it, as it is *de facto* now. Technical issues should not determine the choice of a formalization language. In the end, we believe that our effort can give a substantial contribution to the TEI to envision the shape of its own future.

Digital Palaeography: What is digital about it?

Arianna Ciula
arianna.ciula@roehampton.ac.uk
University of Roehampton, United Kingdom

Compared to the tradition of analytical palaeography it builds on, how is digital palaeography transformative? In this paper[1] I will reflect on the emergent meanings and possible research directions of digital palaeography by analysing the last twelve years of approaches and conceptualisations in the field. Moving between a formal and an historically situated analysis, I will show how digital approaches relate to the scholarly tradition of the study of handwriting and writing systems as a whole. Digital palaeography will emerge well positioned to represent the complexity of handwritten objects from an unfamiliar perspective by departing from the structure of the expression of handwriting (text as shape).

Words in context

The adoption and development of digital tools and resources for palaeography and manuscript studies are intertwined with fluctuating cultural attitudes (Busa, 1961; Morando, 1961;[2] McCarty, 2014b; Nyhan et al., 2015). The convergence towards the use of digital[3] coupled with humanities — digital humanities[4] — and therefore palaeography — digital palaeography — denotes the methodology of research being enabled rather than the symbolic form of its objects of analysis or of its outcomes. The scope within which I propose to discuss digital palaeography[5] is hence mainly methodological.

Terms	Semantics	Overall emergent meaning
Computational (e.g. Computational Palaeography)	Process-ability of data	Digital Palaeography ⊃ Computational Palaeography
Digital (e.g. digital vs. analogue)	Representational form of data	
Digital +(e.g. Digital Humanities; Digital Palaeography)	Research methodology	

A formal knowledge of handwriting — e.g. about scripts morphology or terminology used to describe it —[6] Not only palaeography as a discipline — from the 1930s with Bischoff at least, onwards — has subscribed to analytical methods, but more in general the perception of text as divisible entity in opposition to the notion of the ungraspable composition of images has prevailed in humanistic enquiries with few exceptions (e.g. semiotics of art).[7] Computer sciences and image processing techniques offer an *addendum*, a perspective that suits nicely methodological traditions and inclinations of the classificatory minds of palaeographers. Yet, my aim in this paper is to identify any transformative aspects (table 1). So, even if digital palaeography follows a long tradition of analytical approaches to handwriting and an even longer human wish to control writing systems, does it actually affect our conceptualisation of handwriting? How is digital palaeography transformative (in the sense of **digital** +)? or is there a **digital + palaeography**?

Projects rationales and self-narratives

I will summarise some 2004-onwards projects and activities (Ciula, 2004a, 2004b, 2005a, 2005b, 2005c, 2009;DigiPal, 2011-14; *Exploratory Workshops*, 2011)[8] which witness a critical engagement with digital technology, informed by diverse modelling processes and a constructive discussion of the limitations of computational tools. These approaches challenge the notion of palaeography as an auxiliary discipline towards a renewed return to an "integral" (Boyle, 1984) perspective which places palaeography within a wider multi and interdisciplinary framework, linking it with philology, linguistics and even cognitive sciences.[9] The analysis on terminology as well as an overview of practices put the emphasis on a self-reflective approach around the analysis of handwriting beyond strictly computational concerns.

Creating and deflating models

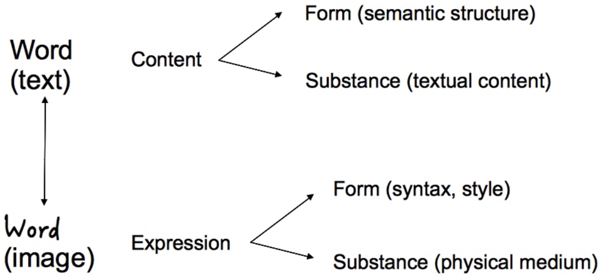
In addition, I will reflect on the potentially productive dilemma digital palaeography approaches suffer from; a dilemma that is made more acute in recent practices compared to the already vivid debates in the 1970s between the historical and "Cartesian" approach (Gumbert, 1976) and in the 90s (Costamagna et al., 1995, 1996). On one hand, palaeographers engaged with the digital are busy building things, what Godfrey-Smith (2009: 108) would call a specific type of models or "imaginary concreta" (creatures in between reality and fiction, between the schematic and the concrete); on the other hand, they are engaged in reflecting about their own practice and in so doing deflate the same models they build.[10]

In a paper questioning the connections between a scriptorium and its products, Ganz states: "searching for the distinctive details of letter forms shared by scribes may risk the application of an over rigid positivism to the study of manuscripts." (Ganz, 2015)

Not to dismiss this warning against positivism in digital humanities,[11] I will claim that what a digital palaeography approach as contextualised earlier on brings to the fore is precisely this awareness and hence the questioning of the 'mechanics' of a topographical or taxonomical analysis. By asking "what is the unit of handwriting? what we considered it to be?," a digital palaeographer is aware that even by getting closer to the supposed materiality of the artefact — e.g. through high resolution images and microscopically segmented image features — she does not lose the lenses palaeographers have being using for interpreting such artefacts in the past, but can consciously decide to put them to test. In this lies one of the paradoxes of the digital and of modelling more in general: it brings perceptual materiality to our scrutiny while taking us away from it. The digital models are used to analyse the objects they are models of, but are also self-reflective tools to question those same models.[12]

Semantics and materiality

Palaeographic research with its focus on the perception of handwriting in morphological terms is a reminder that the handwriting manifests itself as an artefact that is rationalised and divided (hence constructed) only after it is given. By bringing to the fore the picture of writing or the writing as picture (cf. "text as shape" vs. "texts as meaning" in Hassner et al., 2012: 193), palaeographical studies live on the intermedia dimension of handwriting. By this I intend the crossing of the analytical media border between the sensorial and the conceptual qualities of handwriting, form and meaning, visible and invisible, between token and type, *langue* and *parole*. An adapted Hjelmslevian semiotic model of language exemplifies this intermedia dimension of writing.[13]



Word (text)
Content
Form (semantic structure)
Substance (textual content)
Word (image)
Expression
Form (syntax, style)
Substance (physical medium)

Figure 1. Interplay between the substance of the expression (the physical medium, the ink on the parchment) and the form of the content (the semantics of the text, its meaning)

These reflections will allow me to sketch the intermedia borders where I think digital palaeography sits. I will build on an unpublished paper (Ciula, 2006) where I used McCloud's (1994) triangular map of visual iconography to represent the relationships between cultural textual objects and their digital (visual) representations both in graphical and in textual forms.[14]

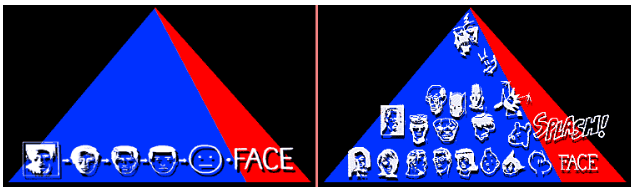


Figure 2: McCloud's Big Triangle or a map of visual iconography (http://archive.is/Vg6OQ)

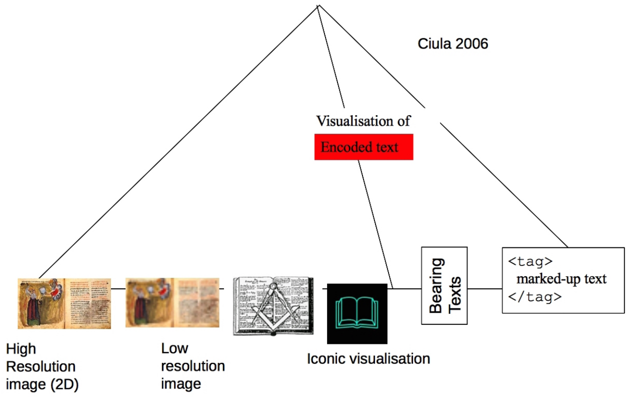

Figure 3. By following the analogy to McCloud's triangle, in Ciula (2006) I showed how the variety of ways of representing a textual object in visual terms can assume both the form of more or less resemblant representations—images of the physical object bearing the handwriting—or their textual counterparts

The visualisation of encoding is an example of structure-oriented visualisation which shows how a graphic rendering of the text does not have to relate unequivocally to features of the textual object as expression (whether form or substance of the expression) but can rather represent one or more supposed structures of the textual content. When made explicit and visible, the structure of the content on the textual-symbolic side can play a fundamental role in the implementation of a thoughtful connection between the image-iconic representation/s of the text and the textual-symbolic content representation/s of a cultural object.[15]

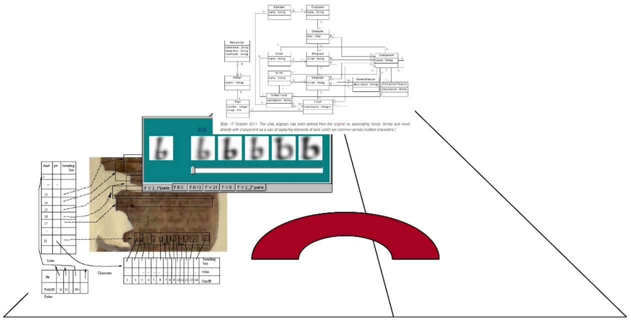

Figure 4. Digital paleographic methods as enhancers of iconic representations of textual artefacts

Following this analysis, digital paleographic methods (inclusive of image processing, image annotation and conceptual models blending morphology and semantics) will be theorised as enhancers of iconic representations of textual artefacts. They can bridge the sensorial/perceptive and structural/conceptual interpretations of handwriting, material and mental knowledge of text, visual and textual, spatial and temporal.

In my 2006 paper, I concluded that for a digital resource to be inspired by and to promote research based on the material/perceptual aspects of a cultural object, a high quality graphical representation of the cultural object is essential but not sufficient. In specular terms to what Buzzetti (2006)[16] says about the symbolic components of textual objects, this paper will argue that the scope of digital palaeography lies in anchoring the structure of the expression of image-texts to the structure of their content, in other words in bridging the "semantic model" of a handwritten source to at least some of the material aspects of the artefact.

Conclusions

Digital palaeography builds on the tradition of analytical palaeography. How is it then transformative or is there a digital + palaeography? Some digital palaeography projects and initiatives, including my own doctoral research, claim to be transformative by advocating for "integral" palaeography and by distancing themselves from a purely computational approach. Some also adopt a self-reflective perspective on the modelling of handwriting in a digital environment, for instance, by testing ontological commitments, categories, classifications of handwriting; in so doing they deflate the models they build. Further, when contextualised within an analysis of the border between form and meaning of handwritten sources, digital palaeography approaches can can be used to connect the structure of expression of handwriting with structures of meaning. A digital model which embeds both structure of expression and structure of content of the handwriting is then theorised as a unique contribution to reconstruct material textuality of cultural artefacts by bridging visual and symbolic elements of texts, spatial and temporal, perception and interpretation. Ultimately, digital palaeography can be transformative by bridging the semantics of written artefacts with their materiality.

Notes

[1] A preliminary version of this paper was presented at the international workshop *Digital Paleography. Projects, Prospects, Potentialities* (Università Ca' Foscari, Venice, April 10-11, 2014), by invitation of the organisers, Università Ca' Foscari (Venice) and Digital Humanities Lab (DHLAB), EPFL (Lausanne).

[2] My thanks to Willard McCarty for recommending and providing access to these two references.

[3] On the cultural understanding of digital, calling for a wider semantic spectrum that transcends the opposition with analogue, see for example McCarty (2014a). The **plus** sign is a deliberate borrowing of Cecire's reflections on the "problem of the plus" being addictive rather than transformative (McCarty, 2014b: 292): "it should not be possible to have the "plus" without the two terms—"digital" and "humanities"—themselves changing" (Cecire, 2011).

[4] For a recent discussion on the first occurrence of the term digital humanities and its uptake in the first decade of 2000 see Faulhaber (2015).

[5] My thanks to Peter Stokes for having pointed out to me another sense of digital paleography as attributed by Hirtle (2000), who talks about this new "speciality" as the ability to convert obsolete file formats containing digital information (e.g. HTML, JPEG) into current formats. For an overview on the term see Stokes (forthcoming).

[6] Cf. the 15th century treatises on scriptural typologies e.g. as described in Montecchi (1998: 119).

[7] Modern art has exploited this cultural conflict between reading practices that put emphasis on symbolic aspects of written text as opposite to the morphological and sensorial aspects of other artefacts. See for example the works of *Information as Material* (Dworkin, C. et al., 2012) such as the exhibition *Learn to Read Differently* (Northern Gallery of Contemporary Art, Sunderland, August 10– September 23, 2013).

[8] In addition, various events connected to research in digital palaeography took places towards the end of the first decade of 2000 in Europe; in particular, two dedicated symposia on

Codicology and Palaoegraohy in the Digital Age took place in Munich and resulted in two volumes (Rehbein et al., 2009; Fischer et al., 2011). The ESF workshop also had a follow up in the Dagstuhl Perspectives Workshop on *Computation and Palaeography: Potentials and Limits* held in 2012 (see http://www.dagstuhl.de/en/program/calendar/semhp/?semnr=12382) which resulted in the publications Hassner et al. (2012, 2013).

[9] See for instance the ORIFLAMMS project blog (Stutzmann) where the connection to neurosciences is explicit (this project started in 2012).

[10] For a broader adaptation of Godfrey-Smith's "deflationary view" (2009: 115) as a "deflationary account of modelling practices" in digital humanities see Ciula and Marras (in press).

[11] This is a concern beyond digital palaeography with respect, for instance, to trends in distant reading; see for example Eyers (2013).

[12] A similar point with respect to computational modelling of literary novels was made recently by Piper (2015: 68): "We not only gain insights into the specific subset of texts identified by the model, as the model provides the interpretive horizon through which these texts assume new meanings. But we recursively gain insights into the computational model itself through the detailed analysis of the texts it has identified."

[13] While this model can be applied to handwriting and writing alike, the variety of grades of expressions as demarcated in handwriting are more diverse than, for instance, in printed documents.

[14] An alternative circular graph representing the multidimensionality of text encompassing the whole spectrum from physical medium (substance of the expression) to semantics (form of the content) can be found in Sahle's wheel of text (2006, 2013). See also Pierazzo (2013, 2015: 52) who drew two graphs collocating respectively editorial theories and editorial formats on a continuous axis with respect to their relationship with the materiality of text.

[15] Visualisations of dynamic editions (Buzzetti and Rehbein, 2008) integrating textual expression (form or structure of the expression) and semantic model (form or structure of the content) could also exemplify this connection. A concrete example of a project which is attempting at revealing visually the deep connections between the palaeography of texts (handwriting styles of Scottish charters in this case) with the textual content (the representation of authority) is *Models of Authority* (2014-17).

[16] My translation: "The challenge for the representation in digital form of any kind of information and for its adequately exhaustive and functional preservation is therefore given by the possibility of representing the text as a digital complex object and by the ability to reproduce in functional terms the forms of interaction between the structure of the expression and the structure of the content of textual information." (Buzzetti, 2006: 55)

Introduction

Beyond simple annotation and visualization tools or expensive proprietary software, open access software for accessing and analyzing audio is not widely available for general use by the humanities community. Speech recognition algorithms in projects such as MALACH (Multilingual Access to Large spoken ArCHives) are often not built as Web-accessible interfaces for broader audiences. Analysis and visualization software such as PRAAT, which is used by linguists, and Sonic Visualizer, which is often used by music scholars, are desktop tools that typically allow users to focus on one file at a time, making project-sharing difficult for collaborative research and classroom projects. In bioacoustics, researchers use Raven (from the Cornell Lab of Ornithology) and Avisoft (expensive, proprietary software), which perform well with clean data from a single animal. Most of these tools are either not used in multiple domains or with large collections and none of them do well with noise or with multiple signals. As a result of these factors, humanists have few opportunities to use advanced technologies for analyzing large, messy sound archives. In response to this lack, the School of Information (iSchool) at the University of Texas at Austin (UT) and the Illinois Informatics Institute (I3) at the University of Illinois at Urbana-Champaign (UIUC) are collaborating on the HiPSTAS (High Performance Sound Technologies for Access and Scholarship) project. A primary goal of

HiPSTAS is to develop a research environment that uses machine learning and visualization to automate processes for describing unprocessed spoken word collections of keen interest to humanists.

This paper describes how we have developed, as a result of HiPSTAS, a machine learning system called ARLO (Adaptive Recognition with Layered Optimization) to help deal with the information challenges that scholars encounter in their attempt to do research with unprocessed audio collections.

ARLO (Adaptive Recognition with Layered Optimization) Software

ARLO was developed with UIUC seed funding for avian ecologist David Enstrom (2008) to begin exploring the use of machine learning for data analysis in the fields of animal behavior and ecology. ARLO software was chosen as the software we would develop through HiPSTAS primarily because it extracts basic prosodic features such as pitch, rhythm, and timbre that humanities scholars have called significant for performing analysis with sound collections (Bernstein, 2011; Sherwood, 2006; Tsur, 1992).

Filter Bank Signal Processing and Spectrogram Generation

ARLO analyzes audio by extracting features based on time and frequency information in the form of a spectrogram. The spectrogram is computed using band-pass filters linked with energy detectors. The filter bank approach is similar to using an array of tuning forks, each positioned at a separate frequency, an approach that is thought to best mimic the processes of the human ear (Salthouse and Sarpeshkar). With filter banks, users can optimize the trade-off between time and frequency resolutions in the spectrograms (Rossing, 2001) by choosing a frequency range and 'damping factor' (or damping ratio), a parameter that determines how long the tuning forks 'ring.' By selecting these features, users can optimize their searches for a given sound. For these reasons,

Machine-Learning Examples and the ARLO API (Application Programming Interface)

In ARLO, examples for machine learning are audio events that the user has identified and labeled. Audio events comprise a start and end time such as a two-second clip, as well as an optional minimum and maximum frequency band to isolate the region of interest. Users label the examples of interest (e.g., "applause" or "barking"). Other control parameters such as damping factor are also provided for creating spectrograph data according to optimal resolutions for a given problem. The algorithm described below retrieves the features of the tag according to the user's chosen spectra and framing size (e.g., two frames per second, each 0.5 seconds) from the audio file through the ARLO API.

ARLO Machine-Learning Algorithms: IBL (Instance-Based Learning)

The ARLO IBL algorithm finds matches by taking each known classified example and "sliding" it across new audio files looking for good matches based on a distance metric. The average of the weighted training set classes determines prediction probability. The number of match positions considered per second is adjustable and is set to the spectral sample rate. In addition to simple spectra matching, a user can isolate pitch and volume traces, compute correlations on them, and weight the different feature types when computing the overall match strength. This allows the user to weight spectral information that might correspond to such aspects as pitch or rhythm. In the IBL algorithm, accuracy is measured using a simulation of the leave-one-out cross-validation prediction process described above.

Use Case: Finding Applause in PennSound Poetry Performances

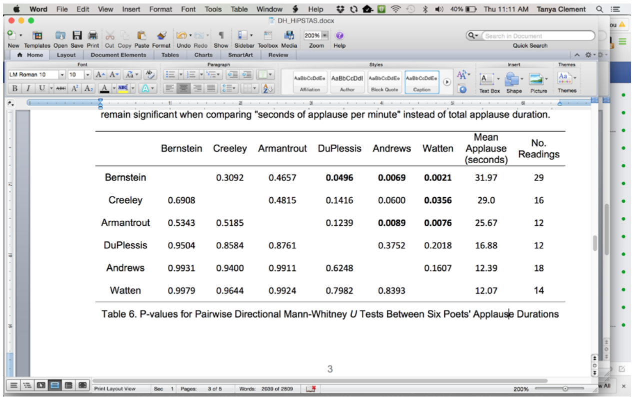
Humanities scholars have identified the sound of applause as a significant signpost for finding patterns of interest in recorded poetry performances. Applause can serve as a delimiter between performances, indicating how a file can be segmented and indexed. Applause can also serve as a delimiter between the introduction to a performance and the moment when a performance has ended and a question-and-answer period has begun, both of which indicate contextual information such as the presence of people who might not appear in traditional metadata fields (Clement and McLaughlin, 2015). A means for quantifying the presence of applause can also lead researchers to consider more in-depth studies concerning the relationship between audience responses and a poet's performance of the same poem at different venues as well as the differing responses of audiences at the same venue over the course of a poet's career or perhaps as a point of comparison between poets. Examples of these results are described below.

For this use case, we ingested approximately 30,257 files remaining (5374.89 hours) from PennSound into ARLO. We chose 2,000 files at random, manually examined them for instances of applause, and chose one instance of applause per recording until we had an example training set of 852 three-second tags, including 582 3-second instances of non-applause (3492 0.5-second examples) and 270 3-second instances of applause (1620 0.5-second examples). Optimization for the IBL test went through 100 iterations. As a result of this optimization process, we used the following parameters for both tests: 0.5-second spectral resolution; 0.5 damping factor; 0.8 weighting power (for IBL); 600 Hz minimum frequency; 5000 Hz maximum frequency; 64 (IBL) and 256 (Weka) spectral bands; spectral sampling rate of 2 (i.e., half-second resolution).

Preliminary Results

We first evaluated our models using cross-validation on the training data. Using the leave-one-out approach, the IBL classifier achieved an overall accuracy of 94.52% with a 0.5 cut-off classification threshold. After comparing 676 configurations, we found that the optimal approach was using IBL with Hann smoothing over 14 windows (7 seconds). The accuracy for this configuration was 99.41%.

In our initial analysis of classification data, we identified significant differences between measured applause durations for six poets, each with more than ten readings in the evaluation set. Table 6 presents the results of pairwise single-tailed Mann-Whitney (Mann and Whitney, 1947) *U* tests of applause durations that have been predicted by our IBL classifier. The alternative hypothesis states that the performer in the left column tends to receive more applause than the corresponding one listed in the top row. Results that are significant at the p<0.05 level appear in bold, with the counts and overall means of each set of observations provided in the right two columns. It appears, for instance, that the poet Rae Armantrout tends to receive more applause than either Bruce Andrews or Barrett Watten. These two differences remain significant when comparing "seconds of applause per minute" instead of total applause duration.



remain significant when comparing "seconds of applause per minute" instead of total applause duration.

	Bernstein	Creeley	Armantrout	DuPlessis	Andrews	Watten	Mean Applause (seconds)	No. Readings
Bernstein		0.3092	0.4657	**0.0496**	**0.0069**	**0.0021**	31.97	29
Creeley	0.6908		0.4815	0.1416	0.0600	**0.0356**	29.0	16
Armantrout	0.5343	0.5185		0.1239	**0.0089**	**0.0076**	25.67	12
DuPlessis	0.9504	0.8584	0.8761		0.3752	0.2018	16.88	12

Table 1. P-values for Pairwise Directional Mann-Whitney *U* Tests Between Six Poets' Applause Durations

Discussion and Future Work

This is preliminary work in an ongoing attempt to create a virtual research environment for analyzing large collections of audio. These data warrant further scrutiny, however, since multiple factors might be skewing the results. First, recording technologies have changed over time and as a result some earlier recordings likely include more noise and thus more false positives. Second, editing practices and event formats can vary widely between venues and over time. Finally, recordings that are included in the PennSound archive represent curation decisions that may favor certain kinds of performers over others. Part of the challenge is to determine what use such analysis might serve for scholars in the humanities and in other fields. Some of the HiPSTAS participants have written about their experiences using ARLO in their research (MacArthur, 2015; Mustazza, 2015; Sherwood, 2015; Rettberg, 2015), but we are interested in feedback from multiple user communities including linguists and scientists who have recorded too much sound data for traditional forms of analysis and processing (Servick, 2014). Furthermore, the IBL algorithm produced promising results, but could be improved with more training data, for example. Or, in extended experiments in which users wish to increase the accuracy of the model, we could develop a voting mechanism on the predictions by comparing the models. Users could validate newly identified examples and include them as new training examples, building each model again on the new data. We are currently working on further testing the models and developing a means for these iterative approaches.

The advent of digital infrastructures for arts and humanities research calls for deeper understanding of how humanists work with digital resources, tools and services as they engage with different aspects of research activity: from capturing, encoding, and publishing scholarly data to analyzing, visualizing, interpreting and communicating data and research argumentation to co-workers and readers. Digitally enabled scholarly work, and the integration of digital content, tools and methods, present not only commonalities but also differences across disciplines, methodological traditions, and communities of researchers. A significant challenge in providing integrated access to disparate digital humanities (DH) resources and, more broadly, in supporting digitally-enabled humanities research, lies in empirically capturing the context of use of digital content, methods and tools. This paper presents recent and ongoing work on the development of NeMO, an ontology of digital methods in the humanities, and its deployment for the development of a knowledge base on scholarly work.

Several attempts have been made to develop a conceptual framework for DH in practice. In 2008, a project funded by the UK's Arts and Humanities Research Council, the AHRC ICT Methods Network, based at King's College, London, developed a taxonomy of digital methods in the arts and humanities. This was the basis for the classification of over 200 digital humanities projects funded by the AHRC in the online resource arts-humanities.net. This taxonomy was subsequently modified by Oxford University as the basis for the classification of digital humanities initiatives at the University (Digital Humanities at Oxford). Other initiatives to build a taxonomy of Digital Humanities include TaDiRAH and DH Commons. From 2011 to 2015 the European Science Foundation funded the Network for Digital Humanities in the Arts and Humanities (NeDiMAH). This Network was established to develop a better understanding of the practice of DH across Europe, and ran over 40 activities structured around key methodological areas in the humanities (digital representations of space and time; visualisation; linked data; creating and using large scale corpora; and creating editions). Through these activities, NeDiMAH gathered a snapshot of the practice of digital humanities in Europe, and the impact of digital methods on research. A key output of NeDiMAH is NeMO: *the NeDiMAH Ontology of Digital Methods in the Arts and Humanities*. This ontology of digital methods in the humanities has been built as a framework for understanding not just the use of digital methods, but also their relationship to digital content and tools. The development of an ontology, rather than a taxonomy, stands in recognition of the complexity of the digital humanities landscape, the interdisciplinarity of the field, and the dependencies that impact the use of digital methods in research.

NeMO was developed by the Digital Curation Unit (DCU), IMIS-Athena Research Centre, in collaboration with NeDiMAH, as a conceptual framework capable of representing scholarly work in the humanities, addressing aspects of intentionality and capturing the diverse associations between research actors and their goals, activities undertaken, methods employed, resources and tools used, and outputs produced, with the aim of obtaining semantically rich structured representations of scholarly work. It is grounded on earlier empirical research through semi-structured interviews with scholars from across Europe, which focused on analysing their research practices and capturing the resulting information requirements for research infrastructures. Its intellectual foundations lie in earlier work of the DCU on conceptualizing and modelling scholarly activity in the arts and humanities, conducted within the Preparing DARIAH,DYAS / DARIAH-GR, and EHRI projects, and manifested in the Scholarly Research Activity Model (SRAM), an ontological representation of scholarly information activity drawing from cultural-historical activity theory and process modelling, and compatible with CIDOC's Conceptual Reference Model (CIDOC CRM, ISO 21127:2006).

Architecturally, NeMO adopts a three layer structure, spanning from abstract/general to concrete/special concepts, to provide a flexible framework suitable to the multidisciplinarity of DH. Its top tier concepts (*Actor, Activity, Object*) provide a general reasoning frame, and function as semantic links to reference ontologies such as CIDOC CRM. These abstract notions are specialized in the second layer by way of domain-specific concepts covering every aspect of scholarly work: *Methods* employed in activities of various degrees of complexity or taught in *Courses*, *Tools* used, *Information Resources* taken as input or produced as output, *Groups/Organizations* or *Persons* participating in various roles, *Goals* addressed, *Topics* covered, etc. Furthermore, in this second layer, several semantic relations capturing the context of the aforementioned core concepts allow for modeling scholarly work through four complementary perspectives: (1) Process-related, centered around the concept of *Activity* and capturing temporal and spatial aspects; (2) Methodological, centered around the *Method* concept and capturing "how" aspects; (3) Agency-related, centered around the *Actor* and *Goal* concepts and capturing "who" and "why" aspects; and (4) Resource-related, centered around the *Information Resource* concept and covering "what" aspects of scholarly work.

In the third layer of NeMO, fine-grained notions supporting domain-specific detailed descriptions are represented as specializations of second layer concepts. Respective vocabularies are organized as SKOS thesauri. More specifically, controlled vocabularies of lexical terms are structured hierarchically under the concepts of *ActivityType, MediaType, InformationResourceType, TopicKeyword, ActorRole, SchoolOfThought* and *Discipline*, which are specializations of the *Type* concept of the second layer, and are used for characterization/classification in parallel to ontological classification. The role of these taxonomies is, thus, twofold: (1) as a vocabulary of terms that can be used for flexible tagging of the objects of interest; (2) as entry points for the alignment, or mapping, of terms from NeMO to terms from other existing taxonomies. The latter enables integration with related work, as well as effective use of these taxonomies as documentation instruments or entry points for content in NeMO knowledge bases. For instance, the *ActivityType* taxonomy is organized in five hierarchies roughly corresponding to Unsworth's "cholarly primitives", and offers a flexible tagging system for modelling the intentionality of actors, scope adherence of activities, or purpose of use of tools and methods. On the other hand, mappings through broader/narrower term relations from the *ActivityType* terms to terms of other method taxonomies, including TaDiRAH, Oxford ICT and DH Commons, allow using those taxonomies transparently within NeMO.

The development of NeMO contributes to the work of the Digital Methods and Practices Observatory Working Group of DARIAH (DiMPO), as well as of Europeana Research within the Europeana Cloud project, providing an intellectual foundation for the analysis of evidence on arts and humanities scholarly activities and needs with regard to digital resource access across Europe. The relevance of the ontology to the DH community was validated through interviews and web surveys, to elicit information needs and patterns in working practices among humanities researchers, as well as two workshops in which these patterns were explored through use cases contributed by researchers. The evidence collected demonstrates that NeMO addresses adequately the knowledge representation needs manifested there. A variety of complex associative queries articulated by researchers in these workshops were also collected, demonstrating the potential of NeMO as an effective mechanism for information extraction and reasoning with regard to the use of digital resources in scholarly work; queries were encoded in SPARQL, a language appropriate for exploiting the serialization of NeMO in RDF Schema (RDFS), thus highlighting the benefits of its potential use as a knowledge base schema.

A prototype implementation of the above functionalities provides an easy to use demonstration of NeMO's potential. Users can articulate queries in structured English, without prior knowledge of any specific query language, using an intuitive user interface offering dynamic feedback of suggestions based on the conceptual schema. Input to the knowledge base is also supported by the same mechanism, guiding the user according to relations and classes provided by the model. A use case will be presented by way of example.

In sum, NeMO offers a well-founded conceptualization of scholarly work, which can function as schema for a knowledge base containing information on scholarly research activity, including goals, actors, methods, tools and resources involved. NeMO can thus be useful to researchers by (a) helping them find information on earlier work relevant for *their own* research; (b) supporting goal-oriented organization of research work; (c) facilitating the discovery of yet uncharted paths with regard to resources, tools and methods suitable for particular contexts; and, (d) promoting networking among researchers with common interests. Additional benefits for research groups include support for better project planning by explicitly representing links between goals, actors, activities, methods, resources and tools, as well as assistance for discovering methodological trends, future directions and promising research ideas. Furthermore, for funding organisations, research councils, etc., NeMO can (a) provide a bird's eye view of funded scholarly activities; (b) enable the systematic documentation of research projects; (c) support evaluation of proposals, monitoring and control of project work, and validation of project outcomes.

Planned improvements include the development of mechanisms for providing recommendations based on semantically related instances and for the semi-automatic population of the knowledge base, as well as specialization of core classes and addition of new terms in Type taxonomies to reflect developments in DH scholarship.

Frequency and Meaning

Hugh Craig
hugh.craig@newcastle.edu.au
University of Newcastle, Australia

1. Introduction

Computational stylistics now has thirty years or so of publications and has been celebrated as one of the success stories of Digital Humanities (McCarty, 2014: 289). It brings together statistical methods and literary analysis, inferring meaning from the frequency of literary features. In this paper I explore this connection between frequency and meaning, and consider some of the objections which have been made to the statistical approach to style.

Much research in linguistics focuses on individual sentence-level structures. Stylistics introduces a new dimension of extension and cumulation, placing a net of continuing co-occurrence over a language sequence. The added dimension of time, or extent, opens up the analysis of meaning not only in the instance itself but in the series that it forms with other instances of the same feature. Computational stylistics takes a routinely quantitative approach to this cumulative aspect.

Critics have laid down significant challenges to this frequentist approach. They have questioned whether language features are really countable, whether frequency matters in meaning, whether the inevitable choice of features to count undermines the objectivity of the results, and whether quantitative results can ever usefully relate the text to any wider context.

2. Are language features countable?

The first key enabling assumption of computational stylistics is that the language features being counted are homogenous. In his 1970s articles attacking stylistics, Stanley Fish argues that meaning is constructed by the reader at the moment of reading and concludes that stylistics is therefore an invalid practice. There is no meaning in the word on the page, so it is pointless to count instances of the word, of combinations of words, or of any other language feature (Fish, 1973; Fish and Graham, 1979). John Frow, likewise, argues that in literary study features are not stable or commensurate but relational, so counting them is pointless (cited in Bennett, 2009: 287).

3. Is frequency meaningful?

Many would also question the relation between frequency and salience. It seems unwise to assume that an unusual accumulation of a feature is necessarily noticed by writer or reader. Fish in a recent online post critiquing digital humanities argues that only patterns intended by the author are worth discussing (Fish, 2012). Different frameworks influence the noticeability of language elements, and a single instance may be highly salient, and a cluster of instances may pass without any conscious reaction.

4. Function words

Considering function words as a basis for counting helps counter these objections. Computational stylistics has a natural alliance with function words. Function words lend themselves to computation since they are easy for a machine to recognise and appear regularly and in large numbers, offering opportunities for analysis by statistical methods whose power is well established in other domains. On the other hand, computation has a special benefit for function words analysis because counting on a scale not possible for the unaided reader makes it possible to reveal hitherto latent patterns in the behaviour of these words.

Function words do not have a semantics in the usual sense: *if* has a structural function rather than a meaning. The stylistic import of the word only becomes clear in repetition. By contrast, lexical words are rich in meaning in the individual instance and do not necessarily achieve any cumulative effect through a series. Function words bear traces of larger structures and hence, though not salient in themselves, their frequencies bear meaning as indexes to wider discourse orientations. They help show how a language feature can be sufficiently homogenous to justify counting, and how frequencies can have a literary dimension.

There are two other important objections to consider: the possible bias arising from the fact that a judgement has to be made about which features to count, and the difficulty of relating patterns found within a corpus to extra-textual factors.

5. Features have to be chosen, so results are arbitrary

Tony Bennett points out that researchers have to choose the units to count in – there are no "given units" – and argues that this choice has a necessary influence on results, which undermines any claims to objectivity (2009: 290, 291).

This is a fundamental critique of quantitative study, i.e. of any quantitative study. The logical extension would be that the choice of units always determines the results, so there can be no surprises and nothing new can be learned. It is easy to show that there are cases where this is not so. If we ask, do women write differently from men? - we have a way of validating the units: if the pattern of use of a given unit shows a significant difference in a balanced and commensurate sets of samples of the writing of women and the writing of men, then it does not matter how the unit was chosen. Here we have an external basis, the difference between two objectively based classes, on which to discard some units and accept others. Then there are cases of classification, e.g. by author and by date. We can seek markers of the classes, check them with known members of the classes, and then apply them to disputed cases. We have an objective way of validating the units, so we don't care much about where they came from.

6. Formalism

Computational stylistics begins with textual features, focuses on finding patterns in their use, provides striking visualisations of the patterns, and then struggles to relate the patterns to extra-literary events. The textual data is well defined, easy to explore, and with the help of statistics it can be shown that there are robust structures within it. The world of possible causation beyond is hard to limit and hard to quantify. If there is (say) a consistent and marked increase in the Shannon Entropy of the language of Victorian novels from early in the period to late, how could that be described in terms of the reading experience? And how could that be related to the forces acting on the novel? Computational stylistics is lop-sided: very well developed on the textual side, but weak - tentative and fragmentary - in relating statistical findings to the extra-textual world. Another way of saying this is to call computational stylistics formalist. In this sort of approach the evidential force of the explanation for a pattern will always be less than that for the pattern itself. However, it is only fair to point out that in this it is in the same situation as other literary methods. A literary effect may be demonstrable, but its genesis in composition, and the larger forces to which it relates, are always matters of judgement and selective contextualisation. The text is available, even if dauntingly complex, but the conditions which made it possible have to be painstakingly and always speculatively recreated. It is easier to show that Hamlet changes in the course of his play than that this observed change relates to Early Modern beliefs about the typical course of melancholia.

7. Conclusion

Computational stylistics has proved itself in the realm of classification. In this area the methods can be thoroughly tested and success or otherwise can be demonstrated. There are some well-established and significant findings, leading to a reassessment of some commonplaces such as the downplaying of authorship as a factor in style (Egan, 2014). This presents a problem for those who think that counting literary features is inherently unsafe, that frequencies in language cannot have any real force, and that all feature choice is fatally arbitrary. Beyond classification, though, these objections still have some force, and a new one intrudes, the argument that computational stylistics is disablingly formalist. Computational stylistics now needs to produce findings in more properly stylistic areas of the same weight as its justly celebrated classification ones, findings which match the style within a corpus to the world beyond it. Only then will we be confident that frequency in literary language is linked to meaning, and that computational stylistics has the methods to do justice to this link.

Introduction

This paper introduces the TEI P5 XML – EpiDoc corpus of inscriptions on stone for ancient Sicily, I.Sicily. The project is one of the first attempts to generate a substantial regional corpus in EpiDoc. The project is confronting a number of challenges that may be of wider interest to the digital epigraphy community, including those of unique identifiers, linked data, museum collections, mapping, and data conversion and integration, and these will be briefly outlined in the paper which will concentrate on the conversion and technical development of the project.

Technical Background of I.Sicily

I.Sicily is an online, open access, digital corpus of the inscriptions on stone from ancient Sicily.[1] The corpus aims to include all texts inscribed on stone, in any language, between approximately the seventh century BC and the seventh century AD. The corpus currently contains records for over 2,500 texts, and when complete is likely to contain c. 4,000. The corpus is built upon a conversion from a legacy dataset of metadata in MS Access to EpiDoc TEI XML. The XML records are held in an eXist database for xQuery access, and additionally indexed for full-text search using SOLR/Lucene. The corpus and related information (museum list, bibliography) are published as Linked Data, and are manipulated through a RESTful API. The records are queried and viewed through a web interface built with AngularJS and jQuery javascript components. Mapping is provided in the browser by the Google Maps API, and ZPR (Zoom, Pan, Rotate) image- viewing is provided by the IIIP image server.

At the time of writing, the main conversion routine is being refined, and the epigraphic texts are being collated for incorporation into the records. An ancillary database of museum collections in Sicily has been constructed and bibliography is held in a Zotero library. Extensive search facilities will be provided, including map-based and bibliographic searching. Individual inscriptions and individual museums will both be provided with URIs, as will personal names and individuals; places will be referenced using Pleiades, epigraphic types, materials, and supports using the EAGLE vocabularies.

The motivations for I.Sicily

The existing epigraphic landscape in Sicily is extremely diverse in two primary regards: on the one hand, the island has a very mixed cultural and linguistic make-up, meaning that the epigraphic material is itself extremely varied, with extensive use throughout antiquity of both Greek and Latin, as well as Oscan, Punic, Sikel, and Hebrew[2]; on the other hand, the publication of this material has a very uneven record and despite an excellent pre-twentieth century tradition, the existing corpora are far from complete and the ability of key journals such as SEG or AE to keep pace with local publication has been limited. A limited number of museum-based corpora have been published in recent decades (for Catania, Palermo, Messina, and Termini Imerese, as well as the material from Lipari), but this has not greatly improved the overall situation. The combination of these two factors already means that locating, identifying, or working with a Sicilian inscription, or its publication record, is extremely challenging for anyone without extensive experience of the material. I.Sicily has been conceived in the hope of improving the situation in all these areas.

Multilingualism

Sicily is traditionally described as a 'melting pot', the 'crossroads of the Mediterranean'. The situation created by basic technologies such as Unicode and TEI P5 EpiDoc XML mean that there is now no reason not to be language agnostic in the inclusion of material. The opportunities and possibilities offered by these technologies are considerable, since, for example, searching can be made language specific or language neutral. One obvious area where Sicilian studies are currently hampered by this disciplinary partitioning is in the study of onomastics. The Lexicon of Greek Personal Names records most instances of Greek names for the island, but Sicily is no less rich in non-Greek names (Latin and others), and at present there is no onomasticon for the island.[3] Simply by the marking-up and indexing of all names in the island's inscriptions, I.Sicily will have generated a powerful tool for future study.

Identification and Bibliography

The PHI database of Greek inscriptions has a rich record of Greek texts, but again is text only and limited in outputs.[4] SEG references are available for 733 inscriptions on stone and AE references for 328 (data taken from the I.Sicily database and based upon comprehensive manual trawls of SEG and AE). One major aim of I.Sicily, therefore, is to generate unique identifiers for each inscription - the I.Sicily number, in the form ISic 1234 maintained as URIs, of the form: http://sicily.classics.ox.ac.uk/isicily/inscriptions/1234. I.Sicily is well placed to do this since its initial dataset is primarily a bibliographic concordance of the lapidary inscriptions of Sicily. One of the associated outputs of the project will therefore be an online bibliography for Sicilian epigraphy, and an online Zotero library has already been created with over 700 records which are referenced in the EpiDoc. A locally cached version of the bibliography will be presented at the I.Sicily site to facilitate detailed bibliographic searching (including the identification of inscriptions by publication) and to allow the generation of customised concordances.

Location, location, location

I.Sicily is actively generating rich geo-data for the individual inscriptions, both for the original findspot/provenance and the current location (whether museum-based, on-site, or elsewhere), and we aim to provide map-based searching for inscriptions, as well as text-based searching by ancient and modern place-names. In addition to full listing wherever possible of both ancient and modern place names for epigraphic provenance, we are working to provide detailed location information for each find-spot and current location, through a combination of library and map-based research and the use of autopsy and GIS recording. At present geo-data is being recorded in two forms, both through the use of explicit geographical locations in the form of longitude and latitude records in decimal degree form, and through the use of Pleiades URI references wherever possible.[5] We are committed to the long-term use of Pleiades as our primary reference for ancient places, and to that end we aim to update and improve the Pleiades data for Sicilian locations, in particular name data and sub-locations, in conjunction with the editing of the I.Sicily records.

Translations

The creation and availability of translations is a major goal of the EAGLE project and its collaborators, and I.Sicily is no less committed to that ambition.[6] Translations are very rarely available for any of the published Sicilian inscriptions. It is obvious that the inclusion of translations will make the material much more accessible to a wider audience both of students and the general public. Equally, provision of translations will add to the value of the database as a resource for museums and others curating the inscriptions recorded in the database. To that end, a long-term ambition of I.Sicily is to include translations wherever possible in both English and Italian. We see this as one obvious area where public contribution ('crowd-sourcing') will be invaluable.

Limitations and future ambitions

The scale of the enterprise, and the available resources, mean that in its current form the project has limited itself to inscriptions engraved on stone (the coverage of rupestral inscriptions/graffiti and of inscriptions painted on stone/plaster is regrettably uneven). However, there is no reason in principle not to extend coverage in future to include inscriptions on other materials. Similarly, although the current project does not include a programme to mark up linguistic features of the texts, the commitment to the long-term maintenance of the corpus and the open availability of the underlying XML records means that such a project would be entirely possible in the future.

It is our long-term ambition that I.Sicily might become the default location for the publication and dissemination of Sicilian inscriptions; in the shorter term, we hope that it will serve as valuable portal in the world of Sicilian epigraphy and of ancient world open linked data, greatly improving the accessibility of Sicilian epigraphy and so enriching the study of the 'crossroads of the Mediterranean'.

Sustainable publishing – Standardization possibilities for Digital Scholarly Edition technology

Alexander Czmiel
czmiel@bbaw.de
Berlin-Brandenburg Academy of Sciences and Humanities, Germany

After decades of building digital resources for humanities research, such as Digital Scholarly Editions (DSE), and making them available to researchers and the broader public, we are at the point where many of these resources can be connected to one another and are more and more accepted by the scholarly community. However, we also experience the challenge to maintain all the various Digital Scholarly Editions which were built on a diverse base of different technologies. This is especially complex as Digital Scholarly Editions are "living" objects. On the one hand that means that the content can be extended and refined continuously. Hence they are never finished. On the other hand the technological basis must be kept accessible, secure and running. Those two processes can be summarized under the term "data curation".

If we assume that a Digital Scholarly Edition not only consists of the marked up texts, mostly XML documents, but also of another layer on top of the XML documents, the functionality layer – all the interactive parts, the visualizations and the different views on the texts, indexes or other research material, such as images or audio documents – it is obvious that data curation can become an unlimited complex task. This functionality layer provides an enormous additional benefit to the texts. A Digital Scholarly Edition can be seen as a tool which is used to analyze the XML documents, thus as part in the research process which must be preserved to reproduce research results which often cannot be achieved without the functionality layer.

A Digital Humanities resource usually undergoes a typical life cycle and is built by a team of team members with a variety of competences that are needed for each task:

1. Analysis of the sources to be edited (humanities scholars)

2. Requirement Engineering (the whole project team)

3. Design of the data or document model, choosing what standards to use (scholars, database-, markup-, metadata-specialists)

4. Choosing, adopting, and/or developing software tools for transcription, editing and publishing (software developers, scholars)

5. Installing and maintaining development servers and web servers (system administrators)

6. Conceptual design and implementation of the web publication of the Digital Scholarly Edition (web designer, web developer, scholars)

7. Preparation for long term access and archiving (documentation- and metadata-specialists)

8. Service support and maintenance after project finished (data curators)

At each step of this life cycle decisions are made which have impact on the subsequent steps. The first two steps of the list constitute the foundation on which the whole Digital Scholarly Edition is built on, from the data model over the choice of software tools until the publication as well as data curation.

Digital Scholarly Editions are sufficiently described from a methodically point of view regarding the document and text modeling (Pierazzo 2015, Sahle 2013). An analytical description from the technological point of view still is a desideratum. To make a comprehensive data curation possible a technological publishing concept which uses standardized components is needed. Such a concept can consist of standards for a formal project documentation, a description of the used technologies, the provided interfaces and APIs, a design paradigm for typical user interaction tasks, and many more. Standards on the data- and metadata-layer are broadly accepted and in use – one example are the Guidelines of the Text Encoding Initiative (TEI – http://www.tei-c.org) – but they are still missing for the functionality layer.

A high standard critical Digital Scholarly Edition can only be built in a sustainable way and be maintained when it follows technological standards which still have to be developed. The paper will present a first tiny step of a proposal for a minimal standard from the technological point of view of a Digital Scholarly Edition. It focuses on experiences made during the last ten years working on XML-based Digital Scholarly Editions built with certain tools, such as eXistdb (http://exist-db.org). Hence the proposed solution cannot be valid for all the different kinds of Digital Humanities scholarly resources.

A possible next step towards such a formal description could be to package those XML-documents together with the source code of the functionality layer in a standardized self-descriptive format. An option for this task could be the EXPath Packaging System (http://expath.org/modules/pkg/), which works well for XML-based Digital Scholarly Editions and is widely used by Digital Scholarly Editions which are published using eXistdb. The main purpose of such a packaging system is not connectivity or interoperability rather than maintenance and data curation. The packaging system can be extended gradually to a technological publishing format which incorporates the aforementioned aspects such as a project description format.

A possible formal project description format for the documentation will consist of the following information:

- The name of the project and all involved institutions and persons.
- The status of the project: planned, work in progress, published, or finished.
- The applied technologies and standards.
- The licenses, which are used for research data, source code and other components such as fonts, audio or video documents.
- Information about where to find the source code, if the source code is available under an open source license.
- Information about provided APIs and other interfaces to retrieve the research data and metadata in various formats (XML, JSON etc.) or get structured information about persons or places to be processed further in other contexts (In case of a correspondence edition metadata about the letters should be prepared in the Correspondence Metadata Interchange Format (CMIF) to be reused by http://correspsearch.bbaw.de).
- Contextual details about the data producers, how data are collected etc. (More at Faniel 2015)
- Canonical citation rules and instructions for persistent referencing of current parts and older versions of the research data.
- A standardized change log, which can be evaluated by other services.

Of course this list can be just a first suggestion and does not provide all the information that can be given about a project. The project description must be accessible under a standardized URL (e.g. http://home.of.project/api/projectdescription) and can be serialized in different formats, such as XML or JSON, for further processing. That would allow a Digital Scholarly Edition to be registered at a central directory where all information and updates of various Digital Scholarly Editions which follow the same publishing model are collected automatically. Such a central directory does not exist yet. Currently existing directories collect information manually and describe projects externally, so changes and updates are harder to track.

The success of such a publishing model depends on pragmatic usage possibilities and a critical mass of Digital Humanities scholars and projects who publish their Digital Scholarly Edition using this publishing model. It is difficult to find a standardized, generic approach in the world of Digital Scholarly Editions as every project encounters a different set of problems and a different set of uses. Thus it is important as developers to not make too many assumptions about the nature of a project and further the development of a technological publishing standard in continuous exchange with the scholarly community and in very small steps which take into account the diversity across the Humanities.

The digitization of large databases of works of arts photographs opens new avenue for research in Art History. For instance, collecting and analyzing painting representations beyond the relatively small number of commonly accessible works was previously extremely challenging. In the coming years, researchers are likely to have an easier access not only to representations of paintings from museums archives but also from private collections, fine arts auction houses, art historian photo collections, etc. However, the access to large online databases is in itself not sufficient. There is a need for efficient search engines, capable of searching painting representations not only on the basis of textual metadata but also directly through visual queries. In this paper we explore how convolutional neural network descriptors can be used in combination with algebraic queries to express powerful search queries in the context of Art History research.

Context and Method

This project is part of project called *Replica*, conducted in collaboration with the Cini Foundation in Venice. This project is based on two parallel developments, the digitization of the Cini Foundation's photo library, a collection of about a million photographs of paintings, engravings, plastic arts and architecture (1300 - 1900) and the creation of a dedicated search engine allowing for searches for visual patterns in this database. As the digitization is currently ongoing, the results reported in this paper are performed on a subset of only 39 000 paintings. However, the progressive densification of the database, including a large set of so-called minor painters, should, in the coming months, unfold the full discovery potential of this search engine.

The field of visual pattern recognition has been recently transformed by the surprising performances of so-called deep learning approaches using Convolutional Neural Networks (CNN). CNN are multi-layers architectures used for supervised learning, especially for object classification. Each layer is representing an operation on the previous layer: convolution layer, fully-connected layer, pooling layer, regularization layer, etc. These networks have many parameters (filter parameters, fully-connected weights) that can be learned via backpropagation in a supervised manner. Traditionally, the input (first) layer is a full raster image and the output (last) layer is a vector representing the score of the input image for each class. By showing the network some labeled images and comparing the network's output to the desired label, one can update the parameters of the model.

The theory of deep neural methods have been known for decades, and were already successfully applied with the first convolutional neural networks in the 90s to digit recognition (LeCun et al., 1989). However, their computational complexity and the necessity of important amount of training data have seen them being ignored for a long time. With very large datasets available like *ImageNet*, and GPU computation being more accessible, there has been a sudden surge of interest in deep methods (Deng et al., 2009).

In 2012, a convolutional neural network shattered the competition in a difficult 1000 class object recognition challenge, attaining the impressive result of a top–5 error of 15.3% compared to 26.3% for the runner-up (Krizhevsky et al., 2012). Ultimately, this work had an important impact on the machine vision community starting the so-called deep learning revolution. A clear manifestation of this trend was that just a year later at the next iteration of this object recognition challenge, almost every entry was based on CNNs as well.

Despite being trained to recognize a precise set of classes. It has been observed that some of the learned parameters of the CNNs will most likely be similar across different datasets. For instance, the first convolutional layer usually learns various edge detectors and basic filters. Some researchers have evaluated the representative power of CNN trained for a specific task to other problems. Using a model that outperformed the others in 2012 on the *ImageNet* data, results seemed extremely promising, suggesting that task transfer is possible (Donahe et al., 2014).

To calculate the descriptors of our search engine, we use a pre-trained Convolutional Neural Networks similar to the one described in (Donahe et al., 2014). Each painting of our database is associated with 1000 features, corresponding to the last convolutional layer of the pre-trained Convolutional Neural Network. These features are thought to represent high-level characteristics directly usable for the classification tasks. Through this process each painting is associated with a single point in a high dimensional space. When a single image query is sent to the search engine, the results are simply shown, ranked by their distance to the query.

However, similarity between paintings could not be the results of single homogenous distance. To enable the users to specify the kind of similarity they want to explore, a more refined language has been introduced. Searches take the form of *algebraic formulas* in which the user can add or subtract examples. For performing such searches, we use a binary support vector machine (kernel Radial Basis Function). In the cases where no negative examples are provided, a one-class-support vector machine is used (in the case of a query with a single image, this corresponds to a simple nearest neighbor algorithm). The rest of the paper shows examples of such algebraic queries and the corresponding results.

Examples of queries and results

The classic principles for classifying visual similarities in Art History include various dimensions like recurrence of particular pictorial patterns or common compositional structures. As a query illustration, the first criteria of classification chosen is the search for common 'dominant and multiple pictorial motif' in the composition. One classic example in this typology is the *Still life*, featuring for instance only a large bouquet of flowers. The development of this subject has a long history, from the late sixteenth century, before arriving at its codification during the seventeenth-century. The results of a query with Juan de Arellano's *Still life of flowers* (Fig. 1) include other famous interpreters of the genre, almost identical in composition and also close in terms of chronological and pictorial influences: de la Corte, Snyders, Casteels. However, there are also seventeenth-century painters, Gentileschi, Régnier, Bonito, Vouet, who, while not painting Still lifes, are characterized by the same tonality of *chiaroscuro* typical of this precise moment in history of art. Without further information the similarities found by a single image query include various families of resemblances combining pictorial patterns and color tones.

Birth of the Virgin, *VOUET, Simon*
id : 37070, score : -0.28

Figure 1 : A query of a Still Life of Flowers by Juan de Arellano returns several paintings with flowers but also other subjects

To focus only on the pictorial motif of flowers excluding any paintings with figures, we subtract one of the paintings by Gentileschi to the initial query (Fig. 2). We obtain all the 'key painters' in this genre including for instance Daniel Seghers. He does not paint a real Still life but flowers around a sacred figure, the Virgin, one of the first subjects, probably invented by Jan Brueghel the Elder. It is probably from this initial subject that evolves the *Still Lifes with flowers*. So, in this case, the algebraic query recovered the evolution of a specific pictorial motif with its significant variations during the Seventeenth century.

Figure 2 : By subtracting to the flower painting the Finding of Moses by Orazio Gentileschi, only painting featuring flower are returned

Another criteria of classification in Art History are structural analogies between compositions (Gombrich, 1960). Structure of the composition is understood here in a geometrical sense, with the reoccurrence of similar geometrical patterns in various paintings. The formal analysis of paintings have classically focused on such kinds of structural similarity (Focillon 1964; Didi-Huberman 1996).

The *The Gallery of Archduke Leopold* painted by David Teniers the younger, in 1639, is also known to have four different variants. This painting is considered a reference of a long tradition of paintings subjects featuring cabinet of art lovers and collectors, a well studied genre (Findlen 1996; van der Veen 1993). A single query returns variations of the same painting (Staatsgalerie Schleissheim, Münich; Prado, Madrid; Kunsthistorisches Museum, Wien), but also painting featuring squares within squares (Fig. 3). For instance on *The Ambassadors depart by Vittore Carpaccio and Baptism of St Libertus by Colijn de Coter,* squares are on the floor or on the wall. To refine further our search and find the "good neighborliness" (Warnke 2000; Freedberg 1989) of David Teniers structure, we can try to exclude these two examples by subtracting them to the initial query. Results of such a query exclude now interior scenes featuring geometrical squares but now include various scenes of the *Passion of the Christ* organized as sequences of "squares", non featuring any elements in perspective (Fig. 4). In a third attempt, we can now exclude those by substracting them to the initial query and reinforce the focus on search by adding variant of the first painting by Teniers. Indeed, all the first results feature now paintings with galleries of collectors with examples of the most important authors of the genre, thus facilitating the study of their mutual influence (Fig. 5).

Perspectives

Pattern recognition methods have made extremely impressive progresses in the recent years, thanks to the advances of convolutional neural network and the advent of very large databases of images. As Art History deals with the study of the migration of patterns, this is surely a great opportunity for designing new tools to search through large databases of paintings photographs. This paper is a first examination of the typologies of search use cases that could be envisioned combining convolutional neural network features and simple algebraic formulas. This initial study illustrates that this new way of expressing queries allows for the incremental definition of various kinds of "similarities" between paintings. Convolutional neural networks features manage to capture many dimensions of similarity between paintings, including composition, colors and also common iconographic elements. Combined with a simple language for expressing the specificity of the traits that the user looks for, it could enable new powerful search tools that may in turn have important impact on history of art studies.

Urban Youth and Community Media: A Digital Place-Making Process in Vanuatu

Thomas Dick
tom.dick@scu.edu.au
Further Arts, Vanuatu

Sarah Doyle
info@furtherarts.org
Further Arts, Vanuatu

In this paper, we focus on media (and multimedia) production as a spatial practice of ni-Vanuatu youth. We explore the contexts and practices of youth media production in a contemporary postcolonial urban society and how organizational forces shape these practices. Articulation theory is used as a framework for thinking about the way that young urban ni-Vanuatu are negotiating community, institutional, and professional obligations as well as leveraging opportunities for producing media that demonstrate new modes of relating to place. The authors draw on long term coactivity and co-performance (Conquergood and Johnson, 93) via participant engagement with artists and producers from Vanuatu. Both authors have lived and worked in Vanuatu for over five years and much of our engagement with the young producers is through our roles with Further Arts – an NGO based in Port Vila. We employ a radical empiricism that blurs the boundaries between observer and observed – a form of dialogic performance that embraces and complicates diversity, difference, and pluralism (Conquergood and Johnson, 93). Madison describes it as living in "embodied engagement of radical empiricism, to honor the aural/oral sounds that incorporate rather than gaze over" (168, emphasis in original). A range of visual media productions is analyzed, principally video productions. We also draw on interviews conducted with members of Nesar Studio – a community access media production studio located at Further Arts – who constitute an emergent social category in Vanuatu, that is: young independent media producers or the 'youth media crew'.

The contemporary inflections of the precolonial ni-Vanuatu relationship to place reveal contingent openings for indigenous people to transform their world through ontologically liberating participation in media production (and consumption). From another perspective, multinational companies in the resource extraction (mining, forestry, fishing), agriculture, tourism, and creative industries, operate in ways that diminish Oceanic ontologies and subjectivities through processes that undermine local agency, knowledge, wisdom, value systems and biocultural diversity. But a dualistic framing such as this reinforces tired false binaries. It sets us a dangerous path to navigate through essentialism, exceptionalism and reductionism that, even if successfully negotiated ultimately leads to intellectual dead ends. There needs to be another way of understanding the: dynamic trajectories of visiting and returning, assembling and reassembling; the pluralism of Oceanian actuality, beyond the static divisions of rural villages and urban towns. In this paper we extend Clifford's reading of Hall's articulation theory (Hall; in Grossberg "On Postmodernism and Articulation: An Interview with Stuart Hall"), and demonstrate ways that "the partial entanglements of indigenous and local societies in global structures are not simply the world system's unfinished business. They have their own roots and trajectories." (Clifford, 475). We explore these roots and trajectories through – "a praxis of spatial articulation" (Tawa, 49). Dick has documented elsewhere forms of ni-Vanuatu cultural production and expression that reflect a chorographic engagement with place (Tawa; Olwig; Maxwell; Dick).

In this paper, we extend these ideas exploring the performative inflections of media production in a praxis of youth participation and spatial articulation. We will make visible the roots and trajectories of ni-Vanuatu youth and "the forces (the articulations) that create and maintain identities that have real concrete effects" (Slack, 126). Recognizing the joining and the un-joining, the assembling and the reassembling, the creating and the recreating, the articulating and re-articulating, imbues this approach with its efficacy (Slack; Clifford) and interdisciplinary approaches can converge to refine the way that we understand the contemporary media world (Horst, Hjorth and Tacchi).

The paper begins with a description of the major historical and cultural forces and tensions that influence the locative identities of people in urban Vanuatu, integrated with a contextualization – a re-articulation – of the Vanuatu mediascape from the perspective of young urban ni-Vanuatu producers. We explore the specific case study of the establishment of Nesar Studio and how this studio is facilitating the emergence of young independent (and interdependent) producers, or the 'youth media crew' (henceforth YMC), as differentiated from the category of media consumers. The dissolution of observer and observed in the project, that is, our embedded-ness in the data, creates an opportunity for a deeply integrative analysis of contemporary indigenous engagements with media and place and multilateral strategies of articulation and de-articulation. Working in this radically empiricist way, it is often difficult to balance the requirements of the academy and the expectations of the community; it is difficult to "shape the data", as it were, when one is both in and part of the data (Grossberg We Gotta Get out of This Place: Popular Conservatism and Postmodern Culture 55-56). Thus we have integrated discussion and analysis into the presentation of data to which it directly relates.

Despite major challenges, the young producers at Nesar Studio assert the importance, and indeed their ownership, of the structure and its organizational relationships – in particular with FA. This is evidenced in the extent to which they worked to maintain their momentum after massive damage from Cyclone Pam. 'Nesar' means 'nasara' in a local language – nasara is the Bislama term used throughout Vanuatu to talk about the ceremonial meeting place of a village for the intergenerational transmission of kastom knowledge and wisdom (through song, dance, art and other practices) is transmitted. Taking on this word and its connotations, Nesar Studio becomes a digital urban nasara in an age of increased use and access to telecommunications and media platforms as ways to transmit messages and knowledge. Providing the community with education on these tools is a powerful means to enact change through engaging people with their rights.

Developing the capacity of young media professionals in Vanuatu is not a simple process. Stakeholders must navigate divergent interests and compete for resources within an environment where the digital media and creative industries are poorly understood by state mechanisms and supported in an ad-hoc fashion by development partners at both national and regional levels. The bodies that do exist to advocate for and stimulate this sector, including the Vanuatu Cultural Centre, Secretariat of the Pacific Community, and the Pacific Arts Association (amongst others) have not been overly influential or consistently effective. This means that the role of shaping and nurturing the capacity of young media professionals rests in the hands of civil society actors, either in cooperation with, or struggling alongside, the dominant media and communications companies.

Functions, processes, and forces historically familiar to ni-Vanuatu communities are deployed in the articulation of youth (id)entities through media production practices in urban settings. Only a small number of the more talented and adept media crew members of Nesar Studio have been able to penetrate the industry in an independent and professional capacity, acquiring employment in other cultural and media agencies or as contractors for national and international organizations. While these opportunities are few and far between, they require a certain level of application and assertiveness on the part of the media producer, something that Nesar Studio aspires to for its members, but perhaps does not emphasise enough since its media work is based foremost on the principles of collaboration and teamwork. Achieving this requirement for astuteness is furthermore hindered by social and cultural factors in Vanuatu that implies doing things communally and for the common good rather than outshining others for personal benefit.

Sequentiality in Genetic Digital Scholarly Editions. Models for Encoding the Dynamics of the Writing Process

Wout Dillen
wout.dillen@uantwerpen.be
University of Antwerp, Belgium

When TEI P5 version 2.0 was published in 2011, scholarly editors who are interested in the writing process of literary works gained an important instrument for encoding their genetic Digital Scholarly Editions in TEI-conformant XML. After a long process of deliberation, this version of the TEI's encoding schema incorporated a large number of modifications proposed by the TEI MS SIG's Workgroup on Genetic Editions that aimed to re-evaluate the existing TEI tagset in order to facilitate the encoding of genetic phenomena (TEI Consortium, 2011). The Workgroup's 'Encoding Model for Genetic Editions' (2010) reveals two major points of interest in this proposal: (1) the need for the ability to encode features of the document rather than those of the text; and (2) the need for the ability to encode time, sequentiality and writing stages in those documents' transcriptions.

The main answer to the first point of interest was the introduction of the <sourceDoc> element (as well as its <surface> children), that was allowed to exist on the same hierarchical level as the <teiHeader>, <facsimile>, and <text> elements. Since the Text Encoding Initiative has (as its name implies) historically favoured 'text' over 'document', this can be regarded as a powerful statement to the TEI community that documents are as valuable as texts in textual scholarship, and that it should be possible to transcribe them as such. As a result, this encoding model has been gratefully adopted by editors who are taking a more document-oriented approach to the transcription of their materials – like those of the *Shelley Godwin Archive* (*S-GA*) for instance (Shelley, 2013). The question remains, however, whether the use of this vocabulary is enough to classify a Digital Scholarly Edition as a 'genetic' edition. While the document will take up a central position in any genetic edition, the use of the 'Genetic Editions' document-oriented transcription model is not a distinctive feature of the genetic edition in itself.

The Workgroup's second point of interest (the encoding of 'time') is much more central to genetic criticism. In 'The Open Space of the Draft Page', Daniel Ferrer makes a compelling argument that 'the draft is not a text […], it is a protocol for making a text', comparing it to a musical score that, though by itself inherently mute, can be interpreted as a set of instructions for a future performance (1998, 261). Likewise, a draft document leaves the writer with a set of instructions that help her transport the unfinished text from one writing stage to the next. The interpretation of these instructions, and of the distinction between different versions and writing stages, is one of the most important tasks of genetic criticism. This is what makes sequentiality such a key aspect of genetic editing: only by interpreting the draft materials as an interconnected sequence of writing acts can we expose the dynamics of the author's writing process.

There are many ways of encoding this sequentiality in the transcriptions of draft materials, across varying levels of granularity. The Workgroup's suggestion to use the <change> element to highlight distinct revision campaigns, for instance, effectively differentiates between individual versions of the same text when they are found within a single document. As Pierazzo and André's 'Proust Prototype' demonstrates, this method can even be employed to sequence individual stages within a single version (2012). Going even further, projects like the CD-ROM edition of Willem Elsschot's *Achter de Schermen* (2007) and the *Melville Electronic Library's* TextLab software (2009-) analyze what John Bryant has called the internal 'revision sequences' of individual sentences (Bryant, 2008). The danger of analyzing the writing process on this small a level, however, is that the *mechanics* of the writing process may start to interfere with the *dynamics* of that writing process. From a genetic perspective, it is more important to expose the dynamic relation between the textual elements involved in a modification (e.g. 'this is a substitution') than the mechanical order in which that modification was made (e.g. 'first this word was deleted, then this other word was added'). Since the exact writing sequence of such a modification is often impossible to reconstruct with any degree of certainty, consistently analyzing and sequencing all the work's revision sites may introduce a number of hypotheses in the edition that the editor is not necessarily comfortable with committing to.

On the other side of the spectrum, analyzing larger macrogenetic processes across documents, the 'Encoding Model for Genetic Editions' refers to the TEI's 'Graphs, Networks, and Trees' module, suggesting to encode the relations between documents as the <arc>s between <node>s in a <graph> element. Depending on the complexity of the writing process, this <graph> may result in an intricate data structure that can be used to visualize the chronology of the writing process on a highly abstract level. For writing processes that are less complex on the macrogenetic level, however, this model may be too much pain for too little gain, as a manually designed timetable could also do the trick.

The Beckett Digital Manuscript Project's approach to encoding sequentiality into its genetic Digital Scholarly Edition of Samuel Beckett's works tries to seek a middle ground between these two extremes: rather than analyzing the way in which individual sentences were written, the BDMP's encoding model allows the user to discover how those sentences were changed from version to version, across different documents. By linking related semantic clusters on the sentence level across versions, this model allows for the on the fly generation of a chronological overview of all the different versions of each sentence in the corpus. As such, this model combines the ability of comparing different versions of the same work of more macrogenetically oriented approaches with the higher granularity of more microgenetically oriented approaches.

After illustrating the challenges and opportunities of these different models of encoding sequentiality in genetic editions, this paper will demonstrate how the BDMP transcribes its genetic materials in view of visualizing their sequentiality in the edition's 'Synoptic Sentence View' (see 'Figure 1'). The paper will conclude by presenting an example of how this encoding model may also be used to interpret the macrogenetic writing sequence of individual documents by means of an animated visualization of the writing process of the first draft of Beckett's *L'Innommable*.

correspSearch - A Web Service to Connect Diverse Scholarly Editions of Letters

Stefan Dumont
dumont@bbaw.de
Berlin-Brandenburg Academy of Sciences and Humanities, Germany

Letters are an important historical source: First, they may contain comments from contemporaries about the most different events, persons, publications, and issues. Second, letters allow insights about connections and networks between correspondence partners. So, questions occur which can only be answered across the borders of scholarly letter editions due to the fact that these editions are usually focussed on partial correspondences (of a certain person or between two specific persons). But this requires time-consuming searches across various letter editions. This has been a well-known problem for quite some time, now (Bunzel, 2013: 117) and has already evoked work on a few databases dedicated to correspondence, like e.g. "Early Modern Letters Online".[1] But these databases have some limitations: firstly, they focus on specific research questions, time periods, geographic areas, or certain material. Secondly, they don't provide an open, standard-based and well-documented way to provide and update data. Furthermore, the data can be searched and displayed, but only on a simple website. In none of the existing databases dedicated to edited letters it is possible to query and retrieve the data via an Application Programming Interface (API) and under a free license for subsequent use.

The mentioned methodic problem has lead Wolfgang Bunzel, who works in the field of research about the Romanticism, to request:

> 'the creation of a decentralized, preferably open digital platform, based on HTML/XML and operating with minimal TEI standards, which is extensible in different directions and allows for existing web portals and websites to contribute at the lowest possible cost. This doesn't request some kind of super structure which covers the entire amount of letters from the Romantic era (which could not be estimated exactly, anyway) but rather an intelligent linking system, which associates existing documents with one another. The creation of such nexus will naturally lead to research options reaching from searches for persons and places to specific keyword-based searches […]' (Bunzel, 2013: 123)[2]

With "correspSearch" (http://correspSearch.bbaw.de) this paper will present a web service, which takes a step in this direction by aggregating metadata of letters from various (digital or printed) scholarly editions and providing them collectively via open interfaces (Fig. 1). In doing so, it is independent from specific research questions as well as from temporal, geographic, or thematic limits.

The basis of the web service are digital indexes of letters provided by the editions in the "Correspondence Metadata Interchange Format" (CMIF), that has been (and will further be) developed by the Correspondence Special Interest Group of the Text Encoding Initiative (TEI).[3] The CMI format is based on the TEI Guidelines and allows to interchange metadata of letters, postcards etc. between scholarly editions by restricting and normalizing the essential elements of a communication act, namely sender, addressee, dates and places of writing and receiving. Besides the consistent TEI XML encoding, interchange will be enabled by usage of ISO dates and authority controlled identifiers. Sender, addressee, sender's place as well addressee's place are identified unambiguously using authority IDs, as e.g. provided by the Library of Congress.[4] When reading the indexes of letters the web service retrieves the most common authority controlled IDs from the Virtual International Authority File (VIAF). This way, IDs from different authority files are mapped onto one another. Up till now, the web service supports VIAF, GND ("Gemeinsame Normdatei" from the Deutsche Nationalbibliothek) as well as the authority files of the Bibliothèque nationale de France (BNF), the Library of Congress (LC), and the National Diet Library (NDL) in Japan. As for place names the web service uses "GeoNames".

The scholarly editions themselves provide such digital indexes of letters in CMI format, online and under a free license (CC-BY 4.0). For this purpose the CMI format and its creation process is extensively documented on the correspSearch website including a FAQ section.[5] After providing a CMI file online, it is only necessary to register its URL for the web service. After that the file is automatically retrieved by correspSearch periodically (and in that way updated, if necessary).

The aggregated letter indexes are searchable on the correspSearch website by correspondent, location, and date. Correspondent and location can be specified according to their role in the communication process. Search results are displayed based on the metadata of the individual letter, together with biographical details. Letters from digital editions are directly linked.

Apart from the website an API has been implemented which allows for automatic requests to the web service.[6] In this scenario, the results are provided in TEI-XML in the described CMIF under a CC-BY 4.0 license, thus ensuring and facilitating further use and processing of the search results. Furthermore, the web service offers BEACON files as well as an experimental TEI-JSON output.

Thanks to the API it is possible to automatically refer or even link from one digital letter edition to related letters provided by other editions. This function was already implemented in a prototype for the digital scholarly edition "Schleiermacher in Berlin 1808-1834" (Fig. 2).[7] This feature helps researchers avoid methodological problems when interpreting a piece of correspondence: When analyzing a letter they usually consider the preceding and following letters in the correspondence between the sender and addressee, as well. However, their interpretation often does not include the letters which the correspondents send to or receive from *other* persons. With this feature the background of historical correspondences can be easily explored.

Via the API scholars can also exploit the data basis by usage of their own innovative technologies as well as of technologies which the web service itself does not yet support technically. Therefore, with a sufficiently extended data basis and the suitable software it will be possible to perform research on e.g. social or correspondence networks based on correspSearch.[8] Furthermore, the correspSearch API was connected with the web service "XTriples", developed by the Academy of Sciences, Humanities and Literature in Mainz (Germany). Thus the results can be converted into RDF and provided for further analyses with the help of semantic web technologies.[9]

The web service correspSearch and the CMIF are still under development. In the future it should be possible to search also for mentioned persons, events, publications etc. For this purpose the enhancement of the CMI file is currently discussed (Dumont, 2015). Also additional authority files will be supported, e.g. the Getty Thesaurus of Geographic Names.[10]

The web service correspSearch was granted the "Berlin Digital Humanities Award 2015" (First Prize, endowed with 1.200 €).

Introduction

This paper presents first empirical analyses and visualizations of a large corpus of graphic novels – an increasingly popular form of book-length comics aimed at adults – that is currently in the process of being assembled and digitized. We introduce an XML vocabulary and visual editor that we have developed for the annotation of our corpus, and reflect on the challenges presented by a cultural form that is characterized by the complex interaction of text and images. Analyzing the specific narrativity of this and other multimodal cultural forms (including illustrated books and magazines, theater, film, television and computer games), we argue, calls for a combination of quantitative and qualitative methods drawn from such diverse fields as narratology, digital art history, and cognitive science. In contrast to corpus analyses of literary texts, which have made great strides in recent years, comparable work on visual narrative still remains in its infancy and at the periphery of the digital humanities. While this can be traced, in part, to copyright issues, such scholarship also faces a number of crucial technical and methodological hurdles – from image description, classification, and object recognition to the operationalization of narratological concepts. Given the dominance of visual storytelling in modern and contemporary culture, overcoming these hurdles will represent an important contribution to the further development of DH research.

The introduction presents our corpus and the wider research questions of our interdisciplinary group. This is followed by a brief overview over the "Graphic Narrative Markup Language" (GNML), which builds on TEI, and the visual editor developed for the annotation of graphic novels, but which is also applicable to other multimodal forms. A version of this editor will be available as open-acess software by the time of the conference. Part two introduces a number of analyses and visualizations combining the study of text and images that make up graphic novels. The final part moves to the quantitative and qualitative analysis of graphic novels with the help of eye-tracking. This approach allows us to study the construction of storyworlds by empirical readers, and thus opens up an aspect of narrative that remains severely underrepresented in DH, and the humanities at large.

1. GNML-Editor: Tools for (Semi-)Automatic Annotation

Whereas the automatic analysis of text corpora has become feasible in many instances, such automation currently remains a pipe dream for multimodal narratives. In the case of comics and similarly hand-drawn, or otherwise non-perspectival, images, object identification depends on lengthy training efforts and registers a relatively high error rate. Similarly, standard OCR programs fail at recognizing the (quasi) hand writing that dominates comics. As a consequence, our corpus study presently depends on manual and semi-automatic annotation. For this purpose, we have developed the XML-language GNML, which builds on TEI and previous efforts by John Walsh (2012), to describe all textual and visual properties of graphic novels. To minimize errors during the annotation process, our visual GNML-editor supports annotators with integrated spell checking and auto-completion mechanisms. An automatic recognition of panels is complemented by a function that recognizes the borders of individual captions, speech bubbles, and characters to accelerate annotation. Further automations, such as an in-built OCR for narrative text that conforms to standard fonts, are currently under development. As the conceptual basis of the editor (visual objects with graphic and textual characteristics) is not limited to comics but can be applied to other text-image combinations in visual culture (from illustrated manuscripts to film and TV), the editor will be generalized for the annotation of such formats.

2. Quantitative Analyses and Visualizations of Graphic Novels

Part two presents approaches that combine image and text analysis for a number of structural features of graphic novels. Methods developed for digital literary studies, such as topic modeling, are of limited value for the analysis of visual culture given the dominance of images. In contrast, studies of large-scale image sets have so far shown little interest in narrative analysis. To complicate matters further, most narratological concepts are drawn from the study of literary texts, and it remains questionable to what extent they can be successfully applied to visual narrative.

In a first analysis of the corpus, which is still in the process of being digitized and annotated, we look at the historical development of the visual and textual elements of about 150 book covers of graphic novels. This includes a grammatical and semantic analysis of their titles with the help of a statistical language parser, as well as the stylistic and visual attributes of their design and cover images. In a second step, we move to more detailed studies of a first sub-corpus that consists of the ten most-cited titles within our larger set of graphic novels. Such a small sub-set does not allow for genre comparisons or for studying historical developments within the form. However, we can consider the narrative features of representative texts within our corpus. In order to do so, we compare a network analysis of characters with their visual prominence and respective share of text, and complement this with a stylistic analysis of the latter.

3. Eyetracking Analysis of Multimodal Narrative

The experimental observation of eye movements has proven a reliable measure of the human processing of text and images, and allows us to form hypotheses about the construction of storyworlds by empirical readers. The final part of the paper aims to show the value of this method by considering excerpts from a first, explorative corpus of canonical graphic novels. In contrast to theoretical scholarship on comics, which has emphasized the primacy of images (Groensteen, 2009), our experiments demonstrate that readers focus most of their attention on the text. Not only is it usually read first, but many images are either not focused on at all, or analyzed purely in peripheral vision. Whether images are viewed depends, among other variables, on their informational content: if either visual aspects or the storyline continue from one panel to the next, it is much more likely that a panel will be skipped by the reader than if they are distinguished more clearly from its immediate predecessor. We also look at the interaction between visual and textual levels: do reading habits differ if text and images refer to distinct storylines? Finally, we report on experiments that focus on comic reading expertise, for which we propose a new empirical measure. In sharp contrast to the reading of text alone, where experience and reading speed are positively correlated, experienced comics readers focus on the visual aspects of the panels for an extended amount of time. This time appears to be invested wisely, since they are able to better understand the story, as shown by an empirical content test. Taken together, these results suggest that the text and image work together to transmit the narrativity of graphic novels, and that a specific type of expertise is required to understand multimodal narratives. This maps well onto the hypothesis that comics and other forms of sequential art use a particular kind of visual language (McCloud, 1993), which has been analyzed in psycholinguistic terms by Cohn (2013).

4. Summary and Conclusions

We present a new DH project aiming at collecting and analyzing a corpus of graphic literature, enriched by human annotations as well as by a corpus of eye-movement recordings to measure the momentary distribution of readers' attention. First example analyses on both global and local levels demonstrate the potential of this approach. A toolchain for description, annotation, and analysis of these data is being developed, and is of potential use for a wider field of studies in cultural analytics of image-related and multimodal material. In perspective, the corpus will be further enhanced by automated description, using features developed in the field of computer vision (Farabet et al., 2013; Krizhevsky et al., 2012; Rigaud et al., 2015; Serre et al., 2007).

Les sites de rencontres ont acquis depuis plusieurs années une place centrale dans nos pratiques sociales. L'idée de pouvoir utiliser des dispositifs algorithmiques pour rencontrer des personnes n'est plus une nouveauté et n'est pas née avec Internet. Il suffit de penser qu'en France, plusieurs plateformes de rencontres étaient déjà disponibles sur Minitel dans les années 1980. Mais la rapide diffusion des connexions Internet et la naissance du web dans les années 1990 ont rendu possible un développement impressionnant de ce type de service. Match.com a été fondé en 1995 et est probablement aujourd'hui le plus utilisé au monde ; d'autres plateformes comme eHarmony ou OkCupid ou Plenty of Fish sont apparues dans les années suivantes, proposant chacune sa vision de la rencontre amoureuse.

Comment analyser ce phénomène? Comment le comprendre? Plusieurs approches sont possibles et beaucoup a été écrit sur le sujet. La question que nombre de sociologues et psychologues se sont posé est: est-ce possible de trouver l'amour sur Internet? Dans l'introduction du numéro spécial *Sociologies et Société*, Chiara Piazzesi note "la tension entre d'une part l'omniprésence discursive et sémantique de l'amour et d'autre part notre incapacité à savoir de quoi exactement il s'agit" (Piazzesi, 2014).

La question qu'il faut se poser par rapport aux sites de rencontre n'est donc pas tellement s'ils donnent lieu à des "vraies" rencontres, mais plutôt sur quel type de valeurs ils se basent et quelles valeurs ils produisent. En d'autres mots, il faut essayer de comprendre quelle idée de rencontre est proposée par ces services. Nous vivons de plus en plus dans une culture numérique: notre idée d'amitié est forcement conditionnée par la façon de concevoir l'amitié de Facebook, notre idée de pertinence est façonnée par Google, notre rapport à l'espace et au temps structuré par les dispositifs de vidéoconférence, les GPS, etc. Il est certain que notre idée d'amour est ou sera elle-aussi influencée par nos pratiques numériques.

Or les plateforme existantes proposent des types de rencontres très différentes : certaines promettent de trouver rapidement des relations sexuelles (comme AdultFriendFinder, par exemple), d'autres promettent de trouver la personne avec qui se marier (eHarmony). Nous nous concentrons sur les sites qui sont explicitement axés sur l'idée d'amour : ce que ces plateformes visent est de rendre possible une rencontre de laquelle pourra naître une relation amoureuse. Deux exemples pertinents sont Match.com et OkCupid. Concrètement ces sites permettent la création d'un profil et mettent en place un algorithme qui relie les profils entre eux : comme tous les autres algorithmes de recommandation, l'algorithme des sites de rencontre est un ensemble de règles formelles qui permettent l'analyse des données d'un profil pour le mettre en relation avec un autre profil.

La question qu'il semble fondamental de poser est donc quelle conception de l'amour se cache derrière ces règles? Qu'est-ce que l'amour pour une plateforme comme OkCupid? Quelle est l'idée d'amour à partir de laquelle sont pensées les règles formelles qui constituent l'algorithme? Cette question s'accompagne forcement de la question opposée; car si d'une part les algorithmes se basent sur une idée de ce qu'est l'amour, en même temps, dans la pratique, ils ont un effet normatif: en d'autres termes ils produisent eux-mêmes une idée d'amour.

Commençons par une note méthodologique: il est nécessaire de préciser que nous n'avons bien évidemment pas accès au code source de ces algorithmes. L'ensemble du code est propriétaire et il n'est donc pas possible de l'analyser d'un point de vue mathématique ou informatique. On est dans la même situation quand on essaye de comprendre le fonctionnement de PageRank. Nous n'avons accès qu'aux textes avec lesquels les entreprises communiquent sur leur algorithme. Si cette limitation empêche une évaluation objective du fonctionnement des algorithmes, elle ne limite pas tellement le type de questionnement que nous proposons ici : il ne s'agit pas, en effet, de comprendre le réel fonctionnement des algorithmes mais d'analyser leurs bases culturelles, leurs valeurs. La communication publicitaire sur leur fonctionnement est donc déjà un excellent point de départ.

Les algorithmes peuvent facilement donner une réponse à la première: la plateforme va chercher dans les profils de millions de personnes et avec sa capacité de calcul l'algorithme sera capable de trouver la bonne personne, la seule bonne personne, au milieu d'un nombre immense de profils. La rencontre est donc nécessaire : les deux personnes qui se rencontrent ont été sélectionnées dans la totalité – ou presque – des personnes possibles. La puissance de calcul assume en quelque sorte le rôle du destin: grâce à la capacité de regarder dans une énorme masse de données, on sera capable d'aller au delà des aléas qui pourraient empêcher une rencontre. Or dans les faits cette idée n'est pas du tout respectée par la pratique de ces plateforme, car les rencontres proposées sont très ciblées et, par exemple, très axées sur la proximité géographique. Mais la promesse est d'aller chercher dans l'ensemble des profils. Cette promesse permet de ne pas assimiler la nature du service offert à une pure démarche commerciale. Il ne s'agit pas de « vendre » le bon profil, mais d'identifier la bonne personne, la seule avec qui une relation amoureuse sera ensuite possible. Ce type de rhétorique caractérise la quasi-totalité de ces plateformes. Une analyse attentive de ce discours nous fait comprendre que ce que les sites de rencontres essayent de proposer – du moins dans leur discours – est vraiment une relation amoureuse, une *romance*.

Mais la puissance de calcul pourrait être un obstacle à la deuxième idée que nous venons d'évoquer: comment retrouver, dans le cadre d'une rencontre "calculée" par une machine la magie qui devrait caractériser l'amour? Comment ces plateformes peuvent-elles rendre possible le coup de foudre qui caractérise, dans notre imaginaire la relation amoureuse? Deux réponses sont possibles. D'une part on peut constater que plusieurs sites de rencontres essayent de réintroduire un élément de hasard ou de non calculé dans leurs propositions. C'est notamment l'exemple d'OkCupid qui proposa durant une période des "blind dates". L'algorithme met en relation deux personnes de façon aléatoire et propose un rendez-vous sans dévoiler le profil de la personne qu'on va rencontrer.

Mais il y a un autre facteur qui peut relier l'amour calculé à l'amour magique: la complexité du dispositif technologique est très souvent perçue comme magique. Le fait qu'on ne connait pas les algorithmes et que leur fonctionnement est mystérieux pour la plupart des usagers implique une sorte de rapport magique à l'objet technologique. Le fait qu'il y ait un calcul n'enlève donc rien à la possibilité de retrouver un côté de hasard et de magie.

De cette manière, les algorithmes essayent de ne pas mettre en danger l'aspect d'enchantement qui semble devoir caractériser une relation amoureuse. Cela pousse à penser qu'au lieu que transformer l'amour en une marchandise, ces plateformes essayent de récupérer un élément d'authenticité: en d'autres termes on pourrait affirmer que les sites de rencontres ont comme effet de promouvoir même auprès des sceptiques l'idée de la possibilité d'une rencontre amoureuse romantique. L'élément algorithmique se présente comme une sorte de garantie rationnelle de la possibilité de l'amour. Il nous semble que trois conceptions de l'amour influencent la notion qui se cache derrière les sites de rencontres : celle du Moyen-Âge, l'idée romantique et la conception du cinéma hollywoodien. Au Moyen- Âge on peut notamment retrouver le rapport étroit entre amour et vision qui semble être un des piliers de l'amour proposé par les sites de rencontres : on peut tomber amoureux car on peut tout voir. Dans l'amour romantique et surtout dans une réinterprétation *mainstream* hollywoodienne de l'amour romantique, on peut retrouver l'idée de la nécessité de la rencontre et celle de la magie. Une analyse de ces topoï littéraires accompagnée par une étude approfondie des textes qui présentent le fonctionnement des algorithmes pourrait nous aider à mieux cerner la façon qu'ont les sites de rencontres de concevoir l'amour. L'impact du numérique est culturel et les pratiques numériques façonnent nos visions du monde. Comprendre quelle est l'idée d'amour qui s'exprime à travers les algorithmes des sites de rencontres devient donc indispensable pour comprendre quelle est la conception de l'amour dans notre société.

Background

In the last decades, quantitative linguistics (following exact and social sciences) has developed several statistical methods providing an insight into measurable phenomena of natural language. Although to a lesser extent, it also applies to the analysis of diachronic changes. Obviously, the so-called philological method in historical linguistics (unlike historical comparative and internal reconstruction methods) was always a kind of "corpus linguistics", which means that a linguist studying a given period of a language investigated, via close reading, available written records. Consequently, the text was usually treated as a (mistrustful) informant. The implication of this attitude is that in principle, a single attestation of a linguistic fact in a text was considered a strong evidence. Paradoxically, it is synchronic corpus linguistics that changed the overly conservative approaches to diachrony. The most significant here is the shift from purely qualitative to quantitative argumentation. Certainly, the availability of machine-readable corpora allows for much more sophisticated quantitative analysis these days.

A significant drawback of many of the quantitative methods applied so far is a tacit assumption that the researcher knows in advance which elements of the language are subject to change. In other words: the method of, say, plotting and inspecting the trend for a given phenomenon may be applied only to verify hypotheses stipulated earlier by traditional (that is qualitatively oriented) diachronic linguistics. A real challenge, however, is to develop such a method that would allow to trace chronological change in the language without a prior knowledge which linguistic features are responsible for the change. Promising results may be expected using some of the stylometric techniques based on the statistical analysis of style, especially the so-called multidimensional methods. The combination of stylometry and historical linguistics is not an entirely new idea. The problem of automatic recognition of relative chronology of texts was recently addressed by Stamou (2008; 2009), Štajner and Mitkov (2011), Popescu and Strapparava (2013), Štajner and Zampieri (2013), Zampieri et al. (2015). We shall note, however, that the first who sought to solve the question of chronology of texts via their stylistic features was Lutosławski (1897).

Stylometric methods are particularly efficient when applied to frequencies of function words (or, the most frequent words). However, an interesting question arises what if we disregard words and examine grammatical features instead? Obviously, the usage of archaic vs. modern inflected forms alone will differentiate texts written in two distinct (yet still close) periods. What is less obvious, however, is whether processing solely POS-tags, i.e. grammatical labels, can show the dynamics of language change. Note that the sequences of POS-tags are a good approximation of syntax, even if they cannot replace parsing (Hirst and Feiguina, 2007; Wiersma et al., 2011). To scrutinize the above research question, we performed a number of stylometric tests using different (tailored) methods and different combinations of lexical and grammatical features' *n*-grams.

Chronology at a glance

Standard stylometric methods are aimed at tracing differences between (groups of) texts. They proved to be successful in detecting a predominant stylistic signal, which in most cases is the authorial voice. However, when the number of analyzed texts is high enough, the emerging authorial groups (clusters) tend to form larger lumps reflecting the existence of other stylometric signals, such as genre, gender or chronology. This phenomenon can be observed very clearly when bootstrap consensus network – an enhanced version of cluster analysis (Eder, 2015) – is applied.

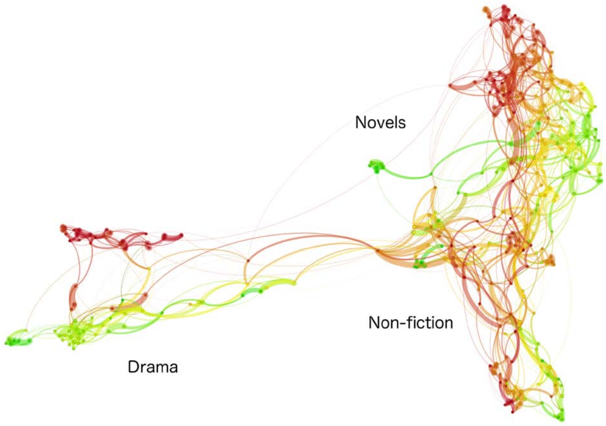

Figure 1: Stylometric network of similarities between 333 English texts

In Fig. 1, a network of an exemplary corpus of 333 English texts (De Smet, 2005) covering the period 1700–1930 is shown. The network was produced using most frequent words as predictors. One can notice a clear split into three distinct areas of the network that is due to a strong genre signal. However, despite the overwhelming division into novels, non-fiction, and drama, an additional chronological signal – represented by a transition from green (the earliest works) to red (the latest works) is fairly noticeable within each of the three sub-groups. Networks for other style markers (word *n*-grams, POS-tag *n*-grams) showed a similar behavior.

Modeling stylistic drifts

Certainly, the general picture revealed by the above network is by no means satisfactory, at least from the perspective of historical linguists. In particular, one would like to know how to pinpoint the observed chronological transition, in terms of identifying interpretable trends and/or breaks. The idea discussed in this section addresses this problem by combining multivariate stylometry with linear regression models.

Multidimensional scaling is a way of compressing (or projecting) a highly complex space into its simpler, usually two-dimensional, representation. Even if such a procedure always involves some loss of information, it is believed to reveal actual differences between samples. Now, since the technique allows to reduce the original space into an arbitrary number of dimensions, one can squeeze the data into just one dimension. This single MDS score can be plotted against the timeline, in order to test if any correlation between the two variables exist. The more diagonal is the shape of the plotted points, the higher the correlation.

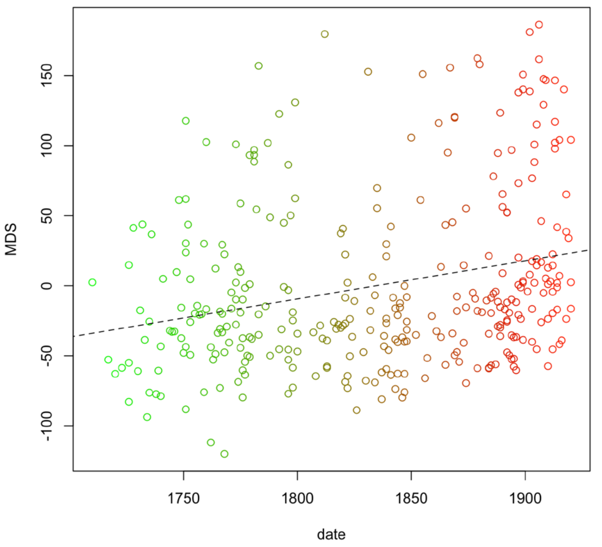

Figure 2: Multidimensional Scaling of 333 English texts (250 most frequent word 3-grams), compressed into one dimension and plotted against the timeline

In Fig. 2, some correlations between the timeline and the MDS values are fairly visible with a naked eye. However, when the results are scrutinized using a standard linear regression model $yi = xi\beta_1 + \beta_0 + \varepsilon$ (where β_1 and β_0 are parameters of the model, and ε is a random effect), their correlations become even more obvious. The estimated model (a dashed line in Fig. 2), is formulized as $\hat{y}_i = 0.272 * d_i - 499.94 + \varepsilon$, where *d*i denotes the *i*-th text's date of publication. In terms of the *p* value, the model is statistically significant ($p < 0.01$); however, the goodness of fit as represented by the adjusted *R*2 value is rather poor (*R*2 = 0.06), due to the overwhelming genre signal hidden in the dataset. When one splits the corpus into three genres and analyzes them separately, however, the explanatory power of the model is far higher.

Supervised classification and the timeline

One of the most interesting aspects of language development – overlooked in a vast majority of the existing studies – is the question of the dynamics of linguistic changes. Presumably, one should expect epochs of substantial stylistic drift followed by periods of stagnation, rather than purely linear trends.

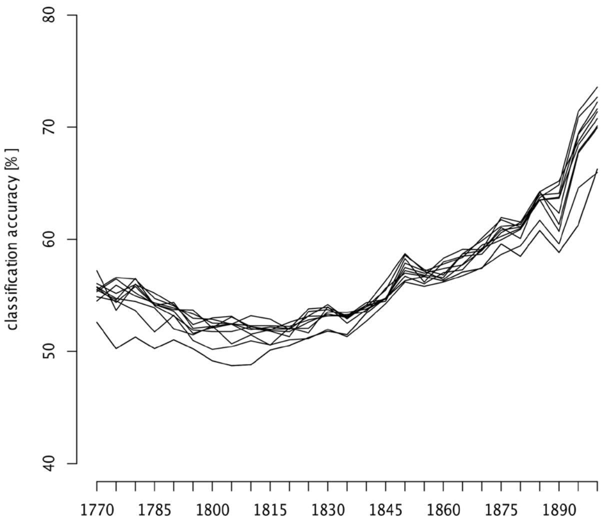

Figure 3: A sequence of Nearest Shrunken Classification tests on 333 English texts: cross-validated results for different vectors of most frequent POS-tag 2-grams

To assess this issue, we apply an iterative procedure of automatic text classification. First, we formulate a working hypothesis that a certain year – be it 1750 – marks a major linguistic break. We divide the text samples into the *ante* and *post* subsets, according to particular texts' publication date. Next, we randomly pick a number of train and test samples representing the both classes (*ante* and *post*), and we train a supervised classifier. We perform a standard classification, and record the cross-validated accuracy rates. Then we dismiss the original hypothesis, in order to test new ones: we iterate over the timeline, testing the years 1755, 1760, 1765, 1770, ... for their discriminating power. The assumption is simple here: any acceleration of linguistic change will be reflected by higher accuracy scores.

In Fig. 3, the classification accuracy rates for the aforementioned corpus of 333 English texts were shown (POS-tag 2-grams, NSC classifier). As one can observe, the scores obtained for the period 1750–1850 are only slightly higher than the baseline, betraying no revolutionary changes in this period. Later, however, the stylistic drift accelerates, reaching 70% of correctly recognized test samples.

Conclusions

in this paper we used a set of tailored stylometric methods to assess the question of language change over time. Our chosen techniques proved to be useful indeed; the further research will focus on tracing the very linguistic features that were responsible for the observed change. However, an important question has to be asked here: is it a change of Saussurean *langue* what we track with our approach, or rather the change of *parole*. Obviously, if texts written earlier can be separated from texts written more recently, they must share some features common for a given stage of language development. However, it is not clear if an observed change is due to, say, literary taste of the epoch or, if we face an actual change in the system here. Theoretically, the former and the latter are possible, as well as both answers together. It is also very likely that the change takes place in between: in the *norm* in the sense proposed by Coseriu (1958). Still there are no means to answer this question with any stylometric method, what for a linguist might be seen as a drawback. However, the proposed method informs the linguist about the fact of change, which takes place not only in lexis but also in syntax; about the speed of change and, above all, about the points where this speed accelerates.

Go Set A Watchman while we Kill the Mockingbird in Cold Blood, with Cats and Other People

Maciej Eder

Jan Rybicki
jkrybicki@gmail.com
Jagiellonian University, Krakow, Poland

Even before Harper Lee's "new" book, *Go Set A Watchman*, was published earlier this year (2015), rumors as to its authorship abounded. Alabama police looked into alleged abuse of Lee's rights; suspicion suddenly (re) surfaced about the strange fact that one of the greatest bestsellers in American history was its author's only completed work; Lee's childhood friendship with Truman Capote (portrayed as Dill in *To Kill A Mockingbird*) and their later association on the occasion of *In Cold Blood* fueled more speculations on the two Southern writers' possible, or even just plausible, collaboration; finally, the role of Tay Hohoff, Lee's editor on her bestseller, was discussed. Desperate media turned to the usual front for stylometry, Matt Jockers, who graciously ceded this opportunity onto us. A story about our early results appeared in *The Wall Street Journal* (Gamerman, 2015), and it echoed even in our native Poland, where the country's major newspaper, *Gazeta Wyborcza*, also devoted a whole page to this international success of Polish stylometry (Makarenko, 2015).

The truth proved to be at once much less sensational than most of the rumors – and much more interesting. Stylometric evidence is very strong in this case: Harper Lee is the author of both *To Kill A Mockingbird* and *Go Set A Watchman*. The first method applied here was part of stylo, a stylometric package (Eder et al., 2013) for R (R Core Team, 2014): series of most-frequent word frequencies in a collection of texts were compared using Burrows's Delta measure of distance (Burrows, 2002); Delta distances were compared for each pair of the texts in this corpus by cluster analysis, and the results of clustering were used to create a bootstrap consensus tree. The resulting Fig. 1 shows the two Harper Lee books as two nearest neighbors just as it does the other authors included for comparison here. More importantly, perhaps, Truman Capote is far away. Most importantly, her editor's only available book, *Cats and Other People*, betrays no similarity to her charge. Since this sort of diagram is oriented at deciphering the strongest signal in word usage, authorship, the various rumors should be finally set at rest – the more so as the two Harper Lee novels have always been each other's nearest neighbors in a whole series of rigorous machine-learning classification tests performed using stylo's "classify" function.

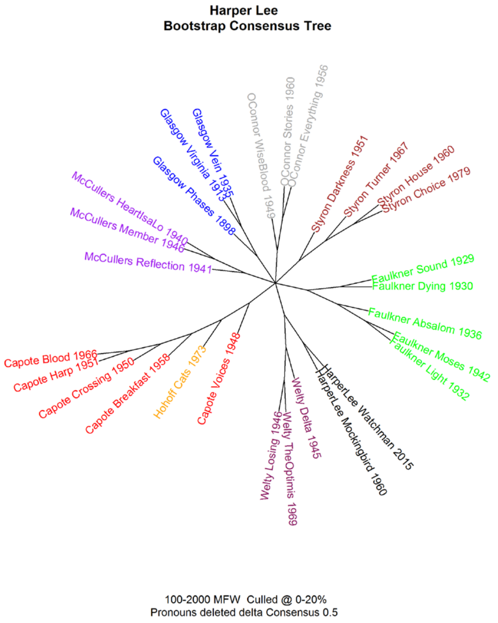

Figure 1: Harper Lee and selected authors of the American South, compared at 100–2000 most frequent words

Lesser affinities between texts are preserved in Fig. 2, which presents a network analysis of the same data treated with an enhanced version of the aforementioned consensus statistical method (Eder, 2015b) and produced with the Force Atlas 2 layout (Jacomy et al., 2014) in Gephi (Bastian et al., 2009). The degree of similarity is shown by the thickness of the curves that connect the particular texts: the thicker the line, the stronger the similarity. Additionally, the algorithm also spatially distributes the nodes (representing each text) to provide an additional visualization effect.

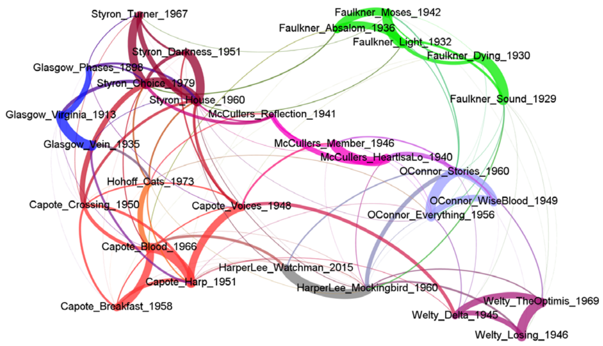

Figure 2: Network analysis of the same collection of novels

It is no surprise that this diagram echoes the previous one as far as the strongest similarities are concerned. Lee is still Lee; now, Faulkner stands almost alone. But then the lesser forces, represented by the slightly narrower connections, also count. The first thing that strikes the eye in the Lee neighborhood is the *Watchman*'s affinity to *In Cold Blood* and a more heterogeneous pattern for the *Mockingbird*: the book researched by Capote with Lee is still linked to her 1960 bestseller, but now only by the minutest of lines. This rephrases the Lee/Capote question in a more interesting way. Is there a drop of Capote in Lee? Perhaps not in the entirety of her work – perhaps just in a passage or two. This should be answered with a modification of the method: since it is difficult to see overlapping stylometric signals in an entire novel, one can see much more when the novel is split into equal and smaller fragments; then, the usual stylometric analysis is applied to the particular slices according to the "rolling. classify" procedure (Eder, 2015a).

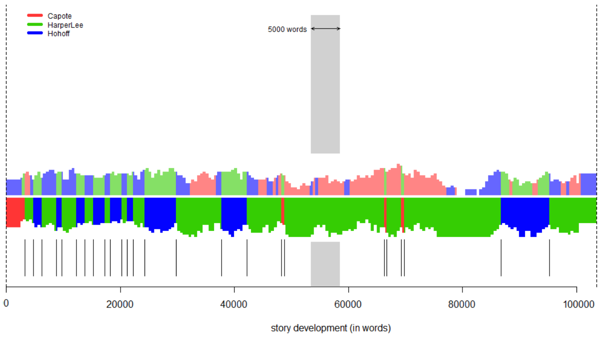

Figure 3: To Kill a Mockingbird contrasted sequentially against Capote's In Cold Blood (red), Hohoff's Cats and Other People (blue) and Lee's Go Set A Watchman (green). The lower band represents the strongest authorial signal; the upper band (in less intense colors) is the second-strongest signal

The most reasonable texts to be thus compared to *To Kill A Mockingbird* are Capote's *In Cold Blood* (since Lee helped with the research for that book), Lee's own *Go Set A Watchman* (to see how much of the *Watchman* might be found in the *Mockingbird*) and Tay Hohoff's *Cats and Other People* (to find out how much of Lee's rewriting of her original proposal might have been influenced by her experienced editor). This is presented in Fig. 3, and the result is quite interesting.

The signal in a little more than a half of the segments in *To Kill A Mockingbird* is that of the novel she originally brought to be published by Lippincott. It is highly significant that its longest stretch coincides with the trial that was only mentioned in the *Watchman* and became the focus of the book in the *Mockingbird*. This seems to suggest that while this refocusing of the book was made following the advice of the editor, the rewriting was indeed done by Harper Lee.

The rest of the *Mockingbird* is a veritable mosaic of her own and her editor's hand. Tay Hohoff's impact seems to be especially visible towards the end of the story, and it coincides with the novel's climax in Chapter 28: Scout, dressed in her elaborate and cumbersome ham costume, is attacked by Bob Ewell, who, following the struggle with Jem and then with Arthur "Boo" Radley, is left with his own knife stuck under his ribs.

We will never know, of course, whether Tay Hohoff really wrote that scene (and the others that seem to bear her mark) for Lee. But it is sensible to argue that while *To Kill A Mockingbird* is obviously a novel by Harper Lee, traces of someone who helped her along the way for two whole years – and who, at one point, talked the author into running down to the street to collect the manuscript that had been flung through the window in frustration (Shields, 2006: 121) – must be there somewhere. The results produced by the different functions of stylo are not in conflict when they show the overall strength of the *Watchman* signal in the *Mockingbird* and the possible echoes of Hohoff (or even, at the very onset of the novel, of Capote) in selected segments. Rather, they seem to provide new insights into the traces of various people involved in the making of a novel – and into how some of these traces may be identified and discerned by stylometry. It is equally sensible to find such traces in a work of a very particular kind: a novel that has been reprocessed almost beyond recognition in a long process of authorial and editorial collaboration; where the final version keeps the setting and the characters of the first, but changes its focus, its historical moment in time and, perhaps more importantly, its ideological message.

Introduction

3D modeling is transforming scholarship and teaching. In 2004, when Taliban militia destroyed the Buddhas of Bamiyan (one, the tallest Buddha in the world), a team of researchers from the Swiss Federal Institute of Technology responded by generating 3D models of these lost Buddhas (Grün et al., 2004). Indeed, 3D and virtual reality (VR) have sparked scholarly interest because VR projects, such as the Buddhas and Rome Reborn (an international effort to generate a virtual surrogate of the ancient city), allow for the modeling of inaccessible or lost historic spaces and objects and the interactive testing of scholarly hypotheses (Dylla et al., 2010).

Now, with advances in digital imaging and replication, 3D models have proliferated. They can be easily downloaded from sites such as SketchFab, Smithsonian X3D, and NASA 3D Resources. Moreover, scholars can publish them in a new journal: *Digital Applications in Archaeology and Cultural Heritage*. However, this proliferation raises questions about best practices for viewing, archiving, and interacting with these complex digital assets. The primary interface for 3D remains the flat, relatively small, computer screen—miniscule when compared to a 53-meter Buddha.

One solution is to provide an immersive experience through VR, enabling viewers to share space with 3D artifacts. Such an interface, however, presents further problems. VR systems tend to follow one of two models: 1. The model of Rome Reborn, in which a virtual system houses one surrogate of a physical space, or 2. A laboratory, such as Stanford University's CAVE system, in which sophisticated and costly VR equipment is employed for research. Can a virtual ecosystem be developed that not only makes uploading, hosting, and viewing VR assets easy but also is cost efficient and yet provides a robust, flexible, and accessible environment to meet divergent needs across a university and beyond?

In this presentation, we will discuss our answers to these questions derived from building a VR ecosystem housed in the library of the University of Oklahoma: the Oklahoma Virtual Academic Laboratory (OVAL). OVAL is a fully functioning VR environment. It is designed to deliver ease in uploading and engaging 3D assets, especially for non-technical users. Through digital immersion, multiple scholars and students simultaneously encounter VR assets, moving through and around and rotating and resizing them. Such engagement represents a paradigmatic shift in the computer interface: scholars and students are no longer limited by a flat monitor and instead share the virtual space with their objects of study.

Furthermore, OVAL encourages enhanced experiential learning (Hermon and Kalisperis, 2011; 60-61). It gives students and scholars opportunities to engage digital materials beyond their normal reach (such as interacting with atomic structures or cultural heritage artifacts). And, when partnered with museums, medical centers and other stakeholders, OVAL makes VR accessible to a wide scope of people, institutions, and industries. Thereby, OVAL offers a new model of accessible VR.

Challenges

Building a VR ecosystem for a whole university poses daunting challenges. For OVAL, the overriding hurdle was cost. To accommodate scholars and students across the disciplines, building multiple, multi-million dollar VR labs was not feasible. Therefore, cost constantly reigned-in decisions but rarely reigned-in performance.

There were also challenges for choosing compatible hardware and software. To keep costs reasonable and minimize spatial requirements, we opted to have users seated while immersed in OVAL, with head, upper body, and hands tracked and imported into the VR environment. This reduces major challenges to selecting a software platform to develop the VR environment, graphics processing unit (GPU), head mounted display (and its software), hand-gesture sensor (and its software), computer, and chair assembly. When full-body sensing hardware and software become available at a reasonable price, we will explore incorporating them into OVAL.

For building the VR environment, perhaps the most important choice is selecting the software platform. Currently, game engines (software platforms for generating 2D and immersive 3D environments) are the best option. To select an appropriate game engine, we established five criteria:

1. Minimally priced or free during development of VR environment

2. Compatible with multiple platforms, including desktop, mobile, and Web

3. Compatible with multiple headsets, such as Oculus Rift, HTC Vive, Google Cardboard, Gear VR, and Microsoft HoloLens

4. Active and robust developer community

5. Extensive online documentation.

Our solution

Our criteria limited our choices to two main video game engines: Unity3D and Unreal. Although, since our initial choice, a number of major companies (Google, Amazon, etc.) have developed game engines, we still champion Unity3D because of its low cost and robust developer community, which attests to its capability and compatibility. Part of Unity3D's appeal is one of our main criteria: strong cross-platform compatible. Currently, it is compatible with 21 different operating systems, including Apple, Windows, Linux, and a variety of mobile devices. Furthermore, Unity3D provides strong online documentation, including tutorials.

For software sub-systems, choices had their complexities, and we will discuss them more fully in the presentation. They included Photon Unity Networking for networking the headsets; Oculus runtime software to support a camera with two "eyes"; and the LeapMotion SDK for hand-tracked interactions. These choices allow OVAL to preserve embodied interaction with hand and upper body tracking (leaning in produces a closer look at an object, and hand movements control features such as scaling and rotating objects) (Shapiro, 2014).

Selecting hardware was less complicated. Available headsets are surprisingly limited. Our only real choice was Oculus Rift. Another headset, the HTC Vive, is set for release soon. Most headsets are developed and sold as part of a complete VR system.

For the chair-assembly, a unique on-campus resource simplified our choice. The University of Oklahoma houses a high-powered physics fabrication lab. We worked with them to develop a custom railed-chair assembly (ergonomically designed for a 360° range of motion). This railed-chair allows the computer to reside under the chair and out of the way. For a robust virtual environment, the computer contains a GeForce GTX 980 graphics card. It delivers a 75-frames/second refresh-rate (the human eye generally resolves 25 frames/second), insuring an instantaneous visual experience when manipulating 3D objects or when turning one's head.

Finally, by integrating networking software into OVAL, a shared VR experience can occur across a range of clients. All changes made on a master workstation—including scale, rotation, lighting, and background imagery—are immediately transmitted to all co-participants, regardless of their physical location. In a classroom environment, for example, this means that students automatically see what the teacher sees. But this also allows OVAL to become a worldwide network. To facilitate such a network, all 3D models are uploaded via a public Dropbox, which immediately syncs with all OVAL clients. This means that all uploaded 3D asset are available to all OVAL clients. For a shared VR experience, each client only needs a short set of instructions concerning file names and how to manipulate them during a session.

Research and teaching

In our presentation, we will also discuss ongoing uses of OVAL at the University of Oklahoma and explore their implications. Despite its recent completion, OVAL has already had extensive use. Undergraduate biology students have analyzed the atomic structure of hemoglobin and oxyhemoglobin. Architecture faculty has analyzed student projects for unseen flaws pertaining to safety and accessibility of interior spaces. The Sam Noble Museum of Natural History has uploaded their recently discovered *Aquilops Americanus* skull into the OVAL system for curators and researchers. Art History faculty has begun analyzing sculpturally significant 3D scans for preserving what was once ephemeral art. A budding partnership with the Medical Imaging Facility has demonstrated how CT-to-OVAL workflows facilitate mammographic research. Finally, Bill Endres has begun to develop guided, immersive tours of the St Chad Gospels, an 8th-century illuminated manuscript.

Conclusion

The rapid production of 3D models makes having VR systems available for their viewing a pressing concern. 3D models of massive structures, such as the large Buddhas of Bamiyan, highlight the limitations of interacting through a computer screen. OVAL provides one cost-efficient solution. In our next phase, we plan to add collaborators and make OVAL available. We are also interested in hosting 3D assets in an archive-quality database. However, the most effective and efficient means of doing these has yet to be determined. We are looking forward to presenting at DH 2016 and conversing about possibilities for OVAL and the wide-ranging opportunities for research and teaching through VR.

The state of the art

Burrows' Delta is one of the most successful algorithms in computational stylistics (Burrows 2002). A series of studies have proven its usefulness (e.g. Hoover 2004, Rybicki & Eder 2011). There are two essential steps in Burrows' Delta. The first is to standardize the relative frequencies of words in a document-term-matrix through a z-score transformation. In the second step, the distances between all texts are calculated. For each word, the difference between the z-score of the word in one and the other text are calculated. The absolute values of the differences are added for all words taken into account. The usual interpretation is that the smaller the sum, the more similar two texts are stylistically, and the more likely it is that they have been written by the same author.

Despite the fact that Burrows' Delta is as simple as it is useful, there is still a lack of a good explanation why the algorithm works so well. Argamon (2002) has shown that the second step in Burrows' Delta is equivalent to taking the Manhattan distance between two points in a multi-dimensional space. He suggests, among other things, using the Euclidean distance instead. An empirical test of his proposals has shown, however, that none of them lead to an improvement in performance (Jannidis et al. 2015).

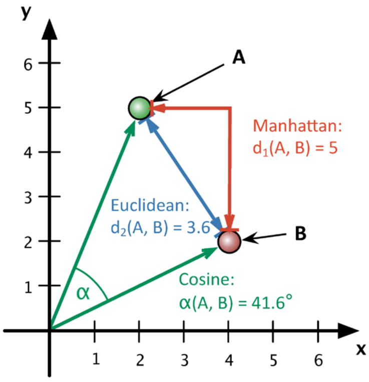

Figure 1: Illustration of the distance between two texts made up of just two words

Smith and Aldrige (2011) have suggested to use the cosine of the angle between the document vectors for the second step, as is customary in Information Retrieval (Baeza-Yates & Ribeiro-Neto 1999:27). The Cosine variant of Delta (Delta *Cos*) outperforms Burrows' Delta (Delta *Bur*) in many different settings and has the advantage of not showing the drop in performance typical ofother Delta variants when large numbers of MFW are used (Jannidis et al. 2015). The question now is why Delta *Cos* is so much better than Delta *Bur* and other variants, that is, in what way Delta *Cos* captures the authorship signal more clearly than other variants of Delta.

Of decisive importance for our further analyses was the insight that using the Cosine Distance is equivalent to a vector normalization in the sense that (in contrast to Manhattan and Euclidean Distance) the length of the vector does not play a role for the calculation of the distance (see figure 1). Previous experiments have shown that an explicit, additional vector normalization also substantially improves performance of the other Delta measures (Evert et al. 2015).

Hypotheses

Having discovered that impact of the normalization effect, we have developed two empirically testable hypotheses:

- (H1) Performance differences are caused by single extreme values, so-called outliers. These are particularly large positive or negative *z-scores* specific to single texts rather than all texts of a single author. As the Euclidean distance should be more sensitive to single extreme values than the Manhattan distance, this hypothesis would explain the comparatively bad performance of Argamon's "Quadratic Delta" Delta *Q*. The positive effect of vector normalization originates from the reduction of outlier amplitudes ("outlier hypothesis").
- (H2) The author specific "style profile" manifests itself more in the qualitative combination of word preferences, i.e. in the pattern of over- and under utilization of vocabulary, rather than in the actual amplitude of *z-scores*. A text distance measure is particularly successful in authorship attribution if emphasizing structural differences of author style profiles without being too much influenced by actual amplitudes ("key-profile hypothesis"). This hypothesis explains directly why vector normalization results in such impressive improvements: it standardizes the amplitudes of author profiles in different texts.

New insights

Corpora

For the experiments in this paper, we use three similarly composed corpora in German, English and French. Each corpus contains 25 different authors with 3 novels each, thus 75 texts in total. The corpora have been described in Jannidis et al. (2015). Due to space issues, the following section will only present our observations on the German corpus. The results for the corpora in both other languages show only small deviations and also support our findings.

Experiments

To further investigate the role of outliers and thus the plausibility of H1, we complement Delta *Bur* and Delta *Q* with additional variants based on the general Minkowski distance (for $p \geq 1$):

$$\Delta_p = \left(\sum_{i=1}^{m} |z_i(D_1) - z_i(D_2)|^{p} \right)^{1/p}$$

We generally name these distance measures L *p*-Delta. The specific case $p = 1$ equals the Manhattan distance (L *1*-Delta = Delta *Bur*), $p = 2$ the Euclidean distance (L *2*-Delta = Delta *Q*). The higher the value for *p*, the larger the influence of single outliers on L *p*-Delta.

Fig. 2 compares four different L *p* distance measures (for p=1, √2, 2, 4) with Delta *Cos*. The method of comparison is the same as in Evert et al. (2015): 75 text are automatically clustered in 25 groups according to Delta distances; clustering quality is estimated with the adjusted rand index (ARI). An ARI of 100% signifies perfect author recognition whereas a value of 0% shows that the clustering is entirely random. The performance of L *p* Delta obviously decreases with increasing *p*. Additionally, the robustness of the measures also decreases with an increasing number of MWF used. As already reported in Jannidis et al. (2015) and Evert et al. (2015), Delta$_{\text{Bur}}$ (L_1) consistently outperforms Argamon's Delta *Q* (L 2). Especially if many features, i.e. a large number of MFW is considered, high p values result in low performance. Delta *Cos* is more robust than other variants and achieves almost perfect attribution success (ARI > 90%) over a wide range of the MFW.

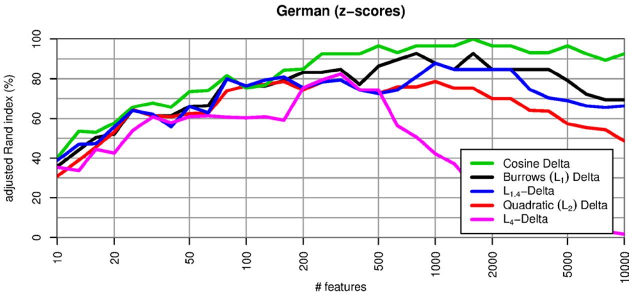

Figure 2: Clustering quality of different Delta measures as a function of the number of the MFW considered

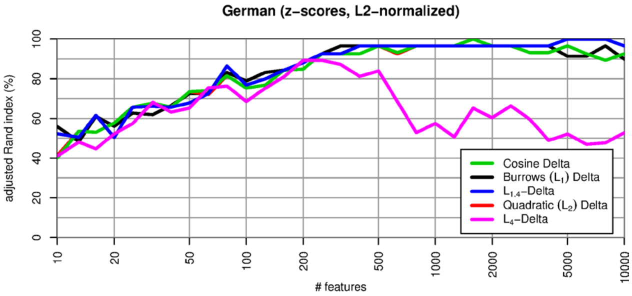

Figure 3: Cluster quality of various Delta measures with length-normalized vectors

Normalizing the feature vectors to length 1 improves the quality of all Delta measures significantly (fig. 3). In this case, Argamon's Delta *Q* is identical to Delta *Cos*: the red line is completely covered by the green one. The other Delta measures (Delta *Bur*, L *1.4*-Delta) now reach about the same quality as Delta *Cos*. Only L *4* Delta, which is especially prone to outliers, falls short considerably. These results seem to support H1.

A different approach to limit the influence of outliers is to truncate extreme *z-scores*. To do so, we set all $|z| > 2$ to +2 or −2, depending on the original *z-scores*'s sign. Fig. 4 shows the effects of various normalizations on the distribution of the feature values. Vector length normalization (lower left) produces only slight changes and practically does not reduce the number of outliers at all. Pruning large *z-score* values only affects words with above-average frequencies (upper right).

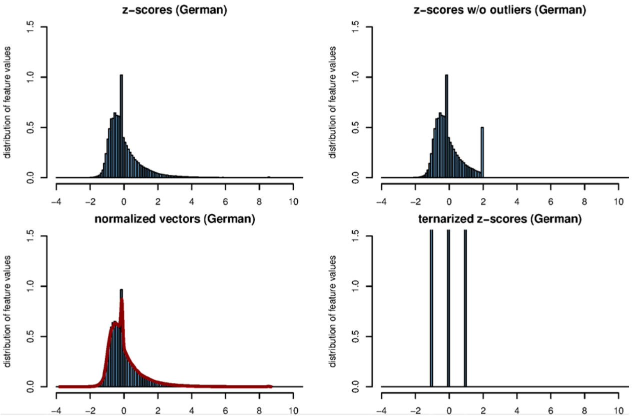

Figure 4: Distributions of feature vectors for all 75 texts, using vectors of 5000 most frequent words. The table shows the distribution of the original *z-scores* (upper left), the distribution after length-normalizing the vectors (lower left), the distribution after clamping outliers with $|z| > 2$ (upper right) and a ternary quantization to the values −1, 0 and +1 (lower right). The red curve in the lower left graph shows the *z-scores* before normalization; the direct comparison shows the normalization has only minimal effect and almost does not reduce outliers. The thresholds for the ternary quantization, $z < -0.43$ (−1), $-0.43 \leq z \leq 0.43$ (0) and $z > 0.43$ (+1), have been selected such that in an ideal normal distribution, a third of all feature values would fall into each of the classes −1, 0, and +1.

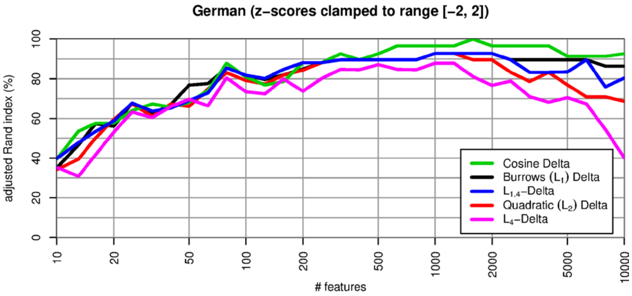

Figure 5: Cluster quality after clamping outliers, i.e. feature values with $|z| > 2$ have been replaced with the fixed values −2 or +2, depending on *z-score*'s sign

As Fig. 5 shows, this manipulation improves the performance of all L *p* Deltas considerably. However, its positive effect is noticeably smaller than that of vector normalization.

With these differing effects of the normalizations on outlier distributions and Delta results, H1 cannot be upheld. H2 is supported by the good results of vector length normalization. However, on its own, it cannot explain why clamping outliers leads to a considerable improvement as well. To examine this hypothesis further, we created pure "key profile" vectors that only discriminate between word frequencies that are above average (+1), unremarkable (0), and below average (−1; cf. Fig. 4, lower right).

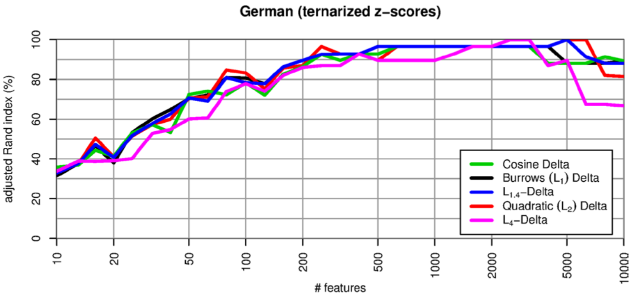

Figure 6: Cluster quality with ternary quantization of the vectors in frequencies that are above average (+1, $z > 0.43$), unremarkable (0, $-0.43 \leq z \leq 0.43$), and below average ($z < -0.43$)

Fig. 6 shows that these key profile vectors perform remarkably well, almost on par with vector normalization. Even the especially outlier-prone L *4* Delta reaches a quite robust clustering quality of more than 90%. We interpret this observation as giving considerable support to hypothesis H2.

Discussion and perspectives

H1, the outlier hypothesis, has been disproven as the vector normalisation hardly reduces the number of extreme values and the quality of all L *p* measures is still considerably improved. On the other hand, H2, the key profile hypothesis, has been confirmed. The ternary quantification of the vectors shows clearly that it is not the extent of deviation resp. the size of the amplitude, but the profile of deviation across the MFW which is important. Remarkably, the measures behave differently if more than 2000 MFW are used. Almost all variant show a decline for a very large number of features, but they differ in when this decline starts. We suppose that the vocabulary in those parts is less specific for an author than for topics and content. Clarifying such questions will require further experiments.

University of Basel, Switzerland

Das Forschungsprojekt “Digitale Materialität” des Schweizerischen Nationalfonds ist eine Kooperation des Digital Humanities Labs und des Kunsthistorischen Seminars der Universität Basel. Ziel dieses Projektes ist es, Verfahren zur digitalen Reproduktion von Kunstwerken zu entwickeln sowie bereits bestehende Methoden zu optimieren, um sie in der kunsthistorischen Forschung besser einsetzen zu können.

Ein Themenbereich, in dem diese Vorgehensweise erprobt wird, sind frühe experimentelle Druckgrafiken, die im 15. Jahrhundert entstanden sind. Sie sind Teil der Medienrevolution, die der Erfindung des Buchdrucks folgt. Anders als konventionelle Graphiken nutzen die experimentellen Drucktechniken Farb- und Reliefeffekte, um attraktiver und wertvoller zu wirken. Beides sind Oberflächeneigenschaften die sich nur schwer fotografisch aufnehmen lassen.

Zu diesen graphischen Experimenten gehören die sogenannten Teigdrucke (Mabbott, 1932; Bowman, 1985; Bertalan, 1993; Scheld, 2009). Sie bestehen aus mehreren übereinanderliegenden Schichten. Ein Papieruntergrund ist mit einer verformbaren Substanz bedeckt. Sie wurde mit einer dünnen Metallfolie überzogen, um den Eindruck zu erwecken, als sei Gold verwendet worden. In diesen mehrschichtigen "Teig" wurde eine Metallplatte gepresst, in die man zuvor das abzubildende Motiv graviert hatte. Die Oberfläche der Platte wurde für den Druckprozess mit schwarzer Farbe bedeckt. Dieses Schwarz übertrug sich beim Drucken auf den golden schimmernden Untergrund.

Solche Drucke sind sehr selten, ausgesprochen fragil und deshalb meist in schlechtem Zustand erhalten. Ihre Oberfläche ist an vielen Stellen abgebröckelt. Auch der metallische Glanz ist nur noch an wenigen Stellen sichtbar. Darum fällt es schwer, sich eine Vorstellung vom einst so filigranen, kostbar schimmernden Relief zu machen. Aufgrund der Oberflächenkomplexität wirken Teigdrucke auf konventionellen Fotografien unansehnlich, obwohl sie in Wirklichkeit einiges von ihrer faszinierenden Materialwirkung bewahrt haben.

Um diese interessanten Objekte besser reproduzieren zu können, verbindet das Projekt “Digitale Materialität” Komponenten aus der Fotografie und der Computergrafik, welche es ermöglichen, die materiellen Eigenschaften der Originale so abzubilden, dass sie mit der beobachtbaren Realität in einem überprüfbaren Zusammenhang stehen. Um das ursprüngliche Aussehen in der digitalen Domäne zu representieren, wird für die fotografische Aufnahme das sogenannte Reflection Transformation Imaging (RTI) eingesetzt (Malzbender, Gelb, Wolters, 2001; Mudge et al., 2008; MacDonald, 2015). Mit diesem Verfahren wird aus mehreren statischen Aufnahmen ein mathematisches Relexionsmodell gerechnet, welches erlaubt die Reflexionseigenschaften der Oberfläche eines Objekts interaktiv darzustellen. So wird es möglich, die Reflexe unter sich verändernder Beleuchtung verlässlich zu simulieren. Die grundsätzliche Methodik von RTI besteht im systematischen Aufnehmen von Fotografien unter unterschiedlichen Lichteinfallswinkeln. Dieses Aufnahme-Set dient als Datenbasis, um eine mathematische Funktion so zu parametrisieren, dass sie die physikalischen Gegebenheiten für jeden Ort (jedes Pixel) möglichst exakt wiedergeben kann. Das auf diese Weise generierte Modell kann anschliessend am Computer betrachtet werden, wobei sich das Aussehen des Objekts unter wechselnden Lichtsituationen interaktiv simulieren lässt.

Die erreichten Ergebnisse zeigen, dass RTI die Oberfläche, ihre Reflexionseigenschaften und den aktuellen Erhaltungszustand von Teigdrucken aussagekräftiger dokumentieren und darstellen kann, als konventionelle Fotografien. Insbesondere das feine dreidimensionale Relief der Teigdrucke lässt sich an RTI-Modellen besser nachvollziehen.

Im Rahmen des Basler Projekts wird das Verfahren aber nicht nur angewendet, sondern auch weiterentwickelt. Das konventionelle RTI Verfahren stösst bei Objekten mit kombinierten glänzenden und matten Oberflächen an seine Grenzen. Dies liegt am einfachen mathematischen Modell – im Normalfall eine einfache Parabel – sowie an der Tatsache, dass das selbe Modell für das ganze Bild verwendet wird, also nicht auf einen ggf. vorhandenen Materialmix eingegangen wird. Durch das Überlagen eines aus der Computergrafik stammenden Glanzmodells – z.B. Phong (Phong, 1975) oder Ward (Ward and Glencross, 2009) – kann dieses Manko behoben werden, um so dem Reflexionsverhalten unterschiedlicher Materialien Rechnung zu tragen. Die Weiterentwicklungen werden laufend von kunsthistorischer Seite begleitet, um zu bewerten, wie die verbesserten Modelle im Vergleich zu den bislang verwendeten Verfahren als neues Analyseinstrument für geisteswissenschaftliche Forschungen genutzt werden können.

Um schliesslich die im Projekt generierten digitalen Objekte der Forschung zur Verfügung zu stellen, werden sie in ein Virtual Research Environment (Rosenthaler and Subotic 2012, Carusi and Reimer, 2010) integriert. Zur Wiedergabe der Modelle setzen wir auf WebGL (https://www.khronos.org/webgl/). Die Verbreitung der Daten im Rahmen von Open Access Anforderungen wird durch eine standardisierte Schnittstelle (JSON, JSON-LD) realisiert.

Am Beispiel der Teigdrucke zeigt sich im Basler Projekt, wie Entwicklungen der Digital Humanities Voraussetzung für neue Forschungsfragen in den Geisteswissenschaften schaffen können. An die Stelle des erprobten Dokumentations- und Vermittlungsmediums der konventionellen Fotografie tritt mit RTI ein innovatives Verfahren. Es wird jedoch nicht nur zweckmässig eingesetzt, sondern muss anwendungsbezogen optimiert werden, um den hohen Ansprüchen kunsthistorischer Dokumentationspraxis gerecht zu werden. Gefordert sind nämlich nicht etwa multimediale sondern gänzlich neuartige Forschungsdaten, die andernfalls für wissenschaftliche Diskurse nicht verfügbar wären.

Hinzu kommt die Aufbereitung des Verfahrens für den Gebrauch in einer neuen, virtuellen Forschungsumgebung, die ihrerseits traditionelle Formen der wissenschaftlichen Vernetzung ergänzt. Dies geschieht unter anderem durch den Einsatz semantischer Technologien, die nur im digitalen Raum ihr Potential entfalten können. Die virtuelle Forschungsumgebung wird schliesslich in Kombination mit webfähigen Applikationen und Open Access-Schnittstellen zum Angelpunkt für eine dauerhafte Sicherung der digitalen Daten, die zugleich nutzbar und archivierbar gemacht werden.

Introduction

As Susan Schreibman (2014) points out, a digital edition, as opposed to a printed one, is never really complete as several layers of annotation may always be added to represent and enrich the original content. TEI (Burnard, 2014) allows for several types of information - textual, linguistic and semantic - to be layered and made explicit and retrievable by a machine. Such is the case for instance with what is commonly known as semantic tagging.

In this paper, we focus on Named Entities (NE), in particular names of Persons and Geographical Places. Adding

NE mentions is supported by TEI with appropriate tags (such as <persName> and <placeName>), whose addition in a digital critical edition has somewhat the same function that indexes of places and persons have in a printed one. As mentions may be ambiguous (same string for different people, same place with different names,....) some referencing and disambiguating identifiers are required. But digital editions allow for much more than simple internal referencing. By pointing to external sources, structured information contained in the form of linked data in the semantic web becomes available to scholarly research.

In this work we present REDEN ONLINE, a system that enables scholars to automatically add external references to annotations of persons and places. The system is a web interface taking TEI as input, where mentions are already marked up, and automatically disambiguates and links such entities to an appropriate linked data set using a graph based algorithm for disambiguation. Moreover, our system provides data aggregation and visualization facilities by using the information found in the reference sources.

Previous work and general context

Semantic tagging is a hot topic in the digital humanities. Tools for semantic enrichment are, such as *Pundit* (Grassi et al., 2012, 2013), already available and allow for the interactive and intuitive annotation of portions of text. Automatic Named Entity Recognition and Linking techniques may be implemented to detect mentions and to suggest links to external knowledge bases.

Input formats to such systems may vary from plain text to html, but ideally a tool should process available standard formats, such as TEI-XML for text and RDF/OWL for information. Using linked data sources for disambiguation and enrichment is thus strongly recommended. By doing this, external sources of structured and regularly updated information can be made available to the scholar without having to be directly incorporated into the inline annotation, that can be left as simple as possible. This in turn allows for several customizable views, as linked data sources may be queried with the SPARQL query language to retrieve only the amount of external information that is necessary for a given task.

The treatment of spatial and temporal information is a typical task for which this approach is particularly effective; the availability of geographical databases and the complexity of the information are best accessed by pointing from within the digital edition to an external link. But also other types of semantic information seem to be particularly apt for connection to rich linked databases. So for instance bibliometric sources can be used to enrich texts with additional information on authors.

Typical targets for references are DBpedia and Geonames, that, for their genericity and connection to other sources, are at the heart of the linked data cloud. But they may be supplemented by more domain specific sources of information. For instance, Pleiades provides geo-historical information for ancient places.

Our project

REDEN ONLINE is set against the background of work carried out at LABEX OBVIL in Paris, where quality digital editions for French literary texts and criticism are produced and used in research and higher education. Recently a series of projects were carried out to semi-automatically annotate and reference places, organizations and authors. Gold standards were also produced, in close contact with researchers in French literature, so as to establish guidelines of annotation that best suit their ongoing research.

The general purpose is to provide tools for both:

- augmented close reading, to enable researchers to access more information on a specific text portion
- distant reading and data aggregation, so as to be able to detect trends in large portions of texts (Moretti, 2007)

OBVIL literary scholars are interested in plotting the distribution of the mentions of given authors over time in French literary criticism, in order to study the appreciation of Molière over the centuries, or in producing charts representing the distributions of professions in authors mentioned in given periods, to trace the influence of scientists and their ideas on art and literature in the age of positivism (Riguet, 2015). Other visualizations captured the emerging influence of foreign countries in the French literary panorama over time by combining the date of the publication of the essays with the detected toponyms.

NLP technologies are used to facilitate various aspects of the semantic enrichment of TEI editions, in an annotation echosystem where texts are first processed and then manually checked. The detection of mentions of places, authors (and also organizations) was tackled by using a Named Entity Recognizer and Classifier (UNERD, Mosallam et al., 2014).

Once the entities are correctly detected and classified, external references need to be added to disambiguate mentions and to connect them to additional information. To this purpose we developed REDEN[1], a Named Entity Linker that uses a graph-based algorithm and linked data sets to identify the correct referent for each mention (Brando et al., 2015, Frontini et al., 2015a, Frontini et al., 2015b for the technical details).

REDEN's input consists of a TEI text with detected mentions and several parameters specifying among others the class of entities to be detected, the reference base to use and a set of pre-compiled indexes. REDEN is applied for each class of entities separately, and works at best when several mentions are disambiguated at the same time. It retrieves all candidate referents for each mention of a context (say a paragraph) and then all the available information from the semantic web. It builds a sub-graph of all candidates and chooses the correct referents for each mention with the help of the formal relations between them. From Figure 1 you can get an intuition of how REDEN works.

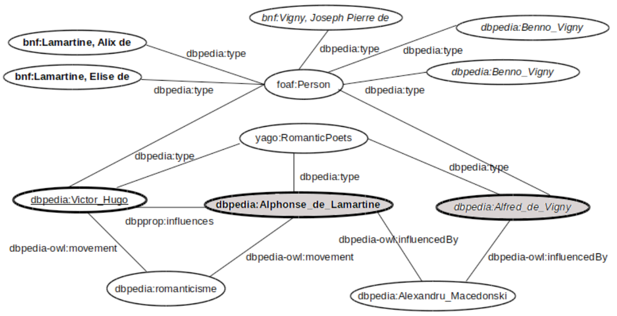

Figure 1 The graph based algorithm disambiguates between different possible referents for the mentions of "Victor Hugo" (unambiguous in this example), "Lamartine" and "Vigny" (both having several candidate referents) based on information found in DBpedia. Correct referents (in grey) are chosen based on how well connected they are within the context Here the crucial node is clearly that of yago:RomanticPoets.

So far our efforts have concentrated on the production of a text annotation and referencing pipeline for the production of such enriched TEIs with annotated and referenced mentions. Their exploitation for data aggregation and visualization was carried out offline and with ad hoc processing tools. With REDEN ONLINE we now want to make linking technology available online while at the same time providing users with some generic visualization of the results.

In what follows, we present the REDEN ONLINE interface with some screenshots from an example where two texts of the Labex OBVIL[2] digital library have been automatically linked to external sources, namely:

- *L'Hérésiarque et cie*, a collection of short stories by Guillaume Apollinaire, published in 1910 - place mentions linked to DBpedia entries.

- Réflexions sur la littérature a series of essays on French literary criticism by Albert Thibaudet, published in 1936 - author's mentions linked to entries in the linked data base of the Bibliothèque Nationale de France (BnF).

The user (Figure 2) loads a TEI text with annotated <placeName> or <personName> tags, chooses which class of entities to process (places or nouns) and the system runs the disambiguation and linking algorithm against the given linked data base - here French DBpedia and/or BnF. Then external information is extracted from the source and used for generating a particular view of the text. The result is a summing up of the disambiguated locations (some place names may be non resolvable because they are absent from the linked data base) and a visualization.

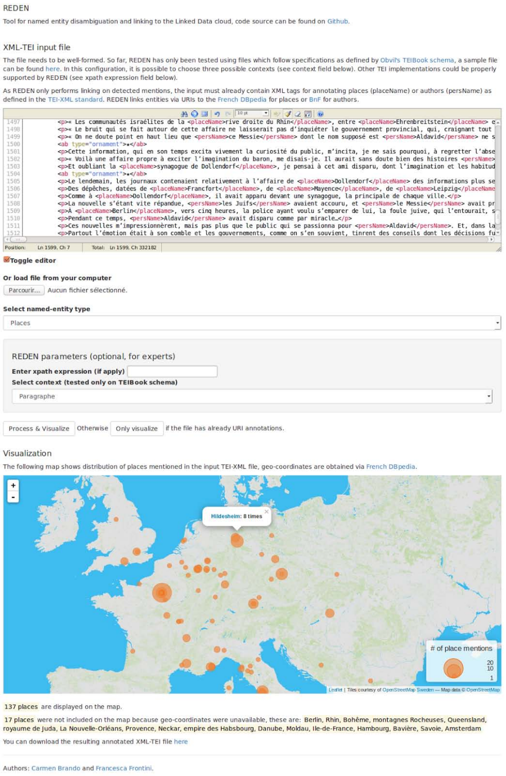
For locations the visualization consists in an interactive map that also takes frequency of mention into account. Coordinates are retrieved from DBpedia when available and the map can be zoomed in, up to the level of streets (see Figure 3 where some places in Paris have been identified in the text by Apollinaire), when relevant.

For persons (see Figure 4), portraits of authors are automatically downloaded and visualized.

Conclusion

The conference presentation will demonstrate REDEN ONLINE, a web based tool that enables researchers to connect place names and person names in their texts to existing linked data sources. The underlying technology will also be explained, in particular its use of standard formats, such as TEI and RDF for the linking algorithm, and GeoJSON for the creation of the map. We will also argue in favour of our economicity approach, namely the choice of not embedding semantic information in the TEI, which enables the use of different databases and the production of ad hoc "views" of the document.

It is well known that aggregation and visualizations techniques may "assist the critic in the unfolding of interpretive possibilities" (Ramsay, 2008) when analysing texts. This tool has been particularly designed for the study of literature and literary criticism; in the presentation examples of use will be given using ongoing research on Apollinaire, highlighting how the visual representation of the itineraries contained in the stories may be considered as a form of novel "digital reading" of the text.



REDEN

Tool for named entity disambiguation and linking to the Linked Data cloud, code source can be found on Github.

XML-TEI input file

The file needs to be well-formed. So far, REDEN has only been tested using files which follow specifications as defined by Obvil's TEIBook schema, a sample file can be found here. In this configuration, it is possible to choose three possible contexts (see context field below). Other TEI implementations could be properly supported by REDEN (see xpath expression field below).

As REDEN only performs linking on detected mentions, the input must already contain XML tags for annotating places (placeName) or authors (persName) as defined in the TEI-XML standard. REDEN links entities via URIs to the French DBpedia for places or BnF for authors.

New DH Publishing Models and Geopolitical Diversity

Isabel Galina Russell
igalina@unam.mx
Instituto de Investigaciones Bibliográficas -Universidad Nacional Autónoma de México - UNAM, Mexico

Ernesto Priani Saisó
epriani@gmail.com
Facultad de Filosofía y Letras, Universidad Nacional Autónoma de México - UNAM, Mexico

The aim of this paper is to discuss how the new scholarly publishing models proposed by the Digital Humanities, if properly executed, may also serve to increase geopolitical diversity in the field. If not, they may well replicate vicissitudes of the traditional scholarly system and perpetuate the current deficiencies. The scholarly communication and publishing system currently in place is a highly complex and international structure that has over the past few decades come under increasing criticism as scholars debate its effectiveness, in particular in relation to new possibilities enabled by digital technologies. At the centre of these debates is the fact that scholarly publishing is both a communicative and collaborative practice that is vital for knowledge construction, as well as being an integral part of the academic reward system and therefore a essential part of both power and prestige within academia. It is directly linked to activities such as hiring, tenure, assignment of grant money, to name a few.

Researchers from periphery countries are sorely underrepresented in the global scholarly publishing system. They have relatively little participation in "international journals" where we find a dominance of publications from researchers in developed nations. Scientific production is measured in a number of 'core journals' that are determined by indexing services that tend to favour publications from certain regions of the world and published in English. This leads to the invisibility of research produced in periphery countries as "structural obstacles and subtle prejudices that prevent researchers in poor nations from sharing their discoveries with the industrial world and with each other" (Gibbs, 1995). The work being done in periphery countries does not participate on the global stage. Fiormonte (2015) analyzed Digital Humanities literature and found a strong predominance of citations to publications in English and articles about English speaking institutions and projects. In terms of knowledge construction it is important to note: "how the values of the Western intellect traditions are reflected in the conventions and practices of academic communities and their communications; how mainstream journals and their publishing practices are congenial to the interests of center knowledge while proving recalcitrant to periphery discourses; and how academic writing/publishing functions are an important means of legitimating and reproducing center knowledge" (Canagarajah 2002). As such we find that there is a marginalization of peripheries in the production of knowledge and the impact of the research.

The predominance of knowledge production from a handful of countries has important consequences, in particular the Humanities that require multilingual, multicultural heterogeneous environments if they are to fully represent the wide spectrum of human diversity. The Digital Humanities is a community that not only represents itself as collaborative and open (Spiro, 2012) but also sees itself as potentially transformative of the Humanities: "The tension between the digital humanities and the academic establishment is multifaceted and involves institutional hurdles to doing interdisciplinary and collaborative work, need for space and technological infrastructure, tenure systems not adapted to digital production and publications, and the need for non-faculty experts and corresponding career paths (Svensson, 2012). In this sense Digital Humanities in on the periphery of academia, seeking validation of the types of digital scholarship it is developing against established power structures and recognized and suitable forms of what is deemed 'valid scholarship'.

DH scholarship is produced in a variety of formats that are not necessarily monographs or journal articles that make up the traditional scholarly publishing system. Datasets, web pages, digital scholarly edition, textual markup and visualizations, to name a few, are part of DH production and the community has focused on how to certify them as valid outputs and forms of communicating knowledge. New forms of publishing, peer review and career paths are part of DH literature as it challenges the traditional ways of producing, disseminating, validating and certifying knowledge through the types of scholarly output it is producing.

For the Digital Humanities the possibility of new modes of communication and publishing have been fundamental in its construction. Initial work concentrated on digitizing and publishing texts online, what Davidson (2012) refers to as Humanities 1.0. The first attraction of online publishing is making available material that is of difficult access and/

or dispersed geographically (Priani, 2015). For others an important feature, with the relative low cost compared to publication on paper, was the possibility of making lesser-known materials available, such as non-canonical texts (Earhart 2012). From the periphery the possibility of electronic publishing offered a way of getting information published and noticed. Many Open Access projects, which focus on journal publishing, have worked towards this (Alperin, Fischman and Willinsky, 2008).

Since then however, it has become clear that the Internet provides the opportunity to change the way we think about publishing and what types of outputs can be considered valid forms of communicating knowledge. This in turn has led to discussion on how we can validate and certify this production. In order to change the system however, it requires "substantative rethinking (…) of the ways those faculty do their work, how they communicate that work, and how that work is read both inside and outside the academy" (Fitzpatrick, 2011). If we consider that the traditional scholarly publishing system has systematically excluded research from periphery countries, there is an opportunity, as we work towards new types of publishing and communication systems, to find ways of being deliberately inclusive. Although not referring specifically to periphery research Davidson (2012) idea of Humanities 2.0 which is "distinguished from monumental, first generation data-based projects not just by interactivity but also by an openness about participation grounded in a different set of theoretical premises, which decenter authority and knowledge", can be applied.

Many (Fiormonte, 2012; Liu, 2012; Rodríguez, 2012; Clavert, 2013; Dacos, 2013; Risam, 2015) have argued that DH must reflect more on the nature of the digital medium and the technologies that are being employed as well as addressing issues related to geo-linguistic diversity in the community. At the same time Digital Humanities is also a community about building and creating (Ramsay, 2011). If DH is indeed a transformative motor of academia, then reflecting from a critical perspective on the new types of digital scholarship that we are proposing is indispensable. We could propose new models that adequately incorporate digital scholarly output from countries on the periphery that are left out of the global publishing system within the traditional scholarly publishing model. If DH is proposing and fighting for new types of scholarly publishing, then should we not seek to build a model that takes this into consideration?

It is not possible of course to resolve this in a single conference presentation. The aim of this paper is to bring this subject to the table and to initiate a discussion in the different ways that this can be addressed. It is important to invest more in understanding the effects of the new types of publishing that we are advocating for as well as the digital infrastructures, primarily publishing platforms that we are developing and/or using. Discussing the implications of what we are building, the methods and structures we are using for communicating and publishing as well as the languages and materials we are prioritizing as part of the necessary self-reflection on what we are and what we do. As we advocate for new types of scholarship and we discuss new forms of peer review, certification, validation, publication and dissemination of these new types of publications we must make sure we do not incorporate tacit assumptions about the role and validity of periphery scholarship if not we shall inevitably continue to replication long-held prejudices and marginalization.

Crossed Semantic Analysis of Literary Texts with DeSeRT

Introduction

Doing comparative researches on a large literary corpus is often lengthy and demanding. With the digitization of contents, scholars have started using computers. Semantic information is essential for an appropriate understanding of texts and is an extremely important factor in cross-textual analysis. This is why we have developed a new semantic engine built especially for Digital Humanities, called DeSeRT[1]. This paper presents some of the results that were obtained from a corpus of the 17th and 18th century texts characteristic of the debates about theater in the classical age. The following paper is divided into four parts: after a first section that briefly describes the search engine used and the different investigations it allows, a second section introduces the corpus used. Then, the third section shows some of the results obtained.

The DeSeRT Search Engine

DeSeRT has been designed to identify and compare rewriting, paraphrasing or reformulation. It is based on an idea, already developed (Barron-Cedeño et al., 2013; Ferrero and Simac-Lejeune, 2015), according to which, even if the reformulations cannot be reduced to paraphrases, they retain the meaning of original texts by using either the same words or words of similar meaning. As a consequence, the detection of co-occurrences of a few semantically equivalent lemmas in small blocks of texts is sufficient to capture the equivalent meaning and, therefore, to identify the reformulation of the same ideas.

This is implemented in four steps:

1. Dividing texts into small blocks of words that are partially overlapping. Typically each block may contain 300 words and two consecutive blocks overlap by one-half, but both the block size and the proportion of overlap can vary.

2. Extracting the meaningful lemmas using a POS tagger. This step enables the exclusion of some syntactical categories, such as prepositions or articles, and to get the lemma associated to each word. The current implementation makes use of TreeTagger[2], but this could easily be changed.

3. Indexing each block with the lemmas obtained at step 3. Without going into implementation details, let us remark that the index is stored using the SQLite[3] database management system.

4. Retrieving blocks that contain many identical or semantically equivalent lemmas. This fourth module exploits a dictionary of synonyms to recover blocks that have similar meanings. It is also possible to use a thesaurus to restrict the search to a set of predefined terms, but this is not a necessity. The proximity between two blocks of text is based on an Okapi similarity measurement (Spärk-Jones et al, 2000), of which evaluation is greatly simplified by the fact that all blocks have the same size.

More precisely, the Okapi similarity measure of a block B with a set of terms T = *t*1, … *t*n is given by the following formula:

$$score(B,T) = \sum_{i=1}^{n} IDF(t_i).\frac{f(t_i,B).(k+1)}{f(t_i,B)+k.(1-b+b.\frac{|B|}{avdl})}$$

where *f*(t_i, *B*) is the frequency of the term t_i in the block *B*, |*B*| is the size of block *B*, *k* and *b* are two free parameters chosen in advance (usually chosen as k∈[1.2, 2] and b=0.75), *avdl* is the average document description length in the collection and *IDF*(t_i) is the *Inverse Document*

$$IDF(t_i) = Log(\frac{N-n(t_i)+0,5}{n(t_i)+0,5})$$

Frequency of term *t*i is given by:

It appears that, when the size of each block is the same and when the frequency of terms in blocks is supposed to be at max 1 (this approximation is justified since the blocks are small), this formula can be simplified. It then becomes equivalent to the information theoretic measure of the terms in blocks, i.e.

$$score(B,T) = \sum_{i=1}^{n} IDF(t_i) = \sum_{i=1}^{n} -\log(\Pr(t_i))$$

where *Pr*(t_i) is the probability of the term t_i in the overall corpus.

Using this score, it is possible to measure the similarity between blocks or between a block and a set *T* of terms t_i. As a consequence, DeSeRT can be used in different ways. The research queries may be done through words or concepts, i.e. words that are expanded using the dictionary of synonyms. It is also possible to compare any text (or file) to a corpus: then, DeSeRT detects corpus blocks where the meaning is similar to blocks of the given text, which allows, for instance, the arguments in a dispute or the anecdotes and the common places that are reused to be followed. Lastly, it is also possible (but not mandatory) to add a thesaurus or ontology to focus the search on a given semantic field.

Note that, based on techniques developed to detect plagiarism, many tools already exist that are designed to identify paraphrases, reuses and borrowings, i.e. sequences of words that are approximately identical, e.g. (Ganascia et al. 2014; Horson et al. 2010). However, these techniques are unable to spot reformulations of the same ideas or allusions to previous texts. DeSeRT has been designed to overcome these limitations.

The Hate of Theater

The project *Haine du Théâtre*[4] ("The Hatred of Theater" in French) aims to analyze theater disputes in Europe using scientific approaches and critical editions of polemical texts. The team's reflections are mainly focused around the discovery of the circumstances and the arguments used in theater controversies all across Europe, not limited to France, but also in England, Spain, Italy, and the Germanic area, from the last decades of the 16th century up to the beginning of the 19th century.

The corpus of the project collects many texts written in French during the 17th and the 18th centuries. The purpose of this project is to explore the gray areas of theater controversies in order to outline a global overview and to discover where and how the polemics began, their chronological discrepancies and the links between them and their contemporary resurgences. The total collection of the *Haine du Théâtre* texts is, by now, made up of 27 texts.

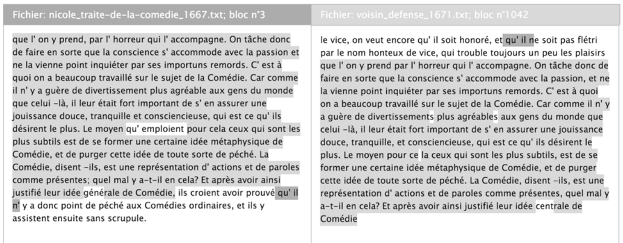
Exploitation of DeSeRT on the Hate of Theatre Corpus

Discovery of reuses

Querying the 27 texts of the *Haine du Théâtre* corpus, we found much reuse of similar passages and texts. DeSeRT is not only useful for detecting those parts of text that deal with the same concept, but is also a very good tool to find borrowings.

For example, comparing two texts, the *Défense* of Voisin (1666) and *Traité de la Comédie* of Nicole (1667), we discover immediately that the *Traité* has been included in the *Défense* by Voisin, which is a very long text, not only once, but twice. The first time, Voisin presents it as a re-publication, then he re-uses phrases similar to those employed by Nicole in different passages and he sprinkles them in his *Défense*.

The keywords of this correspondence are very well detected by DeSeRT, as can be seen in the example below.



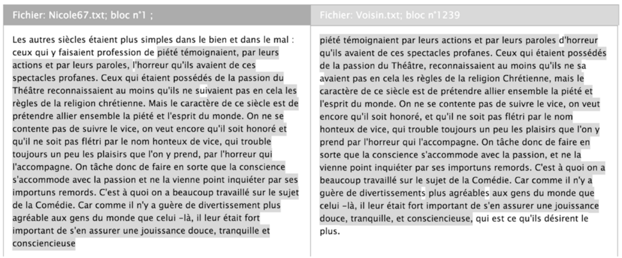
Fichier: nicole_traite-de-la-comedie_1667.txt; bloc n°3

que l' on y prend, par l' horreur qui l' accompagne. On tâche donc de faire en sorte que la conscience s' accommode avec la passion et ne la vienne point inquiéter par ses importuns remords. C' est à quoi on a beaucoup travaillé sur le sujet de la Comédie. Car comme il n' y a guère de divertissement plus agréable aux gens du monde que celui –là, il leur était fort important de s' en assurer une jouissance douce, tranquille et consciencieuse, qui est ce qu' ils désirent le plus. Le moyen qu' emploient pour cela ceux qui sont les plus subtils est de se former une certaine idée métaphysique de Comédie, et de purger cette idée de toute sorte de péché. La Comédie, disent –ils, est une représentation d' actions et de paroles comme présentes; quel mal y a–t–il en cela? Et après avoir ainsi justifié leur idée générale de Comédie, ils croient avoir prouvé qu' il n' y a donc point de péché aux Comédies ordinaires, et ils y assistent ensuite sans scrupule.

Fichier: voisin_defense_1671.txt; bloc n°1042

le vice, on veut encore qu' il soit honoré, et qu' il ne soit pas flétri par le nom honteux de vice, qui trouble toujours un peu les plaisirs que l' on y prend par l' horreur qui l' accompagne. On tâche donc de faire en sorte que la conscience s' accommode avec la passion, et ne la vienne point inquiéter par ses importuns remords. C' est à quoi on a beaucoup travaillé sur le sujet de la Comédie. Car comme il n' y a guère de divertissements plus agréables aux gens du monde que celui –là, il leur était fort important de s' en assurer une jouissance douce, tranquille, et consciencieuse, qui est ce qu' ils désirent le plus. Le moyen pour cela ceux qui sont les plus subtils, est de se former une certaine idée métaphysique de Comédie, et de purger cette idée de toute sorte de péché. La Comédie, disent –ils, est une représentation d' actions et de paroles comme présentes, quel mal y a–t–il en cela? Et après avoir ainsi justifié leur idée centrale de Comédie

Furthermore, continuing the analysis of the text we discover that in these two texts the actor is frequently associated with the idea of purity in religion.



Fichier: Nicole67.txt; bloc n°1 ;

Les autres siècles étaient plus simples dans le bien et dans le mal : ceux qui y faisaient profession de piété témoignaient, par leurs actions et par leurs paroles, l'horreur qu'ils avaient de ces spectacles profanes. Ceux qui étaient possédés de la passion du Théâtre reconnaissaient au moins qu'ils ne suivaient pas en cela les règles de la religion chrétienne. Mais le caractère de ce siècle est de prétendre allier ensemble la piété et l'esprit du monde. On ne se contente pas de suivre le vice, on veut encore qu'il soit honoré et qu'il ne soit pas flétri par le nom honteux de vice, qui trouble toujours un peu les plaisirs que l'on y prend, par l'horreur qui l'accompagne. On tâche donc de faire en sorte que la conscience s'accommode avec la passion et ne la vienne point inquiéter par ses importuns remords. C'est à quoi on a beaucoup travaillé sur le sujet de la Comédie. Car comme il n'y a guère de divertissement plus agréable aux gens du monde que celui –là, il leur était fort important de s'en assurer une jouissance douce, tranquille et consciencieuse

Fichier: Voisin.txt; bloc n°1239

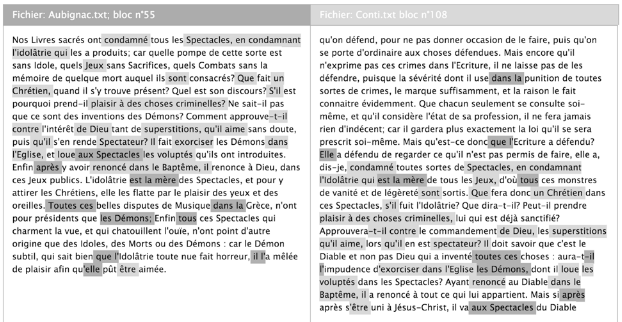
piété témoignaient par leurs actions et par leurs paroles d'horreur qu'ils avaient de ces spectacles profanes. Ceux qui étaient possédés de la passion du Théâtre, reconnaissaient au moins qu'ils ne sa avaient pas en cela les règles de la religion Chrétienne, mais le caractère de ce siècle est de prétendre allier ensemble la piété et l'esprit du monde. On ne se contente pas de suivre le vice, on veut encore qu'il soit honoré, et qu'il ne soit pas flétri par le nom honteux de vice, qui trouble toujours un peu les plaisirs que l'on y prend par l'horreur qui l'accompagne. C'est à quoi on a beaucoup travaillé sur le sujet de la Comédie. Car comme il n'y a guère de divertissements plus agréables aux gens du monde que celui –là, il leur était fort important de s'en assurer une jouissance douce, tranquille, et consciencieuse, qui est ce qu'ils désirent le plus.

Reformulations of Ideas

DeSeRT also shows in detail the parts of the corpus that are similar or that develop the same ideas. This may either be done on demand, according user requests, i.e. to given texts, or to the overall corpus, which automates the process.

For instance, we have found many topics common not only to the texts by Nicole and Voisin, but also to two others e.g. the theme of the idolatry as the "mother of all spectacles" in (Aubignac, 1666) and (Conti, 1666).

Note that, in the following figures, we have greyed the identical passages with the MEDITE system, which only spots strict homologies, without considering many words that appear identical to DeSeRT because they correspond to the same lemma or to two synonymous lemmas. As a consequence, the number of gray zones considerably underestimates the semantic proximity detected by DeSeRT.

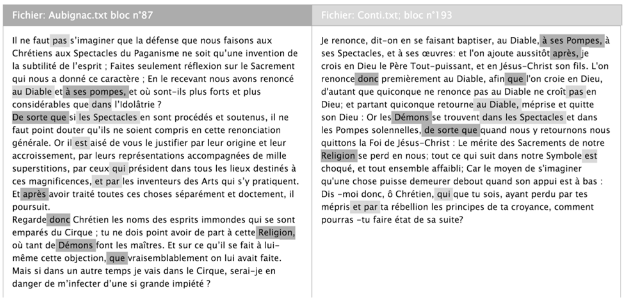


Fichier: Aubignac.txt; bloc n°55

Nos Livres sacrés ont condamné tous les Spectacles, en condamnant l'idolâtrie qui les a produits; car quelle pompe de cette sorte est sans Idole, quels Jeux sans Sacrifices, quels Combats sans la mémoire de quelque mort auquel ils sont consacrés? Que fait un Chrétien, quand il s'y trouve présent? Quel est son discours? S'il est pourquoi prend–il plaisir à des choses criminelles? Ne sait–il pas que ce sont des inventions des Démons? Comment approuve–t–il contre l'intérêt de Dieu tant de superstitions, qu'il aime sans doute, puis qu'il s'en rende Spectateur? Il fait exorciser les Démons dans l'Eglise, et loue aux Spectacles les voluptés qu'ils ont introduites. Enfin après y avoir renoncé dans le Baptême, il renonce à Dieu, dans ces Jeux publics. L'idolâtrie est la mère des Spectacles, et pour y attirer les Chrétiens, elle les flatte par le plaisir des yeux et des oreilles. Toutes ces belles disputes de Musique dans la Grèce, n'ont pour présidents que les Démons; Enfin tous ces Spectacles qui charment la vue, et qui chatouillent l'ouïe, n'ont point d'autre origine que des Idoles, des Morts ou des Démons : car le Démon subtil, qui sait bien que l'Idolâtrie toute nue fait horreur, il l'a mêlée de plaisir afin qu'elle pût être aimée.

Fichier: Conti.txt bloc n°108

qu'on défend, pour ne pas donner occasion de le faire, puis qu'on se porte d'ordinaire aux choses défendues. Mais encore qu'il n'exprime pas ces crimes dans l'Ecriture, il ne laisse pas de les défendre, puisque la sévérité dont il use dans la punition de toutes sortes de crimes, le marque suffisamment, et la raison le fait connaitre évidemment. Que chacun seulement se consulte soi–même, et qu'il considère l'état de sa profession, il ne fera jamais rien d'indécent; car il gardera plus exactement la loi qu'il se sera prescrit soi–même. Mais qu'est–ce donc que l'Ecriture a défendu? Elle a défendu de regarder ce qu'il n'est pas permis de faire, elle a, dis–je, condamné toutes sortes de Spectacles, en condamnant l'Idolâtrie qui est la mère de tous les Jeux, d'où tous ces monstres de vanité et de légèreté sont sortis. Que fera donc un Chrétien dans ces Spectacles, s'il fuit l'Idolâtrie? Que dira–t–il? Peut–il prendre plaisir à des choses criminelles, lui qui est déjà sanctifié? Approuvera–t–il contre le commandement de Dieu, les superstitions qu'il aime, lors qu'il en est spectateur? Il doit savoir que c'est le Diable et non pas Dieu qui a inventé toutes ces choses : aura–t–il l'impudence d'exorciser dans l'Eglise les Démons, dont il loue les voluptés dans les Spectacles? Ayant renoncé au Diable dans le Baptême, il a renoncé à tout ce qui lui appartient. Mais si après après s'être uni à Jésus–Christ, il va aux Spectacles du Diable



Fichier: Aubignac.txt bloc n°87

Il ne faut pas s'imaginer que la défense que nous faisons aux Chrétiens aux Spectacles du Paganisme ne soit qu'une invention de la subtilité de l'esprit ; Faites seulement réflexion sur le Sacrement qui nous a donné ce caractère ; En le recevant nous avons renoncé au Diable et à ses pompes, et où sont–ils plus forts et plus considérables que dans l'Idolâtrie ?

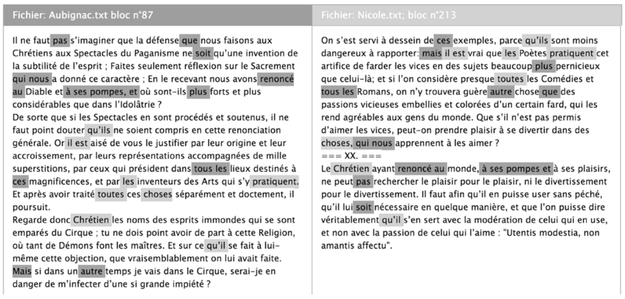
De sorte que si les Spectacles en sont procédés et soutenus, il ne faut point douter qu'ils ne soient compris en cette renonciation générale. Or il est aisé de vous le justifier par leur origine et leur accroissement, par leurs représentations accompagnées de mille superstitions, par ceux qui président dans tous les lieux destinés à ces magnificences, et par les inventeurs des Arts qui s'y pratiquent. Et après avoir traité toutes ces choses séparément et doctement, il poursuit.

Regarde donc Chrétien les noms des esprits immondes qui se sont emparés du Cirque ; tu ne dois point avoir de part à cette Religion, où tant de Démons font les maîtres. Et sur ce qu'il se fait à lui–même cette objection, que vraisemblablement on lui avait faite. Mais si dans un autre temps je vais dans le Cirque, serai–je en danger de m'infecter d'une si grande impiété ?

Fichier: Conti.txt; bloc n°193

Je renonce, dit–on en se faisant baptiser, au Diable, à ses Pompes, à ses Spectacles, et à ses œuvres: et l'on ajoute aussitôt après, je crois en Dieu le Père Tout–puissant, et en Jésus–Christ son fils. L'on renonce donc premièrement au Diable, afin que l'on croie en Dieu, d'autant que quiconque ne renonce pas au Diable ne croît pas en Dieu; et partant quiconque retourne au Diable, méprise et quitte son Dieu : Or les Démons se trouvent dans les Spectacles et dans les Pompes solennelles, de sorte que quand nous y retournons nous quittons la Foi de Jésus–Christ : Le mérite des Sacrements de notre Religion se perd en nous; tout ce qui suit dans notre Symbole est choqué, et tout ensemble affaibli; Car le moyen de s'imaginer qu'une chose puisse demeurer debout quand son appui est à bas : Dis –moi donc, ô Chrétien, qui que tu sois, ayant perdu par tes mépris et par ta rébellion les principes de ta croyance, comment pourras –tu faire état de sa suite?

Secondly, as shown in the following figures, the topic "renouncing the Devil" (*Renoncer au Diable* in French) is regularly present in the texts written by Aubignac, Conti and Voisin,[5] while it appears only once in (Nicole, 1667: 477).



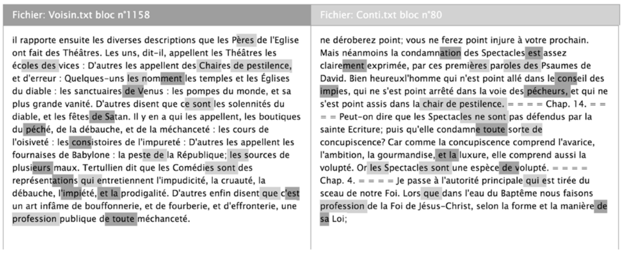
Fichier: Aubignac.txt bloc n°87

Il ne faut pas s'imaginer que la défense que nous faisons aux Chrétiens aux Spectacles du Paganisme ne soit qu'une invention de la subtilité de l'esprit ; Faites seulement réflexion sur le Sacrement qui nous a donné ce caractère ; En le recevant nous avons renoncé au Diable et à ses pompes, et où sont-ils plus forts et plus considérables que dans l'Idolâtrie ?
De sorte que si les Spectacles en sont procédés et soutenus, il ne faut point douter qu'ils ne soient compris en cette renonciation générale. Or il est aisé de vous le justifier par leur origine et leur accroissement, par leurs représentations accompagnées de mille superstitions, par ceux qui président dans tous les lieux destinés à ces magnificences, et par les inventeurs des Arts qui s'y pratiquent. Et après avoir traité toutes ces choses séparément et doctement, il poursuit.
Regarde donc Chrétien les noms des esprits immondes qui se sont emparés du Cirque ; tu ne dois point avoir de part à cette Religion, où tant de Démons font les maîtres. Et sur ce qu'il se fait à lui-même cette objection, que vraisemblablement on lui avait faite. Mais si dans un autre temps je vais dans le Cirque, serai-je en danger de m'infecter d'une si grande impiété ?

Fichier: Nicole.txt; bloc n°213

On s'est servi à dessein de ces exemples, parce qu'ils sont moins dangereux à rapporter: mais il est vrai que les Poètes pratiquent cet artifice de farder les vices en des sujets beaucoup plus pernicieux que celui-là; et si l'on considère presque toutes les Comédies et tous les Romans, on n'y trouvera guère autre chose que des passions vicieuses embellies et colorées d'un certain fard, qui les rend agréables aux gens du monde. Que s'il n'est pas permis d'aimer les vices, peut-on prendre plaisir à se divertir dans des choses, qui nous apprennent à les aimer ?
=== XX. ===
Le Chrétien ayant renoncé au monde, à ses pompes et à ses plaisirs, ne peut pas rechercher le plaisir pour le plaisir, ni le divertissement pour le divertissement. Il faut afin qu'il en puisse user sans péché, qu'il lui soit nécessaire en quelque manière, et que l'on puisse dire véritablement qu'il s'en sert avec la modération de celui qui en use, et non avec la passion de celui qui l'aime : "Utentis modestia, non amantis affectu".

Further results of DeSeRT lead us to understand that many others expressions are common to the four authors, such as the description of the theatre as a "flesh of pestilence" (*chair de pestilence*) or as a "school of the debauchery".

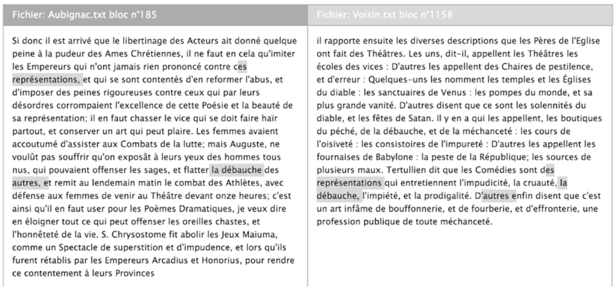


Fichier: Voisin.txt bloc n°1158

il rapporte ensuite les diverses descriptions que les Pères de l'Eglise ont fait des Théâtres. Les uns, dit-il, appellent les Théâtres les écoles des vices : D'autres les appellent des Chaires de pestilence, et d'erreur : Quelques-uns les nomment les temples et les Églises du diable : les sanctuaires de Venus : les pompes du monde, et sa plus grande vanité. D'autres disent que ce sont les solennités du diable, et les fêtes de Satan. Il y en a qui les appellent, les boutiques du péché, de la débauche, et de la méchanceté : les cours de l'oisiveté : les consistoires de l'impureté : D'autres les appellent les fournaises de Babylone : la peste de la République; les sources de plusieurs maux. Tertullien dit que les Comédies sont des représentations qui entretiennent l'impudicité, la cruauté, la débauche, l'impiété, et la prodigalité. D'autres enfin disent que c'est un art infâme de bouffonnerie, et de fourberie, et d'effronterie, une profession publique de toute méchanceté.

Fichier: Conti.txt bloc n°80

ne déroberez point; vous ne ferez point injure à votre prochain. Mais néanmoins la condamnation des Spectacles est assez clairement exprimée, par ces premières paroles des Psaumes de David. Bien heureuxl'homme qui n'est point allé dans le conseil des impies, qui ne s'est point arrêté dans la voie des pécheurs, et qui ne s'est point assis dans la chair de pestilence. = = = = Chap. 14. = = = = Peut-on dire que les Spectacles ne sont pas défendus par la sainte Ecriture; puis qu'elle condamne toute sorte de concupiscence? Car comme la concupiscence comprend l'avarice, l'ambition, la gourmandise, et la luxure, elle comprend aussi la volupté. Or les Spectacles sont une espèce de volupté. = = = = Chap. 4. = = = = Je passe à l'autorité principale qui est tirée du sceau de notre Foi. Lors que dans l'eau du Baptême nous faisons profession de la Foi de Jésus-Christ, selon la forme et la manière de sa Loi;



Fichier: Aubignac.txt bloc n°185

Si donc il est arrivé que le libertinage des Acteurs ait donné quelque peine à la pudeur des Ames Chrétiennes, il ne faut en cela qu'imiter les Empereurs qui n'ont jamais rien prononcé contre ces représentations, et qui se sont contentés d'en reformer l'abus, et d'imposer des peines rigoureuses contre ceux qui par leurs désordres corrompaient l'excellence de cette Poésie et la beauté de sa représentation; il en faut chasser le vice qui se doit faire haïr partout, et conserver un art qui peut plaire. Les femmes avaient accoutumé d'assister aux Combats de la lutte; mais Auguste, ne voulût pas souffrir qu'on exposât à leurs yeux des hommes tous nus, qui pouvaient offenser les sages, et flatter la débauche des autres, et remit au lendemain matin le combat des Athlètes, avec défense aux femmes de venir au Théâtre devant onze heures; c'est ainsi qu'il en faut user pour les Poèmes Dramatiques, je veux dire en éloigner tout ce qui peut offenser les oreilles chastes, et l'honnêteté de la vie. S. Chrysostome fit abolir les Jeux Maiuma, comme un Spectacle de superstition et d'impudence, et lors qu'ils furent rétablis par les Empereurs Arcadius et Honorius, pour rendre ce contentement à leurs Provinces

Fichier: Voisin.txt bloc n°1158

il rapporte ensuite les diverses descriptions que les Pères de l'Eglise ont fait des Théâtres. Les uns, dit-il, appellent les Théâtres les écoles des vices : D'autres les appellent des Chaires de pestilence, et d'erreur : Quelques-uns les nomment les temples et les Églises du diable : les sanctuaires de Venus : les pompes du monde, et sa plus grande vanité. D'autres disent que ce sont les solennités du diable, et les fêtes de Satan. Il y en a qui les appellent, les boutiques du péché, de la débauche, et de la méchanceté : les cours de l'oisiveté : les consistoires de l'impureté : D'autres les appellent les fournaises de Babylone : la peste de la République; les sources de plusieurs maux. Tertullien dit que les Comédies sont des représentations qui entretiennent l'impudicité, la cruauté, la débauche, l'impiété, et la prodigalité. D'autres enfin disent que c'est un art infâme de bouffonnerie, et de fourberie, et d'effronterie, une profession publique de toute méchanceté.

Conclusion

To conclude, DeSeRT allows the discovery of reformulations and similar phrases, as well as related topics and passages in a corpus. It is usable on any kind of corpus that is made up by files in the txt format. As we have briefly shown in this paper, this search engine enables users to identify crucial passages of a specific corpus according to two types of detection: the discovery of reuses, such as plagiarism or hidden rewritings, and the reformulation of ideas, which can be manually given by the user (as words or concepts) or automatically extracted by the DeSeRT search engine.

Pulp Science Fiction's Legacy to Women in Science

Elizabeth Winfree Garbee
egarbee@asu.edu
Arizona State University, United States of America

This study examines a "pulp" science fiction corpus (1930–1965) through corpus linguistic analysis in order to digitally reconstruct the gendered occupational identities created by those authors, and the culture they represent, which perpetuated a stereotype of "the scientist" and how they characterized women in professional scientific roles. I created "occupational archetypes" based on the linguistic analysis of collocates, clusters, and textual examples of science, technology, engineering, and math (STEM) career keywords in order to investigate the culturally informed gender roles demonstrated in modern stereotypes of the scientist. I chose to study pulp science fiction, a sub-genre of science fiction literature that enjoyed a wide readership during the formative decades of the creation of the scientific industrial complex in pre and post-war America. One way to get at the culture that created and then maintained our national scientific industrial complex is through examining the stories about science that people of that time produced. For indeed, stories, and even more simply, language are a transmitter of social and cultural values, especially when it comes to gender roles (Rey, 2001). Pulp science fiction existed as a sub-genre of science fiction from roughly 1930 to 1965, characterized by its wide audience and affordability. The accessibility and engaging style of this literary genre gained it a wide readership, and "the pulps" as they came to be called quickly became a feature of American life during the pre and post-war eras. These stories, and indeed the genre at large, represent popular conceptions of "appropriate" gender identities and reinforce those occupational stereotypes that play such a key role in the lives of women scientists.

The aim of corpus linguistics is to study patterns of language at their most fundamental level of words and phrases, thereby revealing patterns of meaning, making the implicit explicit (Biber, 1998; Biber, 2009; Stubbs, 2001; McEnery, 2001; Lakoff, 2008; Kennedy, 2014; Hettel, 2013). Since patterns of meaning are precisely what I wished to investigate with respect to gendered occupational stereotypes, this method served as the basis for my study. Corpus linguistics is able to harness the power of Moretti's distant reading approach (Moretti, 2013) in uncovering the scope and and nature of the literature, while also providing clues as to which specific pieces within a corpus merit a close reading.

The corpus I constructed for this project consists of 560 full text copies of pulp science fiction stories from 1930 to 1965 (totaling just over 6 million words), published in magazines like Astounding Stories, Amazing Stories, Analog Science Fact and Fiction, Planet Stories, and If Worlds of Science Fiction. These full texts were obtained from public repositories, principally Project Gutenberg (https://www.gutenberg.org/) and The Internet Archive's Pulp Magazine Archive (https://archive.org/details/pulpmagazinearchive). While some of these stories were already conveniently in plain text files, others were scanned copies of the original pulp magazine pages stored as image files. The latter I converted into plain text through the application of Tesseract, an open source optical character recognition (OCR) program. I then organized these stories according to their date of publication in the magazines, stratifying according to five year periods: 1930-34, 1935-39, etc. Each of these five year periods contain 80 stories, coming to 560 in total. This stratification allows for representativeness through ensuring that all five year periods were weighted proportionally over time (Sinclair, 2004).

When I finished constructing the corpus, I used the software suite WordSmith Tools to generate keyword lists for the corpus in its entirety, in addition to each five year period respectively. When I generated the keyword lists for each five year period, I used the rest of the pulp science fiction corpus as my reference, in order to track how these words were being used over time (Bondi, 2010). From these general keyword lists, I chose the keywords which represented careers or occupations that constitute or interact with STEM disciplines: scientist, engineer, mathematician, doctor, nurse, and professor. I then used WordSmith Tools to analyze measures of association for the above science, technology, and engineering occupational words. By focusing on the language used to describe occupations related to the sciences, I was able to get a picture of the characterization of these professions at the time the stories were published. I also did a collocation analysis in order to uncover the words that most frequently co-occurred with these keywords, limited to five words to the right and left of the key word in question (the node). The character of the collocates reflects the nature of the node, and the distinctions offered by collocations are subtle, yet crucial to the creation of a linguistic profile (Hettel, 2013).

In order to determine which collocates were statistically significant, I evaluated the association by its t-score, a statistic which works well with smaller corpora (such as mine) because it also takes frequencies into account, as opposed to mutual information (MI). Using the STEM occupation keywords, collocates, clusters, and qualitative examination of specific examples of the node words in context, I then created "lexical profiles" of each of these science, technology, engineering, and related occupations, which I'm terming "occupational archetypes." The development of these archetypes is based largely on the work done by Hettel on the construction of lexical profiles from collocations, clusters, and context in the language of US nuclear plants and regulatory entities.

Specifically, the archetype I constructed of "the scientist" revealed a middle aged white male, defined by his adherence to "true" or "good" science, and often called upon by other characters to provide scientific or technical insight. Though he spends a good deal of his time talking, others struggle to grasp his meaning and find him difficult to deal with. This occupational archetype is a mirror image of the American stereotype of scientific professionals, one which leaves no room for diversity in race or gender. Furthermore, through this analysis, I discovered that out of the hundreds of scientists in my corpus, only three were women. A linguistic analysis of these women in particular (a chemist, a physicist, and a mathematician) revealed American cultural assumptions about the intersection of femininity and science: a female scientist could either be beautiful or accomplished. And even then, the chemist's beauty came with exploitation (and the physicist's ugliness with prestige), and scientific genius in these women necessitated qualification (i.e. genius "in her own way") while that of their male colleagues did not. The mathematician, the one woman in the corpus with beauty and brains, so to speak, appeared very late on the scene, and perhaps signals a shift in the cultural conception of who a scientist could be and what they could look like. Making these entrenched cultural stereotypes of women in science explicit through linguistic analysis is the first step in creating a STEM workforce strong through its diversity and acceptance.

Building Blocks of Fiction: Lexical Bundles in Nineteenth-Century Novels

Marissa Lynn Gemma
marissa.gemma@gmail.com
Max Planck Institute for Empirical Aesthetics

Ryan James Heuser
heuser@stanford.edu
Stanford University

Introduction

Several decades ago, corpus linguists undertook systematic analyses of a lexical unit larger than the individual word but smaller than syntactical or phrasal units—multiword sequences they called "lexical bundles" (Biber et al., 1999: 989; Biber and Conrad 1999: 58). Lexical bundles are extremely common collocations of three or more words, such as "*I want to*", "*it was a*", or "*going to be a.*" Unlike idioms or clichés, which are statistically very rare—and unlike word n-grams, which can occur with any frequency— lexical bundles are diffused throughout the language, occurring at least ten times per million words, and in many cases much more frequently (Biber et al., 1999: 989).[1] Because of their frequency, lexical bundles are regarded as "discourse framing devices": sequences of words that function as connective tissue in organizing discourse, expressing stance, or conveying referential status (Biber, 2006: 174).

While much of this ground-breaking research has focused on register—i.e., on differences in the use of multi-word sequences in various discourse contexts (like conversation vs. academic prose)—surprisingly little attention has been paid to the role of bundles in fiction. Biber et al. (1999) do not discuss results for fiction in their work, focusing instead on differences between academic prose and conversation (cf. also Conrad and Biber, 2004). Michaela Mahlberg's corpus stylistics approach to Dickens' fiction (2012) was pioneering in the use of lexical bundles to study fiction, but to date, no studies focusing on corpus- or register-wide trends in fiction have appeared.[2] Yet the dramatic differences in the use of lexical bundles in other registers suggest that lexical bundles play an important role in building the discourse of fiction, and also that the bundles that occur in fiction will be significantly different than those occurring in other registers.

This paper analyzes the role of lexical bundles in a corpus of over 1000 novels published in Great Britain and America between 1800 and 1905. The two key contributions of the paper are: 1) to provide a taxonomy of the discourse functions of lexical bundles in nineteenth-century English and American fiction; and 2) to historicize that usage by tracking changes in our corpus over the course of the nineteenth century. We also provide some data about differences between narration and dialogue.

In expanding the unit of analysis beyond the level of the word, this paper also aims to intervene in recent methodological debates about digital humanities research on literary style. Much DH research on style in recent years—including some of the authors' own work—has relied on a bag-of-words approach (Heuser and Le-Khac, 2012; Underwood and Sellers, 2012; for a discussion of the virtues of this approach, see Underwood, 2013). Since the terrain of higher-level lexical patterning in fiction remains under-explored, this paper contributes to the field both a methodological approach and a set of empirical results about the language of the nineteenth-century Anglo-American novel.

Methods

Our corpus derives from two digital fiction collections (licensed to the Stanford University Libraries) by Proquest: "Early American Fiction" (805 American novels published from 1789 - 1875; and "Nineteenth-Century Fiction" (250 British novels published from 1782-1903). To extend the American corpus' historical scope to match that of the British corpus, we added a collection of about 325 American novels published between 1875 and 1905. We selected these texts based on their inclusion in the *Annals of American Literature* (Ludwig and Nault, 1989) and their availability in Project Gutenberg.

To identify bundles in a corpus with an uneven historical distribution of texts, we split each national corpus into four twenty-five year segments, creating eight sub-corpora. Each sub-corpus is derived from an identical number of words per author. Authors with fewer than 100,000 words in a particular period were not included; authors with more than this number were included by selecting 100 random slices of 1,000 words from all of their texts published in the period. Sub-corpora ranged in length from 900,000 words (U.S. publications, 1800-25) to 5.9 million words (U.S. publications, 1850-75), with a median length of 2.3 million words.

Following Biber et al. (1999), we defined lexical bundles as the most commonly occurring tri- and quad-grams in our sub-corpora, with a threshold of at least ten occurrences per one million words (frequency per million [FPM]). After tokenizing each of the eight sub-corpora, we counted the number of occurrences of each unique tri-gram and quad-gram, normalizing by the length of the sub-corpus.[3] Any tri-gram or quad-gram with a frequency above 10 FPM in any of the eight sub-corpora was considered a potential lexical bundle. Biber et al. additionally required that bundles occur in at least five different texts in the corpus, in order to guard against the possibility of individual authorial or textual effects (991). Similarly, we excluded from our list of bundles those that occurred in fewer than three unique authors, so as to exclude idiosyncratic stylistic habits, as well as bundles containing character names or other novel-specific traits.[4]

We manually created an interpretive typology of the most frequent lexical bundles: the 150 most frequent tri-gram bundles (all with a median FPM across sub-corpora above 31), and the 240 most frequent quad-gram bundles (all with a median FPM across sub-corpora above 13). By looking at randomly-selected examples from the sub-corpora, each of these lexical bundles was annotated for its apparent function within fictional discourse. For example, "there was a" (5th most frequent tri-gram bundle, with a median FPM of 184) was annotated as "expletive": grammatically, "expletives" are phrases of the form ["there" or "it" + to be], and within fiction, they provide a means by which the existence or effect of something can be easily introduced.[5]

Finally, because corpus linguistics research has shown dramatic differences in lexical bundles across oral and written registers, we separately tracked their frequency in the narration and dialogue portions of our texts. To separate dialogue from narration, we used a tool developed by Grace Muzny at Stanford University. For this task we used a slightly reduced version of our corpus, which we curated by hand to ensure proper typographic markings of dialogue and thus a high precision and recall for the dialogue separation. We then replicated the corpus design described above, creating eight sub-corpora for each register, dialogue and narration. In this case, however, the periods are of twenty-year increments, from 1825 to 1905, due to the paucity of typographically well-formatted novels previous to 1825; also, each author contributes not 100,000 but 50,000 words to a particular sub-corpus, and authors with fewer than this number are not included in the sub-corpus.

Results

Due to constraints of space, we can provide here only an overview of our findings in each area.

1. The function of lexical bundles in nineteenth-century fiction

From our annotations (see "Methods" above), the most frequently-occurring bundles in fiction have one of the following functions:

- Expletive (*there was a, it was a, there was no, it was not, and there was*)
- Auxiliary forms (*i do not, i did n't, he did not, he had been*)
- Modal forms (*i could not, would have been, i ca n't, as if he*)
- Relative clause markers (*that he had, that he was, which he was, that she was*)
- Temporal markers (*for a moment, as soon as, the first time*)
- Partitive constructions (*one of the, part of the, some of the*)
- Spatial markers (*out of the, at the door, in the house*)
- Stance markers (*do n't know, i am sure, to be sure, seemed to be*)
- *Of*-genitive (*the name of; the voice of; the heart of; the hands of*)
- Discourse organization markers (*in spite of, as to the, in order to*)

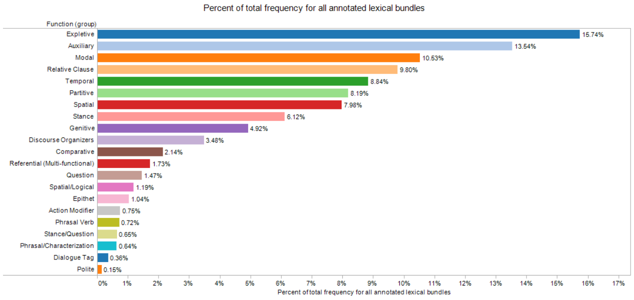

Figure 1: The most frequent 240 4-gram bundles, and most frequent 150 3-gram bundles, were annotated for their primary function in fiction; displayed here is the percentage of occurrences of all 390 annotated bundles within each unique functional type

The discursive mechanisms and requirements of fiction are immediately discernable in this ranked typology, especially when compared to prior work on lexical bundles in other discursive contexts. The prominence of expletives in fiction, for example, seems particularly significant, as they condense a fundamental gesture of storytelling into a phrase: once upon a time, *there was a*... Expletives function in our corpus as a means of positing and sustaining a fictional ontology: *it was* the best of times, *it was* the worst of times. Similarly, the prevalence of temporal and spatial markers (*as soon as, in front of*) help perform another fundamental task of fictional narration, that is, maintaining a complex and evolving network of persons, objects and events in their changing relationships to one another.

2. Historical behavior of lexical bundles

On the whole, the historical trends we find in the use of lexical bundles suggest an increasing specialization of certain narrative functions over the course of the century, especially in the language of dialogue and its narrative orchestration. For example, the most frequent functional type of lexical bundle—the "expletive" bundles described above, like " *there was a*"—are actually more frequent in dialogue than in narration earlier in the century, but are then increasingly adopted by fictional narrators as part of their machinery for coordinating the existence of fictional objects (see Figure 2).

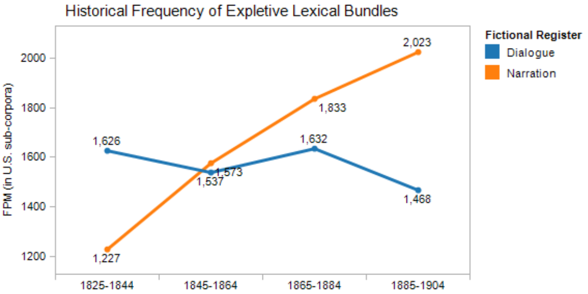

Figure 2: The sum frequency per million of 21 lexical bundles annotated as expletives. Frequency is calculated in the dialogue and narrative portions, per period, of U.S. fiction

We also see evidence of historical changes that do not depend on internal register differences in fiction (narration vs. dialogue). Particularly striking is the general decline in the use of *of*-genitives in both narration and dialogue, in both British and American fiction (see Figure 3)—presumably replaced by the more concise Saxon genitive (*'s*) or by noun phrases (as in *the center of the city* vs. *the city center*). This may be an instance of a broader shift towards more informal, concise diction as the nineteenth century progresses, since the Saxon genitive and such noun phrases privilege efficiency of expression over the rhythmical advantages of the *of*-genitive.

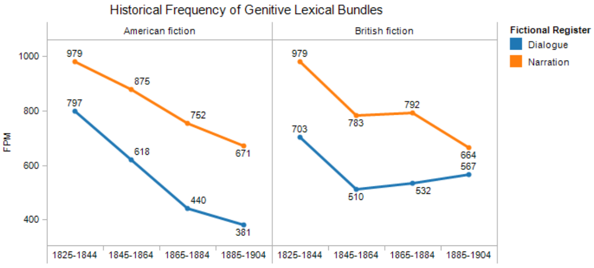

Figure 3: The sum frequency per million for 35 lexical bundles annotated as genitive, per period, in the dialogue and narrative portions of U.S. and British fiction

Finally, we find some key differences in the use of bundles between dialogue and narration, largely having to do with national differences in colloquial expressions. In American dialogue, for example, over the course of the century we find an increased use of *going-to* future forms (*are going to; am going to; going to do; are you going; going to be*), along with an increase in colloquial discourse markers (*sort of thing; kind of a; all the time*). In the British dialogue corpus, similarly, we find a decrease in formal and polite phrases over time (*to be sure; i have no doubt; my dear sir; depend upon it; god bless you; as you please;*

by the bye; the honour of), and a concurrent rise in more informal modern phrases (*in spite of; at any rate; here and there; now and again*). Taken together, such trends suggest that this shift towards more informal bundles is particularly concentrated in fictional dialogue.

Notes

[1] In stylometry, there has been lively debate about the use of n-grams for authorship attribution. Our study differs in focusing on very common n-grams (i.e., on lexical bundles) rather than the rare n-grams studied by Vickers (2011), and it does so not for the purposes of authorship attribution, but rather to identify how fiction's most common lexical bundles may have evolved over time, and may have done so differently in narration and in dialogue.

[2] Jonathan Culpeper's 2012 book is another recent study that uses bundles to study literary texts, but Culpeper's object of inquiry is the early modern English dialogue, not the novel.

[3] Departing from Biber et al., we decided to tokenize contractions as separate words (with "won't" becoming "wo" + "n't"), in order to place bundles involving contractions in direct comparison with their uncontracted equivalents ("i wo n't" and "i will not" being both tri-gram bundles).

[4] Biber and Conrad (1999) argue, and we agree, that lexical bundles often serve as mechanisms for bridging syntactic and semantic units. Accordingly, we allow lexical bundles to cross punctuation as well as clause and phrase boundaries.

[5] For example, in the 1835 novel by William Gilmore Simms, *The Partisan: A Tale of the Revolution*: "but there was a reckless audacity in his replies to the friendly suggestions of the landlord, which half-frightened the latter personage out of his wits."

Performance, the Document, and the Digital: the Case of Lynn Hershman Leeson's 'Robertas'

Gabriella Giannachi
g.giannachi@exeter.ac.uk
University of Exeter, GB

Performance at Tate, an Arts and Humanities Research Council funded project which run between 2014-6, set out to trace the history of performance at Tate from the 1960s to today by investigating practices of collection, display, documentation and exhibition in the museum. At the heart of the project was the desire to conduct a wider re-evaluation not only of the place of performance in the museum, but also of the specific role played by documentation, including digital documentation, as well as the documentation of digital works, within collections, archives and displays. Here, I explore what the introduction of the digital has meant in this particular field by conducting a close examination of Lynn Hershman Leeson's *Roberta Breitmore* (1972-8), in which the artist created a fictional persona and interpreted its role for a period of six years using surveillance technology to capture various moments in her life. I will also discuss her subsequent works *CyberRoberta* (1995-8) and *Life to the Second Power* (2007) in which the character of Roberta was re-invented across different media. Focussing on the different types of documentations that these works generated, including photos, drawings, a cartoon, a film, a second-life re-enactment, postcards, among others, I then establish a best practice framework towards their curation and preservation that will be applicable more broadly for digital art practice.

To establish the role played by documentation in this context, Performance at Tate aimed to move beyond existing debates on the ontology of the relationship between performance and documentation. These debates may be traced back to the 1970s when, writing on performance-based work, the art historian Douglas Crimp asserted that 'you had to be there', implying that performance needed the presence of the spectator to be activated and often required 'that registration of presence as a means toward establishing meaning' (1979: 77). This approach underpins the performance studies scholar Peggy Phelan's well known assertion that 'performance's only life is in the present' and that performance 'cannot be saved, recorded, documented, or otherwise participate in the circulation of representations *of* representations: once it does so it becomes something other than performance' (1993: 146). A different position was adopted by media studies scholar Philip Auslander who in his identification of different types of performance (and documentation) counter-pointed that 'documentation does not simply generate image/statements that describe an autonomous performance' and states that it can produce 'an event as a performance' (2006: 5).

Instead, Performance at Tate aimed to build on approaches initiated by Amelia Jones (1997) and, subsequently, Barbara Clausen, who challenged the positioning of the document as secondary to performance, as well as the positioning of the document as equivalent to performance suggesting that performance should not be seen as beginning with or ending with the 'authentic experience', or live moment, but rather that it should be seen as 'an ongoing process of an interdependent relationship between event, medialization, and reception' (2005: 7). In other words, performance, in the course of its transcriptions, is subject to significant shifts caused by the constantly altering reception of its documents over time. Performance documents should therefore be considered, utilising Suzanne Briet's term from 1951, as an ecology of inter-documents, comprising primary documents, created at the time of an event, secondary documents, created from the initial documents, and auxiliary documents, created by a juxtaposition of documents. Rather than delivering remains of an isolated event, the document, for Briet, forms part of a matrix or network of signs. So, she noted, 'through the juxtaposition, selection, and the comparison of documents, and the production of auxiliary documents', the content of documentation becomes 'inter-documentary'.

Performance and documentation have always been somewhat inter-dependent. So, for example, art historian and critic Barbara Rose pointed out the significance of Hans Namuth's famous photographs of Jackson Pollock's work as *documents* of his practice that radically affected any subsequent perception of his paintings (1979: 12). Likewise, it was performance studies scholar Philip Auslander who noted that Harry Shunk's photographs of Yves Klein's *Leap into the Void* (1960), a photomontage, in fact constitute the work itself (2006). And it was Paul Schimmel who noted how Chris Buren's actions, such as in *Shoot* (1071), in which the performer asked his assistant to shoot him in his left arm, were 'distinguished by their ability to be captured by a single photographic image and described in a brief paragraph' (1998:97) almost as if to imply that the performance was designed so as to work for the photo. Most of these works nowadays exist primarily as documents. One such work is Hershman Leeson's *Roberta Breitmore* (1972-8) which comprises of a series of documents charting Roberta's internal (i.e. a list of cosmetics for her make-up) and external transformations (i.e. a movement chart), testifying also to her social existence (i.e., she placed an advert, and underwent a psychiatric evaluation) and financial existence (i.e. she owned a checkbook). Nearly twenty years after Hershman Leeson exorcised the character of Roberta at the Palazzo dei Diamanti in Ferrara in 1978, Roberta was re-invented as *CyberRoberta* (1995-8), a tele-robotic doll who was dressed identically to Roberta, and whose fictional persona was, as in Hershman Leeson's words, 'designed as an updated Roberta' who navigate the internet, and was described as a 'cyberbeing' (1996: 336). Roberta also appeared as a bot in the Second Life remake of an early work by Hershman Leeson, *The Dante Hotel,* called *Life to the Second Power* (2007-) , which turned parts of the Hershman Leeson archive at Stanford Libraries into a dynamic mixed reality experience where visitors could explore digital reproductions of fragments of the original archive of *The Dante Hotel* under Roberta's guidance in Second Life (Roberta had started her existence when she arrived in San Francisco on board of a Greyhound bus and checked herself in at the Hotel Dante).

The first work, *Roberta Breitmore,* consists of documents which are now preserved as the artwork in public and private collections (MOMA, SFMOMA, Tate, Walker Art Center, as well as the Hess collection, to name a few). Each museum also has a documentation of the work, which usually consists of gallery, curatorial, and preservation records. These may disclose significant information about how the artist wishes the work to be installed, for example, or about the work's preservation strategy. *CyberRoberta*, which is in the Hess collection, does not consist of documents, though, unlike in the case of *Roberta Breitmore*, some documents were produced by users and are available on social media. These documents are not works, though it is only by seeing them that, if we have not experienced the work ourselves, we can understand how the work operated. No museum, to my knowledge, has been preserving these user-generated documents. Finally, *Life to the Second Power* is available on Second Life and a set of photographic documents were collected by Exeter and Stanford Universities at the time the work was shown. Again, a number of visitors generated photographs (both in first and second life) but these were not collected. The work was shown as The Montreal Museum of Fine Arts and at SFMOMA, so it is likely that these museums have kept a documentation of the work, though most museums only do so when the work entered the collection. In short, in the case of *Roberta Breitmore,* the artist created the documents that are now known as the work. In the cases of *CyberRoberta* and *Life to the Second Power,* most documents showing the work in use were produced by users or viewers, and none of them are systematically preserved. In the case of *Life to the Second Power,* the work is hosted by a commercial platform and may cease to exist once the platform becomes obsolete or is terminated by its owners.

I conclude by suggesting that Museums should draw from performance studies and digital humanities and create records documenting the experiences of these works, noting also how these have changed over the years. I also look into the challenges paused by their preservation, particularly in terms of born digital works. Finally, I show that by capturing this knowledge, Museums will not only preserve important historical information about the exhibition and reception of these works, but also create, to use Briet's term, an inter-documentary ecology comprising 'live' performance (whether by the artist or the user), documents (created by the artist, the museum or the user) and the digital (showing the web and social media life of a work in different formats).

RICardo (*Research on International Commerce*) is a database gathering bilateral flows of international commerce extracted from a large number of historical statistical sources during the 1787-1938 period. The foundational principles of this database are described in a working paper (Dedinger and Girard, 2015) submitted to the Historical Methods journal. This database begun to be developed by researchers in Economy and History in 2004 with the goal of renewing research on the history of trade globalization. In 2013, an entire new direction was given to the RICardo project. Economists and historians worked together with data scientists and designers in order to build a completely innovative digital tool susceptible to be used for both teaching and research[1].

Exploring international trade during the 19th century

To this day, there is no equivalent digital resource to the RICardo database that focuses on such an ancient and lengthy time period. The only comparable tools are web applications from the IMF (data.imf.org), the WTO (stat.wto.org) and the United Nations (comtrade.un.org) that offer data and visualizations on commerce during the post-50's period. As we will show, the methodological problems posed by historical trade statistics (19 th-20 th centuries) are more complex. The first result of our work is a web application [2] available online:http://ricardo.medialab.sciences-po.fr. The database will be publicly released in 2017 upon the start of an international conference marking the two-hundredth anniversary of the publication of Ricardo's main work (Ricardo, 1817).

We will discuss the methodological choices made during the creation of this data exploration tool – what we call *datascape* (Latour et al., 2012) – and will quickly present the research and educational perspectives that the tool allows for, before concluding on the method of transdisciplinary work that was used.

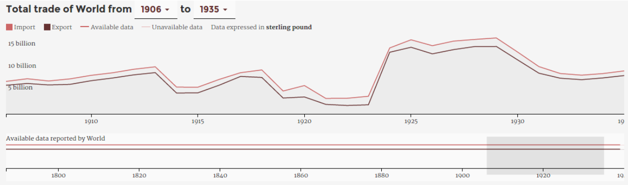
Representing data in their uncertainty

In RICardo, the basic informational unit is a trade flow (exportation or importation) between a *reporting* unit and a *partner* unit. In its present version, the database contains

267 000 flows. The *partners* are the commercial partners recorded in the annual trade statistics reports of the *reporting* countries. The large spatial and temporal coverage of the database raises certain problems. First off, the entities cover very heterogeneous realities: partners can be countries ("United Kingdom"), groups of countries ("United Kingdom & Ireland") or geographic areas ("British colonies"). Further, the availability of trade statistics before the end of the 19 th century is very problematic (Dedinger and Girard, 2015), which is translated into an absence, in the database, of a non-negligible (17 000) amount of flows throughout the observed period. The challenge we then had to take up was to aggregate heterogeneous data without crushing the corpus' complexity and accounting for missing data in the series. We attempt to resolve this thorny question by the exploratory analysis of the data (Tukey, 1977).

Three levels of exploration

The exploration interface developed offers three levels of entry from global to local: *world view, country view* and *bilateral view*. Each representation offers a specific point of view on the data within the database. The complexity increases as we move from the world view (*World*) to the national point of view (*bilateral*). In order to lead the exploration throughout these different levels, we have decided to construct a common structure to all three viewpoints.



Total trade of World from 1906 to 1935

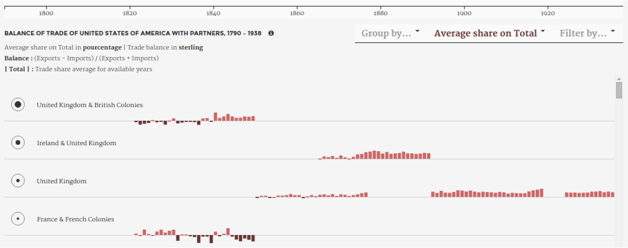
Data expressed in **sterling pound**

Figure 1: Temporal filtering

Each one opens unto a main curve representing total flows per year (representation of countries' total trade for the *world view*, of one country's total trade for the *country view*, or tradebetween two specific countries for the *bilateral view*) in addition to temporal limits. It is represented as a discontinuous line that is interrupted when there is no known value. In addition, these discontinuities appear also in an underlying temporal axis, indicating the absence of data in the form of a projection on the X-axis. This graphic object is also useful as an interface for temporal filtering: one can graphically select a sub-period to study more specifically (Becker and Cleveland, 1978). As footer for each view's page, a spreadsheet allows to navigate within the visualized source data and export it as spreadsheet format (CSV). This way, the user can continue the analysis in an external statistical tool. At the center of this common structure, each view offers more detailed exploration.

Studying a country through the prism of its partners

The country view allows users to center their analysis on a *reporting* country by representing annual trade balances with each *partner* under the form of histograms.



BALANCE OF TRADE OF UNITED STATES OF AMERICA WITH PARTNERS, 1790 - 1938

Average share on Total in **pourcentage** | Trade balance in **sterling**

Balance : (Exports − Imports) / (Exports + Imports)

| Total | : Trade share average for available years

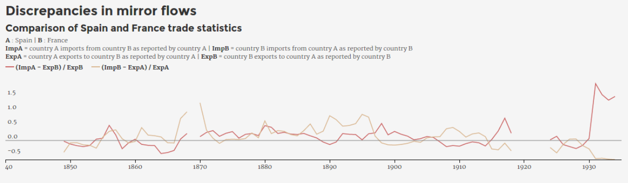
Group by... ▾ Average share on Total ▾ Filter by... ▾

Figure 2: Trade balances of partners

This use of *small multiples* (Tufte, 1990) facilitates comparisons between partners. The choice of detailing trade balances per year holds the fact that an aggregation on the entirety of the period would have introduced a bias by masking the year in which some data is missing. Furthermore, the ordering of the partners corresponds to the average annual share of each partner on the available years. This metric, represented as a circle at the start of the line, allows on the one hand to display the partners by decreasing importance, and on the other hand to let appear similar *partner* entities. Figure 2 therefore shows that "Ireland & United-Kingdom" and "United Kingdom" were the 2 nd and 3 rd partners of the United States during the 19 th century. They are two different entities but a similar partner in reality: the United Kingdom (the overlapping of years 1864-1876 is a consequence of the inclusion of two different sources).

The distorting mirror of bilateral trade flows

In the bilateral view, the tool offers to interrogate a pair of *reporting* countries by using a representation of their mirror flows. It's one of the great strength of the RICardo database: a same bilateral flow is declared as an export by one of the countries and as an import by the other, however these two recordings are rarely the same (Dedinger and Girard, 2015). Thanks to the calculation of an indicator (Dedinger, 2012), the bilateral view offers an immediate view of the deviation between mirror flows and its fluctuations over the selected period.



Discrepancies in mirror flows

Comparison of Spain and France trade statistics

A : Spain | **B** : France

ImpA = country A imports from country B as reported by country A | **ImpB** = country B imports from country A as reported by country B

ExpA = country A exports to country B as reported by country A | **ExpB** = country B exports to country A as reported by country B

Figure 3: The bilateral view

A tool for researchers and students in social sciences

The exploratory formatting of data brings powerful tools to help research on the history of economics. It's an excellent way to detect possible inconsistencies in data (Leclercq et al., 2013) in order to determine its cause. To achieve such a result, our method consisted in considering data visualizations as both results and media of research (Stefaner, 2010), in fostering collaboration between researchers, engineers and designers through workshops where each data visualization was discussed by articulating the methodological constraints of Economics and History, the ideas and principles of Design and technical workability.

Researchers have at their disposal an incomparable tool to deepen an analysis of trade statistics reliability (bilateral view), to compose monographs on the trade history of the world's countries (country view), to study the history of trade globalization since the beginning of the 19 th century (world view) and to experiment data-driven teaching methods.

Augmented Reality (AR) superimposes geolocated digital text and images on a real-time view of the world. Museums, urban spaces and cultural heritage sites are using AR to virtually restore and enhance historical displays and environments on smartphones or tablets. We have created an AR application that combines dynamic, interactive content, including realistic 3D models, video, animation, game, and website portal, to immerse a diverse public in the history and culture of an important and well-trafficked setting: Flushing Meadows-Corona Park (FMCP), a 1255-acre urban park in Queens, NY. Littered with dramatic remnants of two World's Fairs, FMCP is steeped in a largely-forgotten history as the site of the 1939/40 and 1964/65 World's Fairs (NYWF), the first UN General Assembly, activities of European colonists, and early habitation by Algonquian speaking Native Americans. Additionally, the park served as the backdrop for the novel *The Great Gatsby* and as a site for an interesting natural history.

Our public venture partner, the Queens Museum, is situated within FMCP, in the most diverse immigrant neighborhood in New York State. In 2014 the population of Queens was composed of 49.1% Caucasian, 28% Latino, 25.8% Asian, and 20.8% African American. 47.8% of households are headed by individuals born outside the United States (http://quickfacts.census.gov/qfd/states/36/36081.html). By harnessing the multimodal possibilities of AR, we have engaged an ethnically, generationally and educationally diverse audience in the cooperative - and critical - exploration of history and culture.

The application will provide users two complementary experiences: an intergenerational learning game which enables children and adults to be partners while learning about the history of FMCP, and a guided tour that explores the two World's Fairs through comparison of their common, recurrent themes such as futurism, technological optimism, citizenship, progress, race and nationalism. Through these modalities, the application supplies a greatly enhanced destination experience to users of all ages and backgrounds, whether they are families from the surrounding neighborhoods, Queens Museum goers or tourists to New York City.

The project is informed by interdisciplinary humanities scholarship, including World's Fair history, anthropology, theme park studies, cognitive psychology, AR mobile design,and game design for STEM and cultural learning (http://srealserver.eecs.ucf.edu/chronoleap/).

I. Intergenerational Game

Based upon the activity Geocaching, an intergenerational learning game is under development to provide children a scaffolded way to learn about the history and heritage of FMCP. Geocaching is a scavenger hunt-style game, which sends individuals or teams searching an environment for hidden physical items. By making the caches virtual, there are no limitations on items and avoid impacting park operations. An adult led by the child must surmount the challenge of locating virtual geocaches, while exploring the past of FMCP. Teams will also drill virtual core samples in the park and examine them to find geocached items within.

Game play proceeds as users are provided clues and instructions guiding them to a physical locations. For example, a clue might read "Find the ancient column" (referring to the extant Roman Column of Jerash, presented to NYC by Jordan's King Hussein at the close of the 1964-65 NYWF) (Wingfield, 2011). Player's devices notify them when reaching the location and are then provided new GPS coordinates. The device enables them to find the location, as well as see the landscape of the park as it appeared in the past and find the virtual artifact. Artifacts are stored by the application for future examination. This process continues for a set of artifacts – each artifact being one piece of a puzzle. In geocaching tradition we provide a final reward at the end.

Another feature entails the collection of virtual pieces of artifacts from the core-sample's strata, which are eventually reassembled at the relevant location. Examples of artifacts which might be found and assembled by users include the Videophone displayed at the Bell Telephone Pavilion during the 1965/65 Fair, the first television displayed at the RCA Pavilion during 1939/40 Fair, and a Mastodon from the Pleistocene Era. The application can provide supplemental content (e.g. video, audio and images), questions that open up further pathways for thought, and fun quizzes that challenge a user's knowledge and memory.

As children have yet to develop a mastery of most subjects, they can often learn better when they are provided support from a familiar adult (Vygotsky, 1978). Such support, commonly known as scaffolding, is essential for them to integrate new information into their base of knowledge. This dovetails well with Lave and Wenger (1991), where learning is a communal, interactive activity where less experienced individuals learn from master practitioners. Our app provides an intergenerational pathway, where the adult can both support learning information presented and share associated information from their own life. A child will likely to engage with media prompts when with an adult (Takeuchi et al., 2011). Participatory mediation of learning, where adults and children collaborate, sharing a dialogue stimulated by the geocaching activity offers the potential for learning in such application (Clark, 2011). This could be extended to encompass the sharing of deep-rooted memories and experiences for the adult, while also enabling children to share their experiences.

II. The Deep Experience

This modality targets individuals who are interested in advanced content and interpretation for deeper, critical understanding of the 1939/40 and 1964/65 Fairs at Flushing Meadows, remnants of which form a dramatic backdrop. World's Fairs were typically experienced as spectacles of culture, industry, and technology. (Benedict,1981; Geppert et al., 2005; Greenhalgh, 2011; Corn and Horrigan, 1984; Garn et al., 2007; Rydell, 1984, 1993; Rydell and Gwinn, 1994; Rydell et al., 2000) However, they are also environments that shaped popular understanding of society's past, present and future, linked through enduring narratives of citizenship, progress, technological optimism, consumerism, race and nationalism (Hollengren et al., 2014; Gordon, 2005; Marchand ,1991,1995; Samuel, 2007; Tirella, 2014; Winner, 1991). This mode enables users to critically engage with the changing social themes and narratives that tie the Fairs together by sending users to cognate, virtual pavilions.

Designed as a curated tour starting at the Queens Museum, visitors are guided through the park viewing models of Fair pavilions, and learning about common themes through archival images, audio and documentary footage, both within the application itself and on the associated website. Examples include:

Landscapes of the Future

The connected themes of progress, technology, commerce and utopia – as expressions of "the future in the present" – have always dominated in World's Fairs (cf Land, 2011). Visitors are directed to the interstate highway utopia of Futurama at the General Motors pavilion, designed by Norman Bel Geddes (Marchand, 1991; 1995), and also to Futurama II, its updated version in the later Fair, in which "General Motors set out to reveal how technology would conquer the harshest environments for the betterment of humanity" (Walters, 2014:467). Visitors will be able to view archival footage of both exhibits, read contemporary accounts and see original designs.

Protests at the Fair

National and global conditions did not reflect the optimistic themes of the Fairs, nor did Fairs go uncontested by groups who were excluded from self-representation and employment. The 1964/65 NYWF was designed as a virtual bubble away from the emergent civil rights, free speech and anti-war movements. Visitors are invited to explore the CORE (Congress of Racial Equality) protests of 1964 (Peneda, 2014; Jacoby, 1998; Tirella, 2014; http://www.democracynow.org/2014/4/25/protesting_the_1964_world_s_fair)

and to see them come alive at the site of the Unisphere (still extant), through digital overlay of archival footage (see for example http://timetraveler.berlin). Visitors will also access additional material such as pamphlets, flyers and photographs, and hear audio of speeches and meetings.

Racial Representation: two Africas

Both Fairs contained pavilions that represented "Africa" as a project of defining, organizing and displaying people and culture. (Lorini, 1999; Rydell, 1999). Our comparison of these exhibitions highlights the increased agency of the emergent African Republics of 1964/65 to represent themselves as modern members of the family of nations with professional dance performances, art exhibit, displays of industry (cf Benedict, 1993; Lukas, 2007). In contrast, the Great Britain pavilion of 1939/40 contained "natural history" dioramas of traditional scenes in the life of its colonized subjects (http://www.1939nyworldsfair.com/worlds_fair/wf_tour/hall_of_nations/great_britain, https://archive.org/stream/ldpd_11290477_000#page/n1/mode/2up). The static diorama was a key visual strategy that distinguished colonized Africans from its white Commonwealth citizens, also on display. Visitors will be able to compare the 1964/65 professional dance performances with those that took place at the 1939/49 Midway where they were framed as exotic, marginal entertainments.

The interpretive experience provides an associated website that contains contemporary accounts, academic essays, archival media, and exhibition content. The website will also provide an opportunity to upload personal oral histories of the Fairs (cf Anderson, 2003) that will prompt them to critically reflect on the relationship of the historic Fairs and contemporary life.

Introduction

Preparing sources for historical research usually requires making many heterogeneous collections digitally accessible and linking them to compose a multi-faceted and multi-layered resource that supports both distant reading and close reading forms of analysis. In the lifecycle of historical information – a model introduced in 2004 - the Dutch DH-experts Boonstra, Breure and Doorn emphasize three points that should be kept in mind by e-science experts and researchers alike to keep historical information systems alive and useful: durability, usability and modeling (Boonstra et al., 2006: 22).

Timbuctoo, developed at the Huygens ING, offers a system that makes it possible to model and store heterogeneous data but also incrementally enrich and link the data. Furthermore, it also offers facilities to document the provenance of all data as well as all steps in data editing, extraction and linking data. These features are vital for historical research in which researchers need to be able to exert 'source criticism' and go back to the original source or data at all times (Ockeloen et al., 2013).

We will demonstrate the solution Timbuctoo offers with the Migrant, Mobilities and Connection project as a use case, because of its complex and multiple links to datasets from a myriad of cultural heritage institutions (archives, libraries and museums) on several levels.

The main focus of the Migrant project is on the life courses of the migrants. Starting from the limited core data from a connection between (digitized) Dutch emigrant cards and Australian immigration files, the life courses will be elaborated using in depth-analysis of these and other collections. It is important to note that for the purpose of the Migrant project that life courses not only comprise dates and birth, marriage, migration, education and employment but also extend to the interactions of migrants with all sorts of institutions in the Netherlands and Australia and their representatives. The database therefore enables us to analyse and compare the evolution of a multitude of social networks (Arthur et al. (submitted); Van Faassen, 2014a, 2014b).

Migration files as a multi-layer resource

The Migrant, Mobilities and Connection project focuses on the Dutch-Australian post World-War II migration from the Netherlands to Australia. Like all migrants these 180,000 people have left many traces in different cultural heritage collections ranging from (supra) government archives to the photo and memorabilia collections of the migrant families themselves and anything in between. These collections are dispersed over different countries. A lot of the collections are available in a digital form or will be digitized in the future, but like all historical collections they contain partially structured information and partially unstructured information that needs to be made accessible for further analysis. In elaborating the data we will use a variety of methods ranging from computer assisted data extraction and linking of a large collection of life events to hand editing of handwritten registration cards and personal migrant files. From an analytic perspective all these collections and edited data can be seen as different layers that need to be accommodated by the data store in which they are kept (Hoekstra and Nijenhuis, 2012).

Timbuctoo

Timbuctoo is a data repository system aimed at humanities research with the aim of linking together datasets containing structured information concerning people, places and organisations without actually merging them to facilitate scientific analysis and discussion.

To accomplish this it defines a number of primitive types that describe entities that all researchers agree on, such as the afore mentioned persons, places, organisations as well as works, languages, concepts and events. Each research project that makes use of the repository can extend the primitive types with extra fields. On top of that the repository has the ability to store multiple viewpoints on the same entity. In this way, researchers become aware of the different or sometimes even conflicting assumptions about entities, fueling scholarly debates in a conceptual way. Timbuctoo also support versioning and provenance. To make it clear on which information the results are based every change made to the data should have information who made the change, when the change was made and for what reason the change was made. The user interface, analysis and visualization are completely separated from the storage of the data. All services are coupled using REST (Fielding, 2000) APIs. The software is freely available under an open source license (GPL 3) and is published on Github.

Information extraction

During the project data will be added, edited and analysed continuously. As indicated above, at the beginning of the project the data consists of migration information contained in cards, files and information of governance agencies. Apart from the core information already available in a simple database, the cards and files contain much more information that must be digitized to be able to use it for analysis. In the course of the project, a lot of other materials from archives, libraries and other collections from different cultural heritage institutions will be added to the Timbuctoo database. Some of the information will be structured, but most is contained in typed or handwritten files and in images. The aim of information extraction is to extract structured information from unstructured information.

For the elaboration of this wealth of materials we will use an eclectic mix of editing and information extracting methods. Previously, hand editing was the only option for these types of materials, but in light of the amount of material that will be collected, all computer assisted information extraction that is possible will contribute to the database and help analysis.

To automate this process the data needs to be stored in such a way that a context can be build. The computer can search for patterns and suggest links to data already present in the network or calculate statistics to point out interesting or unusual things in the dataset. To begin with, an algorithm needs to be made to link the Dutch and Australian records together. Note that the system should not actually merge the records. Data about persons can be linked together based on (for example) familyname, year and place of birth and indeed all other types of structured information available such as migration date, migration scheme, ship with which they travelled or still very different data depending on the source and the context.

Other examples of computer assisted data extraction include the recognition of certain keywords in the facsimile or transcriptions. Researchers can add or edit information manually through the user interface, either manually or using algorithms. Automatic information extraction should suggest relations between different records or entities, but never actually enforce those changes on the researcher.

We started out to build Timbuctoo with the problem of the large variety of heterogeneous data sources that our institute produced in the course of a hundred years of classical and some twenty-five years of digital source editing and publishing. The use case of the Migrant, Mobilities and Connection project, with data about thousands of personal migrant stories scattered all over the world and its myriad of policy files on national and supranational levels recorded in different datasets, demonstrates the different features of Timbuctoo.

First, Timbuctoo is used as a repository where researchers as well as automatic tools such as parsers store all the heterogeneous data and the relations between it. Since all the data is versioned and provenance information is recorded, it is always clear where the data originates from. Second, Timbuctoo serves as a data source for researchers and parsers. Named entity recognition tools can use all the available names of places, organisations and persons as training data. Researchers can do queries on certain properties and do statistical analysis on the results to either find outliers or confirm or refute a hypothesis on a larger scale in more varied ways than previously possible. Finally, being a graph database, Timbuctoo is a research tool that enables researchers to infer indirect relations from the numerous direct relations in the repository. This makes it possible to perform complex queries and conduct network analysis and visualization. These three features combined enable researchers to discover unexpected phenomena that can lead to new research and methodological questions.

The Single Interface for Music Score Searching and Analysis (SIMSSA) project is building tools and best-practices for performing large-scale document image recognition, analysis, and search on music documents. In this paper, we will describe a novel technique for providing cross-institutional music document image search, allowing for the creation of a search engine for the contents of the world's music collections through a single search interface.

This paper will describe our methodology for building large-scale search systems that operate across institutions. We will describe the optical music recognition (OMR) process, which, like optical character recognition (OCR) for text, extracts symbolic representations from document images and places them in a structural representation for further processing. We will then describe our techniques for music analysis, extracting patterns for indexing the musical contents of these images into searchable representations. Finally, we present our efforts at building a system that will allow users to search musical documents from many institutions and retrieve the digitized document image.

Challenges

Perhaps the most significant challenge to building a global document image search system is how to retrieve, store, process, and serve document page images. These images have been produced through mass digitization efforts by individual institutions. Aggregating document images to provide cross-institutional document search has traditionally been provided through centralized efforts, where a single organization collects digital images and performs document recognition (i.e., OCR) on them.

While this approach provides a central tool for users to search and retrieve document images, it has several disadvantages. It often requires significant storage capabilities, as the central organization must store and manage all the images from its partner institutions. There are logistical challenges, integrating cataloguing data from multiple document collections and maintaining up-to-date information and error-fixes from the partner organizations. There are also legal implications over the ownership and copyrights of document image surrogates, even on out-of-copyright documents (Allan, 2007). This typically requires negotiations and embargoes on who can access certain types of content which differ across partner institutions, and which must be applied at the central organization level (HathiTrust, 2015).

These technical, legal, and logistical challenges may be mitigated if the partner organizations were able to host and control access to their images directly. Until recently, however, direct access to the document images hosted by an institution was difficult as it required interacting with a wide variety of digital repository software, each with their own particular ways of storing and serving images. There were no standardized methods to specify how a document image could be accessed directly in these repository systems.

Interoperable Image Collections

The International Image Interoperability Framework (IIIF) (Snydman et al., 2015) is a new initiative that attempts to standardize methods for retrieving digital images from an institution's digital image collection. The IIIF specifies two mechanisms for this, the Image API and the Presentation API. The Image API sets out a standard URI-based request format to which IIIF-compatible systems must conform. Using this URI format one may specify the size, region, rotation, quality, and format of the requested image, as well as basic information about the image. The Presentation API is used to describe structural and presentation information about an image, or a sequence of images. The Presentation API is structured using JavaScript Object Notation (JSON), which may then be parsed by other software, and within which pointers to images using the Image API are stored.

To give an illustration, a digitized book may be represented as a IIIF Presentation API manifest file. Each page image within the book would be retrievable by a URI to the page image stored on a remote server. To view the book, the manifest would be loaded into a IIIF-compatible image viewer, which would then fetch and load each of the document images and present them in sequence.

The typical use case for a IIIF manifest is for the purposes of retrieving and viewing document page images. However, we are proporsing a novel application of IIIF as a standard interface to perform document image recognition tasks on digital collections from many different institutions.

Distributed Document Image Recognition

We are building a web-based document recognition system, named Rodan, for performing optical music recognition (OMR) on large quantities of page images (Hankinson, 2014). Rodan is a workflow system, where different image processing, shape recognition, and document processing tools can be chained together to produce the sequence of discrete steps through which an image must proceed to extract the symbolic music representation of the content. Crucially, the exact cartesian positions of every musical symbol on the image are stored, providing a way to correlate the musical content with its physical position on the page image (Hankinson et al., 2012).

By providing Rodan with a IIIF Presentation API manifest, the document page images may be downloaded and the symbolic music notation extracted. However, rather than storing the image, we store just the IIIF Image API-formatted URI back to the original image. This allows us to discard the downloaded image file but point back to the image hosted by the originating institution. This approach eliminates the need to store and serve the images on our own systems, while still providing content-level access to document images hosted in different institutional repositories.

Music Analysis

Within music notation there are several levels of representation. The most basic level is that of the symbol–the graphical element printed on the page. Structures such as melodies, phrases, and cadential patterns are built from these symbols, and exist in multiple overlapping hierarchies; a phrase might contain a number of cadential patterns. A music search system must understand the different levels and structures in a musical work, beyond simply understanding the individual notes, as these structures may form structural objects that a user may wish to retrieve. Within the SIMSSA project we are developing tools and techniques for extracting patterns from symbolic music representations using the Music Encoding Initiative (MEI) and other structured music representations (Schubert and Cumming, 2015; Sigler et al, 2015).

The Vertical Interval Successions (VIS) (Antiilla and Cumming, 2014) tool we are developing provides a platform on which pattern analysis and extraction methods may be built. Like the document recognition process, VIS operates on the principle that computational music analysis is a sequence of tasks, where each task is responsible for extracting specific types of information that may then be passed on to subsequent tasks. In this way, the underlying symbolic representation of music notation may be used to build higher-level representations, which may then be sent to an indexing service for use in query and retrieval tasks.

Cross-Institution Indexing and Retrieval

After analysis, the symbolic representations and the structures of the music documents are indexed for retrieval in a search engine. The IIIF Image URI associated with the page image, stored in the document recognition stage and carried along in the analysis stage, provides the mechanism through which the page image may be retrieved from host institutions in response to a query on the symbolic music contents. Through this system, musical full-text (or "full-music") search can be performed on document images hosted and served from IIIF-compatible digital collections. Additionally, metadata and cataloguing data may be embedded in the IIIF Manifest, or linked to other machine-readable representations. This data may also be centrally indexed, allowing users to retrieve documents across institutions with useful textual searches such as titles, composers, or dates.

Impact and Future Work

With cross-institutional music document image search, institutions may make their collections available to a broader audience without the need to host their images with a third-party service. With IIIF-compatible image and manifest services, the barriers to entry for these institutions to provide these capabilities is relatively low; the metadata and images are already part of their digital infrastructure. Furthermore, by serving the images and metadata directly from their own infrastructure, institutions can track collection usage patterns through their own server analytics.

More general applications of this methodology will have significant impacts on libraries, archives, and other institutions' document image collections. By providing machine-readable access to document images directly, third-party services for document analysis, including distributed optical character recognition (OCR) may be built and deployed. This will have implications on large-scale computational re-use of digital resources, and will open up document image collections to distributed analysis by a global audience.

We are currently in the process of building a prototype system that incorporates all elements of the process described in this paper. Our existing tools, Rodan and VIS, are currently being used in research and production, with a third system in development that will provide a platform for developing search and retrieval tools.

One of our biggest unanswered questions concerns the human side of retrieval. With large quantities of recognized musical content, what sorts of tools and interfaces will people use to query the symbolic content of music documents? How will they conceptualize their symbolic music information needs, and what types of interfaces will they use to express these needs to a search system? What types of musical patterns will we need to extract from our musical documents to provide a useful symbolic search system? All of these questions we hope to investigate with a completed system.

Introduction

The automatic classification of literary genres, especially of novels, has become a research topic in the last years (Underwood, 2014; Jockers, 2013). In the following we report on the results from a series of experiments using features like most frequent words, character tetragrams and different amounts of topics (LDA) for genre classification on a corpus of German novels. Two problems will be in the main focus of this paper and they are both caused by the same factor: The small number of labeled novels. So how can experiments be designed and evaluated reliably in a setting like this. We are especially interested in testing results for significance to get a better understanding of the reliability of our research. While statistical significance testing is quite established in many disciplines ranging from psychology to medicine, it is unfortunately not yet standard in digital literary studies.

The scarcity of labeled data is also one of the reasons some researchers segment novels. We will show that without a test for significance it would be easy to misunderstand our results and we will also show that using segments of the same novel in the test and the training data leads to an overestimation of the predictive capabilities of the approach.

Setting

In the following we will describe our corpus and feature sets. Our corpus consists of 628 German novels mainly from the 19th century obtained from sources like TextGrid Digital Library[1] or Projekt Gutenberg[2]. The novels have been manually labeled according to their subgenre after research in literary lexica and handbooks. The corpus contains 221 adventure novels, 57 social novels and 55 educational novels; the rest belongs to a different or more than one subgenre.

Features are extracted and normalized to a range of [0,1] based on the whole corpus consisting of 628 novels. We have tested several feature sets beforehand and found stylometric and topic based to be the most promising (c.f. Hettinger et al., 2015). To represent stylometric features we employ 3000 most frequent words (mfw3000) and top 1000 character tetragrams (4gram). Topic based features are created using Latent Dirichlet Allocation (LDA) by Blei et al. (2003). In literary texts topics sometimes represent themes, but more often they represent topoi, often used ways of telling a story or parts of it (see also Underwood, 2012; Rhody, 2012). For each novel we derive a topic distribution, i.e. we calculate how strongly each topic is associated with each novel. We try different topic numbers and build ten models for each setting to reduce the influence of randomness in LDA models. We remove a set of predefined stop words as well as Named Entities from the novels as we have shown before that the removal of Named Entities tends to improve results.

Evaluation

Classification is done by means of a linear Support Vector Machine (SVM) as we have already shown in Hettinger et al. (2015) that it works best in this setting (see also Yu, 2008). In each experiment we apply stratified 10-fold cross validation to the 333 labeled novels and report overall accuracy and F1-Score (c.f. Jockers, 2013). The majority vote (MV) baseline for our genre distribution yields an accuracy score of 0.66 and F1 score of 0.27 (see fig. 1).

	adventure	educational	social		precision
adventure	221	55	57	333	66%
educational	0	0	0	0	0%
social	0	0	0	0	0%
	221	55	57	333	
recall	100%	0%	0%		Acc: 66%
f1	80%	0%	0%		F1: 27%

Fig. 1: Cross table for majority vote baseline

In the cross tables of Figure 1 and 2 each column represents the true class and each row the predicted genre. Correct assignments are shaded in grey, average accuracy in green and average F1 score in red.

	adventure	educational	social		precision
adventure	218	3	5	226	96%
educational	1	41	14	56	73%
social	2	11	38	51	75%
	221	55	57	333	
recall	99%	75%	67%		Acc: 89%
f1	98%	74%	70%		F1: 81%

Fig. 2: Cross table for mfw 3000 as an example for classification results

Because there are not many labeled novels for genre classification we expanded our corpus by splitting every novel into ten equal segments. Features are then constructed independently for the resulting 3330 novel segments. To test the influence of the LDA topic parameter *t* in conjunction with having more LDA documents we evaluate topic features for *t* =100, 200, 300, 400, 500 (see figure 3 and 4).

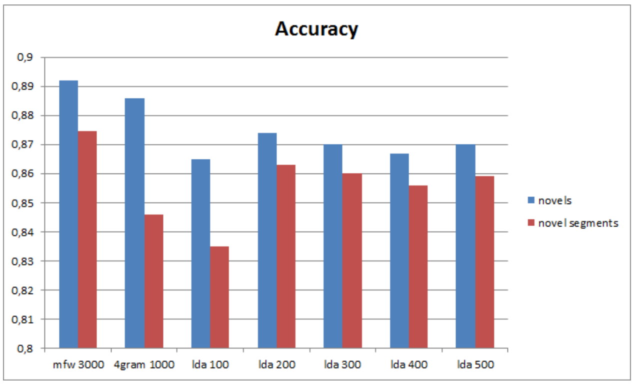

Fig. 3: Accuracy scores for novels and novel segments and different feature sets

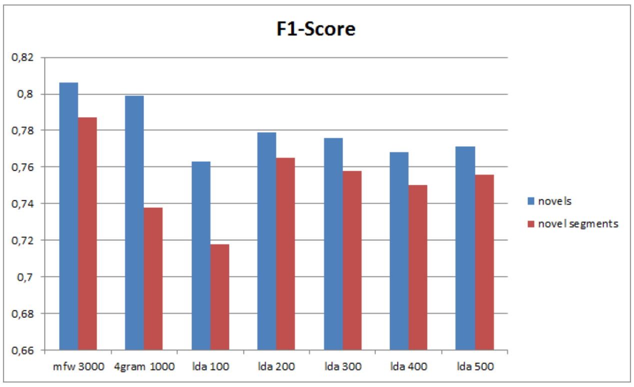

Fig. 4: F1 scores for novels and novel segments and different feature sets

Results show that our evaluation metrics tend to drop if novels are segmented. This could mean that genre is indeed a label for the whole literary work and not parts of it. On the other hand many differences are pretty small. Therefore we would like to test if these differences are statistically significant or if they should be attributed to chance.

Tests of statistical significance

When working with literary corpora there are few genre labels available for two reasons. First, the task of labeling the genre of a novel is strenuous; second, literary studies have mostly concentrated on a rather small sample, the canonical novels. Another issue is the creation of a balanced corpus, because for historical reasons the distribution of literary genres is not uniform and also the process of selecting novels for digitization has made the situation even more complicated. This generally results in data sets of less than 1000 items or even less than 100, see for example Jockers (2013) where 106 novels form a corpus or Hettinger et al. (2015) where we evaluate on only 32 novels.

The problem arising from small corpora is that small differences in results may originate from chance. This can be investigated by using statistical tests (c.f. Kenny, 2013; Nazar and Sánchez Pol, 2006). A standard tool to detect if two data sets are significantly different is Student's t-test which we will use in the following to control the results of our experiments.

We use two variations of Student's t-test with $\alpha = 0.05$:

- the one-sample t-test to compare the accuracy of a feature set against the baseline
- the two-sample t-test to compare accuracy results for two feature sets

In both cases the data set considered consists of ten accuracy results from ten-fold cross validation and accordingly 100 data points for LDA from its ten models. Due to the small sample size we drop the assumption of equal variance for the two-sample t-test. The results for the one-sample t-tests show that every single feature set yields significantly better accuracy than the baseline (66.4%). We can therefore conclude that feature sets classify novels not randomly and that they do incorporate helpful genre clues.

Fig. 5: P-values for two sided t-test with $\alpha = 0.05$ on accuracy of genre classification using 333 German novels

P-values for the two-sided t-tests are reported in Figure 5. Due to the large number of tests we apply Holm-Bonferroni correction; the resulting statistically significant outcomes are shaded in grey. From Figure 5 it follows that differences between segmented and not-segmented novels are **not** statistically significant in most cases except for LDA with $t = 100$. Besides results do not differ significantly for different topic numbers $t = 100, 200, 300, 400, 500$.

An important assumption of the two-sample t-test is that both samples have to be independent. This is the case here as each time we do a cross validation we split the data independently from any other cross validation run. Thus, even if we repeat our experiments for a number of iterations (see e.g. Hettinger et al., 2015) we still get independent evaluation scenarios. Therefore we can apply the two-sided t-test in our setting to support our claims. In case of dependency of samples we could instead use paired t-tests on accuracy per novel.

Novel segmentation

A crucial factor when segmenting novels is how to distribute the segments between test and training data set. We decided that in our case we have to put all of the ten segments a novel was divided into either in the test or in the training data set as we want to derive the genre of a novel not seen before. Another possibility which Jockers (2013) exploited is to distribute segments randomly between training and test set. In his work "Macroanalysis" Jockers investigates how function words can be used to research aspects of literary history like author, genre etc. In the following we want to replicate the part concerning genre prediction using German novels.

When segments of one novel appear in both test and training data we achieve an accuracy of 97.5% and F1 score of 95.9% - that is close to perfect (see fig. 6). Such a partitioning of the novels dramatically overestimates predictive performance on unseen texts. In comparison, Jockers (2013) achieves an average F1 score of 67% on twelve genre classes. His results are worse because we are only using three different genres while he is doing a multiclass classification with 12 classes. But nevertheless 67% probably still overestimates the real predictive power of this approach, because in our setup using the segments in both, test and training data, increased F1 by more than 17%.

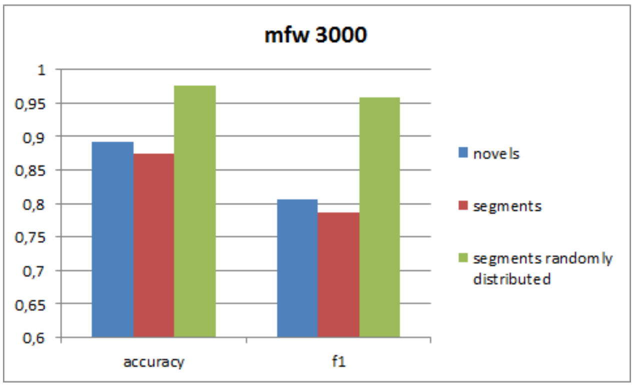

Fig. 6: Results for different partitioning strategies

Conclusion

In this work we looked at the methodology and evaluation of genre classification of German novels and discussed some of the methodical pitfalls of working with data like this. We discovered that only some of our results turned out to be statistically significant whereas for example the statement, that stylometric perform better than topic-based features, could not be fortified. Therefore our opinion is that research findings on small data sets should be scrutinized especially carefully for example by using statistical tests.

Microanalyzing Parts of Texts

David L. Hoover
david.hoover@nyu.edu
New York University, United States of America

Some broad questions require the analysis of huge collections of texts. Other broad questions and many narrower ones require microanalyzing parts of texts. Some microanalyses are unproblematic: narrative structure and its relationship to chapter divisions can be studied simply by dividing texts into chapters. Analyzing narrative or dialogue only, or the relationships between these and chapter divisions, may be much more problematic, as may analyzing a novel that also contains letters, diaries, legends, and poetry. Some or all of these may be more appropriately analyzed separately or ignored. Difficulties multiply for multiple narrators whose narratives contain dialogue and subdivisions.

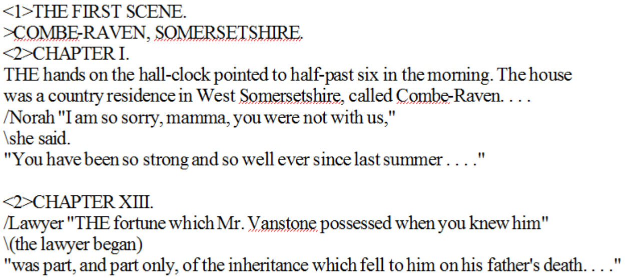
One of the most difficult tasks is analyzing the character dialogue in a novel. Burrows showed that the frequencies of the most frequent words in their dialogue can distinguish Jane Austen's characters from each other (1987), but few scholars have followed his lead, at least partly because of the tedium and difficulty of separating character parts. McKenna and Antonia (1996) were an early exception, but most related work involves epistolary novels or multiple narrators, where the separation of parts is simpler (Stewart 2003; Rybicki 2006; Ramsay 2011; Balossi 2014; Hoover, Culpeper, and O'Halloran 2014; Hoover 2010, and forthcoming).) Consider the case of Sherlock Holmes. Perhaps, as Moretti argues, "Doyle owes his phenomenal success to his greater skill in the handling of clues" (2004, 48), but Holmes and Watson are also extraordinarily fascinating characters. Analyzing their voices for distinctiveness requires comparing them with his other characters. Because reliable results require substantial amounts of text, I focus here on the longest Holmes novel, *The Hound of the Baskervilles* (*Hound*, below).

Extracting the dialogue computationally still requires the tedious and error-prone manual separation of the character parts and identification of the speakers. Typically characters are too numerous to open separate dialogue files for all of them, and multiple files increase copying and pasting errors. Initial decisions about the handling of dialogue may also change, requiring painstaking re-editing. Instead, I introduce very simple markup that is then processed in "Analyze Textual Divisions," an Excel spreadsheet with macros. The markup, powerful enough for texts with quite complex structures, is also simple, flexible, and customizable:

<1> text division 1
<2> text division 2
<3> text division 3
<4> text division 4
[ ] Letter writer
{ } Letter addressee
/ speaker
\ speech marker
> copy without processing
^ special character follows

For Wilkie Collins's complex novel *No Name,* with scenes containing chapters, which contain letters and other documents, the four divisions are "Scene", "Chapter", "Letter", and "Document." (The spreadsheet includes brief excerpts from this novel with mark-up.) Epistolary novels might use "Letter," and others might use "Volume" and "Book." For texts with multiple narrators and for plays "Narrator" and "Act" and "Scene" are obvious divisions. The top-level division, like the rest of the markup, can be modified. For *No Name*, division one is defined as follows: div1name = "Scene". Novels divided into books could use "div1name = "Book." Alternatively, after the macro operates, the labels can be changed as desired.

Here is a truncated version of *No Name*:



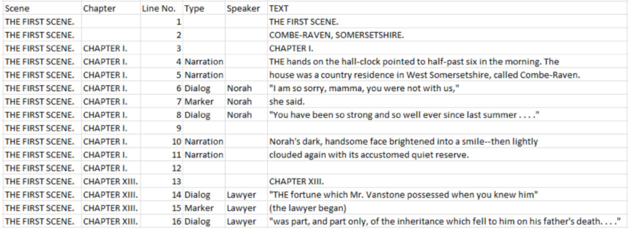
```
<1>THE FIRST SCENE.
>COMBE-RAVEN, SOMERSETSHIRE.
<2>CHAPTER I.
THE hands on the hall-clock pointed to half-past six in the morning. The house
was a country residence in West Somersetshire, called Combe-Raven. . . .
/Norah "I am so sorry, mamma, you were not with us,"
\she said.
"You have been so strong and so well ever since last summer . . . ."

<2>CHAPTER XIII.
/Lawyer "THE fortune which Mr. Vanstone possessed when you knew him"
\(the lawyer began)
"was part, and part only, of the inheritance which fell to him on his father's death. . . ."
```

A "<1>" has been inserted to mark "THE FIRST SCENE." as division one, and all lines in the first scene will be so labeled. In line two, ">" indicates that "COMBE-RAVEN, SOMERSETSHIRE.," which seems like a scene-setting label, not narrative, should not be processed (epigraphs or poems might be treated similarly). In line three, "CHAPTER I." marks division two. In line six, "/Norah" labels lines 6-8 as hers (the person addressed could, like a letter addressee, be marked with {}). In line seven, "\she said" is a speech marker, categorized separately because they sometimes vary interestingly and because "she said" seems to me neither dialogue nor narration. In line eight, the quotation mark indicates dialogue. The blank ninth line changes the label from dialogue to narrative until marked otherwise. The beginning of chapter thirteen is marked similarly. Later in the novel, embedded letters are marked with "Letter writer" and "Letter addressee." Finally, "^" must begin any line that would otherwise begin with "+", "-", or "=" (reserved characters in Excel). (Line-division can be changed instead, except where required line breaks force special characters to the beginning.)

With the Analyze Textual Divisions spreadsheet and the marked-up text open in Excel, the macro processes the text line by line, producing the results below (the marked-up text and empty columns have been deleted). Each line gets a scene label, and, beginning in line three, a chapter label, and all the lines are numbered. Lines 4-5 are marked as narration, lines 6 and 8 as Dialogue, and line 7 as Marker, and the speaker is entered for lines 6-8 and 14-16. The processed text appears on the right with all markup removed.

The text could be marked up in TEI and the character parts extracted with XSLT, but the markup here is much simpler and easier to learn, and the spreadsheet has advantages over XSLT. Excel's built-in sorting function can handle several levels of sorting, for example, so that the dialogue can be sorted by type, scene, chapter, speaker, and line number, all at once. The unmarked processed text, after sorting, can be divided and analyzed however the analyst desires with plain-text tools. Sorting on the line number restores the original order for further analysis, and errors can be corrected in the original text, and the analysis re-run. (See my Excel Text-Analysis Pages at http://wp.nyu.edu/exceltextanalysis/ for detailed instructions.) This method works especially well for short, simple texts like *Hound,* with character parts too short to be analyzed by chapter; the dialogue can be marked with just speaker and speech marker characters, and > and ^.



Scene	Chapter	Line No.	Type	Speaker	TEXT
THE FIRST SCENE.		1			THE FIRST SCENE.
THE FIRST SCENE.		2			COMBE-RAVEN, SOMERSETSHIRE.
THE FIRST SCENE.	CHAPTER I.	3			CHAPTER I.
THE FIRST SCENE.	CHAPTER I.	4	Narration		THE hands on the hall-clock pointed to half-past six in the morning. The
THE FIRST SCENE.	CHAPTER I.	5	Narration		house was a country residence in West Somersetshire, called Combe-Raven.
THE FIRST SCENE.	CHAPTER I.	6	Dialog	Norah	"I am so sorry, mamma, you were not with us,"
THE FIRST SCENE.	CHAPTER I.	7	Marker	Norah	she said.

THE FIRST SCENE.	CHAPTER XIII.	16	Dialog	Lawyer	"was part, and part only, of the inheritance which fell to him on his father's death. . . ."

To test the distinctiveness of the character voices in *Hound*, I selected all character parts at least 1,500 words long, and divided longer parts into 1,500-word sections. Initial testing was disappointing. Although the sections of dialogue by Stapleton, Mortimer, and Watson grouped correctly, those by Baskerville, Barrymore, and Holmes did not, casting doubt on the distinctiveness of their voices. The section of Baskerville's dialogue that groups with Barrymore's, however, consists almost entirely of a conversation between the two, so that similarity of topic may skew the results. More significantly, the first six sections of Holmes's dialogue consistently group correctly. The final two, which consist almost entirely of the final chapter, and which tend to group separately from all others, are Holmes's explanation of the case to Watson. Nominally dialogue, this chapter is more like narration, a genre difference that is almost certainly responsible for the anomalous clustering. Removing the final chapter and sorting the lines of Baskerville's dialogue in random order to blunt any topical or thematic effects produces the cluster analysis shown in Fig. 1, based on the 225mfw (most frequent words).

Cluster analysis is an exploratory statistical method that compares the frequencies of a set of words across a set of texts to determine which texts use those words at the most similar frequencies. The nearer to the left that sections join together into a single cluster, the more similarly they use the words. All sections in Fig. 1 group correctly by speaker, and several sections of Holmes's dialogue are the most similar, and the results are correct across analyses based on the 125-325mfw. Doyle's use of clues may have helped the Sherlock Holmes stories succeed, but the distinct character voices also seem likely to be a factor. (The analysis here uses Ward Linkage and squared Euclidean distance; the often-used complete linkage gives weaker results.)

Separating character dialogue can never be easy, but my spreadsheet makes it much easier. It also provides a versatility in comparing multiple kinds of textual divisions that may encourage more in-depth analysis of dialogue and characterization and enhance our understanding of how texts work.

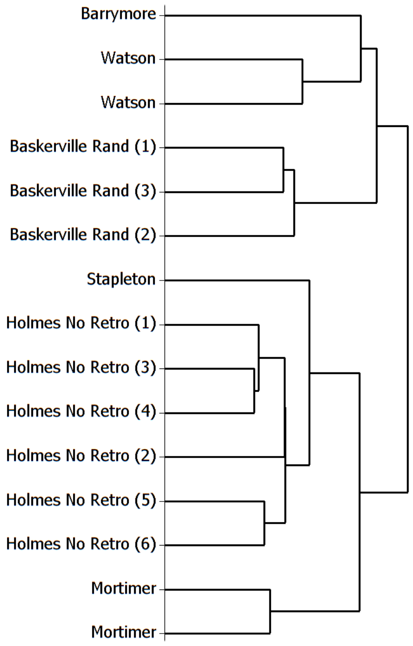

Fig. 1: Character Dialogue in *Hound* (225mfw)

Textual Variation, Text-Randomization, and Microanalysis

David L. Hoover
david.hoover@nyu.edu
New York University, United States of America

Computational stylistics often analyzes style variation, including chronological change and the dialogue or narration of multiple characters or narrators (Craig 1999; Stamou 2008; McKenna and Antonia 1996; Stewart 2003; Burrows 1987; Hoover 2003, 2007). Here I suggest it is sometimes desirable to omit parts of texts, or to randomize a text to mask some variation, either analyzing parts of texts in random order or truncating such parts to create a word list based on equal amounts of text (see also Burrows, 1992).

Analyzing Doyle's *The Hound of the Baskervilles,* shows that two sections of Holmes's dialogue and one of Baskerville's fail to cluster correctly, but both failures likely result from intra-textual variation that should *not* influence the analysis. Holmes's outlier sections are a retrospective explanation more like narration than dialogue. This genre difference disrupts Holmes's otherwise strongly consistent voice. I have similarly suggested ignoring the final "summing up" chapter of *The Waves* when analyzing its six narrative voices (Hoover forthcoming). Baskerville's problematic section is largely a conversation with Barrymore, which may cause their voices to merge and their sections to cluster.

Special pleading in the face of apparent failure seems potentially illegitimate, but removing Holmes's retrospective "dialogue" leaves the rest consistently clustered. Furthermore, Holmes's dialogue from other stories clusters perfectly with his normal dialogue from *Hound*, so that inter-textual consistency supports an intra-textual argument. Retesting *Hound* with Baskerville's dialogue randomly sorted clusters his three sections separately from Barrymore's section, which forms its own cluster. But such randomizing to dampen intra-textual variation seems questionable. Will less distinctive voices cluster with these homogenized parts? Will randomization produce specious clustering of sections that are not "really" consistent in style?

Consider the nine fairly distinct main narrators in Collins's *The Moonstone* (Hoover, Culpeper, and O'Halloran, 2014). Here, randomizing the parts greatly improves accuracy, correctly clustering all sections by all narrators over a wide range of analyses. Normal analysis of Faulkner's *As I Lay Dying* clusters Darl's and Vardaman's sections correctly and clusters all of Tull's sections with Cash's section over a wide range of analyses (Hoover, 2010), but randomizing each character's narrative correctly clusters all the characters, even when divided into much shorter sections.

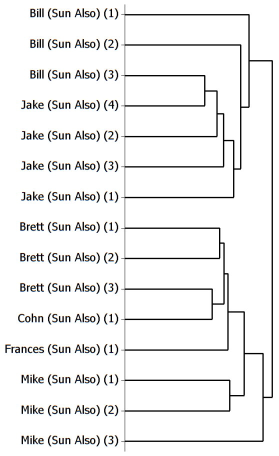

Fig. 1. Character Dialogue in *The Sun Also Rises*–Standard Analysis, 700MFW

What about less distinct character parts? Randomization only slightly improves results for the letter writers in *The Coquette* (an epistolary novel), showing that randomization does not always produce artificial consistency. Jake and Brett from Hemingway's *The Sun Also Rises* are memorable characters, yet their dialogue does not cluster very consistently in standard analyses, never approaching the success with Collins's or Faulkner's narrators . Figure 1 shows the most accurate clustering, based on the 700 MFW (most frequent words); all other analyses are weaker. Randomizing the character parts produces the completely correct results shown in Fig. 2 for analyses based on the 400-800MFW. (Cluster analysis is an exploratory statistical method that compares the frequencies of a set of words across a set of texts to determine which texts use those words at the most similar frequencies. The further to the left that two or more texts form a cluster, the more similar they are.) Randomization transforms the poor character separation in a standard analysis of James's *The Ambassadors* into a clear separation of all except Bilham, in analyses based on the 500-800MFW. The same is true for *Jane Eyre*, though Jane's dialogue seems problematic, as her story ranges from childhood to adulthood in five different settings. Many more texts will have to be analyzed to determine why randomization produces varying results and where it is appropriate.

Dracula reacts similarly. A standard analysis, shown in Fig. 3, fails to cluster all the sections correctly. In the middle of the large lower cluster is a problematic mixed cluster containing Van Helsing's single section and the final sections from Mina, Harker, and Seward. These sections narrate the race to capture Dracula at the end of the novel, and this provides an opportunity to push the question of randomization further. Because the *Dracula* narratives range widely in length, the full word list is skewed away from Lucy (4,400) and Van Helsing (5,200) and toward Mina (22,000), Harker 1 (19,000), Harker 2 (14,000) and Seward (35,000). A word list based on the first 6,000 words from the randomized narratives of these five characters (half from each of Harker's) clusters the narrative much more accurately and clearly distinguishes the narratives of Lucy and Van Helsing (see Fig. 4).

Fig. 2. Character Dialogue in *The Sun Also Rises*–Randomized Parts, 700MFW

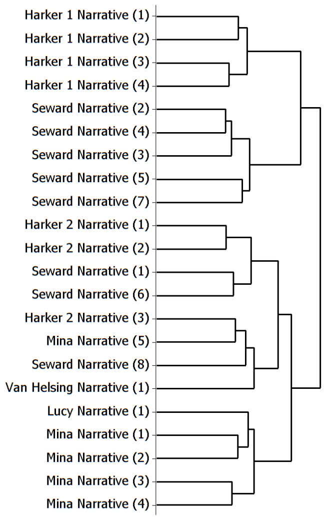

Fig. 3. Six Dracula Narrators–Standard Analysis, 900MFW

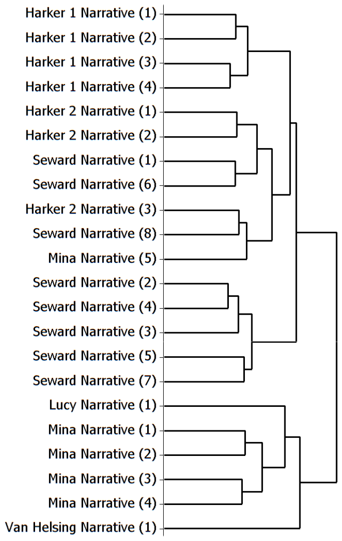

Fig. 4. Six Dracula Narrators–Word List Based on 6,000 Randomized Words, 900MFW

Harker's, Mina's, and Seward's final sections remain clustered in Fig. 4, however. Analyzing these and Van Helsing's in shorter sections, using a word list based on the equalized randomized parts, again improves results. Seward's and Van Helsing's sections cluster separately, as do Mina's second, third, and fourth; only her first section clusters with Jonathan's. Thus the voices remain relatively distinct, though inflected by the effects of the narrative structure. Because Mina's wayward section is mainly a memo, its failure to cluster with the sections from her journal may also be explicable. Further analysis of the sub-genres of *Dracula* should provide additional insights into intra-textual variation.

Consider now a very different kind of text posing different problems–a collection of nearly 400 high-stakes writing exams administered in U.S. high schools. These very short texts (128-1307 words) in multiple genres were written in response to a wide variety of prompts from multiple states (Jeffrey 2010; Jeffrey, Hoover, and Han 2013). This makes testing for the characteristic vocabulary of high- and low-scoring texts very challenging. Here I use a variant of Zeta, which identifies words used consistently by one group and avoided consistently by another (Burrows, 2006; Craig and Kinney, 2009; Hoover, 2013). Because the entire vocabulary is being tested, a normal word list seems appropriate. I also combine the low-scoring texts into one large text and the high-scoring texts into another, randomize the lines of each, and then compare analyses based on sections of the combined texts with analyses based on the combined and randomized texts. Holding out twenty high- and twenty low-scoring sections for testing, I use the eighty-six remaining sections for training. The combined texts distinguish high and low test texts fairly well (Fig. 5), but the combined-randomized texts greatly improve the results (Fig. 6). (The vertical and horizontal axes record the percentage of word types in each section that are characteristic of low-scoring and high-scoring texts, respectively.)

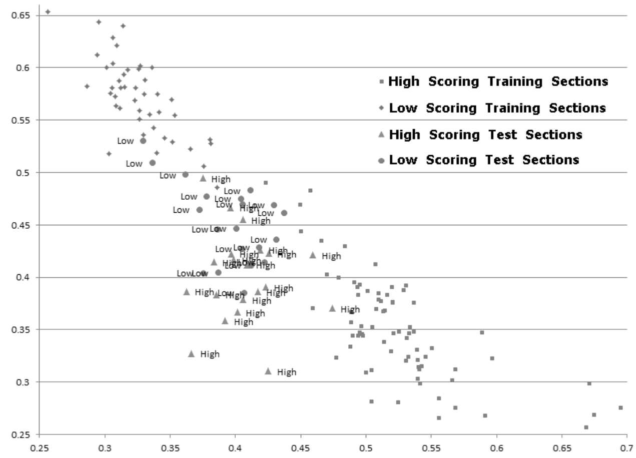

Fig. 5. Combined High- and Low-Scoring Exit Texts

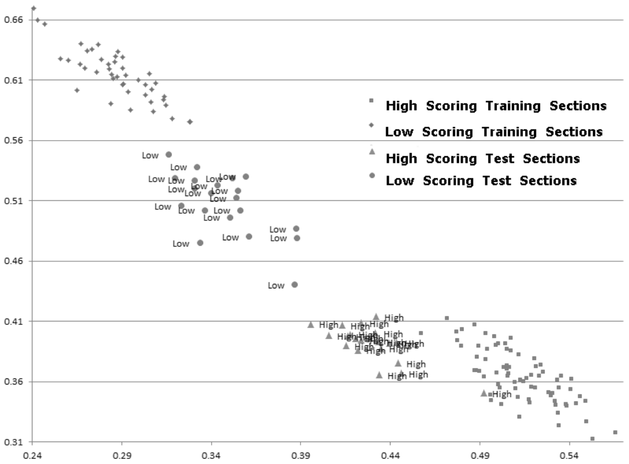

Fig. 6. Combined-Randomized High- and Low-Scoring Exit Texts

Certainly (intra-)textual variation helps to create memorable characters and narrators, and it is often crucially linked to description or narrative action. Some kinds of variation, however, can mask important kinds of consistency and unity, and a reasoned argument can be made for ignoring some sections of texts, or for analyzing them in randomized form. Alternatively, or in addition, word lists based on truncated and randomized sections also often improve results. Though the value and legitimacy of such transformations and truncations will need further study, they seem a promising line of research.

Assessing a Shape Descriptor for Analysis of Mesoamerican Hieroglyphics: A View Towards Practice in Digital Humanities

Rui Hu

Introduction

Technological advances in digitization, automatic image analysis and information management are enabling the possibility to analyze, organize and visualize large cultural datasets. As one of the key visual cues, shape feature has been used in various image analysis tasks such as handwritten character recognition (Fischer, 2012; Franken, 2013), sketch analysis (Eitz, 2012), etc. We assess a shape descriptor, within the application domain of Maya hieroglyphic analysis. Our aim is to introduce this descriptor to the wider Digital Humanities (DH) community, as a shape analysis tool for DH-related applications.

The Maya civilization is one of the major cultural developments in ancient Mesoamerica. The ancient Maya language infused art with uniquely pictorial forms of hieroglyphic writing, which represents an exceptionally rich legacy (Stone, 2011). Most Maya texts were written during the Classic period (AD 250-900) of the Maya civilization on various media types, including stone monuments. A special class of Maya texts was written on bark cloths as folding books from the Post-Classic period (AD 1000-1519). Only three such books (namely the Dresden, Madrid and Paris codices) are known to have survived the Spanish Conquest. A typical Maya codex page contains icons, main sign glyph blocks, captions, calendric signs, etc. Fig. 1 illustrates an example page segmented into main elements (Gatica-Perez, 2014). In this paper, we are interested in the main signs.

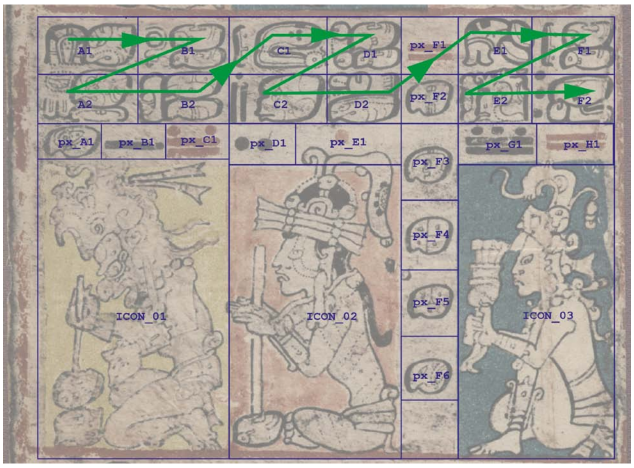

Figure 1. Page 6b of the Dresden Codex, showing individual constituting elements framed by blue rectangles (Hu, 2015), Green arrows indicate reading order of the main sign blocks, generated by Carlos Pallan based on SLUB (http://digital.slub-dresden.de/werkansicht/dlf/2967/1/) online open source image.

Maya hieroglyphic analysis requires epigraphers to spend a significant amount of time browsing existing catalogs to identify individual glyphs. Automatic Maya glyph analysis has been addressed as a shape matching problem, and a robust shape descriptor called Histogram of Orientation Shape Context (HOOSC) was developed in (Roman-Rangel, 2011). Since then, HOOSC has been successfully applied for automatic analysis of other cultural heritage data, such as Oracle-Bones Inscriptions of ancient Chinese characters (Roman-Rangel, 2012), and ancient Egyptian hieroglyphs (Franken, 2013). It has also been applied for generic sketch and shape image retrieval (Roman-Rangel, 2012). Our recent work extracted statistic Maya language model and incorporated it for glyph retrieval (Hu, 2015).

The goal of this paper is two-fold:

1. Introduce the HOOSC descriptor to be used in DH-related shape analysis tasks (code available at: http://www.idiap.ch/paper/maaya/hoosc/);

2. Discuss key issues for practitioners, namely the effect that certain parameters have on the performance of the descriptor. We describe the impact of such choices on different data types, specially for 'noisy' data as it is often the case with DH image sources.

Automatic Maya Hieroglyph Recognition

We conduct glyph recognition with a retrieval system proposed in (Hu, 2015). Unknown glyphs are considered as queries to match with a database of known glyphs (retrieval database). Shape and context information are considered. Fig.2 illustrates a schema of our approach. We study the effect of different HOOSC parameter choices on the retrieval results.

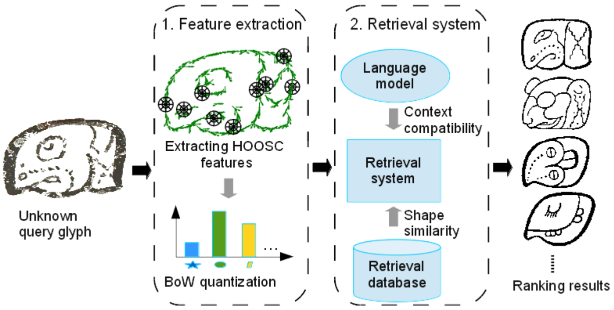

Figure 2. Retrieval system pipeline.

Datasets

We use three datasets, namely the 'Codex', 'Monument' and 'Thompson'. The first two are used as queries to search within the retrieval database ('Thompson').

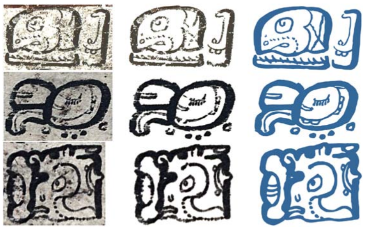

Figure 3. Digitization quality: (left) raw glyph blocks cropped from Dresden codex; (middle) clean raster images produced by removing the background noise; (right) reconstructed high-quality vectorial images.

The 'Codex' dataset contains glyph blocks from the three surviving Maya codices. See Fig.3 for examples. Glyph blocks are typically composed of combinations of individual signs. Fig.4 shows individual glyphs segmented from blocks in Fig.3. Note the different degradation levels across samples. We use two sub-datasets: 'codex-small', composed of 156 glyphs segmented from 66 blocks, for which we have both clean raster and high-quality reconstructed vectorial representations (see Fig.4) to study the impact of the different data qualities on the descriptor; and a 'codex-large' dataset, which is more extensive, comprising only the raster representation of 600 glyphs from 229 blocks.

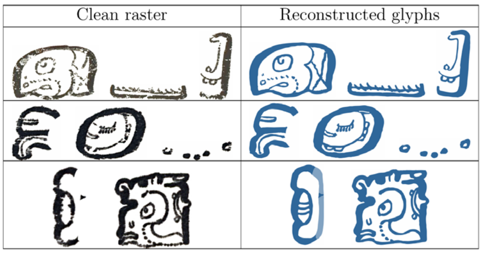

Figure 4. Example glyph strings generated from blocks shown in Figure 3.

The 'Monument' dataset is an adapted version of the Syllabic Maya dataset used in (Roman-Rangel, 2011), which contains 127 glyphs of 40 blocks extracted from stone monuments. It is a quite different data source to the codex data, in terms of historical period, media type, and data generation process. Samples are shown in Fig.5.

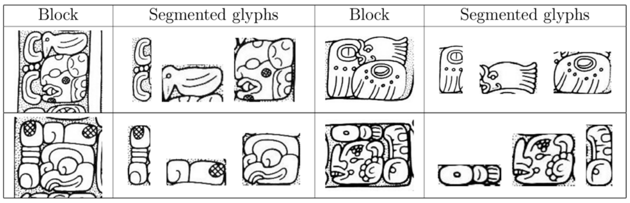

Figure 5. Example blocks and segmented glyph strings form the 'Monument' dataset.

To form the retrieval database ('Thompson'), we scanned and segmented all the glyphs from the Thompson catalog (Thompson, 1962). The database contains 1487 glyph examples of 892 different sign categories. Each category is usually represented by a single example image. Sometimes multiple examples are included; each illustrates a different visual instance or a rotation variant. Fig.6 shows glyph examples.

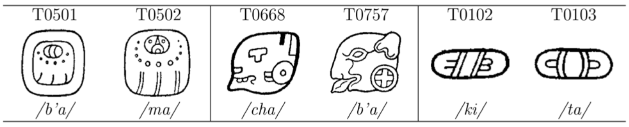

Figure 6. Thompson numbers, visual examples, and the syllabic values of glyph pairs. Each pair contains two different signs with similar visual features (Hu, 2015). All examples are taken from (Thompson, 1962).

Shape-based retrieval

Feature extraction and similarity matching are the two main steps for our shape-based glyph retrieval framework.

Glyphs are first pre-processed into thin lines. To do so, an input glyph (Fig.7(a)) is first converted into a binary shape (Fig.7 (b)). Thin lines (Fig.7(c)) are then extracted through mathematical morphology operations. Fig.7(c)-(d) show the high-quality reconstructed binary image, and the extracted thin lines.

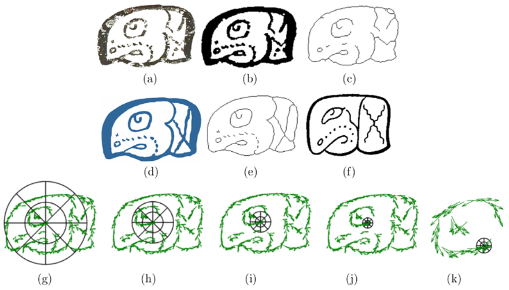

Figure 7. Extracting HOOSC descriptor: (a) input clean raster image; (b) binary image; (c) thinned edge of (b); (d) reconstructed vector representation of (a); (e) thinned edge of (d); (f) corresponding groundtruth image in the catalog; (g)-(k) spatial partition of a same pivot point with five different ring sizes (1, ½, ¼, 1/8, 1/16, all defined as a proportion to the mean of the pairwise distance between pivot points) on the local orientation field of the thinned edge image (c). Note that we zoomed in to show the spatial context of 1/16 in (k).

HOOSC descriptors are then computed at a subset of uniformly sampled pivot points along the thin lines. HOOSC combines the strength of Histogram of Orientation Gradient (Dalal, 2005) with circular split binning from the shape context descriptor (Belongie, 2002). Given a pivot point, the HOOSC is computed on a local circular space centred at the pivot's location, partitioned into rings and evenly distributed angles. Fig.7 (g)-(k) show different sizes of the circular space (referred to as spatial context) partitioned into 2 rings and 8 orientations. A Histogram-of-orientation-gradient is calculated within each region. The HOOSC descriptor for a given pivot is the concatenation of histograms of all partitioned regions.

We then follow the Bag-of-Words (BoW) approach, where descriptors are quantized as visual words based on the vocabulary obtained through K-means clustering on the set of descriptors extracted from the retrieval database. A histogram representing the count of each visual word is then computed as a global descriptor for each glyph. In all experiments, we use vocabulary size k=5000.

Each query is matched with glyphs in the retrieval database, by computing shape feature similarity using the L1 norm distance.

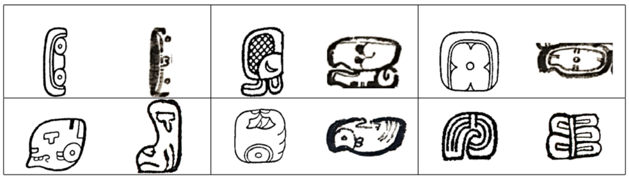

Figure 8. Six pairs of glyph signs (Hu, 2015). Each pair contains a query glyph from the 'Codex' dataset (right), and their corresponding groundtruth in the catalog (left).

Incorporating context information

Shape alone is often ambiguous to represent and distinguish between images. In the case of our data, different signs often share similar visual features (see Fig.6); glyphs of the same sign category vary with time, location, and the different artists who produced them (see Fig.8); additionally, surviving historical scripts often lose visual quality over time. Context information can be used to complement the visual features.

Glyph co-occurrence within single blocks encodes valuable context information. To utilize this information, we arrange glyphs within a single block into a linear string according to the reading order (see Fig.4 and Fig.5), and consider the co-occurrence of neighbouring glyphs using an analogy to a statistical language model. For each unknown glyph in the string, we compute its probability to be labelled as a given category by considering not only the shape similarity, but also the compatibility to the rest of the string.

We apply the two language models extracted in (Hu, 2015), namely the ones derived from the Maya Codices Database (Vail, 2013) and the Thompson catalog (Thompson, 1962), which we refer to as the 'Vail' and the 'Thompson' models. We use Vail model with smoothing factor α=0 for the 'Codex' data, and the Thompson model with α=0.2 for the 'Monument' data.

Experiments and Results

Our aim is to demonstrate the effect of various HOOSC parameters on retrieval results.

Experimental setting

We illustrate the effect of 3 key parameters:

- Size of the spatial context region within which HOOSC is computed

A larger region encodes more context information and therefore captures more global structure of the shape. However, in the case of image degradation, a larger region could contain more noise. We evaluate five different spatial contexts as shown in Fig.7(g)-(k). The circular space is distributed over 8 angular intervals.

- Number of rings to partition the local circular region

This parameter represents different partition details. We evaluate either 1 or 2 rings, the inner ring covers half the distance to the outer ring. Each region is further characterized by a 8-bin histogram of the local orientations.

- Position information

Relative position (i, j) of a pivot in the 2-D image plane can be concatenated to the corresponding HOOSC feature.

Results and discussion

Fig.9 shows the average groundtruth ranking in the retrieval results with different parameter settings, on three query sets, *e.g.* 'Codex-large', 'Codex-small' and 'Monument'. Each query image usually has only one correct match (groundtruth) in the retrieval database. The smaller the average ranking value, the better the result. From Fig.9 we can see the following:

- In most cases, the best results are achieved by using the largest spatial context, with finer partitioning details (2 rings in our case);
- When the location information is not considered, results show a general trend of improving with increasing ring sizes. However, the results are more stable when the position information is encoded, *e.g.* a smaller ring size can also achieve promising results when the location information is incorporated. This is particularly useful when dealing with noisy data, where a smaller ring size is preferred to avoid extra noise been introduced by a larger spatial context;
- The results do not benefit from a finer partition, when a small spatial context is considered. However, results improve with finer partitions, when the spatial context becomes larger.
- Position information is more helpful when a small spatial context is considered.

Fig.10 shows example query glyphs and their top returned results.

Conclusion

We have introduced the HOOSC descriptor to be used in DH-related shape analysis tasks. We discuss the effect of parameters on the performance of the descriptor. Experimental results on ancient Maya hieroglyph data from two different sources (codex and monument) suggest that a larger spatial context with finer partitioning detail usually leads to better results, while a smaller spatial context with location information is a good choice for noisy/damaged data. The code for HOOSC is available so DH researchers can test the descriptor for their own tasks.

Acknowledgement

We thank Edgar Roman-Rangel for co-inventing the HOOSC algorithm and providing the original code. We also thank Carlos Pallán Gayol, Guido Krempel, and Jakub Spotak for producing the data used in this paper. Finally, we thank the Swiss National Science Foundation (SNSF) and the German Research Foundation (DFG) for their support, through the MAAYA project.

Visualizing Mouvance: Towards an Alignment of Medieval Vernacular Text Traditions

Stefan Jänicke

David Joseph Wrisley
dwrisley@gmail.com
American University of Beirut, Lebanon (Lebanese Republic)

Poetry in the Middle Ages changed as it was recopied, recited and passed along. *Mouvance* is a term used by late Swiss medievalist Paul Zumthor to designate the high degree of instability in medieval text traditions. Zumthor qualifies this instability as an "interplay between variant readings and reworkings," balancing both the textual, literary elements of written works with oral, performative ones (Zumthor, 1992; p.44). Twentieth-century text editing came to grips with this instability in large text traditions in different ways. For complex text traditions with a high degree of variance in medieval French, editors sometimes compiled one edition containing all the witnesses in successive chapters, as in the cases of *La vie de sainte Marie l'Egyptienne* (Dembowski, 1977) and *L'Evangile de Nicodème* (Ford, 1973) or they arranged them in a synoptic-style parallel edition as in the case of the *fabliaux* (Rychner, 1960). The alignment of such synoptic editions, although not discussed explicitly by the editors, was no doubt hand-ordered and its page layout was based on rough narrative equivalence of passages.

Cerquiglini has argued that, faced with such variance, the medievalist's "analysis must be comparative, not archeological" (Cerquiglini, 1999; p.44). Such parallel print editions provide readers with a visual frame for comparative reading of variant texts, inviting exploration and giving insight into processes of textual change. There are a number of problems in text traditions with oral influence. There are not only different kinds of variance (single word/string variance, half-line or hemistich variance, transposition and reorganization of rhyming verse lines or interpolation of entirely new lines), but patterns of variance are also not uniform across a text, making the desired comparative visualization of texts difficult. Alignments can also mix and confuse kinds of variance. What are ways of visualizing textual variation in a digital environment? This is the question our paper intends to explore.

Visualization strategies for historical text reuse vary according to the scale of the phenomenon and the nature of the texts involved (Franzini et al., 2015). Sophisticated visualizations for alignment exist at the micro-level, that is, at the level of the word such as the graph visualizations of TRAViz (Jänicke et al., 2015). They facilitate comparative readings of word-level variance in manuscript witnesses or translations. The text in such alignments is fully legible. A clean example of this can be found in the TRAViz alignments of English translations of the Bible (Figure 1), a textual use case in which units and sub-units of text are already commonly agreed upon by tradition (e.g. book, chapter, verse). On the other hand, solutions exist for macro-level text reuse, such as fingerprinting techniques (Jänicke and Geßner, 2015), creating distant patterns of textual similarity without showing the text (Figure 2).

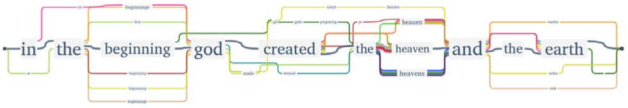

Figure 1: Micro-level alignment of 24 English translations of Genesis 1:1 (Jänicke et al., 2015)

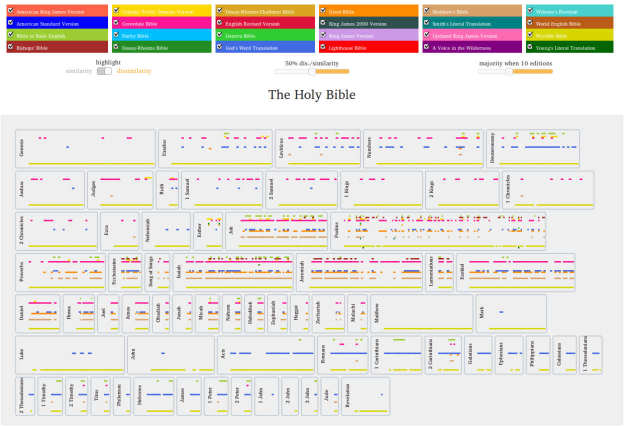

Figure 2: Macro-level fingerprint illustrates similarity between 24 English Bible translations (Jänicke and Geßner, 2015)

A critical discussion of the description and design of meso-level visualization of complex text traditions is missing. Not only are these text traditions large, but they are highly influenced by orality, that is, in Zumthor's words, they present a combination of textual and performative variance. Textual reworking at multiple scales (whole chunks of text, groups of lines, individual lines, sub-line strings) are challenges for both alignment and visualization. Our design attempts to translate the insights of Zumthor and Cerquiglini into an environment for visual exploration using two medieval text traditions: a tradition of short baudy tales known as the fabliaux , and in versions of the well-known epic the Chanson de Roland . These two traditions have been chosen for the kinds of complex variance they exhibit. Our paper focuses on so-called meso-level alignments that visualize patterns of textual variance higher than the word and verse line level, and stress both legibility and human interaction in visualizing patterns.

Existing methods for text alignment in digital environments, generally speaking, favor relatively stable texts with small variance. The Versioning Machine accepts texts encoded "according to TEI's Parallel Segmentation method" and "interprets the encoding, parsing out the text into its constituent parts" (Versioning Machine, 2015). The authors of the Versioning Machine offer a sample alignment of a medieval "Prophecy of Merlin" (Figure 3). The line-to-line alignment has been encoded by the textual scholar. Similar lines are visually connected using customary mouse behavior, however, variance within the line or across lines is not visualized.

Figure 3: Two versions of the Prophecy of Merlin visualized in Versioning Machine

Another environment for the collation of raw text and visualization of textual differences is JuxtaCommons (Wheeles and Jensen, 2013). The example in Figure 4 uses two editions of Chretien de Troyes' medieval romance *Perceval*, one based on BnF, ms. français 12576 (Roach, 1959) at left, and the other Bern, Burgerbibliothek ms. 354 (Méla, 1990) at right. There is basic alignment of the verse line and minor lexical or dialectal variance, and mouse over in JuxtaCommons allows basic comparative reading of word- and string-level variants. In their out-of-the-box implementation, both tools allow for easy comparison of two versions of the text, although the Versioning Machine has been implemented for larger comparison sets.

Figure 4: Two editions of Chretien de Troyes' Perceval visualized in JuxtaCommons

When complex text traditions containing more than just variant readings, but also interpolations, extra or missing lines or a significant amount of orthographic variance are collated automatically in JuxtaCommons, their results, however, are nearly illegible. Figure 5 shows two witnesses of the same old French *fabliau*; the visual alignment, however, does an insufficient job at expressing the performative element of their *mouvance*.

Our design for a sufficient representation of variance in the *fabliaux* is shown in Figure 6. We use the intuitive quality of stream graphs (Byron et al., 2008) in order to support the analysis of aligned verses and to illustrate the transmission of one *fabliau* in four versions. The text editions are juxtaposed in columns in order to minimize edge crossings, in other words, we order the editions according to their similarity.

Figure 6: Four versions of a fabliau in our design

The visualization is available at http://informatik.uni-leipzig.de:8080/Fabliaux/. Clicking on a specific verse line produces a TRAViz micro-view of the line-level variance (Jänicke et al., 2015), whereas the larger meso-view of this portion of the *fabliau* allows patterns between and across verse lines to be clearly ascertained. V ariance in this genre maintains prosody and avoids hypermeter; *mouvance* is characterized here by the interpolation of larger narrative multi-line fragments of text. The exception to this general rule is manuscript Harley 2253 in the column at far right where the narrative is reconstituted almost completely around sparse line re-use, illustrating what Rychner calls in the subtitle of his book "deteriorization" [dégradation] (Rychner, 1960). *Mouvance* occurs in multi-line "chunks," visible in highly legible streams of text re-use. This provides much more insight into textual transformation than reading Rychner's hand-aligned synoptic edition, with the streams here drawing our attention to patterns of re-used text. In his edition, blank spaces and horizontal lines in the page layout effect a more uncertain alignment.

Another example of what we are calling meso-level alignment is the visualization of one stanza from the *Chanson de Roland* tradition contained in six manuscripts.

Figure 7 illustrates laisse 1 of the Lavergne fragment, absent from Oxford, Bodleian Library manuscript Digby, 23. An interactive version of the alignment is available at http://informatik.uni-leipzig.de:8080/roland/index2.html?ftsize=11 .

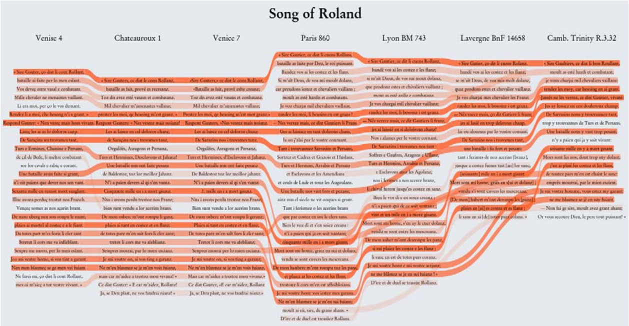

Figure 7: Six editions and one fragment of the Chanson de Roland in our design

To indicate how often lines recur across the whole manuscript tradition, we use streams colored with varying saturation. Highly saturated colors indicate frequently repeated passages, whereas less saturated colors indicate less repeated ones. Such a feature allows for a “consensus” visualization of the tradition at this meso scale. It is easy to see the more complex, transpositional variance of lines in the Chanson de Roland . This compositional feature of French epic visualized here needs to be studied across the entire corpus of seven manuscripts and three fragments. It is perhaps on this point, however, that a principle of visualization clashes with the visual expectations of a medieval textual scholar. As in the above example, we ordered the editions to reduce the number of crossing streams and to maximize legibility. This is potentially at odds with readers who expect to see temporality of manuscript dating represented in the visualization. More thinking needs to be done about the visual semantics of such a large tradition. In such a case, a perfect order that produces less clutter might be hard to determine, and we will be required to extend our proposed design.

Figure 8: Visualization of an aligned verse line in three versions of a fabliau

We began with the alignment of the fabliaux and Chanson de Roland since they are traditions where editors have indexed alignment manually, either using page layout or by numerical cross referencing of the stanzas . As the example shown in Figure 8 illustrates, lines are not identical word for word, but rather our alignment has asserted basic diegetical equivalence.

Figure 9: Alignment of an aligned verse among seven Chanson de Roland editions

In the example portrayed in Figure 9, performative mouvance is reflected in the recombination of words in the line.

In developing our research on this topic, we intend to pursue more granular alignment using computational means, down to the line and perhaps the hemistich. Based on the Relative Edit Distance of strings (Jänicke et al., 2015), we aim to determine spelling variants and rhyme sets automatically. Combined with an n-gram analysis, we will support the discovery and alignment of similar text passages. Due to the high degree of orthographic variance of the medieval French language, a purely computational approach might lead to a high number of false positive alignments. Therefore, we will design a visual analytics system that includes the human in the alignment process in order to configure appropriate settings that maximize the alignment of re-used text passages. This visual analytics process includes the supervised training of a classifier that supplies the parameters steering the alignment. Iteratively, computationally aligned text fragments are scored by the textual scholar according to their relevance. After each scoring session, the alignment will be recomputed taking the scholar's justifications into account.

In contrast to the manual alignment illustrated in the visualizations above (Figures 6-9), such a semi-automated process will potentially yield a very different picture in particular with respect to the degree of difference the human allows in string matching and the presence of shared n-grams required to align certain text passages. A further opportunity of this generic visual analytics approach is its straightforward adaptability to editions in other languages than medieval French. With such a user-centered approach, alignment is not to be understood as a final product, but rather a process, for understanding variant text traditions, exploring their intricacies and supporting generation of hypotheses about textual behavior.

Introduction

To what extent can topic models explain variation in perceptions of literary quality? We try to find correlations between topics and judgments of literary quality using a topic model of 401 recent bestselling Dutch novels. Instead of examining topics on a macro-scale in a geographical or historical interpretation (e.g., Jockers 2013; Riddell 2014), we take a new perspective: whether novels have a dominant topic in their topic distributions (mono-topicality), and whether certain topics may express an explicit or implicit genre in the corpus. We hypothesize that there is a relationship between these aspects of the topic distributions and perceptions of literary quality. We then interpret the model by taking a closer look at the topics in a selection of the novels.

Riddle survey and corpus

This research is part of a Dutch computational humanities project called The Riddle of Literary Quality. In the project we aim to identify textual features that may play a role in readers' evaluations of a novel as being good or bad and as high or low literature. We analyze a corpus of 401 contemporary Dutch-language (including translated) novels in search of textual features they have in common. Within our corpus there is a small variety of novelistic genres, which can be roughly divided into suspense, romantic and general novels. The readers' judgments were gathered in a large online survey. We asked a general public to rate the novels they had read on a 7-point scale from *definitely not* through *highly* literary. Approximately 14,000 respondents participated, providing us with much data on the perceived quality of our 401 novels.[1] The mean rating over all 401 novels is 4.2, with 2.1 being the lowest rating for *Fifty Shades of Grey* by E.L. James, and 6.6 the highest for Julian Barnes' *The Sense of an Ending*.

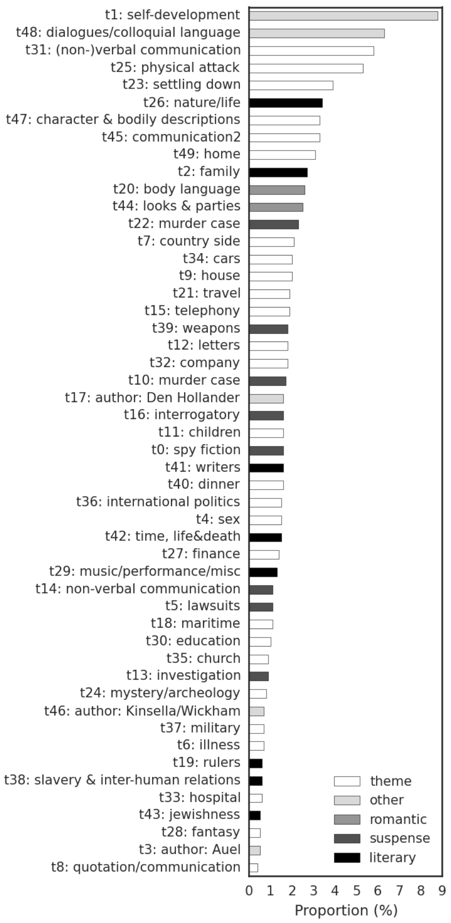

Figure 1: Overview of topics, sorted by proportion of the corpus

Topic model

A topic model aims to automatically discover topics in a collection of documents. We use Latent Dirichlet Allocation (Blei et al., 2003), which assumes the documents have been generated from a fixed number of probability distributions (the topics) over words. The topics reflect word co-occurrence patterns. We preprocess the novels by lemmatizing the words, removing punctuation, function words and names, and splitting the remaining text in chunks of 1000 tokens. We use MALLET to create a topic model with 50 topics. Fig. 1 shows an overview of the topics with their proportion across the corpus.

We have attempted to identify topics for novels with high literary ratings, and topics specific for suspense and romantic novels. According to Jockers and Mimno (2013), the topics can be used to identify literary themes. They use the terms "theme" and "topic" as "proxies for [...] a type of literary content that is semantically unified and recurs with some degree of frequency or regularity throughout and across a corpus" (p. 751). We found that three topics are specific to a single author (for instance t3), and about a third seem genre specific. By inspecting the most important words for each topic we found that most topics (genre related or not) indeed cohere with certain themes (cf. Fig.1). This suggests that the choice for 50 topics is neither too small nor too high.

Quantitative analysis

We aim to gain insight into the distribution of topics in relation to the literary ratings of the novels (predicting literary ratings is not the main aim here). In order to interpret the topic distributions, we introduce the concept of mono-topicality.[2] A mono-topical novel contains little diversity in topic distribution, which means that one or two topics are dominant throughout the novel. A novel which shows more variation in topics has a more even distribution of topics, i.e., such a novel has a larger topic diversity. Fig. 2 shows an example of both cases.

The x-axis shows the distribution of topics, sorted from least to most prevalent. In John Grisham's *The Appeal*, topic 5 ("lawsuits") has a proportion of 47.8 % of all 50 topics. This novel is more mono-topical than the Franzen's *Corrections*, which has a more balanced distribution of topic proportions.

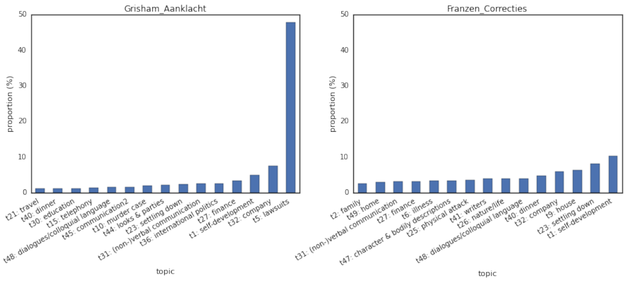

Figure 2: Distribution of the top 15 topics in novels with high (left) and low (right) mono-topicality

Table 1: Themes in fifteen highly literary novels, all of which are originally Dutch Table 2: Six topics from the model that address themes present in the fifteen highly literary novels, but which are not the most prominent as topics in those novels

We hypothesize that the less mono-topical a novel is, the higher the perceived literariness by readers will be. And indeed, Fig. 3 shows that there is a statistically significant correlation between the diversity of topics of a book and its perceived literariness. Books with a single, highly prominent topic, such as Grisham's, tend to be seen as less literary.

Interpretation

There are several possible explanations for the correlation. Genre novels could have a tendency to single out certain topics, as they deal with more 'typical' or genre-specific subject matter than do general novels. If this were the case, we would simply be finding that genre novels are considered to be less literary than general novels, and this would tell us little about literary quality in a more general sense. General novels in the other hand, deal with all sorts of subjects and themes, across and beyond 'genre' subjects, and therefore a topic model may not be able to single out thematic groups of words common to these novels, and thus may not find one single prominent topic. A third explanation could be that highly literary novels *do* deal with specific themes and subjects which are also part of genre novels, but that these are described in wordings that are more implicit or subtle, and therefore do not come up as single, clear topics. If this were the case, that would bring us closer to an explanation of what topics have to do with literary quality. These explanations are not mutually exclusive and we will explore the topic model here to examine the value of the second and third explanation.

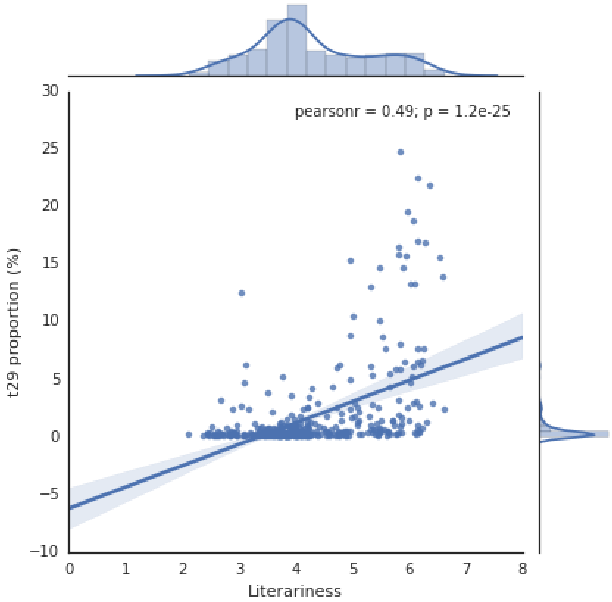

Figure 4: Correlation between topic 29 proportion and mean literariness ratings

The topic that shows the highest correlation (r=0.49) with literary appreciation is topic 29; cf. Fig. 4. This topic is most prominent in fifteen originally Dutch general novels. The twenty words in topic 29 with the highest weights are *begin, music, play, occasion, first, the first, sing, only, year, one, stay, sometimes, even, new, own, always, high, exact(ly), bike, appear*. They show little coherence, making it hard to interpret their context, although 'music and performance' appears to be part of it. To find out more about the novels in which this topic is prominent, we consult a Dutch website maintained by librarians called *Literatuurplein*, which provides information on the themes and content of Dutch novels.

Most of these novels show similarities in themes, such as family relationships. In ten of the novels the protagonist has an artistic profession: a couple of writers, a painter and a stand-up comedian. None of them has a musical or acting career, despite the 'music and performance' words; and vice versa, none of the twenty most prominent words concern writing.

All in all, at first glance topic 29 seems not to address the themes and content of the novels, whereas most other topics in the model do concern specific themes (cf. Fig. 1 and Table 2).

Topic	Name	Top 10 words with highest weight
2	Family relations I	father, mother, child, year, son, girl, brother, woman, older, daughter
6	Health I	doctor, body, pain, illness, pill, blood, death, medicine, child, patient
11	Family relations II	child, mother, mom, baby, dad, little, cry, hand, time, grandma
12	Writing & memories	picture, letter, write, read, paper, book, year, day, enveloppe, memories
33	Health II	doctor, hospital, patient, women, bed, lie, nurse, room, hall, hour
41	Novels	book, writing, story, year, word, writer, human, novel, time

Table 2: Six topics from the model that address themes present in the fifteen highly literary novels, but which are not the most prominent as topics in those novels

For instance, topic 2 and 11 address family relations, topic 12 and 41 are about writing novels, and topic 6 and 33 concern health issues. These topics are present, but as smaller topics. This shows that the second explanation, of the general novels not sharing themes, is not valid. It could be an indication though that the highly literary novels indeed use a more subtle way of describing themes similar to other novels in our corpus, our third explanation. As a final note, in topic 29 there are proportionally more adverbs than in the other topics mentioned, which contain more nouns. Perhaps this shows that style is a more shared element in literary novels than the choice of words. In other words, this brief analysis shows that there is merit to our third explanation. This will therefore become a new hypothesis for further research.

Conclusion

We have explored a topic model of contemporary novels in relation to genre and literariness, and shown that topic diversity correlates with literary ratings. Most topics express a clear theme or genre. However, topic 29, the most literary topic, does not. It rather appears to be associated with a particular Dutch literary writing style.

Teaching Digital Humanities Through a Community-Engaged, Team-Based Pedagogy

Andrew Jewell
ajewell2@unl.edu
University of Nebraska-Lincoln, United States of America

Elizabeth Lorang
llorang2@unl.edu
University of Nebraska-Lincoln, United States of America

Based in five years of experience teaching digital humanities (DH) students at the University of Nebraska-Lincoln (UNL), our paper tells the story of an evolving approach to teaching "practical" skills. We argue that the most important skills DH students need to learn are not particular programming languages or specific research methodologies, but team-based problem-solving. Furthermore, an effective way to achieve this learning is for students to work together to design and build a digital project that addresses a real challenge, draws upon their commitment to the humanities, and serves the mission of a local organization.

Background

When UNL formed its Graduate Certificate Program in Digital Humanities, the organizing committee knew it wanted students to have a substantial engagement with the intellectual theory undergirding digital humanities as well as with DH praxis. To accomplish this, UNL created two courses to form the heart of the Certificate: the Interdisciplinary Reading Seminar in Digital Humanities and the Internship in Digital Humanities.

The Internship in Digital Humanities, originally available only to graduate students, embedded students within faculty DH projects at UNL. Students worked on these projects for seven hours per week and spent one hour in class learning some "basic skills" for digital humanists. After running the course this way for two years, we determined we were not fulfilling the goals of the curriculum or the needs of the students. In the best cases, students were fully integrated into project teams and were challenged with new experiences. Other students, however, performed menial and repetitive work throughout the semester. We also underestimated the challenge of making students collaborators in this limited time, especially when project staff faced deadlines and needed to focus on production rather than instruction. The weekly class sessions, too, were mere introductions; students could not truly learn new skills because their projects did not provide opportunities to work with the introduced technologies and strategies.

The mediocrity of this approach and the inclusion of the course in a new Undergraduate Minor in Digital Humanities forced us to think more deeply about what it means to teach DH project development. We wanted a higher level of student investment in the work and for students to be involved from conception to implementation. And opening the course to undergraduate students made us even more aware of the need to present students with varied projects, not just those emerging from faculty members at a research-intensive university.

Immersive, Community-Based Approach to Digital Humanities Teaching and Learning

For the revised version of the course, known as the Digital Humanities Practicum and launched in 2014, we adopted a service learning--or community-based learning--model. Both undergraduate and graduate students enroll in the course, and it is cross-listed among several departments including Anthropology, English, History, and Modern Languages & Literatures. (We are faculty members in the UNL Libraries, and the Libraries also play an important role in the course.) Under the new design, we partner with local organizations who have identified challenges suited to technological, humanities-engaged solutions. Over the course of the semester, students respond to those challenges, first conceptualizing a solution, iteratively building their solution (and sharing iterations with classmates), and then presenting their solution to a public audience at the end of the semester. The practicum engages and implements key values of community-based learning, including a "recursive style; direct, high-impact method; and emphasis on abstraction embedded in practice" (Grobman and Rosenberg, 2015). In addition, the course now advances a team-based experience that focuses not only on academia but looks outward to the humanities' roles in society more broadly.

A fundamental difference between the Digital Humanities Practicum and the earlier internship course is that the Practicum focuses on team-based problem-solving rather than specific technical skills. For example, Humanities Nebraska, a state-wide humanities advocacy organization, challenged the students to improve communication about their annual Chautauqua event while engaging new audiences. In response, a team of undergraduate students proposed a mobile application that would serve as an information platform and provide opportunities for social media engagement. Entering the course, the students had limited experience with web technologies and no experience with mobile application development. While they researched what might be involved in creating a mobile application, we reached out to others on the UNL campus who could work with students to help them learn specific skills and made sure they would have access to necessary hardware (such as a variety of mobile devices for testing) and software. By semester's end, the application was available in the Google Play store, and shortly after was published to the Apple App Store. During this experience, the students learned much more than new technology proficiencies. They performed research about Chautauqua and the Chautauqua theme ("Free Land"), considered how best to communicate this information to the audiences they sought to reach, and interacted effectively with their client and mentors about their ideas--including accepting and responding to criticism of approaches that were not working.

This model requires significant flexibility on the part of the instructors and students. The syllabus is largely unfixed, as it must respond to the students and their needs, based on their background and experiences and also on the solutions they seek to pursue. Therefore, most of the fifteen-week semester cannot be planned more than a week or two in advance. Students, however, use an agile development approach so that they and we learn early where they will confront difficulties in implementing their solutions and what resources--whether people, hardware, software, or strategies--we need to connect them with in order for them to develop their projects.

Successful implementation of this model also requires that faculty and students are frank about knowledge limitations. As the instructors, we confess at the beginning of the course that we don't ourselves know everything the students will need to learn to be successful. But what we offer the students--and model for them--is the ability to figure out the necessary skills and seek appropriate resources. As we routinely tell the students, the requirements to solve these problems are not technical skills, but courage and perseverance. Our students have learned to weather discomfort not only because we implore them to do so, but because the iterative development model insists upon it. By having the students produce and demonstrate results early and often, we get them accustomed to a new kind of relationship with their coursework and to problem solving.

Based on our observations and student evaluations, it is this iterative process that imparts the learning. Furthermore, student investment in the projects is encouraged by the "realness" of the challenges. Unlike many classroom assignments, the problems in the Digital Humanities Practicum are authentic challenges brought in by external organizations with real missions, and their work can have application beyond the classroom. Students have assisted the Nebraska Commission on Indian Affairs, for example, in their effort to secure federal legislation designating an historic trail. For the next iteration of the course, offered in Spring 2016, we plan to work with organizations that are not principally humanities organizations. These include a children's museum, a community supported agriculture and food education organization, and a social justice organization. Our goal is to broaden understanding of where humanities work can happen as well as demonstrate possibilities for solving problems by joining diverse areas of expertise. While we do not yet know the outcomes of the 2016 Practicum, the course will conclude before DH2016, and we will share both the student projects as well as an evaluation of the approach.

Notes

[1] Full details of the UNL Graduate Certificate Program are available at http://www.unl.edu/dhcert/

[2] Our approach acknowledges Jakacki and Faull's perspec-

tive that undergraduate digital humanities education often focuses on specific tools or techniques rather than "habits of mind" (2014). Our course and pedagogy also take up the "three major questions in digital humanities pedagogy" raised by Smith: is there a "common core of learning objectives" around which DH programs should be structured? How vocational should DH curricula be? Should DH curricula focus on skills, method, "or critical perspectives on technology and its application"? (2014).

[3] The skills we teach with this class are consistent with those outlined by Rockwell and Sinclair (2012): working in interdisciplinary teams, managing projects, applying digital practices, and explaining technologies.

Exploring and Evaluating Cartographic (miss)Representation in a Sample of Web-based Geohumanities Projects

Catherine Emma Jones
catherine.jones@cvce.eu
CVCE, Luxembourg

Introduction

Given the rise in recent years of GeoHumanities projects, this paper considers how historical data are translated and represented geographically within online mapping projects, giving insights into how these representations influence acquired meaning. GeoHumanities predominantly use geographical tools to create, present and explore different types of historical evidence and resources, for example original paper maps transformed into digital representations or geocoding of place names within texts. Factors impacting the resulting representation of historical evidence in geographical form include: choice of the underlying geographic data models, form and style of the original (historical) objects, as well as the selection, transformation and encoding practices. In this study we observe which data models are used and their context, to understand how these choices may influence acquired meaning and cognitive understanding.

Method

The GeoHumanities special interest group of the Alliance for Digital Humanities Organisations has a catalog of 312 geohumanities based projects (data from July 2014). From this list a sample of 30 projects were selected (sample selected based on language, availability and production since 2010) . In these projects, the cartographic representation of historical evidence was evaluated according to a set of 70 different criteria grouped into 4 categories: (1) data structures used to model data; (2) forms of representation (typology, symbolism, use of transparency and uncertainty); (3) data interaction possibilities offered to users and (4) spatial data analysis possibilities offered to users.

The following research questions were investigated:

- How are historical data represented in web mapping applications?
- How rich are geohumanities interfaces?
- How do they influence knowledge acquisition?

In this paper we consider the first research question.

Results: Exploring raster representations

In the sample we observed a mix of both vector and raster data models. Of the 30 projects, 40% (n=12) used raster data models to integrate georeferenced versions of historical paper maps, with 4 types of use scenarios (see figure 1). Firstly, either paper map sheets belonging to a map series were stitched together or individual maps were used as a basemap layer enabling viewing of historical context or comparison of raster map to digitally encoded vector data. The digital versions of the paper map were presented as an optional data layer in the interface that, in the main, could be switched on or off by the user. For 26 out of 30, the historical map was overlaid on top of a contemporary raster base map which displayed either a street map or an aerial view. In only 2 very early period maps, the Agas Map of Early Modern London and The Gough Map of Great Britain, was it not possible to view a contemporary reference basemap.

The second and third types of historical paper map representations in raster format were observed in crowdsourcing methodologies. In these projects users are asked to interact with the map to create new digital data. One category of projects asked members of the public to undertake the transformation from a digital scan of the paper map to a true digital raster using the processes known as georeferencing. The other made use of georeferenced historical maps and asked users to vectorise historical data. Users were asked to encode labels or draw and confirm shapes of buildings. In this type of task the users are effectively tracing the historical map to create a vector representation. The final use observed focused on the search of historical data through the map interface to find metadata records and locate historical maps. The coordinate extents of the original paper maps were used to draw a minimum bounding rectangle within the web-map interface to highlight the represented areas. Users could then search for places and discover which old maps are available digitally at different archives.

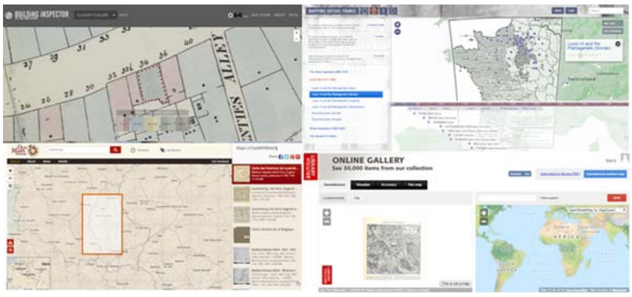

Figure 1: show screenshot of the different models of historical raster representation

Influences of raster representations

After such extensive treatment, to digitally transform the paper map into a web map, it becomes relevant to consider notions of materiality between the source and the transformed map. The "materiality" of the raster map is influenced by the transposition from paper to digital, with the associated loss of integrity. Take the action of cropping the map, observed in two thirds of all the rasters. The deletion of contextual map elements implies a certain loss of meaning from the source. Lost information commonly include: title, coordinate system, data of production, map producer, original legend, handwritten notes, archive stamps and other information. Thus the cropping process ensures that only purely functional cartographic data are retained, whilst the social document context is neglected.

A new type of digital materiality is derived from the transformation of the paper map to the digital into a " *slippy map*", where the historical raster map is cut up into a sets of map tiles that provide small images which are seamlessly joined together (in the same way Google Maps API and others provide users access to contemporary basemaps). By cropping the historical map to show only the cartographic map many map sheets from the same original paper map series can be stitched together to provide a detailed view across a wider geographical extent without having overlapping boundaries or edge effects of the different map sheets that would result otherwise. Of course such a large map with street level detail would not have been possible to draw using traditional paper maps and is facilitated only by advances in technology and web-mapping interfaces. Once the georeferenced maps are tiled, the slippy map enables users to zoom and pan effortlessly. There are certain advantages: (1) users can explore an entire city, region or continent as one seamless entity; (2) viewing of the map is instantaneous as tiling methods do not require lengthy loading times (which can be the case if providing high resolution georeferenced raster maps that are not tiled); (3) users are provided with new types of interactions for engaging with the map and importantly (4) users are provided with digital transformation to enable new ways of consuming "original" historic material.

Results: Exploring point representations

Vector data, especially point objects, were by far the most common representation of historical data in Geohumanities projects. Nearly all of the samples, almost ninety percent of the projects (n=26) used points for their digital conceptualisations of historical phenomena, ideas or events, see figure 2. Moreover, it was particularly common to simultaneously use both raster and point data structures within the interface. Whereby, the historical map in raster form was adopted as the basemap, ie a reference map with the point data provided users with representations of more specific data. Such a mix was observed in 22 projects. A small number of projects also made use of the line (26%) and area (33%) geometry objects that are available as part of the vector data format. No projects used text as a way of representing information (except to label objects label objects).

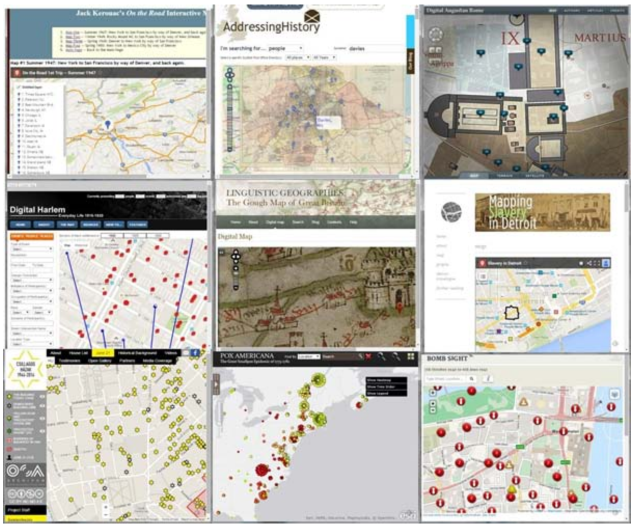

Figure 2: Example of map interfaces uses point data

Influences of Point for representing historical data

The point data object is a ubiquitous form of representation. It is a pervasive feature of geohumanities web-mapping projects and was observed in nearly all the sample projects (almost 90%). The point is used to represent a digital conceptualisation of historical phenomena, ideas, places, events etc. Despite the ubiquitous use of this data model, it is not without issues.

Given that a point marks an exact location, it was often observed that points (miss)represented phenomena that ranged in scale from a building, city and region or wider, sometimes representing all in the same data layer. Such confusing representations were exacerbated by (1) choice of representation - the use of the map pin which implies certainty in location; (2) failure to represent uncertainty in data therefore implying absolute facts – that are actually ambiguous (3) low usage of icons as map symbols reducing the cognitive understanding of the map. The point encapsulates a sense of location accuracy, precision and factual detail that often represented fuzzy historical constructs at best. Thus, in much the same way as text is transposed into digital form (Kirschenbaum, 2001; Hayles, 2005; Drucker, 2011), the digital map transformations and resulting cartographic representations influence the meaning of the mapped data and how it is read, interpreted and understood. By failing to consider carefully the cartographic choices in how the digitised historic data are embodied, it is likely that the cognitive load placed on the user and the efforts required to extract meaning from the maps are significantly increased. It also will strongly influence how these digital translations are interpreted and understood by the user.

Thoughts and Conclusions

This evaluation is a starting point for discussions between humanities scholars and geo specialists, designers, information scientists and human computer interactions experts. It is obvious that digital transformations of historical data into digital geodata world provides many benefits, not least that associated with pattern recognition and presentation of data but it is not without its limitations. Initial results indicate that existing models and cartographic representations of georeferenced historical data need to be extended. It is plausible to suggest that the point data structure is inadequate for representing complex historical phenomena or broad geographical concepts but due to the lack of alternatives it is widely accepted as standard practice. We will reflect on the point as an appropriate mechanism for representing complex historical data? Explore the extent digital representations should stay true to original historic map evidence? And investigate how *digital map translations* influence understanding and aid/hinder interpretation?

Authorship Attribution Using Different Languages

Patrick Juola
juola@mathcs.duq.edu
Duquesne University, United States of America

George Mikros
gmikros@isll.uoa.gr
National and Kapodistrian University of Athens, Athens, Greece

For many at this conference, stylometry and authorship attribution need little introduction; the determination of who wrote a document by looking at the writing style is an important problem that has received much research attention. Research has begun to converge on standard methods and procedures (Juola, 2015) and the results are increasingly acceptable in courts of law (Juola, 2013).

The most standard experiment looks something like this: collect a training set (aka "known documents," KD) representative of the documents to be analyzed (the testing set, aka "questioned documents," QD) and extract features from these documents such as word choice (Burrows, 1989; Binongo, 2003) or character n-grams (Stamatatos, 2013). On the basis of these features, the QD can be classified -- for example, if Hamilton uses the word "while" and Madison uses the word "whilst" (Mosteller and Wallace, 1963) a QD that doesn't use "while" is probably Madisonian.

... unless it's not in English at all, in which case, neither word is likely to appear. The need for the KD to represent the QD fairly closely is one of the major limitations on the use of this experimental methodology. By contrast, the authorial mind remains the same irrespective of the language of writing. In this paper, we report on new methods based on cross-linguistic cognitive traits that enables documents in Spanish to be attributed based on the English writings of the authors and vice versa. Specifically, using a custom corpus scraped from Twitter, we identify a number of features related to the complexity of language and expression, and a number of features related to participation to Twitter-specific social conventions.

We first identified (by manual inspection) a set of 14 user names that could be confirmed to have published tweets in both English and Spanish. Once our user list had been collected, we scraped the Twitter history of each user to collect between 90 and 1800 messages ("tweets") from each user and used the detectlanguage.com server to identify automatically the language of each tweet.

A key problem is feature identification, as most features (e.g. function words or character n-grams) are not cross-linguistic. For this work, we have identified some potentially universal features. One of the most long-standing (de Morgan, 1851) features proposed for authorship analysis is complexity of expression, as measured variously by word length, distribution of words, type/token ratio, and so forth. We used thirteen different measures of complexity that have been proposed (largely in the quantitative linguistics literature) to create a multivariate measure of complexity that persists across languages. Similarly, we identified three specific social conventions (the use of @mentions, #hashtags, and embedded hyperlinks, all measured as percentage of occurrence) that people may or may not participate in. Our working hypothesis is that people will use language in a way that they feel comfortable with, irrespective of the actual language. Hence, people who use @mentions in English will also do so in Spanish. Similarly, people who send long tweets in English also do so in Spanish, people who use big words in English also do so in Spanish, people who use a varied vocabulary in English also do so in Spanish, and of course vice versa.

We were able to show, first, that the proposed regularities do, in fact, hold across languages, as measured by cross-linguistic inter-writer correlations. (Thus, we also showed that our working hypothesis is confirmed, at least for these traits). Second, we showed via cluster analysis that these measures are partially independent from each other, and thus they afford a basis for a stylistic vector space. (Juola and Mikros, under review). This potentially enables ordinary classification methods to apply. The results reported here show that, in fact, they do.

To do this, we apply normal classification technology (support vector machines using a polynomial kernel) to the vector space thus constructed. We first broke each individual collection into 200 word sections (thus conjoining multiple tweets). Each section was measured using each complexity feature and then raw values were normalized using z-scores [thus a completely average score would be zero, while a score at the 97th percentile would be approximately 2.0; this is similar to Burrows' Delta (Burrows, 1989)]. For our first experiment, the English sections were used to create a stylometric vector space, then the Spanish sections were (individually) embedded in this space and classified via SVMs. For our second experiment, the languages were reversed, classifying English sections based on Spanish stylometric space. Since SVM with polynomial kernel is a three parameter model, we optimized the classifier's performance using a grid-search parameter tuning and comparing 3 different values for each of the three parameters (totaling 3^3 models). The classifier's performance was evaluated using a 10-fold cross-validation scheme and the best single language model was used for predicting the authorship of the texts written in the other language from the same authors.

This resulted in 2652 attempts to predict authorship of individual 200 word sections in Spanish, and another 1922 attempts in English, classified across fourteen potential authors. Baseline (chance) accuracy is therefore 1/14 or 0.0714 [7.14%].

Using the English data to establish the stylometric space and the Spanish samples to be attributed yielded an accuracy of 0.095, a result above baseline but not significantly so. By contrast, embedding English data into a Spanish space yielded an accuracy of 0.1603, more than double the baseline. This result clearly establishes the feasibility of cross-linguistic authorship attribution, at least at the proof of concept level. Experiments are continuing, both to establish clearer statistical results, and also to evaluate the additional effectiveness of the Twitter-specific social conventions as features.

We believe this result to be the first recorded instance of using training data from one language to attribute test data from another language using a formal, statistical attribution procedure. This is a very difficult dataset using an extremely small set of predictive variables, and the samples (200 words) are very small (Eder, 2013). In light of these issues, the relatively low (in absolute terms) accuracy may still represent a major step forward.

Like many research projects, these results pose as many questions as they answer. Why is English->Spanish easier than Spanish->English? What other types of language-independent feature sets could be developed, and how would performance compare? Do these results generalize to different language pairs, or to different genres than social media and Twitter in particular? What additional work will be necessary to turn this into a practical and useful tool? Can this generalize to other authorial analysis applications such as profiling (of personality or other attributes)?

Further research will obviously be required to address these and other issues. In particular, this study is obviously only a preliminary study. More language pairs are necessary (but finding active bilinguals on Twitter is difficult). Studies of other genres than tweets would be informative, but again corpus collection is problematic. We acknowledge that the current accuracy is not high enough to be useful. For the present, however, the simple fact that cross-linguistic authorship attribution can be done and has been done, remains an important new development in the digital humanities.

Regional Classification of Traditional Japanese Folk Songs from the Chugoku District

Akihiro Kawase
kawase.ak@gmail.com
National Institute for Japanese Language and Linguistics, Japan

Introduction

This study aims to grasp the regional differences in the musical characteristics inherent in the traditional Japanese folk songs of the Chugoku district (the westernmost region of Japan's largest island of Honshu) by extracting and comparing the characteristics of each area by conducting quantitative analysis in order to promote digital humanities research on traditional Japanese folk songs.

We have sampled and digitized the five largest song genres within the music corpora of the *Nihon Min'yo Taikan* consisting of 1,794 song pieces from 45 Japanese prefectures, and have clarified the following three points by extracting and comparing their respective musical patterns (Kawase and Tokosumi 2011): the most important characteristics in the melody of Japanese folk songs is the transition pattern, which is based on an interval of perfect fourth pitch; regionally adjacent areas tend to have similar musical characteristics; and the differences in the musical characteristics almost match the East-West division in the geolinguistics or in the folkloristics from a broader perspective.

However, to conduct more detailed analysis in order to empirically clarify the structures by which music has spread and changed in traditional settlements, it is necessary to expand the data and do comparisons based on the old Japanese provinces (ancient administrative units that were used under the ritsuryo system before the modern prefecture system was established).

Procedure

In order to digitize the Japanese folk song pieces, we generate a sequence of notes by converting the music score into MusicXML file format. We devised a method of digitizing each note in terms of its relative pitch by subtracting the next pitch height for a given MusicXML. It is possible to generate a sequence T that carries information about the pitch to the next note: $T = (t_1, t_2, \dots, ti, \dots, tn)$. An example of the corresponding pitch intervals for ti can be written as shown in Table 1. We treat sequence T as a categorical time series, and execute n-gram analysis by conducting unigram, bigram, and trigram patterns to clarify major transitions and their trends in the Chugoku district.

t_i	Pitch Intervals	t_i	Pitch Intervals
0	perfect unison	7	perfect fifth
1	minor second	8	minor sixth
2	major second	9	major sixth
3	minor third	10	minor seventh
4	major third	11	major seventh
5	perfect fourth	12	perfect octave
6	aug.fourth/dim.fifth	13	minor ninth

Table 1: Corresponding Pitch Intervals

Overview of Data

In order to quantitatively extract pitch transition patterns from Japanese folk songs, we sampled and digitized folk songs included in the *Nihon Min'yo Taikan*. We sampled all the songs in the music corpora included in the Chugoku Region volume (1966). Table 2 shows the statistics about the song pieces from each area in the Chugoku district. Figure 1 is a map of the provinces in the Chugoku district.

Figure 1: Geographical Divisions of the Chugokuk District Under the Old Province System

Results

Frequency of the First Transition

Figure 2(a) shows the usage frequency of the first transition patter (unigram). The graph implies that pitch transitions occur almost equally in both the ascending and descending directions. Figure 2(b) is a cumulative relative frequency diagram of the first transitions for ascending and descending order that confirms the trends for each interval. The profile shows that most of the voice range does not extend beyond the interval of perfect fifth (±7).

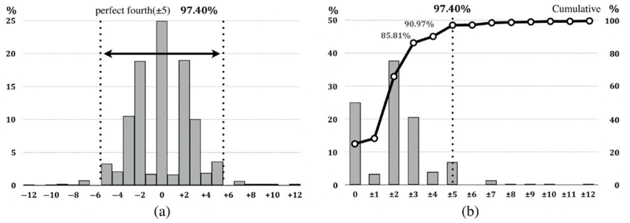

Figure 2: (a) First Transition Frequency and (b) Cumulative Relative Frequency Diagram

Based on studies of musical psychology, step-by-step changes in pitch height (in other words, pitch interval transitions that always involve ascending or descending order) are an indispensable factor by which humans perceive melodic patterns (Scruton 1997). Therefore, to extract the structures buried under repetition of notes, we will exclude the 0 intervals from sequence T in order to seek the pure changes of ups and downs within the melody.

Overall Summary of Bigram Patterns

Table 3(a) shows the top 40 bigram patterns. These components do not exceed the range of the perfect fifths (±7), and the values of the chains (intervals) also add up to a pitch interval between -5 and +5. In addition, we find that transition patterns that add up to 0 ($t_i + t_{i+1} = 0$), transition patterns that add up to ±5 ($t_i + t_{i+1} = \pm 5$, which is the interval of the perfect fourth), and patterns that include the interval of the perfect fourth in either component (e.g. patterns that form (t_i, t_{i+1}) = (±5, *), (*, ±5)) also appear with high frequency.

Table 3: Frequency of Occurrence of (a) Bigrams and (b) Trigram (Top 40 Patterns)

Overall Summary of Trigram Patterns

Table 3(b) shows the top 40 trigram patterns. These components do not exceed the range of perfect fourths (±5), and the feature that stands out is that some of the top-ranked patterns are patterns with a single pitch transition attached to bigram. Most of the transition patterns fall in the range of the intervals of perfect fifths (±7). Furthermore, there are many high-ranked patterns in which the beginning two transitions or the last two transitions add up to form either the same degree of pitch ($t_i + t_{i+1} = 0$ or $t_{i+1} + t_{i+2} = 0$) or a perfect fourth pitch ($t_i + t_{i+1} = \pm 5$ or $t_{i+1} + t_{i+2} = \pm 5$).

Discussion

Koizumi's Tetrachord Theory

To speed things along, we will mention Koizumi's tetrachord theory (1958). The tetrachord is a unit consisting of two stable outlining tones (nuclear tones) with the interval of a perfect fourth pitch, and one unstable intermediate tone located between them. Depending on the position of the intermediate tone, four different types of tetrachords can be formed (Table 4).

Type	Name	Pitch Interval
I	*Min'yo*	minor third (3) + major second (2)
II	*Miyako bushi*	minor second (1) + major third (4)
III	*Ritsu*	major second (2) + minor third (3)
IV	*Ryukyu*	major third (4) + minor second (1)

Table 4: For Basic Types of Tetrachords

Using a bigram model representing pitch transitions, all four types of tetrachords can be expressed as follows in ascending order: *min'yo* (+3, +2), *miyako bushi* (+1, +4), *ritsu* (+2, +3), and *ryukyu* (+4, +1). Depending on the positions of the three initial pitches in a tetrachord, six transition patterns can be considered in perceiving a tetrachord in two steps (bigram). Therefore, the amount of tetrachords within two steps can be obtained by counting the pairs of 24 transition patterns in sequence T.

	Min'yo tetrachord						*Miyako bushi* tetrachord					
	(+3, +2)	(+5, -2)	(+2, -5)	(-3, +5)	(-2, -3)	(-5, +3)	(+1, +4)	(+5, -4)	(+4, -5)	(-1, +5)	(-4, -1)	(-5, +1)
Mimasaka	266	16	49	12	211	62	16	1	3	3	6	3

Table 5: Number of Transition Patterns for the Four Tetrachords

Province Similarities Based on the Frequency of Occurrence of Tetrachords

Table 5 shows the frequency that the 24 transition patterns for the four tetrachords appear for all 12 provinces. Here, we did hierarchical cluster analysis on the 24 transition patterns for each province to objectively demonstrate similarities in the 12 provinces. The dendrogram in Figure 3 shows hierarchical cluster analysis results. When calculating distances between each element, we normalized the frequency that the tetrachords appear, and used the Euclidean distance and the algorithm from the Ward method.

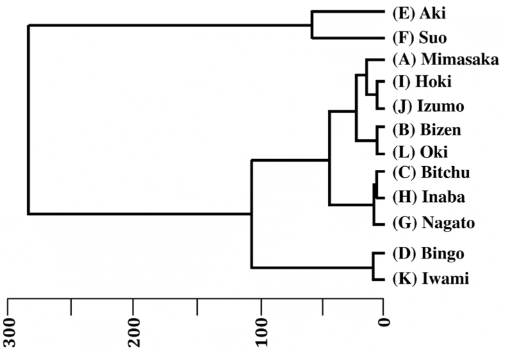

Figure 3: Cluster Analysis Results

If we look for $h = 60$ (a height where there are three vertical lines) and trace them to the individuals, this partition of three clusters separates the 12 provinces into C_1 = {Aki, Suo}, C_2 = {Mimasaka, Bizen, Bitchu, Nagato, Inaba, Hoki, Izumo, Oki}, and C_3 = {Iwami, Bingo}, which almost classifies the Chugoku district into geographically close groups. Meanwhile, it also stands out that only Nagato is separately geographically isolated.

Sea Route Connecting the Provinces

The cluster analysis results did not turn out to match the famous two ancient divisions based on the main road: San'yo = {Mimasaka, Bizen, Bitchu, Bingo, Aki, Suo, Nagato} and San'in = {Inaba, Hoki, Izumo, Iwami, Oki}. However, instead it is possible to consider each cluster based on sea routes (Figure 4).

Since ancient times, the Chugoku district has been an area travelers passed through when traveling from the Kansai district (a center of regional culture in Japan) to get to Kyushu region, which had close relations with China and Korea. Since there wasn't much flat land and there are many mountain ranges, sea routes played an important role in transportation.

The existence of the Ota River, a major river and also a sociocultural and economical foundation in the Chugoku district, supports the grouping of the two provinces in C_1. From an oceanic commerce point of view, the north and south sea routes that link the Nagato and Kansai regions also support the grouping of providences in C_2. It is also possible to say that the Gonokawa River, which functioned as a traffic relay point between San'yo and San'in, supports the grouping of provinces in C_3. In this way, we find that rivers have important functions that exert musical influence as well as indicate boundaries between districts and geographical areas.

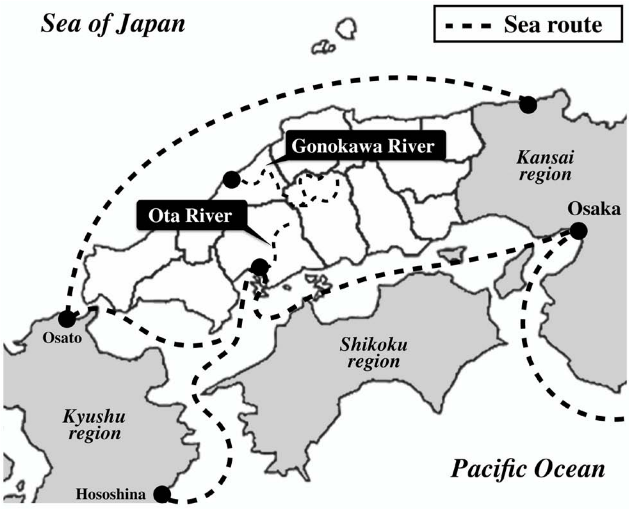

Figure 4: Sea Routes Map of the Chugoku District

Conclusions

In this paper, we digitized the melodies of traditional Japanese folk songs in the Chugoku district, and quantitatively analyzed its pitch transition patterns using n-gram modeling, and did a classification experiment based on the frequency of occurrence of the tetrachords to see the differences in each province. As a result, we constructed the possibility that the melodic features in the Chugoku district spread by land and sea routes based on actual music data analysis. However, we should be able to describe the relationships influencing musical culture between regions in detail if we develop this analysis on a nationwide scale. In further research, it is possible to clarify the structural commonalities and differences between areas by conducting analysis on musical corpora nationwide including folk song pieces from neighboring regions such as the Kyushu, Shikoku, and Kansai regions, which has not really been pursued in existing humanities research fields. We believe this will empirically clarify the musical culture phenomena by which music spreads and changes.

Introduction

Authorship studies have long played a central role in stylometry, the popular subfield of DH in which the writing style of a text is studied as a function of its author's identity. While authorship studies come in many flavors, a remarkable aspect is that the field continues to be dominated by so-called 'lazy' approaches, where the authorship of an anonymous document is determined by extrapolating the authorship of a document's nearest neighbor. For this, researchers use metrics to calculate the distances between vector representations of documents in a higher-dimensional space, such as the well-known Manhattan city block distance. In this paper, we apply the minmax metric – originally proposed in the field of geobotanics – to the problem of authorship attribution and verification. Comparative evaluations across a variety of benchmark corpora show that this metric yields better, as well as more consistent results than previously used metrics. While intuitively simply, this metric generally displays a regularising effect across different hyperparametrizations, and allows the more effective use of larger vocabularies and sparser document vectors. In particular the metric seems much less sensitive than its main competitors to (the dimensionality of) the vector space model under which the metric is applied.

Most authorship studies in computer science are restricted to present-day document collections. In this paper, we illustrate the broader applicability of the minmax metric by applying it to a high-profile case study from Classical Antiquity. The 'War Commentaries' by Julius Caesar (*Corpus Caesarianum*) refers to a group of Latin prose commentaries, describing the military campaigns of the world-renowned Roman statesman Julius Caesar (100-44 BC). While Caesar must have authored a significant portion of these commentaries himself, the exact delineation of his contribution to this important corpus remains a controversial matter. Most notably, Aulus Hirtius – one of Caesar's most trusted generals – is sometimes believed to have contributed significantly to the corpus. Thus, the authenticity and authorship of the Caesarian corpus is a philological puzzle that has persisted for nineteen centuries. In our paper, we shed new light on this matter.

Benchmarking

To properly evaluate the performance of the novel Ruzicka minmax metric, we turn to a publicly available benchmark corpora: the multilingual datasets (Dutch, English, Greek, and Spanish) used by the 2014 track on authorship verification in the PAN competition on uncovering plagiarism, authorship, and social software misuse. This track focused on the "open" task of authorship verification (as opposed to the closed set-up of authorship verification). Each dataset holds a number of "problems", where given (a) at least one training text by a particular target author, (b) a set of similar mini-oeuvres by other authors, and (c) a new anonymous text, the task is to determine whether or not the anonymous text was written by the target author. A system must output for each of the problems a real-valued confidence score between 0.0 ("definitely not the same author") and 1.0 ("definitely the same author"). By outputting the value of 0.5, a system can specify that it was not able to solve a problem. For each dataset, a fully independent training and test corpus are available (i.e. the problems, nor authors and texts in both sets do not overlap). Systems are eventually evaluated using two scoring metrics which were also used at the PAN: the established AUC-score, as well as the so-called c@1, a variation of the traditional accuracy-score, which gives more credit to systems that decide to leave some difficult verification problems unanswered. In the full paper, we offer a complete evaluation of all datasets: for the sake of brevity, this paper is restricted to a representative selection of results.

As common in text classification research, we vectorize the datasets into a tabular model, under a 'bag-of-words' assumption, which is largely ignorant of the original word order in document. Unless reported otherwise, we use character tetragrams below (Koppel et al., 2014), which yield generally acceptable results across corpora. We experiment with a number of different vector space models, the results of which can be summarized as follows:

- plain *tf* (where simple relative frequencies are used);
- *tf-std*, where the *tf*-model is scaled using a feature's standard deviation in the corpus (cf. Burrows's Delta: Burrows, 2002);
- *tf-idf*, where the *tf*-model is scaled using a feature's inverse document-frequency (to increase the weight of rare terms).
- …

In our experiments, we focus on the Ruzicka 'minmax' distance metric, a still fairly novel algorithm in the field of stylometry. Just as the Euclidean or Manhattan distance, this metric will calculate a real-valued distance score between two document vector A and B as follows:

$$minmax(\vec{A}, \vec{B}) = 1 - \left(\frac{\sum_{i=1}^{n} \min(\text{tf}(A_i), \text{tf}(B_i))}{\sum_{i=1}^{n} \max(\text{tf}(A_i), \text{tf}(B_i))} \right)$$

While the formula below uses the tf-model, the Ruzicka distance can of course be easily applied to other vector space models too. In our paper, we will offer a intuitive assessment of the desirable properties of this metric (e.g. in comparison to Burrows's Delta).

General Imposters Framework (GI)

In our experiments, we make amongst others use of the General Imposters Method, a bootstrapped approach to authorship verification which has recently yielded excellent results. Fitting the verifier on the train data involves two steps. First, we calculate a distance score for the anonymous document in each problem, using Algorithm 1, in order to determine whether the anonymous text was written by the target author specified in the problem:

```
Algorithm 1: General Imposters Method
input  : $x$, an anonymous document; $T = \{T_1, \ldots, T_n\}$, a
         set of document by the target author;
         $I = \{I_1, \ldots, I_n\}$, a set of document by other
         authors;
output: $0 <= score <= 1$
Set $score = 0.0$;
for $i \leftarrow 1$ to $k$ do
    Randomly select $rate$% of the available features;
    Randomly select $m$ imposters from $I$ as $I'$;
    if $min(dist(T, x)) < min(dist(I', x))$ then
        $score = score + 1/k$ ;
end
Return $1 - score$;
```

Thus, during *k* iterations (default 100), we randomly select a sample (e.g. 50%) of all the available features in the data set. Likewise, we randomly select *m* 'imposter' documents (default 30), which were not written by the target author. Next, we use a *dist()* function to assess whether the anonymous text is closer to any text by the target author than to any text written by the imposters. Here, *dist()* represents a regular, geometric distance metric, such as the Manhattan or Ruzicka metric. The score returned by Algorithm 1 has been characterized as a 'second-order' metric, because it does not rely on the rather comparison of document vectors. The general intuition here, is that we do not just calculate how different two documents are; rather we test whether the stylistic differences between them are consistent (a) across many different feature sets, and (b) in comparison to other randomly, sampled documents.

In the second stage, we attempt to optimize the distance scores returned by Algorithm 1, in the light of the specific evaluation measures used. We apply a score shifter (Algorithm 2), which attempts to define a 'grey zone' where the results seem too unreliable to output a score (cf. c@1):

```
Algorithm 2: Score shifting
input  : $scores$; $0 <= p_1 <= 1$;
$0 <= p_2 <= 1$;
output: $shifted\_scores$
Set $shifted\_scores = list()$;
for $score$ in $scores$ do
    if $score < p_1$ then
        $new\_score = rescale(score)$ to $range(0.0, p_1)$;
    else if $p_1 <= score <= p_2$ then
        $new\_score = 0.5$;
    else
        $new\_score = rescale(score)$ to $range(p_2, 1.0)$;
    end
    Append $new\_score$ to $shifted\_scores$;
end
Return $shifted\_scores$;
```

Through a grid search of different values between 0 and 1 for p1 and p2, we determine the settings which yield the optimal AUC x c@1 on the train data. In Fig. 1, we plot the optimal results which could be obtained on the train problems in the data set of Dutch Essays, for a specific combination of a metric and a vector space model. We ran the experiment 20 times, with increasing vocabulary truncations (e.g. the 1000 most frequent tetragrams). The results demonstrate how the Ruzicka minmax metric returns the most stable results across the experiments and clearly has a regularizing effect across different hyperparametrizations. In the full paper, we will present a complete evaluation of this system on all the PAN datasets, which in most cases yields surprisingly competitive scores on the test data, even without much corpus-specific parameter tuning. In the table below, we show the test results for Dutch essays corpus in terms of the AUC x c@1. The best combination reaches a AUC x c@1 of 0.886 on the test data (combination of *minmax* and *std*), whereas the best individual system submitted to PAN 2014 only reached 0.823 on that test dataset. Using randomized significance tests, we will additionally demonstrate the regularizing effect of the Ruzicka distance across vector spaces; its strong performance is also evident from Table 1.

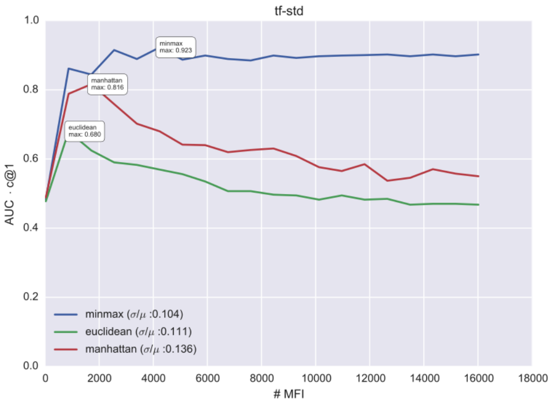

Figure 1: Optimal results on train corpus

Vector Space / Metric	Euclidean	Manhattan	Minmax
Tf	0.676	0.698	0.837
Tf-Idf	0.720	0.750	0.854
Tf-Std	0.614	0.701	0.886

Table 1: Final test results (AUC x C@1)

Corpus Caesarianum

To further illustrate the applicability of the Ruzicka metric for authorship problems in traditional philology, we also report a stylometric case study concerning the *Corpus Caesarianum*. This *Corpus* is a group of five commentaries Caesar's military campaigns:

- *Bellum Gallicum*, the conquest of Gaul, 58 to 50 BC;
- *Bellum civile*, the civil war with Pompey, 49 to 48 BC;
- *Bellum Alexandrinum*, the campaigns in Egypt etc., 48 to 47 BC;
- *Bellum Africum*, the war in North Africa, 47 to 46 BC
- *Bellum Hispaniense*, a rebellion in Spain, 46 to 45 BC

The first two commentaries are mainly by Caesar himself, the only exception being the final part of the *Gallic War* (Book 8), which is by Caesar's general Aulus Hirtius. Suetonius, writing a century and a half later, suggests that either Hirtius or another general, named Oppius, authored the remaining works. We will report experiments which broadly supports the Hirtius's own claim that he himself compiled and edited the corpus of the non-Caesarian commentaries. Figure 2, for instance, shows a heatmap-like visualisation, in which Hirtius's Book 8 of the *Gallic War* clearly clusters with the bulk of the *Alexandrian War* (labeled *x*).

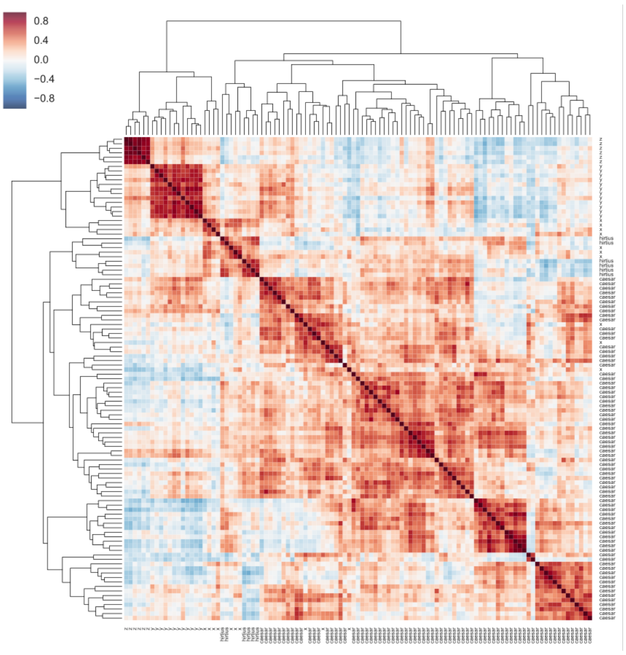

Figure 2: Minmax-based clustermap of 1000-word samples of the *Corpus Caesarianum*.

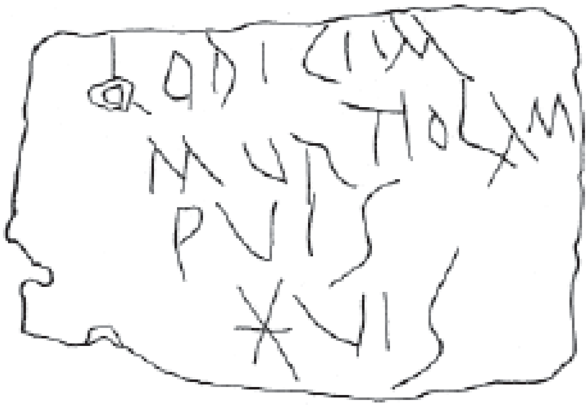
GLAMorous! Edizione Digitale Di Beni Culturali Con Contenuto Testuale, Multidisciplinarietà Ed Epigrafia Digitale.

Marion Lamé
mlame@mmsh.univ-aix.fr
Centre Camille Jullian, MMSH, CNRS, France.; Laboratorio di Cultura Digitale, Università di Pisa; Istituto di Linguistica Computazionale "A. Zampolli", CNR, Italy

Il progetto *Tesserarum Sisciae Sylloge* (TSS) mira alla digitalizzazione di più di 1100 etichette commerciali di piombo di epoca romana (I-III secolo d.C.) conservate nel Museo Archeologico di Zagabria. Hanno le dimensioni approssimattive dei nostri francobolli e portano incisioni con informazioni relative alla tintura della lana (prezzi, prodotti, ecc.).

L'edizione scientifica è a cura di Radman-Livaja, 2014 e il disegno seguente è il fronte dell'etichetta 12563 pubblicata dall'editore



Queste etichette, beni archeologici sotto la responsabilità dei GLAM (Galleries, Libraries, Archives and Museums), sono anche oggetto di studio scientifico, e quindi da considerare sotto vari punti di vista: beni culturali, fonti primarie di informazione per gli studi storici, epigrafi, *Text Bearing Object* (TBO) etc. Sia nell'interesse del pubblico che della ricerca, abbiamo realizzato, tramite l'edizione digitale di queste etichette romane, un open access a questa documentazione (Terras, 2015), facilitato da un *framework* digitale che copre gli aspetti di visualizzazione, divulgazione e informazione scientifica.

Lavori precedenti (vedi ad es. Terras, 2006 con le tavolette di Vindolanda) avevano approfondito le riflessioni riguardo alla rapresentazione digitale e alla decifrazione di un TBO simile per certi aspetti (scritura manoscritta) e sono serviti come punto di partenza in fase preparatoria. Il progetto TSS è stato, durante l'anno 2015, l'ambiente di sviluppo di un aspetto metodologico specifico dell'epigrafia digitale, che mette al centro della procedura di digitalizzazione l'oggetto archeologico, cioè la fonte primaria di informazione dello storico. Si basa sull'analisi dispositiva (*dispositive analysis*) ed è approfondito in Lamé 2015a. L'analisi dispositiva prende in considerazione i vari elementi eterogenei che partecipano al messaggio epigrafico, tenendo conto delle dimensioni sociali e culturali del TBO in quanto oggetto di studio della storia digitale. Propone un insieme di tappe e di procedure che possono includere il *crowdsourcing* (vedi Ridge 2014).

Raggiunti i primi obiettivi prefissati, utilizzando le tecnologie di *Reflectance Transforming Imaging* (RTI), siamo entrati in una fase che potremmo chiamare di *document editing* e che riguarda le metodologie del Cultural Heritage, i *Digital Autoptic Processes* (DAP), la materialità dell'oggetto, e la sua accessibilità a tutti i pubblici dell'Archeological Museum of Zagreb in modo da svolgere sia una missione scientifica che di mediazione museografica verso il suo pubblico. Tuttavia, come sottolinea Pierazzo 2015 (specialmente pp. 70-83), *document editing* (edizione del TBO) e *textual editing* (edizione del testo) sono metodi editoriali complementari: se si possono distinguere non si possono separare. Il *textual editing* è uno dei campi di ricerca più sviluppato nell'ambito delle Digital Humanities ed è ben supportato dal punto di vista tecnico, in particolare grazie allo standard TEI. Il testual editing ha raggiunto la matturità necessaria per essere abbinato e combinato agli aspetti che riguardano il documento.

Il contesto dell'epigrafia digitale del progetto TSS, che presenteremo nella sua versione 1.0, con le conclusioni metodologiche attinenti all'informatica umanistica, in occasione del convegno DH16, fornisce documenti epigrafici la cui funzione è per natura diversa dal manoscritto. Questo genera alcune conseguenze, come, ad esempio, l'assenza del concetto di pagina ma l'uso di quello meno controllabile tecnicamente di 'specchio epigrafico', ovvero la superficie inscritta; essa non viene sempre definita da un rettangolo piano, ma può assumere numerose forme geometriche, come un cipo migliaro, avere confini meno delimitati nello spazio, come nelle iscrizioni arabe, nelle quali le scritte si miscelano a motivi floreali, o come le statue-geroglifiche egiziane. Diventa inoltre importante unire materialità archeologica (*document editing*) e interpretazione del testo (*textual editing*) in una "ricostituzione diplomatica" dell'oggetto in caso di lacuna (Lamé 2015b) tramite un tool dedicato, il MarkOut, che permette di associare calco digitale, paleografia e codifica testuale al momento della decifrazione.

MarkOut è un'interfaccia web (HTML5 e Javascript) che permette di tracciare le iscrizioni su di un'immagine e successivamente di correggere le linee tramite dei punti di controllo, consentendo di ottenere facilmente una rappresentazione fedele con uno strumento, il mouse, non proprio ideale, ma alla portata di chiunque.

Ad ogni segno viene associato un simbolo di un alfabeto predefinito, o eventualmente una variante di una lettera (Unicode code point + un indentificatore della variante). L'interfaccia infine permette di gestire più strati di scrittura e nel caso siano disponibili rappresentazioni RTI, è possibile variare l'illuminazione dell'iscrizione per facilitarne l'osservazione.

Il risultato finale è un file in formato SVG, che può essere condiviso online, processato automaticamente per estrarre la trascrizione in altri formati (es. TEI), inserito in un database ad hoc, o impiegato in algoritmi che analizzino la forma delle varie lettere e la loro posizione topologica sul TBO.

Questa interfaccia è concepita per servire i vari tipi di usi, con alcune varianti nel suo design: la discussione scientifica tra esperti (MarkOut Expert), la formazione degli studenti universitari alla decifrazione di iscrizioni (MarkOut Assisted, see Lamé 2016), la mediazione museografica verso il pubblico generale del museo, adulti e bambini. Di seguito, immagine dell'etichetta 12563 con il MarkOut Assisted.

Specialmente, il MarkOut Kids, in corso di sperimentazione presso i bambini da 4 a 10 anni, permette di mettere in pratica esercizi di scrittura del programma scolastico combinato ad un contatto con l'oggetto archeologico. Il gesto continuo che consiste nel designare la forma di una lettera dell'alfabeto viene associato a quello più astratto di identificazione e riconoscimento di un segno alfabetico con la sua posizione su una tastiera e il suo inserimento in modo tale che compaia associato al disegno sullo schermo.

Il Tesserarum Sisciae Sylloge è finanziato dal Ministero della Cultura Croato, dal Comune di Zagabria e dall'European Association for Digital Humanities. È realizzato dal Laboratorio di Cultura Digitale dell'Università di Pisa con la partecipazione del Consiglio Nazionale delle Ricerche.

Relier deux outils d'indexation pour faire émerger des ponts conceptuels

Ce travail s'applique aux sciences de l'Antiquité et à l'organisation des connaissances (Gnoli et al., 2006; Gnoli, 2012; Gnoli, 2014). Son objectif est de travailler sur la mise en lien entre les annotations appliquées à des sources primaires textuelles et des métadonnées employées pour décrire la littérature scientifique qui en découle. Plus spécifiquement, il s'agit d'étudier la façon dont sont organisés, par le biais de deux instruments terminologiques, des thèmes communs pour la description de contenus relatifs à l'Antiquité. L'un est destiné à l'analyse de textes antiques (*Index* de *Memorata Poetis*) et le second à l'indexation documentaire de publications scientifiques contemporaines (Thésaurus PACTOLS). L'objectif est de créer des relations conceptuelles entre les deux instruments, bien qu'ils ne servent pas à décrire le même type d'objets initialement, pour en améliorer l'utilisation par les usagers dans le cadre de la recherche scientifique, mais aussi d'une mise à disposition à un plus large public (Insertion de liens de références dans Wikipedia). Il fait suite au travail initié par Lamé et Caputo, 2015 sur les dispositifs épigraphiques et l'emploi de cet index thématique de *Memorata Poetis*http://www.memoratapoetis.it.

Pour cet exercice de mise en relation, nous avons choisi de privilégier une thématique familière aux spécialistes de l'Antiquité et au grand public : les dieux et héros de la mythologie grecque et latine. Leurs noms sont fréquemment employés dans la description des objets archéologiques décorés, notamment la céramique ou la sculpture antique et dans l'analyse des textes anciens. Cette thématique est traitée dans les deux outils en question de façons différentes. Le sujet s'attache donc à comparer la façon dont les deux instruments présentent ces éléments de la mythologie antique, l'un à partir de textes primaires, l'autre à partir de l'analyse des publications scientifiques.

L'*Index rerum notabilium* de *Memorata Poetis*

Le projet *Memorata Poetis* (MP) est un projet de recherche intertextuelle (site Internet en cours de finalisation). Il consiste à mettre en lien de courts poèmes (épigrammes épigraphiques et littéraires) composés et transmis de l'Antiquité à nos jours selon des thèmes et des motifs, c'est-à-dire, des schémas récurrents (ex.: La mort, Hercule...). Le corpus contient, à la date de soumission, 15307 textes et s'appuie sur une édition de référence en langue originale (latin, grec, italien anglais et arabe). Il s'agit, au travers de rapprochements textuels et de mises en parallèle, d'identifier l'évolution de l'expression des thèmes et des phénomènes intertextuels qui ont accompagné la transmission, la traduction et la création de ce type de poèmes au travers du temps et des cultures. Ces caractéristiques confèrent au corpus de sources primaires constance et homogénéité, deux critères de sélection importants pour le travail de rapprochement lexicologique.

Ces thèmes sont organisés au sein d'une liste contrôlée et hiérarchisée, l'*index rerum notabilium*, lentement consolidée par plusieurs générations de philologues, selon une arborescence à trois niveaux et six thématiques classiques (Animalia, Arbores et Virentia, Dei et Heroes, Homines, Loca, Res). Il s'agit donc d'explorer une documentation dite primaire et éditée, en amont de la production d'articles scientifiques.

Avec plus de 1300 termes qui le composent ont été traduits, de manière collaborative, une première fois en italien, anglais, allemand, français, grec moderne, avec comme langue de référence le latin en s'en tenant au cadre d'usages disciplinaires de la philologie La traduction entre dans la seconde phase qui consiste à valider ou non des synonymes et des variations linguistiques pour chaque terme.

Le thésaurus PACTOLS de la Fédération et ressources sur l'Antiquité

En aval de ce processus d'élaboration de la connaissance, on retrouve des instruments pour analyser le contenu de la production scientifique. PACTOLS est un thésaurus multilingue (6 langues européennes et l'arabe) développé par la Fédération et Ressources sur l'Antiquité (FRANTIQ), groupement de services du CNRS (Centre national de la recherche scientifique français) http://www.frantiq.fr. Il constitue un outil d'indexation de publications scientifiques spécialisées en archéologie, depuis la Préhistoire jusqu'aux périodes contemporaines et en Sciences de l'Antiquité dans tous les domaines. Il est en particulier exploité dans le Catalogue Collectif Indexé de FRANTIQ (520.000 notices bibliographiques). Le thésaurus est organisé en sept branches (Peuples et Cultures, Anthroponymes, Chronologie, Toponymes, Oeuvres, Lieux, Sujets), elles-mêmes découpées en sous thèmes. Comme dans tout thésaurus, les descripteurs s'inscrivent dans un contexte terminologique précis, spécifié par des relations complexes : hiérarchiques, bien sûr, mais aussi d'équivalences, de synonymie,... Ils sont décrits à l'aide d'une définition et d'une note d'application. Chacun est traduit dans six langues : le français est la langue de référence ; les traductions en allemand, anglais, arabe, espagnol, italien, néerlandais sont mises à jour au fur et à mesure des mises à jour du thésaurus. Certains descripteurs sont illustrés. Enfin, le thésaurus suit la norme ISO 25964 sur l'interopérabilité des thésaurus : chaque terme est identifié par une URI (Unique Resource Identifier) de type ARK (Archival Resource Key - https://fr.wikipedia.org/wiki/Archival_Resource_Key). Cet identifiant lui confère une identité unique dans le web des données et le rend citable. Son format de données est conforme à SKOS (Simple Knowledge Organization Systems) du W3C. Par exemple http://ark.frantiq.fr/ark:/26678/pcrtGYtuX6F7A0 renvoie au concept Némésis et à son environnement sémantique ainsi qu'aux notices liées du Catalogue Collectif Indexé de FRANTIQ.

Ce thésaurus a été créé en 1987 et il est mis à jour en continu par des spécialistes des domaines traités. Il compte aujourd'hui 33.000 descripteurs. Il est utilisé par des bibliothécaires et des documentalistes dans le cadre de catalogues et de bases de données documentaires, comme dans l'enrichissement de bases de données de la recherche. Par exemple, les publications indexées sur la thématique que nous avons retenue dans le cadre de cette présentation sont soit des éditions de textes littéraires antiques, soit des ouvrages avec une riche iconographie : traités sur la sculpture, la mosaïque, les décors architecturaux ou les céramiques…

Dieux et héros de l'Antiquité classique, une thématique commune

On le voit, les deux outils présentés ont été conçus pour répondre à des exigences scientifiques complémentaires qui appartiennent à un même processus global d'élaboration des connaissances. L'organisation des termes comme leurs langues de référence et le multilinguisme des outils et des contenus sont le reflet de l'usage pour lequel ils ont été pensés.

Cependant, des concepts communs se retrouvent, tout au moins sur certaines thématiques. Nous avons choisi de confronter les deux vocabulaires sur les thèmes Dieux et Héros de l'Antiquité classique : comment ces domaines sont-ils traités par l'un, dans le cadre d'analyse du texte antique comme document primaire et par l'autre dans le cadre des publications scientifiques, documents secondaires par excellence ? Comment l'archéologie, l'épigraphie et la littérature élaborent-elles des connaissances sur des sujets similaires ?

Le domaine "Dieux et Héros" de l'*Index rerum notabilium* de *Memorata Poetis* est bien défini: Mythologie, Chrétienne, Musulmane, Religion et Supertitions. Il s'agit d'aligner ce sous-ensemble et ses traductions, avec les branches Anthroponymes/Divinités/Divinités grecques, Divinités romaines, Anthroponymes/Héros/Héros grecs, Héros romains, ainsi que le groupe de termes de Sujets/religion des thésaurus PACTOLS. En effet, les Dieux et Héros de l'Antiquité classique sont regroupés différemment et les termes relatifs à la religion plus généralement sont intégrés à la branche Sujets des PACTOLS, alors que l'ensemble est rassemblé en un seul dossier dans l'*Index* de MP.

La méthode

Dans la mesure où seul le thésaurus PACTOLS est formaté en SKOS avec des identifiants pérennes, nous procéderons à un alignement manuel, terme par terme, avec discussion et ajustement de chacun des systèmes et de son lexique. Les rapprochements stricts ou relatifs des termes, mais aussi l'absence de tel autre dans l'un ou l'autre des outils sont des indicateurs majeurs de positionnement disciplinaires complémentaires qui concernent des moments et des cultures épistémologiques différents. Les théories, méthodes et instruments produits dans le cadre des humanités numériques devraient permettre d'accueillir et de faire converger ces univers terminologiques sur le rapprochement desquels nous travaillons et ce d'autant plus facilement qu'ils en respecteront leurs caractéristiques et les amèneront à dialoguer : exploitation et traitement du réseau de relations entre les termes, confrontation des traductions des vocabulaires, prise en compte, si nécessaire, de l'élaboration d'un métaformalisme commun. Ciotti, 2013, illustre les limites ontologiques rencontrées par les seuls thèmes et motifs. Si ce travail méthodologique de comparaison et de rapprochement entre différents KOS (Knowledge Organization System) ne cherche pas, dans un premier temps à produire un outil numérique, il vise à en préparer l'élaboration.

Par exemple, l'*Index rerum notabilium* contient un seul terme pour identifier Apollon, alors que les PACTOLS comptent neuf façons différentes de qualifier le dieu. L'étude des termes met aussi en avant les écarts contextuels révélateurs des périodes pendant lesquelles ces instruments d'analyse ont été élaborés : par exemple, PACTOLS, bien que régulièrement révisé, gagnerait à être réorganisé pour en faciliter la consultation et mieux suivre l'évolution des connaissances et de la discipline, tout en conservant des descripteurs adaptés aux publications plus anciennes. L'Index s'est construit sur une très lente et longue sélection progressive dont les débuts remontent aux origines de la philologie. Il se caractérise par son unité et sa stabilité mais aussi comme étant un témoin évolutif de la transmission intertextuelle elle-même. Il est destiné à s'enrichir au travers de la mise en parallèle intertextuelle, ce type de recherche scientifique ayant pour but d'identifier des motifs culturels et leurs transformations à l'intérieur des textes.

Bien que les deux instruments se situent sur deux niveaux d'analyse, nombre de concepts se rejoignent et il y a une utilité à pouvoir créer des liens d'un niveau d'analyse à l'autre afin de naviguer transversalement au travers des collections d'informations primaires (ex. textes, ici des épigrammes littéraires et épigraphiques) et secondaires (la littérature scientifique qui en émane). La comparaison des deux instruments permettra aussi leur enrichissement réciproque : les PACTOLS ajouteront les termes latins à ses traductions, l'*Index* bénéficiera d'une troisième phase d'enrichissement de ses traductions, d'une amélioration de sa navigation tout en conservant sa structure traditionnelle. Mais surtout, l'alignement des vocabulaires doit permettre de tirer des conclusions concrètes sur les évolutions que chacun des outils doivent suivre afin de permettre aussi bien au chercheur, mais aussi au grand public de naviguer avec fluidité dans le *mare magnum* documentaire primaire et secondaire en entrant par une même porte conceptuelle.

Résultats attendus

La mise en forme manuelle de ce matériel lexicologique devrait permettre de confronter dans un second temps deux hypothèses. La première est organisationnelle : un système à facettes peut-il permettre une meilleure utilisation de ces connaissances ? L'autre relève de la normalisation : SKOS employé dans le système PACTOLS pourrait-il à terme constituer une évolution nécessaire de l'Index pour finaliser la communication entre les deux systèmes d'indexation ? Les passerelles entre les environnements faciliteront ainsi le passage de l'un à l'autre, au profit des usagers dans la mesure où l'utilisation de termes identiques pour un même concept crée des ponts et des ouvertures à la connaissance en favorisant le dialogue entre les disciplines (archéologie, épigraphie, philologie). La thématique choisie pour cet exercice est bien connue aussi du grand public et fait partie de l'héritage culturel des sociétés gréco-romaines antiques. Pour favoriser encore la circulation des connaissances, nous compléterons les articles Wikipédia avec les termes des vocabulaires pour favoriser l'accès aux ressources primaires (les textes anciens utilisé par *Memorata Poetis*) ou secondaires (les publications scientifiques indexées avec PACTOLS). Il s'agit donc d'ajouter des liens d'autorité externes à la fin de ces articles de l'encyclopédie.

Les résultats de cette analyse appliquée, via l'alignement, au sous-ensemble des dieux et héros de la Mythologie doit permettre d'étendre le travail à l'ensemble des deux vocabulaires, avec un reversement et un enrichissement réciproque des termes traduits dans plusieurs langues européennes et du pourtour du bassin méditerranéen.

Le thésaurus PACTOLS (http://pactols.frantiq.fr) est utilisé par 40 bibliothèques de la Fédération et ressources sur l'Antiquité et par la Très Grande Infrastructure de Recherche française Huma-Num dans son moteur de recherche ISIDORE. Il est l'une des contributions françaises à l'infrastructure européenne DARIAH. Il est aussi impliqué dans des projets européens comme MULTITA, piloté par les Musées royaux de Belgique et dans ARIADNE, infrastructure européenne pour la recherche archéologique.

Le projet Memorata Poetis (financement national PRIN 2010/11 - http://www.memoratapoetis.it/public en cours de finalisation) est dirigé par le Professeur Paolo Mastandrea et implique huit unités universitaires ainsi que de recherche: les Universités de Venise "Ca' Coscari", de Cagliari, de la Calabre, de Padoue, de Pérouse, de Rome "La Sapienza", de Rome "Tor Vergata", et l'Istituto di Linguistica Computazionale "A. Zampolli" du Consiglio Nazionale delle Ricerche (CNR) à Pise.

Harvesting History: Democratizing The Past Through The Digitization Of Community History

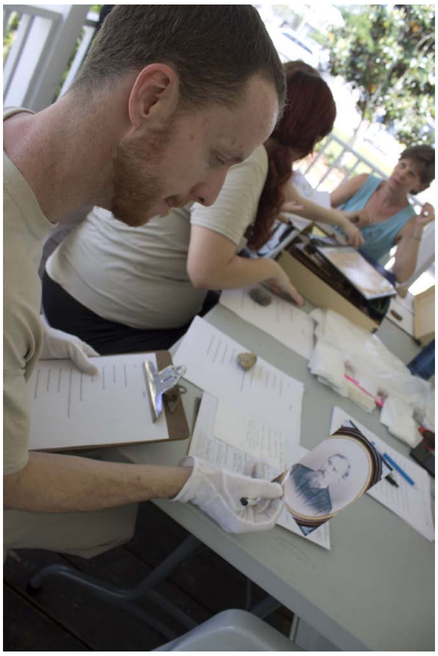
Connie Lee Lester
Connie.Lester@ucf.edu
University of Central Florida, United States of America

In 1993-94 Roy Rosenzweig and David Thelen conducted a set of surveys that resulted in the publication of a seminal work titled *The Presence of the Past*. The team of historians, museum curators and students surveyed the American public about their interaction with history in order to understand "better ways of connecting academic historians with larger audiences" (Rosenzweig and Thelen, 1998). Their study concluded that Americans' interest in history related to those events and groups that intersected with their own lives. They universally trusted museums because they could see the objects and images that were the "stuff" of history, but family stories, letters, and photographs defined history for most of the survey participants. With the publication of the survey, Rosenzweig and Thelen entered a historiographic discussion that centered on ways to incorporate history from the "bottom up" and to make the museum experience more interactive (Wallace, 1996; Hayden, 1997; Gardner and LaPaglia, 2004; Lewis, 2005; Gordon, 2010; Anderson, 2012; and Falk and Dierking, 2012).

Almost twenty years after Rosenzweig and Thelen conducted their survey, William G. Thomas, Patrick D. Jones and Andrew Witmer "advanced a movement to democratize and open history" with the founding of the History Harvest Project at the University of Nebraska (Thomas, Jones, and Witmer, 2013). Incorporating their own digital history experience into the classroom, Thomas, Jones, and Witmer developed student projects that operated at the "intersection of digital history and experiential learning." Beginning in 2010 and continuing to the present, students worked with specific communities to organize History Harvest events at which they photographed objects and scanned images offered by individuals from their personal collections. The photographs and scans were uploaded into an Omeka database and organized into collections and digital exhibits. The project's aim is to "make invisible archives and stories more visible." The founders argue that to be successful, a History Harvest must be "organic, grassroots, and local."

At the University of Central Florida (UCF), a Regional Initiative for Collecting History, Experiences, and Stories (RICHES™) Project has advanced the concept of student-public engagement through the use of History Harvests to collect "invisible archives and stories" by making the presentation of the digitized material interactive and democratizing the ability of site users to utilize the data in the collections to develop their own narratives. This transformational addition to the efforts to democratize history provides the user with the data, the tools to analyze the data, and the digital space to organize the data in order to create a narrative.

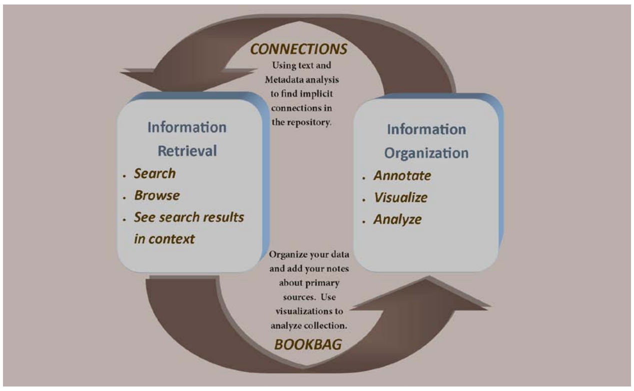
Working in Florida, students have access to a history that celebrates more than 500 years of interaction between Native Americans, Europeans, and Africans. The geographical position of Florida with its extensive coastline means that the history of the area has always been global. Interaction between the people of Caribbean Islands and those living in Florida pre-dated European claims for the region and expands the scope of scholarship. Successive waves of Spanish, French, British and American settlers altered the landscape and created new borderlands that continued until well into the twentieth century. Currently, the third most populous state in the nation, with an economy that ranges from agriculture to tourism to space exploration and high tech industries, Florida's history is deep, diverse, and largely unexplored.



Oviedo History Harvest, 2015

Students in graduate classes in Public History at UCF have completed three History Harvests and three additional Harvests are planned for 2016. The largest of the completed Harvests was accomplished through a partnership between the Introduction to Public History class, the Oviedo (Florida) Historical Society and a RICHES partnership tech firm, EZ-Photo-I/O Track. The students worked with the historical society to understand the history of the 137-year-old agricultural community that was transformed by the founding of UCF and the influx of thousands of students and faculty only three miles from the center of town. Based on the information provided by the historical society and a National Endowment for the Humanities-funded, society-published book (Adicks and Neely) the students conducted sixteen oral histories with descendants of the original settlers. In order to generate community awareness of the upcoming History Harvest students participated in public events and obtained permission to post information on the community and historical society social media sites. Building on the planning documents produced by previous student-led History Harvests, they organized the release forms, prepared to obtain the stories associated with items brought for scanning, and worked with EZ-Photo staff to facilitate the scanning process. More than 500 images, documents, three dimensional items, pamphlets, and scrapbooks were scanned on the day of the History Harvest. They told the story of citrus grove owners, farm laborers and fruit packers, migrants and immigrants to the community, schools, churches, and community social life.

The UCF/RICHES History Harvest pushed the use of the collected data to a new, level by placing the material in RICHES Mosaic Interface™ https://richesmi.cah.ucf.edu . RICHES MI was initially created with the help of a National Endowment for the Humanities Startup Grant, and is an Omeka archive with multiple custom plugins and a front end that is a unique mechanism for searching the archive. RICHES MI users can search the database using natural language, tags, and topics, and browse by collection categories to maximize their search results; analyze the results of their search using the RICHES-developed "Connections" feature to show the relationship between the returned item and other items in the database; and visualize their results on a Google map and through digital exhibits, map overlays, and other visualizations. Users can save their search results in a Bookbag where they can annotate individual items, store items in folders, map the items collected in folders on a Google map and a timeline, and analyze the connections between items in the folders. They can also develop a narrative using the story board feature to organize their data. Finally, a search in the Omeka archive provides the user with links to digitized primary and secondary sources relevant to the individual object as well as links to other databases or websites that might be useful to the researcher.



CONNECTIONS
Using text and Metadata analysis to find implicit connections in the repository.

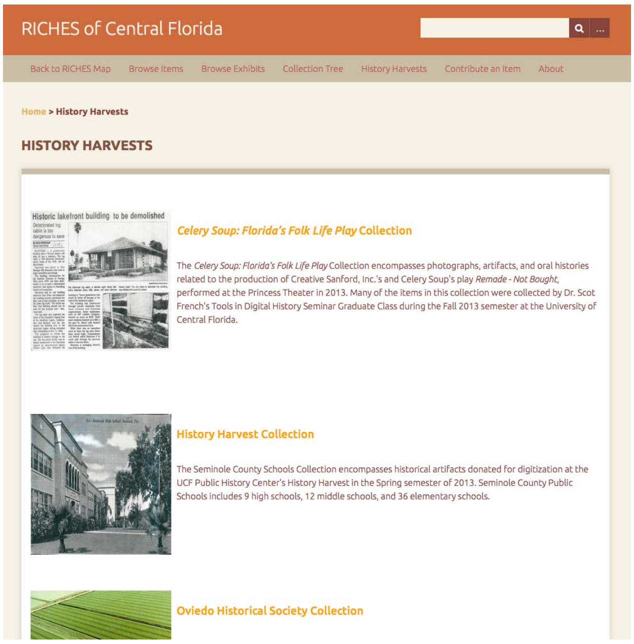
BOOKBAG

Schematic of RICHES Functionality

Student Harvests, like their counterparts elsewhere, also create digital exhibits to organize the collected images and documents into an interpretative narrative. Faculty and students gain much through their participation in the History Harvests. Students acquire digital skills in metadata writing, archiving and exhibit creation; they learn to conduct oral histories and plan events; and they develop an understanding of the connection between local history and national/global issues. Each student's work is cited by name in the metadata and in digital exhibits. Faculty participants are organizing larger projects (i.e. Parramore Project and Glass Bank Project) that include History Harvests and are expected to result in scholarly and pedagogical publications.



HISTORY HARVESTS

Celery Soup: Florida's Folk Life Play Collection

The *Celery Soup: Florida's Folk Life Play* Collection encompasses photographs, artifacts, and oral histories related to the production of Creative Sanford, Inc.'s and Celery Soup's play *Remade - Not Bought,* performed at the Princess Theater in 2013. Many of the items in this collection were collected by Dr. Scot French's Tools in Digital History Seminar Graduate Class during the Fall 2013 semester at the University of Central Florida.

History Harvest Collection

The Seminole County Schools Collection encompasses historical artifacts donated for digitization at the UCF Public History Center's History Harvest in the Spring semester of 2013. Seminole County Public Schools includes 9 high schools, 12 middle schools, and 36 elementary schools.

Oviedo Historical Society Collection

History Harvests in Omeka

The next three projects, which are funded by a National Endowment for the Humanities "The Common Good: The Humanities in the Public Square" grant, will push the boundaries of History Harvests further: students will be using the oral histories and the collections obtained through History Harvests to produce a documentary film on an African American community's struggles with urban development, to understand a coastal community's relationship to an iconic building, and to provide evidence for two MA thesis projects dealing with Orlando's LGBTQ community. The African American community project pairs students in an undergraduate history class with students at a predominantly black high school to explore changes that the construction of public buildings, entertainment and sports venues, an interstate highway, and the proposed expansion of UCF to a downtown campus have had on what was once a vibrant and cohesive African American community. The material collected will be used by a second undergraduate Honors class to produce a documentary film. This will be the fourth student produced film supervised by the course faculty. The second History Harvest will focus on an iconic building, the so-called Glass Bank, in Cocoa Beach, Florida. Constructed in the 1960s, the Glass Bank was demolished in 2014, but not before a partnership between RICHES and the Institute for Simulation and Training produced a 3D scan of the building. Recreated as it existed in 1963, the Glass Bank will serve as a vehicle for collecting images, artifacts and stories about the building as a center of community activity and economic development. See the video of the 3D scan https://www.youtube.com/watch?v=DtVETzCND4M Finally, students will work with the GLBT Virtual Museum and the Orange County Regional History Center to harvest images, oral histories, and artifacts that tell the story of the gay destination, Parliament House, and the effect of the HIV/AIDS epidemic in Orlando.

The RICHES project builds upon the insights of Public History scholarship and Digital scholarship to understand the complex past of local communities and to connect those histories to larger narratives. Using History Harvests to build a bridge between individuals, families, and local museums and historical societies and the academic community of students and faculty provides a service to the public and experiential learning for students. Awareness of the interaction between local and the national/global events enables students to consider their own scholarship in new ways. Placing the material harvested in an interactive database like RICHES Mosaic Interface democratizes the history collected by providing context, analytical tools, and space for organizing personal narratives.

If Paintings were Plants: Measuring Genre Diversity in Seventeenth-Century Dutch Painting and Printmaking

Matthew Lincoln
mlincol1@umd.edu
University of Maryland, United States of America

Tracing the "origins of pictorial species" (to borrow Larry Silver's turn of phrase) has long been an interest of art historians (Silver, 2006). The emergence of distinct genres of painting (e.g. dedicated landscapes or still-lifes) in the sixteenth and seventeenth centuries in Europe, and in the Netherlands in particular, has proven especially fascinating. Historians of art and economics have hypothesized that, by specializing in standalone still-lifes, landscapes, or so-called "genre scenes" of everyday life, painters may have reaped two advantages: an opportunity to distinguish themselves in the uniquely competitive art market in the sixteenth- and seventeenth-century Netherlands; and the ability to efficiently paint similar compositions over and over again (Chong, 1987; Montias, 1988). But would professional printmakers also have adopted this specialization strategy? Or did the medium, which was often put to use making reproductions after other artists' designs, instead favor etchers and engravers willing to render the works of a wide variety of artists? Existing case studies present conflicting evidence. How can we test this question at scale?

While Silver only invokes speciation as a metaphor, ecology may offer a useful quantitative model for thinking about genre specialization. A common measurement of species diversity (Shannon's diversity metric) can be used to characterize artists' relative specialization or diversification in genre, thus allowing us to gain a broader perspective on printmakers' specialization or diversification strategies. I will first demonstrate how this index can detect Dutch painters' trend towards genre specialization from a database of paintings seventeenth-century Dutch household inventories, and a comprehensive database of Dutch paintings in modern-day museum collections. I will then use it to test whether or not we can detect similar results in a database of prints maintained by the Rijksmuseum.

Methodology

Whether looking at the diversity of species within an ecosystem, or the variety of different industries within a state, diversity measures have to account for two dimensions:

1. Categorical: How many discrete classes are observed?
2. Allocation: How even is the distribution of units among categories?

Shannon's measurement of diversity (D_s), a widely-used metric, captures both of these dimensions of diversity.[1] Originally developed to characterize entropy in information transmission, this metric of diversity has been applied to the studies as diverse as ecological diversity, economic specialization, and racial segregation (Gibbs and Martin, 1962; Ottaviano et al., 2003). To measure whether specialization or generalization was more favored by painters and printmakers, each artist's oeuvre is treated as a "population" with a single diversity score calculated per artist. By this measure, a population whose members are distributed evenly across several different species/categories will have a higher diversity index than a population whose members are largely concentrated in just one category.

Data

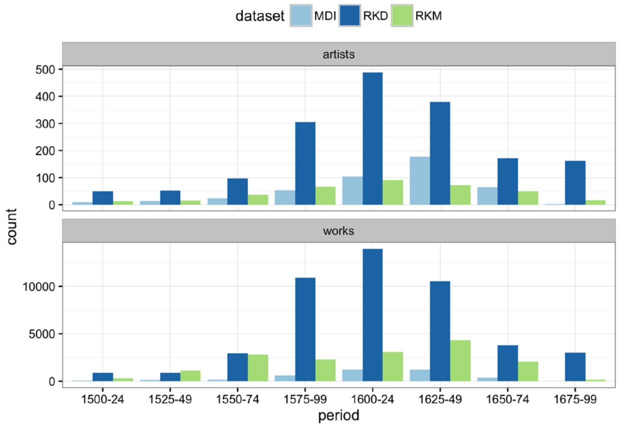

Figure The number of unique artists and artworks represented in each dataset, subdivided by birth year

This study is based on two sources of information about paintings, and one source for prints.

The first, a modern resource, is the *RKDimages* database compiled by the Rijksbureau voor Kunsthistorische Documentatie.[2] This catalog of Dutch and Flemish artworks extant in collections around the world contains approximately 13,000 dated and attributed paintings that have each been tagged with a series of keywords (on average between 6 to 7 keywords per painting) describing their subject matter.[3] The scale of the RKD database makes it unfeasible for the individual researcher to manually categorize each artwork into a single broad subject category. Therefore, I identified clusters of artworks that shared groups of keywords though community detection on a constructed graph where each object was connected to others based on shared RKD subject keywords.[4] I then checked the resulting groups manually to confirm that they did, in fact, corresponded relatively well to common genre categories. The resulting groups roughly encompassed: 1) portraits, 2) still lifes, 3) landscapes, 4) religious paintings, and 5) a looser array of other works that featured multiple figures (generally genre scenes or history subjects).

Because the surviving paintings in the RKD database are a biased proxy of the **actual** patterns of paintings produced in the seventeenth century, it is crucial to compare the trends derived from the RKD's modern database against contemporary archival records. The Montias Database of 17th Century Dutch Art Inventories, maintained by the Frick Art Reference Library, contains information on household inventories from Amsterdam that were recorded between 1575 and 1700.[5] Of these inventories, 1153 contained at least two paintings The Montias Database has 86 different subject headings, which have been manually grouped into the same general set of subject headings that we used for the RKD database.[6] The MDI describes 34,147 paintings, of which 26,349 (about 77% of the total) have an identified subject (the rest are labeled "unknown"), with 4,377 of those described paintings (about 13% of the total) attributed to a specific artist.[7] The Montias inventories are also an imperfect reflection of seventeenth-century painting production, being biased towards rich collectors, mostly in Amsterdam, who died with outstanding debt. However, if both the modern and contemporary datasets reveal similar patterns in specialization, this would strengthen the case for claiming that a trend towards specialization existed historically (De Vries, 1991:259-260.)

Results

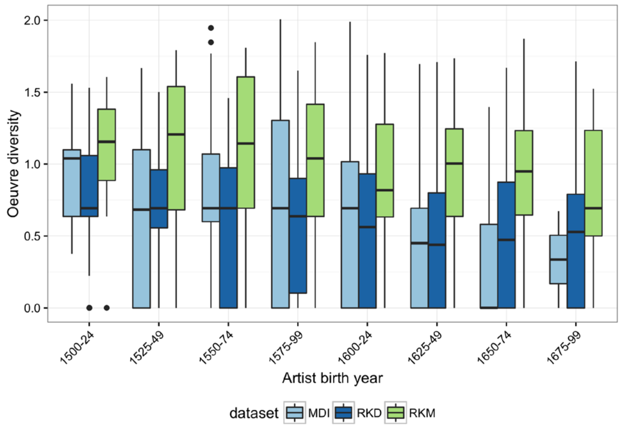

Figure 1. The oeuvre diversity ranges of painters (Montias and RKD datasets) and printmakers (RKM dataset) born at different points between 1500 and 1700

Unfortunately, there are virtually no seventeenth-century inventories that catalog individual prints. Instead, we rely solely on the surviving prints in the collection of the Rijksmuseum[8]: an imperfect source, though one that is also unparalleled in its coverage of known surviving prints from this period. The Rijksmuseum has classified their artworks based on the ICONCLASS system for tagging iconography in European art[9], and this has also been mapped to the same broader categories used in the Montias database. Multiple impressions of the same print have been roughly disambiguated by removing prints with a duplicate engraver, title, and dates. This study is also only considering reproductive prints, so prints made by engravers or etchers after their own designs are excluded from this analysis.

We find that, although both the Montias and RKD paintings datasets show wide variation, with both highly specialized painters and highly diversified ones, both datasets reflect an increasing number of specialized painters born after 1600, as shown by a decreasing median oeuvre diversity. On the other hand, the median oeuvre diversity of printmakers in the Rijksmuseum dataset remains consistent during the entire period of study. This confirms the widely-held hypothesis that an increasing number of Dutch painters defined a niche for themselves by specializing in a particular genre. The results also appear to support the previously-unexamined hypothesis that reproductive printmakers instead favored making prints after a wide array of artworks; printmakers who did define highly specialized niches appear to have been the exception, rather than the norm.

So what subjects did these specialists prefer? Prolific specialized painters overwhelmingly favored landscapes: of those artists in the bottom diversity quartile (i.e. the 25% most specialized painters in the Montias database), almost 85% of their paintings are described as landscapes, followed in a distant second by still-life paintings. Landscape was a genre that was both highly conventionalized - it was easy to produce endless variations on the same general set of topographical motifs - and also amenable to a very efficient technique - a landscape could be rendered in broad brushwork with a limited palette and still be an aesthetic success (Goedde, 1997). Still-life paintings in this period were also, by in large, the purview of specialists. They may comprise a much smaller share of the total number of paintings in the Montias database because, unlike landscapes, the aesthetic effect of still lifes was often dependent on the painter's mimetic skill and illusionistc finish - not a technique conducive to speedy production.

On the other hand, of those printmakers who **did** specialize in particular genres of prints, we do not find a single dominant theme. Rather, a few specialties rise to the top: "news" prints depicting current events, architectural illustrations, and allegorical or biblical series prints. Those printmakers who did specialize (Table 1) did not rely on prints as their main means of support; many were specialist painters who happened to produce prints as well. But these printmakers were outnumbered by those professional printmakers (Table 2) who were willing and able to render reproductions after a wide variety of artists. This flexibility could have presented an attractive insurance policy for print publishers, who had to continually react to the demands of a quickly-moving market for artistic prints and illustrations, while also appealing to the seventeenth-century function of prints as encyclopedic sources of knowledge (MacGregor, 1999:395).

artist name	works	div	subjects
Abraham Dircksz Santvoort	123	0.74	topographical views, history prints
Allaert van Everdingen	113	0.77	landscape, animals
Adriaen van Ostade	85	0.67	genre, low-life
Isaac Vincentsz van der Vinne	82	0.23	heraldry
Reinier Nooms	72	0.58	seascape
Cornelis Dusart	57	0.76	portraiture
Theodoor van Thulden	52	0.68	antiquity, mythology
Cornelis Pietersz Bega	36	0.62	genre
Anthonie Waterloo	35	0.67	landscape

Table 1: The most productive Dutch and Flemish specialist printmakers (those falling below the 45th diversity percentile). Note that the count of "works" treats print series as a single work

artist name	works	div	subjects
Jan Luyken	2,047	1.64	bible scenes, seascape, genre, historical, architecture, titlepages
Caspar Luyken	454	1.74	bible, landscape, historical, genre, maps
Aegidius Sadeler	238	1.80	landscape, portraiture, allegory, mythology, religious
Jacob Matham	229	1.73	allegory, mythology, portraiture, biblical
Hendrick Goltzius	228	1.80	biblical, portraiture, allegory, antiquity, mythology, landscape
Crispin van de Passe (I)	203	1.80	moralizing allegories, portraiture, devotional, botanical, biblical
Johannes Wierix	215	1.54	portraiture, biblical, allegory, genre, mythology, devotional,
Abraham Bloteling	188	1.72	landscape, genre scenes, portraiture, mythological

Cornelis Bloemaert (II)	180	1.69	saints & other religious, biblical, portraiture
Raphaël Sadeler (I)	156	1.57	devotional series, biblical, allegory, mythology, titlepages

Table 2: The most generalist Dutch and Flemish printmakers (those falling above the 85th diversity percentile)

Notes

[1] Shannon's diversity index D_s is defined as the negative sum of the proportions of every class size within the population multiplied by their logged equivalents, where n_i is the number of observations in class i, and N is the total population size: D_s=-$\Sigma n_i N l n n_i N$ For the original derivation of Shannon's diversity, see (Shannon and Weaver, 1949); for the R implementation of this formula, see (Oksanen et al., 2015).

[2] https://rkd.nl/en/explore/images

[3] These keywords have been assigned by hand by researchers at the RKD, building on the index cards typewritten by Hofstede de Groot (1863-1930) that have served as the foundation of the RKD's current digital databases.

[4] On the community detection algorithm, see (Blondel et al., 2008); implemented in R by (Csardi and Nepusz, 2006).

[5] http://research.frick.org/montias/home.php

[6] The number of subject headings detailed by Montias are small enough that it was feasible to manually generate a concordance between the 86 original subject headings and the ten subject headings used by Van der Woude in his study of the same database: "old testament", "new testament", "other religious", "mythology-allegory", "history", "landscape", "genre", "still life", "portrait", "animals", "other", and "unknown"; (van der Woude, 1991).

[7] This limited level of description common in collection inventories from the seventeenth century. While it was common to describe the subject of the painting and its size, notaries generally did not make an attribution of an artwork unless its painter was well-known enough that its attribution would have impacted the painting's monetary value.

Quantitative Analyses of Chinese Poetry of Tang and Song Dynasties: Using Changing Colors and Innovative Terms as Examples

Chao-Lin Liu
chaolinliu@gmail.com
National Chengchi University, Taiwan, Republic of China

Introduction[1]

Tang (618-907 AD) and Song (960-1279) dynasties are two very important periods in the development of Chinese literary. The majority forms of the poetry in Tang and Song were Shi (詩) and Ci (詞), respectively. Tang Shi and Song Ci established crucial foundations of the Chinese literature, and their influences in both literary works and daily lives of the Chinese communities last until today.

Recognizing the importance of Tang Shi, a Chinese emperor of the Qing dynasty (1644-1912), Kangxi, ordered to compile a collection of Tang poems, *Quan-Tang-Shi* (*QTS*, 全唐詩). *QTS* contains nearly 50 thousand works of about 2200 poets. A similar effort for compiling a collection of Song Ci from the private sector began in the Ming dynasty (1368-1644), and achieved a collection called *Quan-Song-Ci* (*QSC*, 全宋詞) in the early Republican period of China (ca. 1937). *QSC* contains around 20 thousand works of about 1330 poets. The exact statistics about *QTS* and *QSC* may vary slightly depending on the sources.

In the past more than a thousand years, literary and linguistic researchers have had done a myriad of research about the poetry of the Tang and Song dynasties. Hence, it is beyond our capacity and not our objective to review the literature in this abstract. Traditional researchers studied and compared poetic works that were produced by different authors and in different time periods to produce insightful and invaluable analyses and commentaries (Tao, 1999). Most of the time, the researchers focused on the poems of selected poets. Even when computing supports become available, studying poems of specific poets (Jiang, 2003) is still an important and popular type of research in poetry.

Software tools facilitate the analysis of poetry from a panoramic perspective, and may lead to applications that would be very challenging in the past. For instance, Zhou and his colleagues (2009) analyzed the contents of collected couplets and Tang poems for creating couplets. Yan and his colleagues (2013) considered topic modeling in automatic composition of Chinese poetry. Lee (2012) concentrated on the linguistic analysis and teaching of *QTS*.

In this presentation, we will discuss some interesting findings in some quantitative analyses of *QTS* and *QSC*.

Colors and Imageries

Colors are an important ingredient in everyday lives, and actually carried important meanings in religion and social statuses in pre-modern Chinese societies. Wong (2011), a specialist in colors, discussed hidden meanings of colors in China in his book on “The colors of China”.

The beauty and imageries conveyed in the poetry originate from the collocations of the written words in the poems. Lo (2008) and Huang (2004) attempted to classify terms in the poetry by their semantic categories. The results can then serve as a foundation for analyzing the imageries hidden in the poems. Liu and his colleagues (2015) emphasized that colors play a crucial role in painting the imaginaries of poems: “colors in poems are like audios in movies”, and they analyzed the words related to colors in *QTS*.

Using methods for text analysis, one may analyze occurrences and collocations of colors in *QTS* and *QCS*. The main contribution of our work will be illustrating meaningful applications of text analysis for linguistics and literary. The collocations of color words that appeared frequently in *QTS* are certainly interesting (Liu, 2015). Yet, the analysis can be extended in at least two directions. First, did a poet have specific preferences on some collocations? Second, how were the collocations used by different authors?

Bai Juyi[2] has the largest number of works in *QTS*. He used “白髮”[3] with “青衫”[3], “青雲”[3], “丹砂”[3], and “青山”[3], and “白首”[3] with “青山” and “紅塵”[3] relatively often. Liu Changqin[2] , another important poet in the mid Tang period, used “白髮” with “滄洲”[3], and “白首” with “青山”, “滄洲”, and “青春”[3] relatively often. These different words and collocations convey the imagery of “aging”, and the variations in the word choices shed light on the subtle differences between the poets about how they expressed emotions about aging.

“白雲”[4] is a very frequent word in *QTS*. Collocating with different words would create different imageries in the poems, e.g., “黃葉”[5], “滄海”[6], “清露”[7], and “流水”[8]. Each of these collocations may brew a different scene in readers’ minds, and some of these collocations are more popular than others. It should be interesting for researchers to extract the source poems[9] from the *QTS* to thoroughly study them.

Liu et al. (2015) reported that white (“白”) is the most frequent color in *QTS*. We may check and find that red (“紅”) is the most frequent color in *QCS*. It is interesting to investigate the changes (and their causes) of the popular colors from *QTS* to *QCS*. Again, using text analysis methods, we can find a good approximation of the trend, though obtaining the precise frequencies of the colors requires the techniques of word sense disambiguation (WSD). For instance, “金”[10] could represent a material or a color, so WSD is necessary to achieve precise statistics.

In *QSC*, the most frequent six colors are in the order of “紅”, “青”, “黃”, “綠”, “白”, and “碧”[11], while, in *QTS*, the most frequent six colors are “白”, “青”, “紅”, “黃”, “碧”, and “綠”. “紅塵”, “殘紅”, “紅妝”, “紅葉”, “紅袖”, “紅日”, and “紅樓”[12] are some of the most frequent red words in *QSC*. The changes in the dominant colors from *QTS* to *QSC* may be a result of the selection process and may be a result of the cultural shift, and is an academically interesting issue to purse further.

Word Inventions and Influences

Liu and Wang (2012) proposed a method to measure and compare the influences of the poems of a poet. Their methods considered whether or not the poems were selected to be included in famous collections.

While our goal is not to challenge Liu and Wang's viewpoint, we would propose to consider also whether poets created new words that were used by later Chinese generations. Isn't it practically meaningful and academically significant to create new words that future generations continue to use? At the time of Tang and Song, poets were at an excellent stage of the Chinese history to achieve such a cultural impact.

We conduct an analysis of frequent bigrams in *QTS* and *QSC*, and compare the differences. Words that appeared only in *QSC* are candidates of new words which were invented in Song dynasty. Words that appeared only in *QTS* are candidates of words that failed to survive in Chinese language. Although this process does not really guarantee a water-proof theoretical foundation for word invention, the findings should still serve as a persuasive factor in linguistic, literary, and historical research.

Here are some of such findings. “紅塵”[13] appeared in both *QTS* and *QSC*. “惺忪”[13] is a word that appeared in *QSC*[14] but not in *QTS*, and is still being used in modern Chinese. “空門”[13] is a word that appeared in *QTS* but not in *QSC*, and is being used in Chinese. “武皇”[13] is a word that appeared in *QTS* but not in *QSC*, and is not normally used in Chinese. “酴醾”[15] represents another type of instance. This word appeared much often in *QSC* than in *QTS*.

Discussions

A major challenge in analyzing the words in Chinese poetry is word segmentation. Traditional experience indicates that most words in poetry consist of one or two characters (2005). Relying on this heuristic, we can algorithmically analyze the corpora containing about 4.9 million characters at least approximately. To really understand and appreciate the poetry, one should not read them verbatim. Metaphor recognition can be essential for revealing the real intentions of the poets.

Observations resulting from quantitative analysis of *QTS* and *QSC* open windows to promising research opportunities about *QTS*, *QSC*, and their transition. In addition to colors, terms about astronomical objects, floral entities, meteorological phenomena, and geographical sights, are important participants in poetry. Innovative collocations of them paint impressive imageries in readers' minds. Good computational tools can help researchers explore poets' worlds more efficiently.

Responses to the Reviews

We are thankful for the precious critiques and comments of the DH2016 reviewers. Our responses, which could not exceed 300 words, for the comments cannot fit into this final version because of length constraints, so we place our complete responses in a separate file online at <http://www.cs.nccu.edu.tw/~chaolin/papers/dh2016liu.responses.pdf>.

1. Introduction

Language use performs as a screen or filter to reality, reflecting speakers' perception and organization of the world around them (Wardhaugh, 2002). In language, modality deploys various kinds of meaning filter (types of modal expression) which variously color and modify our conceptualizations of the world and enable us to represent it with such purposeful diversity (Hoye, 2005). Modality acts as stance-taking or attitudinal qualifications, e.g. necessity (must, should) and possibility (can, may), expressing the speaker's opinion of a proposition or a predicate and its subject. Simon-Vandenbergen (1997) shows that modal certainty is an important feature of the discourse of political speakers and give a functional explanation of modal selections in political interviews. Garzone (2013) conducts a corpus-based study to show the decline in the use of "shall" in U.K. legislative texts and the use of other modal/non-modal substitutes for the somewhat offensive "shall." In this paper, we examine modality use in a corpus of historical news to observe the rhetorical stance of government propaganda at a time of governance crisis. The results indicate that a strong sense of moral persuasion and demand was manifested by significant modal use for social responsibility.

2. Theoretical framework and methodology

Theoretical studies to modality include generative, cognitive-pragmatic, and typological approaches (Hoye, 2005). The central notions to linguistic modality in typological sense are possibility and necessity (Lyons, 1995). We adopt Li's (2004) Chinese modal system which was derived from an English modality framework (van der Auwera and Plungian, 1998).

The semantic categories of the modal types and the primary Chinese modal verbs are listed below. Chinese modal verbs are poly-functional, each may indicate more than one modal senses.

- Epistemic uncertainty: estimates whether something will become a fact or not and suggests objective possibility, which corresponds to epistemic possibility. The modal verbs in Mandarin Chinese that express epistemic possibility are 能 neng2 (can), 能夠 neng2 gou4 (can), 會 hui4 (may), 可 ke3 (may), 可以 ke3 yi3 (may), 得 de2 (can).
- Epistemic probability: predicts the necessity about a finite event or state or concludes about the necessity of a current event. The modal verbs that are used to express a note of conjecture include 該 gai1 (should), 應該 ying1 gai1 (should), 要 yao4 (will), 得 dei3 (must).
- Ability: expresses subjective possibility of participant related ability, function, property, or quality. Chinese modal verbs indicating participant-internal possibility include 能 neng2 (can), 能夠 neng2 gou4 (can), 會 hui4 (can), 可 ke3 (can), 可以 ke3 yi3 (can), 得 de2 (can).
- Need: concerns with subjective necessity that corresponds to need internal to the participant involved in the state of affairs. It relates to hope, intention, and interest which come to cause the ultimate action or event. The Chinese modal verbs identified for expressing need are 要 yao4 (need), 需要 xu1 yao4 (need), 須 xu1 (need), 必須 bi4 xu1 (must), and 得 dei3 (must).
- Permission and circumstantial possibility: deals with possibility out of deontic sources like rules, regulations, authority, or non-deontic objective circumstances. Chinese modal verbs that express the notional categories of permission and circumstantial possibility are: 能 neng2 (can), 能夠 neng2 gou4 (can), 可 ke3 (may), 可以 ke3 yi3 (may), 得 de2 (can).
- Obligation and circumstantial necessity: involves deontic necessity out of morality or social conventions, and non-deontic necessity out of objective situations and reasons. Modal verbs that express obligation and circumstantial necessity include 要 yao4 (must), 該 gai1 (should), 應該 ying1 gai1 (should), 應 ying1 (should), 當 dang1 (should), 應當 ying1 dang1 (should), 須 xu1 (must), 必須 bi4 xu1 (must), 得 dei3 (must).

The corpus for our investigative purpose is the 228 event Taiwanese news archive, published by the 228 Event Memorial Foundation to compile local news articles during a short period, dated from 2/28/1947 to 5/15/1947, of widespread riot after Chinese takeover of Taiwan at the end of World War Two. The current study focuses on news articles from Taiwan Shin Sheng Daily News (TSSDN), controlled by the government at that time, while all private news publishers were shut down one week after the incident erupted. As a baseline benchmark, we use the Academia Sinica Balanced Corpus of Modern Chinese (Sinica Corpus), designed to be a balanced collection from different areas of genre, style, mode, topic, and source (Huang and Chen, 1992). The two corpora are both Mandarin (modern Chinese) without notable language variants and are considered as comparable.

For both TSSDN and Sinica corpora, we use CKIP segmentation and part-of-speech (POS) tagging for first-line processing (Chang & Chen, 1995). The size of the TSSDN corpus is a total of 0.237 million word tokens. The Sinica Corpus (version 3.1), dated approximately from 1981 to 1997, contains a total of 5.738 million word tokens, which is about 24 times the size of the TSSDN corpus. For the purpose of comparing modal use in the TSSDN corpus and the Sinica corpus, the following procedure was used to extract and observe respective modal use distribution.

Step 1. For each word token in the list of common modal verbs, extract sentences that contain the specified word token with the POS tag of auxiliary verb.

Step 2. Rank the modal verbs by its occurrence frequency, i.e., the number of the extracted sentences for each modal verb.

Step 3. Exclude the bottom half of the list of modal verbs that show insignificant use and compare the use of significant modal verbs with both absolute frequency and normalized frequency (per million word tokens).

Step 4. For the TSSDN corpus, assess each sentence in use of a modal verb and determine its actual modal type.

Step 5. Compile the actual use frequency of the modal types in the TSSDN corpus.

Step 6. Compile the top five verb semantics following the use of each modal verb for observing the association of modal sense and semantic notion.

3. Results and discussion

An initial frequency observation on the list of common modal verbs in the TSSDN corpus is shown in Table 1. This led us to focus on the top half of the modal verbs that are clearly of more significant use in the investigated corpus.

Rank 1 ~ 4	Rank 5 ~ 8	Rank 9 ~ 12	Rank 13 ~ 16
應 ying1 (should) 535	可以 ke2 yi3 (can, may) 206	會 hui4 (may, can) 77	應當 ying1 dang1 (should) 21
要 yao4 (will, must) 476	須 xu1 (must) 170	得 de2, dei3 (can, must) 69	能夠 neng2 gou4 (can) 13
可 ke3 (can, may) 416	應該 ying1 gai1 (should) 138	需要 xu1 yao4 (need) 68	該 gai1 (should) 11
能 neng2 (can) 403	必須 bi4 xu1 (must) 123	當 dang1 (should) 66	需 xu1 (need) 6

Table 1. Rank list of common modal verbs by frequency in TSSDN corpus

Modal Verbs	TSSDN Corpus		Sinica Corpus		Increase Ratio	Sinica corpus Newspaper subset		Increase Ratio
	Absolute Frequency	Normalized Frequency	Absolute Frequency	Normalized Frequency		Absolute Frequency	Normalized Frequency	
應ying1 (should)	535	2257.4	3250	566.4	398.5%	1228	728.6	309.8%
要yao4 (will, must)	476	2008.4	15783	2750.7	73.0%	3135	1860.2	108.0%
可ke3 (can, may)	416	1755.3	8318	1449.7	121.1%	2439	1 447.2	121.3%
能neng2 (can)	403	1700.4	10867	1893.9	89.8%	3038	1802.6	94.3%
可以 ke2 yi3 (can, may)	206	869.2	9546	1663.7	52.2%	1981	1175.4	73.9%
須xu1 (must)	170	7 1 7.3	786	137.0	523.6%	237	140.6	510.1%
應該 ying1 gai1 (should)	138	582.3	2787	485.7	119.9%	522	309.7	188.0%
必須 bi4 xu1 (must)	123	519.0	3181	554.4	93.6%	788	467.6	111.0%

Table 2. Benchmark comparison of modal verbs use

能neng2 (can)	了解le3 jie3, 明瞭ming2 liao3 (39) (9.7%) 恢復hui1 fu4 (24) (6.0%) 實現shi2 xian4, 達成da2 cheng2 (22) (5.4%) 解決jie3 jue2, 克服ke4 fu2 (19) (4.7%) 看懂kan4 dong3, 讀寫du2 xie3 (16) (4.0%)	under stand Restore achieve solve, overcome read/write
須xu1, 必須bi4 xu1 (must)	登記deng1 ji4, 註冊zhu4 ce4 (12) (4.1%) 持有chi2 you3 (12) (4.1%) 注意zhu4 yi1 (11) (3.8%) 懲辦 cheng2 ban4, 處分chu3 fen4 (8) (2.7%) 肅清su4 qing1, 鎮壓zhen4 ya1 (7) (2.4%)	register carry (valid permit) Reed punish exterminate, suppress

Table 5. Primary verb semantics following modal verbs

Table 2 compares the use of major modal verbs in TSSDN corpus, Sinica corpus, and the newspaper subset of Sinica corpus (29.4% of the whole corpus). It is observed that TSSDN corpus shows a considerable frequency variation of modal verb use when compared with Sinica corpus and its newspaper subset. Among the eight modal verbs, three pairs of modal verbs are actually variants of each other and may be aggregated to better represent the semantic notions of the modal verbs.

In Table 3, we aggregate three pairs of modal verb variants of the same semantic notion and re-calibrate the relative amount of modal use in the two corpora and one sub-corpus. The comparison shows that the use of 應 ying1, 應該 ying1 gai1 (should) and 須 xu1, 必須 bi4 xu1 (must) in TSSDN corpus are significantly frequent than in Sinica corpus and its newspaper sub-corpus, while the use of the other modal verbs are somewhat comparable. This indicates that TSSDN corpus contains a strong attitude and stance through the unusual emphasis of should and must.

Next, we observe how the use of modal verbs is distributed in the modal system to depict various aspects of attitude and stance. Each occurrence of a modal verb in a sentence is categorized in modal type by independent coders. Disputed codes are discussed to reach consensus decision. Table 4 breaks down the occurrence of modal type expression by the poly-functional modal verbs. The results reveal an extremely high concentration on the modality type of obligation, signaling a heavy dose of demand and persuasion of social responsibility from government propaganda.

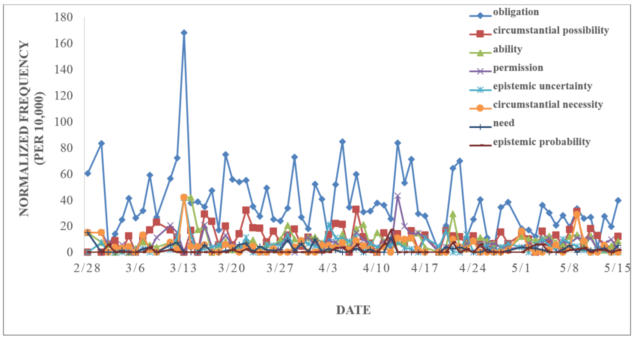

Figure 1. Chronological occurrence of modal types on a daily timeline

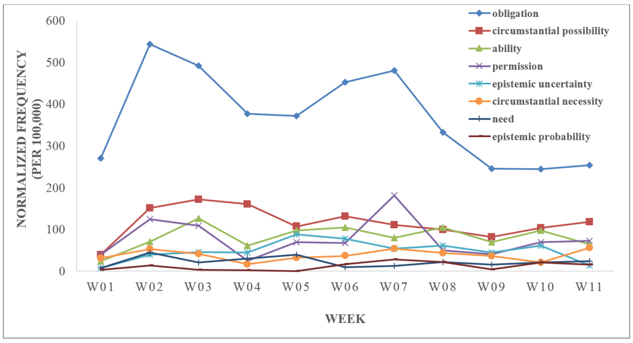

Figure 2. Chronological occurrence of modal types on a weekly timeline

We also observe the normalized occurrence with respect to word count of news reports on a daily timeline in Figure 1 and weekly timeline in Figure 2. The temporal variation depicts a process of employing the rhetoric of obligation that immediately peaks in the second week, followed by a lower peak in the seventh week before gradually reduced in the third month, over the period in which social order was lost and regained, social activities was disrupted and restored.

Table 5 compiles the top five verb semantics, ranked by the occurrence frequency and ratio, associated with the use of each modal verb in a sentence. This helps provide a better rhetorical picture of what is being said, appealed, urged, or even warned. Overall, we observe a rhetoric sense of strict attitude and firm stance on exercising and restoring control of social order.

In conclusion, our study seems to indicate that modality is an effective linguistic feature for extracting narrative stance and provides a convenient contextual view of a corpus. Our future work includes examining more comprehensive modal expression and evaluating against corpora of various historical context.

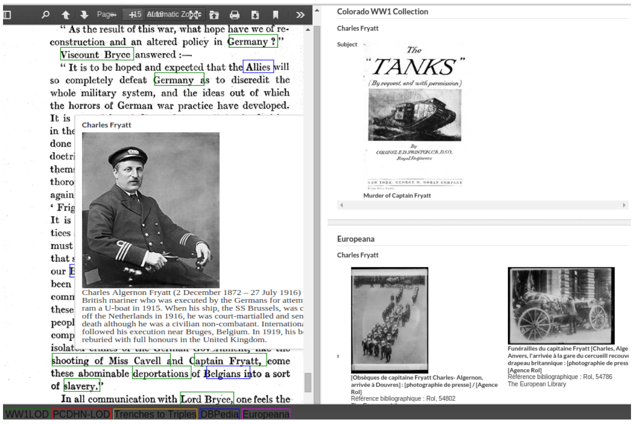
Motivation

In a relatively recent study on the needs of humanities faculty and students in using digital sources (Lindquist and Long 2011), two major issues were identified: 1) locating data relevant to a topic when online collections are distributed across institutions and systems; and 2) being able to explore the items found in context. In addition, problems were identified with crossing language barriers and with ambiguities and variants in names.

The CORE contextual reader is an application that uses natural language processing and Linked Data (Heath and Bizer 2011) techniques to address these issues in the context of close reading of primary source material[1]. Particularly, the CORE application has been designed to improve the user reading experience with texts in a domain not entirely familiar to them. Examples of this situation include a history student approaching a new topic through primary sources, or a layperson trying to make sense of law texts.



" As the result of this war, what hope have we of reconstruction and an altered policy in Germany ? "
Viscount Bryce answered :—
" It is to be hoped and expected that the Allies will so completely defeat Germany as to discredit the whole military system, and the ideas out of which the horrors of German war practice have developed. It is

Figure 1. The contextual reader interface

The CORE user interface

CORE supports contextualization in and understanding of unfamiliar documents by utilizing Linked Data reference vocabularies and datasets to identify entities in any PDF file or web page. For each discovered entity, CORE can then present configurable information sourced from these reference datasets on a mouse-over inside the web browser being used to read the document. Figure 1 shows this functionality in the context of reading a primary source document dealing with the First World War. The document, a scanned PDF, is shown in the interface on the left-hand side. Colored boxes highlight all of the entities identified by CORE. Here, the user has moused over "Captain Fryatt", and the interface has brought up his picture and a short biography. Other examples of contextual information shown are word definitions for domain-specific vocabulary, maps showing the geographical context of unfamiliar places mentioned, and so on.

If further information is needed, an entity can be clicked on to load more information and context into the pane on the right-hand side of the reader. In this pane, contextualization is further supported by visualizations, for example, locating the entity of interest temporally on a timeline and geographically on a map. Figure 2 shows these visualizations for an identified event, in this case the execution of Nurse Edith Cavell by the Germans in Belgium during WW1. At the top of the pane, the event is contextualized temporally among other war events. These are color-coded to differentiate: 1) important top-level wartime events sourced from the Imperial War Museum, 2) all events happening in the same timeframe, and 3) other wartime events happening nearby. Below the timeline, all of these events are presented on a map to give a geographical perspective. Clicking on any of the entities visualized loads the information pertaining to that entity into the contextualization pane, allowing further navigation of the context.

In addition to providing more nuanced context, the right-hand pane of CORE also facilitates serendipitous discovery of further related content. Using the configured Linked Data vocabularies, CORE is able to extract relevant search terms for an entity of interest. These search terms can then be used to discover related content from configured endpoints, even if they support only simple text searches. In Figure 1, this functionality is seen on the right-hand side of the user interface. First, formally encoded metadata brings in another relevant primary source from the University of Colorado Boulder's (CU-Boulder) WWI Collection Online[2]. Images of the burial of Captain Fryatt from Europeana[3], on the other hand, are found not through formally encoded keywords, but rather a match on his name that appears in the textual description of the images.

Among the extracted terms used in the query are multilingual labels for places, variant names for actors and events, etc. Leveraging these terms enables CORE to cross language barriers and handle naming variations. To improve recall even further, the search term extraction can be configured to include terms for related entities, such as the actors participating in an event or the names of all villages in a particular municipality under investigation.

Because CORE is able to dynamically process most HTML and PDF content, any linked resource can be loaded into the contextual reader by clicking on it. This function facilitates endless browsing on a topic through thematic and contextual connections, regardless of from where the linked material comes.

System demonstrators

In contrast to most other similar systems, a CORE instance can relatively easily (and always should be) configured for a particular domain, thus ensuring the contextual information provided is actually useful and interesting to the end-user.

To provide its services, CORE makes use of dynamic, configurable entity recognition, in which modular lexical analysis services are combined with SPARQL queries[4]. This allows multilingual entity recognition against any vocabulary stored at a Linked Data endpoint. A configuration therefore consists of tuning the lexical analysis service to a particular domain and set of languages, as well as defining the endpoints and queries to be used in bringing in contextual information and related resources.

While in future the application is intended to be fully configurable using a web user interface, currently new instances must be configured from the source code, released under the MIT open source license at http://github.com/jiemakel/core/. Thus far, three different demonstrators have been created[5].

The first of these is the contextual reader for First World War primary sources available at http://demo.seco.tkk.fi/ww1/. For vocabularies, it draws on the WW1LOD dataset (Mäkelä et al. 2015), the vocabularies of 1914–1918 Online[6], the Europeana 1914–1918[7] thesaurus, the Out of the Trenches (Pan-Canadian Documentary Heritage Network 2012) and Trenches to Triples[8] vocabularies, and DBpedia (Lehmann et al. 2015). Repositories used for sourcing related content are CU-Boulder's WWI Collection Online, WW1 Discovery[9], Europeana, the Digital Public Library of America (DPLA)[10], and The European Library (TEL)[11].

To further demonstrate multilingual support as well as support for inflected languages, a second contextual reader has been configured to support the study of ancient Roman sources, be they translated into English or still in the original Latin. This installation is available at http://demo.seco.tkk.fi/ancore/. Here, ancient place names are located on maps through the Pleiades gazetteer of ancient places[12], while information on entities like people and mythical characters mentioned in the texts is sourced from the English and Latin DBpedias. Targeted repositories are the Perseus Catalog[13], the various Pelagios datasets[14], and again Europeana, DPLA, and TEL.

The final demonstrator, aimed at supporting the reading of legal documents in the highly inflected language of Finnish, is available at http://demo.seco.tkk.fi/laki/. In this case, the documents are drawn from, for example, the consolidated legislation[15] and the precedents of Finnish supreme courts[16] published by the Finnish Ministry of Justice. In addition to linking these distributed resources to one another, the application is able to bring in news articles[17] dealing with laws of interest published by Edita Publishing.

When reading documents containing precise legal terminology, the reader is supported by definitions from the legal terminology section of the Bank of Finnish Terminology in Arts and Sciences[18], the Asseri vocabulary of the Ministry of Justice, the Edilex legal vocabulary from Edita, the Finnish law vocabulary from Talentum Publishing, and the legal terminology section of the Finnish DBpedia. In addition to Finnish, this reader has also been configured with limited support for Swedish, as Finland is a bilingual country.

Conclusions and future work

The CORE contextual reader clearly demonstrates the potential of utilizing Linked Data vocabularies to bridge institutional silos and language barriers, even in situations where the structured metadata of the corresponding databases is lacking. On the other hand, the core mission of the tool is to support contextualization and understanding.

While initial experience points both to significant overall support, as well as a marked increase in support with regard to less domain-configured alternatives (Csomai and Mihalcea 2007; Olango, Kramer, and Bouma 2009), a formal user evaluation of the reader remains to be conducted. This will be the natural next step for the project, and plans for testing the WW1 version of the reader are already underway.

At the same time, the CORE reader is currently seeing uptake in new contexts, most notably a project to unify disparate material related to the Finnish view of the Second World War (Hyvönen et al. 2015). Supporting these new contexts may require further development of components of the reader. For example, the Second World War material under study contains multiple distinct places and people with the same names. To properly handle these would require better support for disambiguation in the entity recognition component of the reader.

Khepri - a Modular View-Based Tool for Exploring (Historical Sociolinguistic) Data

Eetu Mäkelä

Motivation

Digital humanities needs tools that better support the core processes of humanistic inquiry. This includes support for handling uncertainty and incompleteness in the data, for interactive exploration, and for fluidly moving between close and distant reading (Drucker 2011; Jänicke et al., 2015; Caviglia, Ciuccarelli, and Coleman, 2012; Uboldi and Caviglia, 2015).

The Khepri tool presented here is part of a project to develop a modular set of components that take these requirements into account, and can be connected and configured to respond to the needs of a particular humanities task and data. Khepri targets data stored as Linked Data (Heath and Bizer, 2011), a set of scalable standards that has gained widespread adoption particularly in the sphere of cultural heritage.

Development process

To ensure the tools developed meet the needs of humanities users, they are being developed iteratively, utilizing participatory design in case studies, as advocated by the field of design science (Hevner et al., 2004; Peffers et al., 2007; Wieringa 2009). The task of the computer scientist is to see beyond these individual studies; to identify common components allowing the tools to generalize beyond the projects under scrutiny.

To date, a variety of collaborations have been embarked upon, from the prosopographical study of the Republic of Letters[1], through supporting engagement with WW1 primary sources (Mäkelä, Törnroos, et al., 2015), to developing a contextual network for Finnish fiction (Mäkelä, Hypén, and Hyvönen, 2013). Together, these span a range of research questions, and types of data.

Through these collaborations, a prevalent process of inquiry was identified – the need to explore and contrast differently constrained subsets of a dataset. For instance, this might be looking at the correspondence networks of different individuals and comparing them, or looking at how possible values of a linguistic variable behave with respect to each other as well as associated metadata.

To support this process, Khepri utilizes the view-based paradigm (Mäkelä, 2010), where data is presented simultaneously from different perspectives, with each perspective acting both as a visualization as well as a means to constrain what is shown. A proper implementation of the paradigm also allows for speedy informed variation of parameters, and thus interactive exploration.

Because the views interact in a defined way, they can be developed as separate components targeting major visualization classes such as geographical, temporal or statistical. Each individual Khepri instance can then select from these the views suitable for that particular use.

Thus far, most of the work has been preparatory, with the functionalities simulated through ad-hoc disconnected components, tied together and supplemented by manual work of the computer scientist. However, now a first complete tool for a particular task has been developed. This instance has been configured for historical sociolinguistics.

Khepri for historical sociolinguistics

Historical sociolinguistics is the study of language in relation to social factors through time (Nevalainen and Raumolin-Brunberg, 2003). A possible research question would be to chart the role of gender, age and socioeconomic status in the diffusion of the English progressive (as in *I am writing*). From the viewpoint of the Khepri tool, this is interesting because it requires combining access to unstructured text with access to the structured (meta) data describing their authors.

This is also the area where current tools fall short, for while corpus tools (e.g. CQPweb (Hardie, 2012), Korp (Borin, Forsberg, and Roxendal, 2012) and WordSmith[2]) enable querying texts by linguistic features, they poorly support walking from the texts to the attributes of the authors. On the other hand, tools for visually exploring structured data (e.g. Palladio[3], Europeana4D[4] and RAW[5]) do not support interacting with text corpora.

This makes research currently very labor-intensive. For instance, if one wishes to study the aforementioned progressive, one first searches for instances of *-ing* in the corpus using a corpus tool. The instances are then exported into Excel to analyze them and eliminate false hits such as gerunds (*My favourite hobby iswriting*). Next, the number of hits produced by each person is calculated using another sheet that lists the authors by gender, age, socioeconomic status and time period. These numbers are then exported for statistical analysis and visualization. Because the corpus texts, spreadsheets, visualizations and statistical analyses are not connected to each other, the exploration and interpretation of the observations is cumbersome and time-consuming at every stage.

Figure 1. the Khepri for historical sociolinguistics interface

The user interface configuration of Khepri for historical sociolinguistics

The Khepri interface for historical sociolinguistics is depicted in Figure 1. The interface is divided into three columns, with the views contained in each having different primary purposes.

On the left are views aimed primarily at producing a subset of interest. The first view is for text search. Below the query, matching keywords from the data are presented for evaluation. Notice that two sets of counts are given. One shows the overall amount of hits for a keyword in the corpus, while the other takes into account constraints set in other windows. This way, the view acts not only as a selector, but also as a statistical breakdown of the current subset.

Below the keyword search view, the user can add metadata views. Here for example, a view visualizes and allows one to constrain the data through the lens of the author's education.

The second column shows the items in the current subset. Matches are shown in their textual context, with metadata and additional context available on mouse-over. While tuned for close reading, this view also acts as a filter. Clicking on an item removes it from the current subset. For linguistic research, this is important as the inclusion or exclusion of a particular example of a phenomenon may depend on contextual cues and background knowledge that cannot be defined as search parameters, but require manual evaluation.

When focusing on close reading, the column can be expanded to occupy the whole right-hand side of the interface. Expanded, the view shows additional metadata, such as the author and year of the texts. The view can also be sorted according to these properties, as well as grouped by them, so that for example only a listing of the authors, or the linguistic types (e.g. different words ending with *-ing*) is shown, with the individual matches revealed by expanding.

To further help in keeping a close reading task organized, the interaction between this view and the constraining views has been designed so that it is easy to temporarily restrict the matches shown to only those from e.g. a particular spelling, or a particular social class.

Finally, the column on the right is intended primarily for visualization. In fact, it can visualize and contrast multiple subsets of the data. To facilitate this, the first two columns are subsumed in a tabbing container, with each tab containing the query state of a single subset. In the example of Figure 1, these are spelling variants of the negated auxiliary verb *cannot* (written separately, contraction, written together).

By default, the frequency of each subset is visualized as its own line chart. However, numerous options affecting this are provided, drawn from best practices in the field (Hinneburg et al., 2007). For example, separate lines can be graphed for each of the values of a particular metadata property. In Figure 1 for example, each chart contains lines for male and female writers, showing that the use of the form “can not” seems to follow an approximately linear decline for men, but not for women.

To prevent misinterpretations arising from small samples, each graph can be accompanied by a dotted logarithm representing the size of the corpus as a whole for that metadata value. The interface also supports bootstrapping to visualize confidence intervals. As this takes considerable time to calculate, it should only be enabled when a seemingly significant discovery needs verification.

The interface also offers alternative charts. For example, when comparing possible values of a single linguistic variable, the area chart visualization shown in Figure 2 is appropriate. In addition, a motion chart visualization (Figure 3, inspired by the static scatterplots in Nevalainen, Raumolin-Brunberg, and Mannila (2011)) is provided, used to see how different individuals relate to the variable under study, and even how they change their use through time.

In line with the view-based querying paradigm, all visualizations also act as selectors, enabling delving deeper into interesting phenomena. Through them, one can for example constrain the instance list to show only usage by women in a particular timespan, or in the case of the motion chart, even the use of a single individual.

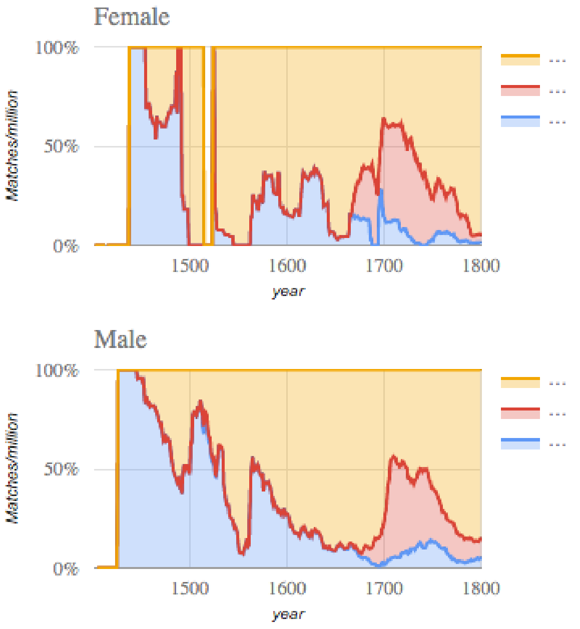

Figure 2. Area charts showing the relative proportions of “can not” (blue), “cannot” (yellow) and “can’t” (red) by time and gender

Discussion and future work

Khepri for historical sociolinguistics is the first complete version of the tool. It is also only in its second iteration, and will continue to improve based on feedback. However, it has already been received with excitement, enabling research that was previously too time-consuming to attempt.

With the architecture of the tool now in place, other instances will soon follow, targeting next the Republic of Letters and Finnish fiction use cases. This can be said because all the views created are actually generic, and can be pointed to different data by reconfiguring. For example, text search is also useful for locating individuals or books, while the metadata facets directly target structured data already. The views requiring most modification are the statistical charts, but even here work will be fine-tuning to match differing metrics. Correspondingly, any visualizations developed for other scenarios can be imported here, to for example visualize language phenomena on maps.

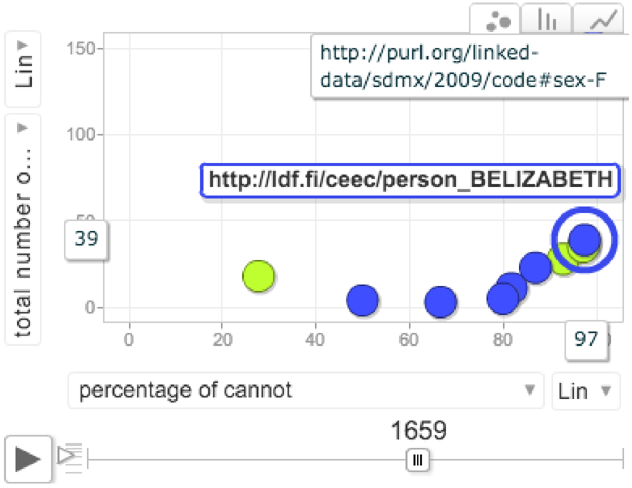

Figure 3. Motion chart showing how many percent of individual writers use the form “cannot”

Where Close and Distant Readings Meet: Text Clustering Methods in Literary Analysis of Weblog Genres

Problem: towards a non-topical classification of weblog genres

The existing typologies of weblog genres - both popular and academic - are based on the blog topic, e.g. cooking blogs, travels, business (cf. Morrison 2008) or its medium, e.g. vlogs, picture logs (cf. Herring et al. 2005). In order to go beyond topical distinctions, Maryl, Niewiadomski and Kidawa (2016) conducted an interpretive study on the sample of 322 popular Polish blogs. They adopted a new-rhetorical approach, basing on Carolyn Miller's (1994) concept of genre as a social action, concentrating mostly on the blog's communicative purpose and functions. Following the principles of the grounded theory (cf. Lonkila 1999) the team interpreted those blogs and created an empirical-conceptual typology which entailed following genres: diaries (subjective, self-referential discourse), reflection (subjective discourse on universal matters), criticism (subjective and expert discourse on general issues), information (objective facts), filter (gateway to the existing web content), advice (subjective and expert instructions on particular issues), modelling (serving as a role model for readers) and fictionality (description of fictional events). Weblogs in the sample were coded by three separate coders with 69% average pairwise percent agreement and Cohen's kappa of .622[1]. Such a moderate agreement could be attributed to the fact that the resulting genres are ideal types, and most of the actual blogs share features of more than one genre.

This subsequent study aims at supplementing this close-reading typology with a distant-reading perspective (Moretti 2013), based on selected tools for language processing and text clustering. We explore the style of those genres, adapting the definition proposed by Herrmann et al.: "Style is a property of texts constituted by an ensemble of formal features which can be observed quantitatively or qualitatively" (2015:41). We chose this approach due to its stress on mixed methods, as we are combining linguistic and literary criteria of selecting style markers to discriminate between blog genres (Leech & Short 2007,57-58). Current research in the field of computational literary genre stylistics focuses on Most Frequent Words (e.g. Schöch and Pielström 2014; Jannidis & Lauer 2014) or functional linguistic categories (or both) (e.g. Allison et. al 2011). Yet, this study applies similar methods to emergent and uncategorised forms of writing. The quantitative methods are incorporated into the qualitative research workflow in order to create a productive feedback loop.

Corpus

The corpus of blogs was collected with the use of *BlogReader* - an extension of a corpus gathering system developed in CLARIN-PL (Oleksy et al. 2014) on a basis of open components: *jusText* and*Onion* (Pomikálek, 2011). From the initial set analysed by Maryl et al., 250 blogs were selected for processing as being long enough and included clean text (comments were omitted). We intentionally left out blogs with exceptionally large or small amount of text in order to balance the sample. The selected subcorpus includes: Diaries (44 blogs), Reflection (12), Criticism (73), Information (10), Filter (11), Advice (59), Modelling (24), Fictionality (5), and 10 'Unblogs', i.e. websites or portals using the label of blogs. Posts from the one blog were merged together into a single text document per a blog that was saved in the CCL corpus format (Broda et al., 2012).

Processing

We followed the blueprint of stylometry to find groups of blogs, e.g. (Burrows 2002), (Stamatatos, 2009) or (Eder, 2011). Blogs were described by feature vectors whose initial values were frequencies of the selected elements. They were next filtered or transformed. The transformed vectors were clustered into a number of groups that could be presented as automatically identified blog types or compared with the original types.

According to the criteria considered for the typology of blogs, we assumed that the interesting distinctions are not of semantic character. Thus we tried to define descriptive features that are not sensitive to the semantics of the blog contents. As a consequence, we have analysed features based on frequencies of lemmas, grammatical classes and sequences of grammatical classes. The brief description below will be elaborated in the presentation:

1. We have selected the 500 most frequent lemmas from the *Polish National Corpus* (Przepiórkowski et al., 2012) and in the series of experiments on the corpus of novels we reduced it to 212 lemmas that did not trigger semantic grouping (e.g. filtering out most of nouns and verbs).

2. Grammatical classes (as defined in the *Polish National Corpus* tagset) were recognised by *WCRFT* morpho-syntactic tagger (Radziszewski, 2013).

3. Features were defined and extracted with the help of the *Fextor* system (Broda et al., 2013).

4. Raw feature values were transformed by measures returning positive results for those features which contribute the significant amount of information to the document description. *SuperMatrix* system (Broda & Piasecki, 2013) for Distributional Semantics was applied during the transformation.

5. Similarity of the transformed vectors were computed by the cosine and ratio measures. The first is not sensitive to the differences in the document lengths that was the case of the analysed collection. The ratio as a heuristic measure that is aimed at comparing how much information is shared by the two vectors:

$$\mathrm{ratio}(V,U) = 2{*}\mathrm{sum}((Vi + Ui)/\max(Vi, Ui) - 1) / (\mathrm{length}(V) + \mathrm{length}(U))$$

6. Clustering was performed by the *Cluto* package for text data clustering (Zhao & Karypis 2005). In addition, *Stylo* package (Eder et al., 2013) for stylometry was used in experiments with visualisation of the possible blog clusters.

In order to understand the clusters better, most significant features for each cluster were identified and ranked. From several tests the Mann-Whitney U nonparametric test was chosen. For each feature its values in the documents of the given cluster were compared with its values in documents from the rest of the collection.

Experiments

We have performed several experiments that can be divided into three main groups:

1. *lexical level analysis*, based solely on the selected most frequent lemmas and punctuation marks and aimed at testing whether those properties can serve as a basis for automated identification of the blog types;

2. *lexico-syntactic level analysis* featured grammatical classes in combination with the lexical features of the lexical analysis in order to assess whether blog styles result in syntactic properties. On both levels we set the expected number of clusters to 20, in order to give algorithm more 'freedom';

3. extraction of significant features for the blog types with the help of the Mann-Whitney U nonparametric test.

Discussion

The generated groups represented relatively high average of clusters purity: 54%-60,4%, i.e. more than 50% blogs in a cluster are of same type. Entropy was higher than expected: 0.438-0.481, i.e. besides dominating types in clusters blogs of other types were scattered (especially smaller types). However, the obtained clusters did not match very well the qualitatively defined types. Lexical analysis combined with the ratio measure produced results that were closest to the qualitative types: entropy of 0.467 and 58% purity, see Figure 1. Yet, lexico-syntactic analysis (lexical features together with grammatical classes and bigrams) yielded better results: 0.438 of entropy and 60.4% of purity, see Figure 2. A slightly worse result: 0.481 of entropy and 54% of purity, was obtained with trigrams instead of bigrams - groups became too small and too specific.

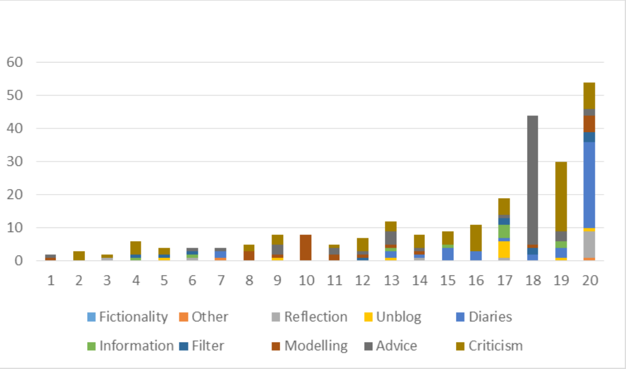

Figure 1. Results of the lexical analysis (features: 212 selected frequent lemmas, punctuation marks), PMI weighting, the ration similarity and, graph clustering algorithm from Cluto

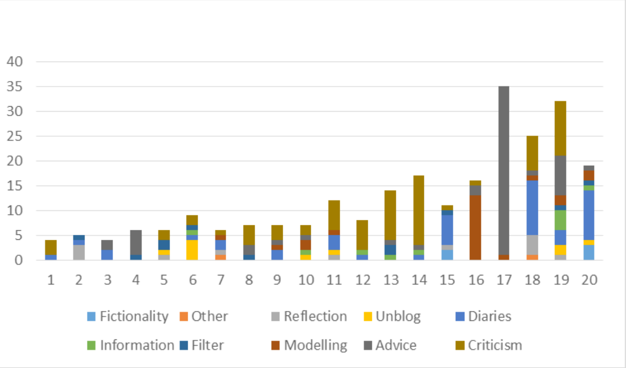

Figure 2. Results of the lexico-syntactic analysis (lexical features plus grammatical classes and bigrams), PMI weighting, ration similarity, graph clustering algorithm

Such genres as advice, criticism and, to certain extent, diaries and modelling were clustered together with others present in multiple clusters. It was caused by distinctive language features of those genres, especially of the advice, which employs instructional vocabulary, or criticism, due to its essayistic style with compound sentences and conjunctions reflecting logical reasoning. Diaries tend to use narrative language, whereas modelling blogs are clearly concentrated on expressing the author's self.

Those differences were further explored through the extraction of blog types' significant features with the use of Mann-Whitney U statistic. The results were in line with the definitions of classes, but provided more detailed information about the linguistic cues in those genres, some of which are presented in Table 1.

Conclusions

This study showed how close readings (literary interpretative practices) and distant readings (computational approaches to genre analysis) could be integrated in a non-topical analysis of the emerging genres. The novelty of the presented approach lies in the fact that we do not aim at assessing existing genres but rather at developing tools and procedures for the analysis and classification of new genres. The automated methods are used not only to verify the qualitative findings, but rather to enhance them by pointing towards the attributes which might have been overlooked by human coders who were able to read only a sample of each of 332 blogs. The aim is not to cluster texts automatically but rather to support human interpretation in an integrated research design.

Recurring problems with clustering genres other than advice could be attributed to the fact that individual blogs within one class may consists of posts which follow different genre conventions. Hence, further studies should explore the genre problem by comparing individual posts (rather than entire blogs) by different authors in order to find stylistic similarities.

Genre	Linguistic features
Advice	infinitive, passive adjectival participle, numerals, measurements (“about”, “large”, “small”)
Criticism	subjective vocabulary: „I”, „mine”; conjunctions pointing to logical reasoning, e.g. “if”, “that”, “given”, “hence”, “but”
Diaries	1st & 2nd person; vocabulary: “self”, “to be”; specific words and verb forms pointing out to a narrative: “certain”, “there”
Fictionality	past tense, 3rd person
Filter	punctuation, substantives
Information	impersonal verb forms, 3rd person
Modelling	interjections (e.g. “eh”), exclamation marks, 1st & 2nd person, vocabulary: “mine”, “thing”, “new”, “why”, “because”
Reflection	1st & 2nd person, vocabulary: “self”, “always”, “everything”

Table 1. Selected linguistic features of weblog genres (Mann-Whitney U)

Wikidition: Towards A Multi-layer Network Model of Intertextuality

Introduction

Current computational models of intertextuality run the risk of ignoring several desiderata: on the one hand, they mostly rely on single methods of quantifying text similarities. This includes syntagmatic models that look for shared vocabularies (unigram models) or (higher order) (*k*-skip-) *n*-grams (Guthrie et al., 2006). Such approaches disregard the two-level process of sign constitution according to which language-related, paradigmatic relations have to be distinguished from their text-related, syntagmatic counterparts (Hjelmslev, 1969; Miller et al., 1991; Raible, 1981) where the former require language models of the sort of neural networks (Mikolov et al., 2013), topic models (Blei et al., 2007) or related approaches in the area of latent semantic analysis (cf., e.g., (Paaß et al., 2004)). On the other hand, computational models should enable scholars to revise their computations. The reason is the remarkably high error rate produced by statistical models even in cases that are supposed to be as “simple” as automatic *pre*-processing. Thus, scholars need efficient means to make numerous corrections and additions to automatic computations. Otherwise, the computations will be hardly acceptable as scientific data in the humanities (Thaller, 2014).

	$\{\textbf{hypotext}_i \mid i = 1\}$	$\{\textbf{hypotext}_i \mid i > 1\}$	$\{\textbf{hypotext}_i \mid i \gg 1\}$
$\{\textbf{hypertext}_i \mid i = 1\}$	(1)	(2)	(3)
$\{\textbf{hypertext}_i \mid i > 1\}$	(4)	(5)	(6)
$\{\textbf{hypertext}_i \mid i \gg 1\}$	(7)	(8)	(9)

Table 1: Nine scenarios of generating Wikiditions out of corpora of (referring) literary (hyper-)texts and their (referred) hypotexts. Examples: (1) Kafka's "Bericht für eine Akademie" (in the role of a hypertext) versus Hauff's "Der Affe als Mensch" (in the role of a hypotext); (2) Kafka's "Bericht für eine Akademie" versus all "Affentexte" (Borgards, 2012) since the end of the 18th Century (including works of, e.g., Hauff, E. T. A. Hoffmann, Flaubert etc.); (3) Kafka's "Beim Bau der Chinesischen Mauer" versus the "Prager Tagblatt" from August 1914 to March 1917; (4) Kafka's "Oeuvre" versus Nietzsche's "Geburt der Tragödie aus dem Geiste der Musik"; (5) a selection of Kafka's "Oeuvre" versus a selection of Nietzsche's "Oeuvre"; (6) Kafka's "Oeuvre" versus a newspaper corpus (e.g., sampled from the "Prager Tagblatt"); (7) the complete works of several authors versus a single hypotext (e.g., Goethe's "Faust"); (8) the complete works of several authors versus a corpus of "Faust" texts; (9) the complete works of several German authors versus the complete works of several French authors.

This paper presents *Wikidition* as a *Literary Memory Information System* (LiMeS) to address these desiderata. It allows for the automatic generation of online editions of text corpora. This includes literary texts in the role of (referring) *hypertexts* (Genette, 1993) in relation to candidate (referred) hypotexts by exploring their *intra- and intertextual relations* – see Table 1 for nine related research scenarios. In order to explore, annotate and display such relations, Wikidition computes multi-layer networks that account for the multi-resolution of linguistic relations – on the side of the hypo- and the hypertexts. The reason is that hypertextual relations (in the sense of Genette) (that occur in the form of transformations, imitations or any mixture thereof) may be manifested on the lexical, sentential or the textual level (including whole paragraphs or even larger subtexts). As a consequence, Wikidition spans lexical, sentential and textual networks that allow for browsing along the constituency relations of words in relation to sentences, sentences in relation to texts etc. In this multi-layer network model, intrarelational links (of words, sentences or texts) are represented together with interrelational links that combine units of different layers. Figure 1 shows the range of sign relations that are mapped. To this end, Wikidition combines a multitude of text similarity measures (beyond *n*-grams) for automatically linking lexical, sentential and textual units regarding their (1) syntagmatic (e.g., syntactic) and (2) paradigmatic use. We call this two-level task *linkification*.

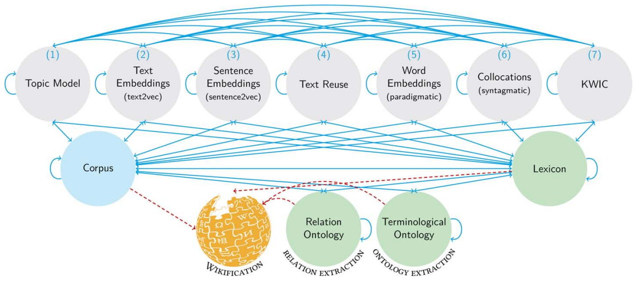

Figure 1: Sign relations that are automatically explored and annotated by Wikidition (Mehler et al., 2016): on the level of words (Module (5) – paradigmatic –, (6) and (7) – both syntagmatic), on the level of sentences (Module (3) – paradigmatic – and (4) – syntagmatic) and on the level of texts (Module (1) and (2) – both paradigmatic). Wikidition additionally includes a component for wikification (i.e., for linking occurrences of concepts to articles in Wikipedia (Mihalcea et al., 2007)) and especially for automatically inducing lexica out of input corpora (i.e., for linkification). Arcs denote links explored by Wikidition; reflexive arcs denote intrarelational (i.e., purely lexical, sentential or textual) links. In this way, intra- and interrelational links are maintained by the same information system.

Beyond linkification, Wikidition contains a module for automatic *lexiconisation* (see Figure 2). It extracts lexica from input corpora to map author specific vocabularies as subsets of the corresponding reference language. Input corpora (currently in English, German or Latin) are given as plain text that first are automatically preprocessed; the resulting wikiditions are mapped onto separate URLs to be accessible as self-contained wikis. By means of lexiconisation, research questions of the following sort can be addressed: *What kind of German does Franz Kafka write? (E.g., Prager Deutsch.) What terminologies does Franz Kafka use in "In der Strafkolonie"? (E.g., engineering terminology.) How does his German depart from the underlying reference language?* Since texts are not necessarily monolingual (because of using citations, translations, loan words, verbal expressions etc.), the same procedure can be applied by simultaneously looking at all foreign languages being manifested in the texts under consideration (right side of Figure 2).

To this end, Wikidition distinguishes three levels of lexical resolution: superlemmas (e.g. German *Tätigkeit*), lemmas (e.g., *Thätigkeit*) and syntactic words (e.g., *Thätigkeiten* (*nominative*, *plural*)) as featured sign-like manifestations of lemmas (lower part of the figure). Note that this model diverges from the majority of computational models to textual data which start from tokens as manifestations of wordforms (referred to as types) and which, therefore, disregard the meaning-side of lexical units. Based on linkification and lexiconisation, Wikidition does not only allow for traversing input corpora on different (lexical, sentential and textual) levels. Rather, the readers of a Wikidition can also study the vocabulary of single authors on several levels of resolution: starting from the level of superlemmas via the level of lemmas down to the level of syntactic words and wordforms (see Figure 2).

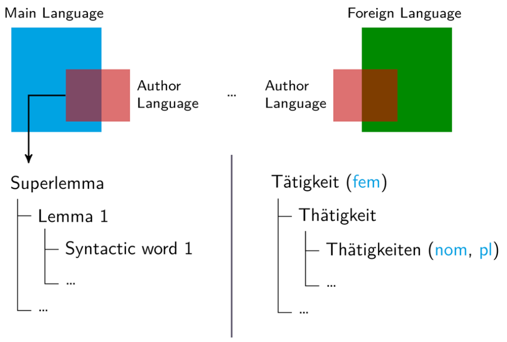

Figure 2: Left side: schematic depiction (red) of the vocabulary of an author (e.g., Franz Kafka) as manifested within Wikidition's input text(s) (e.g., "In der Strafkolonie") as mainly overlapping with the vocabulary of the corresponding reference language (e.g., German).

	Human Close Reading	Distant Reading (Moretti 2013)	Machine Reading (Etzioni 2007)	Machine Close Reading
Research object	$\{T_1 \dots, T_m \mid X_n\}$ $m \rightarrow 1, n > 1$	$\{T_1, \dots, T_m\}$ $m \rightarrow \infty$	$\{T_1, \dots, T_m\}$ $m \rightarrow \infty$	$\{T_1 \dots, T_m \mid X_n\}$ $m \ll n, n \rightarrow \infty$
Quantity of data	small data	big data	small → big	big → small
Quantification	implicit	machine-based	machine-based	twofold
Interpretation	human-based	human-based	machine-based	human based
Research focus	understanding	hidden laws	understanding	hypotheses testing
Resources	human mind	corpus + HM	corpus + SW	corpus+HM+SW

Table 2: Notions of human, computer-supported and machine-based reading. Wikidition addressesmachine close reading by integrating semantic web (SW) resources and the human mind (HM) (asthe ultima ratio of interpreting its computations). T_1, ..., T_m span the input corpus of m (hyper-)texts; X_n denotes the contextualizing corpus of hypotexts of size n that is explicitly consulted by the readingprocess. Machine close reading is similar to human reading in that it focuses on small, rather than bigdata.

While the linkification component of Wikidition relates to principles of WikiSource and Wikipedia, the Wiktionary project is addressed by its lexiconisation module. Wikidition uses numerous computational methods for providing interoperability and extensibility of the resulting editions according to the wiki principle. In this way, the dissemination of computer-based methods is supported even across the borders of digital humanities in that scholars are enabled to make their own exploratory analyses. However, Wikidition does not address a big data scenario in support of distant reading (Moretti, 2013), nor does it aim at emulating human reading in the sense of machine reading (Etzioni, 2007). Rather, Wikidition addresses what we call *machine close reading* in that it aims at massively supporting the process of (scientific or literary) reading by means of computational methods (see Table 2).

Evaluation

We exemplify Wikidition by example of three pairs of text. Regarding the layers of lemmas and sentences, Table 3 shows that Wikidition generates extremely sparse networks (whose cohesion is below 1%) of high cluster values and short average geodesic distances in conjunction with largest connected components that comprise almost all lexical and sentential nodes. In this example, we compute paradigmatic associations among words by means of word2vec (Mikolov et al., 2013) while sentence similarities are computed by means of the centroids of the embeddings of their lexical constituents. Networks are filtered by focusing on the first three most similar neighbors of each node – obviously, this does not interfere with the small-world topology of the networks. Each pair of texts is additionally described regarding the subnetwork of syntactic words and sentences. This is done to account for the impact of inflection on networking. As a result, the networks are thinned out (cohesion is now at most 0.5%), but neither the sizes of the largest connected components nor the cluster and distances values are affected considerably. Obviously, differentiation leads to sparseness, but in a sense that the general topology is retained. By focusing on a single level of resolution (e.g., paradigmatic relations among words), sub-networks are generated that fit into what is known about universal laws of complex linguistic networks (Mehler, 2008). See (Mehler et al., 2016) for additional evaluations of Wikidition.

Edition	**#nodes**	**#links**	**C**	**lcc**	**l**	**coh**
Kafka // Nietzsche	1624	10391	0,27	1	3,31	0,008
	2401	13644	0,34	1	3,56	0,005
Kafka // Rathenau	1749	10782	0,28	1	3,36	0,007
	2473	13609	0,36	1	3,60	0,004
Kafka // Rauchberg	4034	30951	0,25	0,999	3,35	0,004
	6830	44369	0,31	0,999	3,62	0,002

Table 3: Wikiditions of three text pairs (Kafka: Beim Bau der Chinesischen Mauer // Nietzsche: Die Zeit der Zyklopen-Bauten; Kafka: Ein Bericht für eine Akademie // Rathenau: Höre, Israel; Kafka: In der Strafkolonie // Rauchberg: Statistische Technik) compared by their cluster value c, the average geodesic distance of their nodes l, the fraction of nodes in their largest connected components lcc and by their cohesion coh (the number of links in relation to all possible links). First line of each text pair: nodes comprise lemmas and sentences; second line of each pair: nodes comprise syntactic words and sentences. Networking is conditioned by the operative preprocessor (Eger et al., 2016).

Conclusion

We presented Wikidition as a framework for exploring intra- and intertextual relations. Wikidition combines machine learning with principles of several wiki-based projects (Wikipedia, WikiSource and Wiktionary) to generate multi-layer networks from input corpora by integrating syntagmatic and paradigmatic relations on the lexical, sentential and the textual level. Our approach addresses intra- and inter-level networking in a single framework while adhering to laws of networking as being explored by complex network theory. In this way, input corpora get traversable in line with both empirical findings about characteristics of linguistic networks and the multi-resolution of sign relations whose space complexity is preferably reduced. Currently, Wikidition exists as a prototype that is further-developed by means of several edition projects in order to be finally made available as open source software. Wikidition is open for the cooperative development of digital editions.

Introduction

University College London (UCL) owns a large corpus of the philosopher and social reformer Jeremy Bentham (1748-1832). Until recently, these papers were for the most part untranscribed, so that very few people had access to the corpus to evaluate its content and its value. The corpus is now being digitized and transcribed thanks to a large number of volunteers recruited through a crowd-sourcing initiative called Transcribe Bentham (Causer and Terras, 2014a, 2014b).

The problem researchers are facing with such a corpus is clear: how to access the content, how to structure these 30,000 files, and how to get relevant access to this mass of data? Our goal has thus been to produce an automatic analysis procedure aiming at providing a general characterization of the content of the corpus. We are more specifically interested in identifying the main topics and their structure so as to provide meaningful static and dynamic representations of their evolution over time.

Comparison with other works

The exploration of large corpora in the Humanities is a known problem for today's scholars. For example, the recent PoliInformatics challenge addressed the issue by promoting a framework to develop new and original research in text-rich domains (the project focused on political science but can be extended to any sub-field within the Humanities).

Specific experiments have recently been done in the field of philosophy, but they mainly concern the analysis of metadata, like indexes or references (Lamarra and Tardella, 2014; Sula and Dean, 2014). Different experiments have nevertheless involved an exploration of large amounts of textual data (see e.g. Diesner and Carley, 2005 on the Enron corpus) with relevant visualization interfaces (Yanhua et al., 2009).

In this paper, we propose to explore more advanced natural language processing techniques to extract keywords and filter them according to an external ontology, so as to obtain a more relevant indexing of the documents before visualization. We also explore dynamic representations, which were not addressed in the above-mentioned studies.

Corpus exploration strategy

The Text analysis module

Different scripts have been developed to filter the corpus[1]. Then documents are assigned a date whenever possible: Since the corpus mostly contains notes and letters, the first date mentioned in the document often refers to the date of the document's composition (even if this assumption is of course not always true). A large number of documents cannot be assigned a date and are thus not used for the dynamic analysis of the corpus.

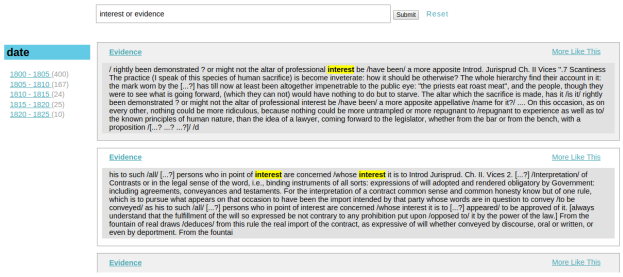
To index the corpus and identify meaningful concepts, we first tried to directly extract relevant keywords from the texts. However, traditional techniques like the use of tf-idf (Salton et al., 1983) and c-value (Frantzi et al., 2000) do not seem very efficient in our case. This is not too surprising: it is well known that texts are too ambiguous to provide a sound basis for a direct semantic extraction. Surface variations, the use of synonyms and hyponyms, linguistic ambiguity and other factors constitute strong obstacles for the task. We thus decided to use natural language processing techniques that provide relevant tools to overcome some of these limitations. The tools we employed are either web-based or possible to execute on a personal computer with average specs.

We tried to refine concept extraction by confronting the text with an external, structured database. We used DBpedia (Auer et al., 2007) as a source of structured knowledge (DBpedia is a database made of information extracted from Wikipedia). DBpedia is not a specialized source of information but this guarantees that the approach is not domain or author specific and could be easily used for other corpora. We then used the DBpedia Spotlight Web Service (Mendes et al., 2012; Daiber et al., 2013) to make the connexion between the corpus and DBpedia concepts. This leads to a much more fine grained and relevant analysis than possible with an entirely data-driven keyword extraction.

Based on the outputs of Spotlight, only concepts that occurred at least 100 times, and with a confidence value of at least 0.1 were kept. Spotlight outputs a confidence value between 0 and 1 for each annotation; a 0.1 threshold removes clearly unreliable annotations while maintaining good coverage. Tagging the full corpus with Spotlight (ca. 30,000 documents) took over 24 hours. We called the Spotlight service one document at a time; parallelizing the process can decrease processing time.

The visualization module

Once relevant concepts are identified, one wants to produce relevant text representations so as to provide a usable interface to end users. We present here three different kinds of interfaces that show the possible exploitation of the analysis described above.



interest or evidence

1800 - 1805 (400)
1805 - 1810 (167)
1810 - 1815 (24)
1815 - 1820 (25)
1820 - 1825 (10)

Evidence

/ rightly been demonstrated ? or might not the altar of professional interest be /have been/ a more apposite Introd. Jurisprud Ch. II Vices ".7 Scantiness The practice (I speak of this species of human sacrifice) is become inveterate: how it should be otherwise? The whole hierarchy find their account in it: the mark worn by the [...?] has till now at least been altogether impenetrable to the public eye: "the priests eat roast meat", and the people, though they were to see what is going forward, (which they can not) would have nothing to do but to starve. The altar which the sacrifice is made, has it /is it/ rightly been demonstrated ? or might not the altar of professional interest be /have been/ a more apposite appellative /name for it?/ .... On this occasion, as on every other, nothing could be more ridiculous, because nothing could be more untrampled or more repugnant to /repugnant to experience as well as to/ the known principles of human nature, than the idea of a lawyer, coming forward to the legislator, whether from the bar or from the bench, with a proposition /[...? ...? ...?]/ /d

his to such /all/ [...?] persons who in point of interest are concerned /whose interest it is to Introd Jurisprud. Ch. II. Vices 2. [...?] /Interpretation/ of Contrasts or in the legal sense of the word, i.e., binding instruments of all sorts: expressions of will adopted and rendered obligatory by Government: including agreements, conveyances and testaments. For the interpretation of a contract common sense and common honesty know but of one rule, which is to pursue what appears on that occasion to have been the import intended by that party whose words are in question to convey /to be conveyed/ as his to such /all/ [...?] persons who in point of interest are concerned /whose interest it is to [...?] appeared/ to be approved of it. [always understand that the fulfillment of the will so expressed be not contrary to any prohibition put upon /opposed to/ it by the power of the law.] From the fountain of real draws /deduces/ from this rule the real import of the contract, as expressive of will whether conveyed by discourse, oral or written, or even by deportment. From the fountai

Evidence

Figure 1: Search interface: users can search via year extracted from the text, which in most cases is the year of writing, allowing users to see texts (especially correspondence) in chronological order.

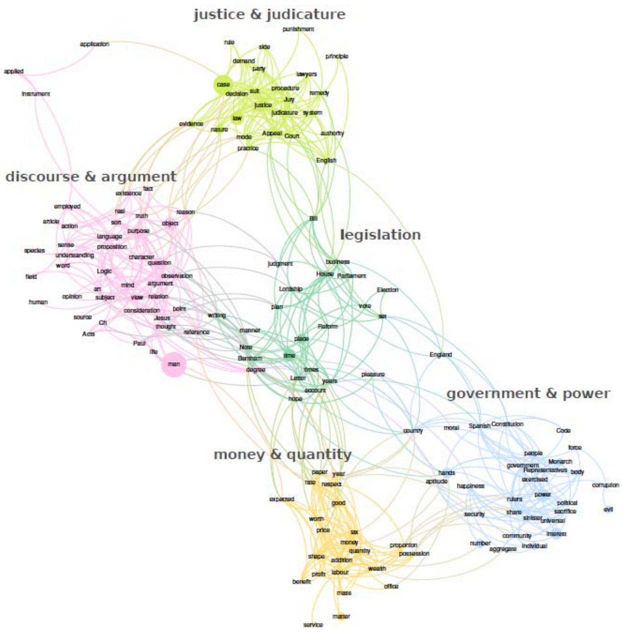

Figure 2: the main topics addressed in the corpus, based on clusters of concepts, showing the main concerns of Bentham's writings, which map closely onto established research areas in Bentham studies. The network was produced by Cortext; colours and fonts were reformatted in Gephi based on Cortext's gexf-format export[4]

The corpus is first indexed in a Solr search index[2] and accessible through a graphical end-user interface. It is possible to query the corpus by date, using Solr's faceted search functions[3] (see figure 1).

It is also possible to cluster together related keywords, so as to get access to homogeneous sub-parts of the corpora representing specific subfields of Bentham's activity (see figure 2).

Dynamic maps are also possible, to see for example the evolution of the different topics addressed in the corpus over time (see figure 3).

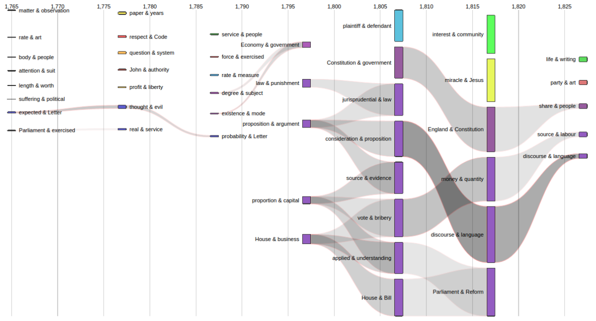

Figure 3: A dynamic view of the corpus, computed with the Cortext plarform *(tubes layout)*, with the evolution of the main topics addressed over time

Scholarly benefits of these tools for the Transcribe Bentham project

Since 1958, UCL's Bentham Project has been producing the new, critical edition of the "Collected Works of Jeremy Bentham". The edition is expected to run to some eighty volumes, the thirty-third of which has recently been sent to the press. The "Collected Works" is based upon texts, which Bentham published during his lifetime, and unpublished texts, which exist in manuscript. It is a major task: UCL's Bentham Papers runs to some 75,000 manuscript pages, while the British Library's has a further 25,000 or so pages. About 40,000 pages have been transcribed to date and, while UCL's award-winning 'Transcribe Bentham' initiative has helped to significantly increase the pace of transcription, a great deal more work needs to be done.

The first task in producing a volume of the "Collected Works" based upon texts in manuscript is to identify all the relevant pages. Bentham Project editorial staff use the Bentham Papers Database Catalogue, which indexes the manuscript collection by sixteen headings, including date, main heading, subject heading(s), author(s), and so forth. It is, however, entirely possible to miss relevant manuscripts using this method. The subject maps produced for this research promise to complement traditional Bentham Project methods; for instance, Bentham's work on political economy encompasses topics as varied as income tax to colonisation, and the subject maps will make it more straightforward to investigate the nexus between these, and other, subjects.

The dynamic corpus view, showing the evolution of topics addressed over time, could also prove useful in editorial work as can be shown in two examples. First, an editor at the Bentham Project is currently working on Bentham's writings on convict transportation, though there is some confusion over when exactly Bentham first broached the topic. The dynamic corpus view could help to clear up whether it was only around 1802 when Bentham wrote about transportation, or if he had investigated the subject in any great detail during the 1790s. Second, Bentham became more radical as he aged, and several Bentham scholars have sought to identify the point at which Bentham abandoned his earlier conservatism and 'converted' to political radicalism, and representative democracy; an analysis of Bentham's language at the turn of the century would be instructive in helping clarify this matter.

Conclusion

In this paper, we have presented a first attempt to give a relevant access to a large interdisciplinary corpus in the domain of philosophy, law and history. We have shown that using tools in concept clustering and visualization can provide an alternative way to navigate large-scale corpora, and confirm and visualise scholarly approaches to large scale textual corpora. Exploring how these tools can be effectively used with a corpus such as Bentham's indicates these methods are applicable to other sources as well.

In the near future, we are planning to refine the linguistic analysis in order to give better representations of the textual content of the corpus. We are also planning experiments with end-user to evaluate in more details the solution and the visualisation techniques used so far in this project.

Acknowledgements

Reading in translation is an impoverishment, not so much because of the fluctuating quality of a translation or the loss of a perceived 'original work' but because of the elision of sociolinguistic context and the difficulty in conveying that lost context to readers. That world literature is taught almost always in translation at universities in America and elsewhere (a situation driven by the low capacity for foreign language instruction at the university level and the broad linguistic reach of world literature courses) compounds this problem. Of the estimated 20.2m American undergraduates in 2015, an estimated 1.6m are enrolled in foreign language courses, and, historically, only 17% of those reach the higher levels of proficiency necessary to read literature (Goldberg et al., 2013). The problem of American monolingualism has even affected the publishing industry; as noted translation theorist Laurence Venuti argued (1998), there are more translations of English texts into other languages than ever before while fewer foreign texts are translated into English. This trend means that American students are even less likely to feel comfortable with literature in translation than students from non-English speaking countries.

However, conversations about literary summarization, a core practice of critical reading, take place globally and are preserved in the background of pages on every national language Wikipedia. As each language community summarizes their translations of works of world literature in the form of Wikipedia articles, they generate for every crowdsourced entry a discussion page and a history of that page; together, they reveal that literary work's history of reception for a reading community in a given language. By striving to synthesize an authoritative, peer-reviewed summary of text native to or translated into that community's language, each group highlights their concerns, thought processes, and the challenges posed by a given work. The goal is to make these differences and conversations more visible to readers through techniques from natural language processing for automatic translation, topic modeling, and the visualization of topic models; in so doing, we aim to develop a method by which the digital humanities can address a core problem in comparative and world literature.

Machine translated Wikipedia discussions can help reveal to monolingual audiences the degree to which cultural pragmatics influence the reception of key (and popular) works of world literature. Although flawed, automatic translation has been found in some languages to be comparable with human translation, at least in regards to cohesion and formality (Li et al., 2014). Presenting parallel national-language conversations – such as the national language conversations about topics like translating the title for Camus' *L'Étranger / The Stranger / Der Fremde/ The Foreigner* and a visualization of the change-over-time of Goethe's *Faust I* summarizations in English, German, and Spanish – would help demonstrate the practical reception of a work in a language community. While work has been done on multi-lingual topic models (Ni et al., 2009), our research assumes that there will be both alignment and misalignment of topics across the various languages of a work; as such, our project resists the urge to normalize those topics into one category on the basis of an imperfect vector model of semantic similarity. Furthermore, experiments on iterative summarizations, such as elements of *The Tale of Genji*, demonstrate how even basic tasks in literary scholarship contain cultural dimensions and can thus reveal strong cultural patterns and biases held by different populations (Kashima, 2000). Along with the works mentioned above, this research explores the Wikipedia conversations around J.D. Salinger's *Catcher in the Rye / Der Fänger im Roggen / El guardián entre el centeno o El cazador oculto / L'Attrape-cœurs / Il giovane Holden* and Homer/Omero's *The Odyssey / Die Odyssee / Odisea / L'Odyssée / Odissea* across English, German, Spanish, French, and Italian Wikipedia pages.

In an increasingly digitized cultural landscape, the pedagogical use of Wikipedia and similar platforms has gained a great deal of traction in certain fields. While it is often derided as a dubious source for information, Wikipedia has proven to be a successful arena for instructing students on the distillation of information, writing in the public sphere, and collaborative writing (Purdy, 2009; Vetter, 2014; Sweeney, 2012). As a multilingual space, Wikipedia has offered many scholars the opportunity to examine the ways in which the cross-cultural sharing of information takes place (Nothman et al, 2013; Filatova, 2012). In some instances, Wikipedia specifically has been used as a place for the comparison of knowledge and representation across cultural and geographic divides (Callahan and Herring, 2011). These scholars provide a framework for examining the cross-linguistic aspects of Wikipedia in order to highlight cultural differences and deconstruct colonial power structures that privilege the English language (Ensslin, 2011). In the available scholarship, the use of Wikipedia in teaching literature has been largely ignored; only a few studies exist and those mainly address literary studies' reticence to incorporate Wikis into pedagogy (Bayliss, 2013). However, quite a few studies suggest that Wikipedia can occupy a distinct operational space in the university that supplements established pedagogical spaces and practices (Gorard and Selwyn, 2015; Knight and Pyke, 2012).

Our computational framework follows these possibilities to supplement two established methods of teaching translation in a world literature classroom. The first method consists of placing a work of literature in translation – a passage from a novel, for example – in relation to the same work in its original language. The hope is that students can analyze the differences between the original and the work in translation and, thereby, understand the way the literary text undergoes a 'new life' in translation. This method not only assumes a sophisticated knowledge of foreign languages among the majority of students but also brackets the question of how these works are read in the original language by native-language readers. The second method juxtaposes several translations of the same work into English. This has the advantage of not assuming knowledge of a foreign language. For example, students might read various translations of the 19th-century French poet Baudelaire in English, starting from English translations from the late 19th century and continuing through translations that have been published in the last twenty years. The advantage of this method is clear: students can easily see, in their own language, the way translation can change the meaning of a poem as they read it from one translation to another. While this method successfully bypasses the problem of foreign language competency, it amplifies the second problem: the student is even more divorced from the source-language context since all emphasis is placed on the way *English speakers* respond to a work of literature.

New methods, therefore, are needed to expose foreign texts and foreign contexts. Using computational methods to enter the themes and arguments about specific texts in other languages precludes some of the need for high-level competency in a foreign language in order to understand the debates about world literature in a non-American – and especially non-English – context. Automatic translation and topic modeling facilitate encounters with Wikipedia 'talk' pages in other languages. The rough output of these automated and annotated procedures preserves some of the estrangement of working across languages as the translation is rough, clearly communicating its nature as translation — and therefore serves its purpose without fully replacing the source text. With such experiments, our project broadly addresses two questions: how different language populations create summaries that are culturally distinct, and how these differences can be folded back into meaningful encounters for readers of works in translation. The overall method for this project is to identify the subset of well-documented and significant works, mine the relevant Wikipedia entries and conversations, and develop preliminary code to identify the linguistic features of the entry (e.g. topics, use of modals, noun density, phraseological structures, complexity measures, etc.) and the nodal points of the crowd's conversation that yielded the page. As an example, consider the discrepancies across the Italian and English discussion pages of *The Odyssey / Odissea* as represented by ten 5- to 10-term topic models.

Terms, Italian Discussion Page	Topic Name
odissea originali palla contributi registrami	Contributions and Registration

Table 1. Named Topics Models from English and Italian Discussion Pages of Omero/Homer’s *The Odyssey / Odissea*

What comes across in this comparison is the somewhat different concerns of the two reading communities. The Italian discussion reflects concerns with the expertise of the editing community, a social reflection common to Wikipedias, and with connections between Homer and Dante, a figure more central to Italian literary identity. The English page reflects a concern with the Odyssean journey and its possible real-world correspondences. More commonality was found in another example comparing the discussion pages of J.D Salinger's *The Catcher in the Rye*. These alignments and misalignments of reader's concerns can destabilize the primacy of concerns held by a given reading community and speaks to one of the core benefits of reading world literature.

Introduction

Big Data is reshaping the historical profession in ways we are only now beginning to grasp. The growth of digital sources since the advent of the World Wide Web in 1990-91 presents new opportunities for social and cultural historians. Large web archives contain billions of webpages, from personal homepages to professional or academic websites, and now make it possible for us to develop large-scale reconstructions of the recent web. Yet the sheer number of these sources presents significant challenges: if the norm until the digital era was to have human information vanish, "now expectations have inverted. Everything may be recorded and preserved, at least potentially" (Gleick, 2012).

While the Internet Archive makes archived web content available to the general public and mainstream scholarly community through its "Wayback Machine," (at http://archive.org/web) which allows visitors to enter a Uniform Resource Locator (URL) to visit archived web versions of a particular page, this system is limited: not only do visitors need to know the URL in the first place, but they are limited to individual readings of single webpages.

By unlocking the Wayback Machine's underlying system of specialized files, primarily ISO-standardized WebARChive (WARC) files, we can develop new ways to systematically track, visualize, and analyze change occurring over time within web archives. Warcbase, an open-source platform for managing web archives built on Hadoop and HBase, provides a flexible data model for storing and managing raw content as well as metadata and extracted knowledge. Tight integration with Hadoop provides powerful tools for analytics and data processing. Using a case study of one collection, this paper introduces the work that we have been doing to facilitate web archive access with warcbase. We have growing documentation at http://docs.warcbase.org.

Project Rationale and Case Study

In 1996, the Internet Archive launched a complementary research services company, Archive-It, which offers subscription-based web archiving to collecting institutions.

The University of Toronto Library (UTL) began collecting a quarterly crawl in 2005 of Canadian political parties and political interest groups (the collections were separate in 2005, merging in 2006) (University of Toronto, 2015). The collection itself has a murky history: UTL had been part of a broader project that would have collected political websites. It fell through, but UTL opted to carry out their crawl on their own and the librarian was responsible for selecting the seed list herself (faculty and other librarians did not respond for calls for engagement). While formal political parties are robustly covered, the "political interest groups" collection was a bit more nebulous: sites were discovered through keyword searches, and some were excluded due to robots.txt exclusion requests. Beyond this brief sketch, we have little information about the decisions made in 2005 to create this collection. This lack of documentation is a shortcoming of this collection model, as if a historian was to use this material in a peer-reviewed paper, questions would be raised about its representativeness.

Figure 1: Archive-It Search Portal

If a user wants to use the Canadian Political Parties and Interest Groups Collection (CPP) through Archive-It today, they visit the collection page at https://archive-it.org/collections/227 and enter full-text search queries. In August 2015, our group also launched http://webarchives.ca, based on the British Library's SHINE front end for web archives; this was a way to facilitate a different form of more casual user access, aimed at the general public (we discuss this in a separate paper).

The Archive-It portal is limited. There are no readily-available metrics of how many pages have been collected, how they break down by domain and date, and the portal undoubtedly provides skewed results unless the search phrase is dramatically narrowed down.

Consider the search for "Stephen Harper," Canada's Prime Minister between 2006 and 2015 in Figure 1.The results are decent: Harper's Facebook page from 2009, a Twitter snapshot from 2010, and some long-form journalism articles and opposition press releases. But amidst the 1,178,351 results, there is no indication as to how the ranking took place, what facets are available, and how things may have changed over the last ten years of the crawl.

The data is there, but the problem is access.

Warcbase: A Platform for Web Archive Analysis

Warcbase is a web archive platform, not a single program. Its capabilities comprise two main categories:

1. Analysis of web archives using the Pig or Spark programming languages, and assorted helper scripts and utilities

2. Web archive database management, with support for the HBase distributed data store, and OpenWayback integration providing a friendly web interface to view stored websites

One can take advantage of the analysis tools (1) without bothering with the database management aspect of Warcbase – in fact, most digital humanities researchers will probably find the former more useful. This paper focuses on the former capabilities, showing how we can use the warcbase platform to carry out text and network analyses.

Using Warcbase on Web Archival Collections: Text Analysis

We have begun to document all warcbase commands on a GitHub wiki, found at https://github.com/lintool/warcbase/wiki. We begin with installation instructions, and then provide simple scripts written in Apache Spark to run the commands.

While possible to generate a plain text version of the entire collection, a more fruitful approach has been to generate date-ordered text for particular domains. If a researcher is interested in say, the Green Party of Canada's evolution between 2005 and 2015, they can extract the plain text for greenparty.ca by running the following script:

```
import org.warcbase.spark.matchbox.{RemoveHTML, RecordLoader}
import org.warcbase.spark.rdd.RecordRDD._

RecordLoader.loadArc("src/test/resources/arc/example.arc.gz", sc)
  .keepValidPages()
  .keepDomains(Set("greenparty.ca"))
  .map(r => (r.getCrawldate, r.getDomain, r.getUrl, RemoveHTML(r.
  getContentString)))
  .saveAsTextFile("out/")
```

All they would need to change would be the path/to/input to the directory with their web archive files, the path/to/output for where they want to save the resulting plain-text files, and the greenparty.ca value to whatever domain they might be interested in researching.

They then receive a date-ordered output of all plain text for that domain (as per the extractCrawldateDomainUrlBody command). It can then be sorted and used in other research avenues. For example, this plain text could be loaded into a text analysis suite such as http://voyant-tools.org/ or other digital humanities environments.

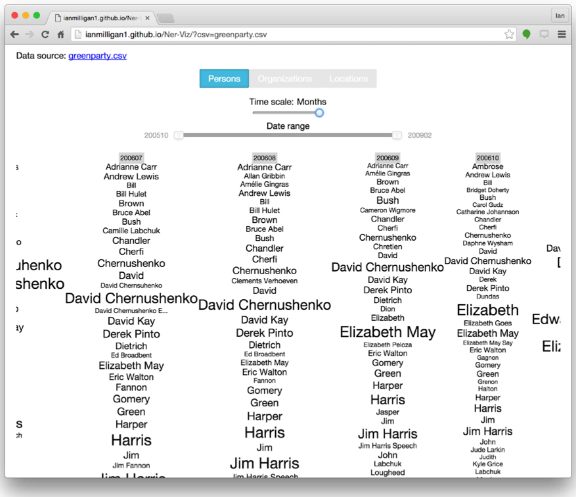

Figure 2: Named Entity Visualization within Warcbase

Termite
Topic Model Visualization

Figure 3: Termite Topic Model

We have also been experimenting with other visualizations based on the extracted plain text. Computationally intensive textual analysis can be carried out using warcbase itself. Using the Stanford NER package in parallel, we have a script that extracts entities, counts them, and then visualizes them using D3.js to help see overall changes in a web archival collection. Figure 2 below shows the output of the NER visualizer.

Finally, another text approach is topic modelling (Blei et al., 2003). LDA works by finding topics in unstructured text. To visualize topic models, we elected to use the Termite Data Server, which is a visual analysis tool for exploring the output of statistical topic models ("uwdata/termite-data-server," n.d.). As Figure 3 demonstrates, the visualization allows you to get a top-down view at the topics found in a web archive.

Warcbase presents versatile opportunities to extract plain text and move it into other environments for analysis. Unlike the keyword-based Archive-It portal, we now have data that can be inquired in many fruitful ways.

Using Warcbase on Web Archival Collections: Hyperlink Analysis

Warcbase can also extract hyperlinks. While text can be very important, these sorts of metadata can often be more important: allowing us to see changes in how groups link to each other, what articles and issues were important, and how relationships changed over time.

Consider Figure 4, which visualizes the links stemming from and between the websites of Canada's three main political parties.

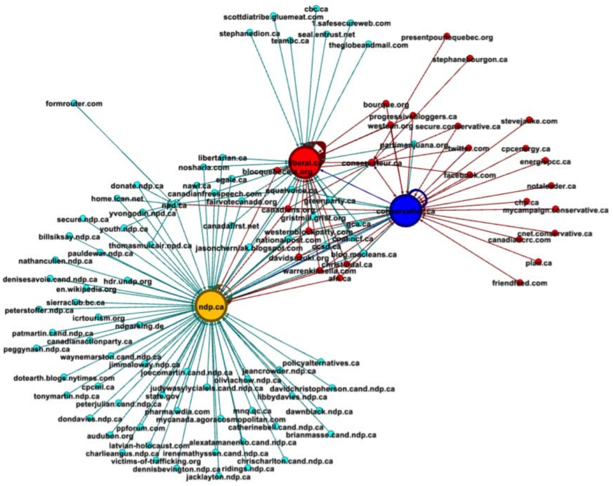

Figure 4: Three major political parties in Canada

Above, we can see which pages only link to the left-leaning New Democratic Party (ndp.ca), those that link only to the centrist Liberals (liberal.ca) in the top, and those that only connect to and from the right-wing Conservative Party at right. We can use it to find further information, such as in Figure 5.

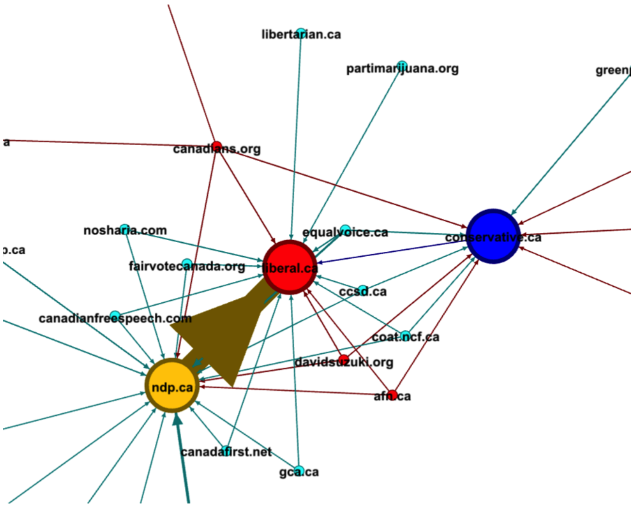

Figure 5: NDP attack

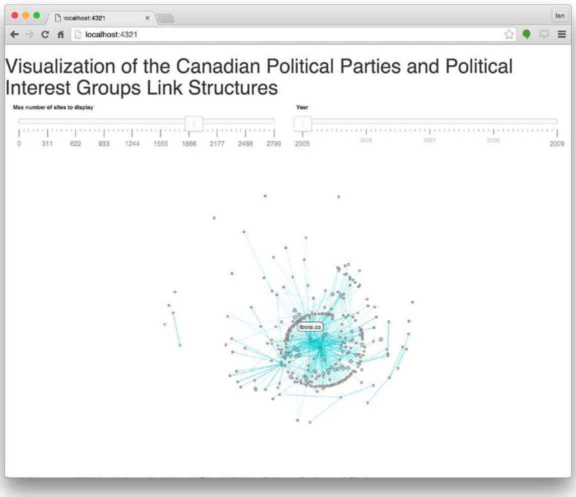
The above links are from the 2006 Canadian federal election. The Liberal Party was then in power and was under attack by both the opposition parties. In particular, the left-leaning NDP linked hundreds of times to their ideologically close cousins, the centrist Liberals, as part of their electoral attacks, ignoring the right-leaning Conservative Party in the process. Link metadata illuminates more than a close reading of an individual website would. It contextualizes and tells stories itself.



Visualization of the Canadian Political Parties and Political Interest Groups Link Structures

Figure 6: Link Visualization

While we have traditionally used Gephi to do analysis, importing material into Gephi from warcbase required many manual steps as documented at https://github.com/lintool/warcbase/wiki/Gephi:-Converting-Site-Link-Structure-into-Dynamic-Visualization. We have been prototyping a link analysis visualization in D3.js, which can run in browser (Figure 6).

Conclusions

With the increasingly widespread availability of large web archives, historians and Internet scholars are now in a position to find new ways to track, explore, and visualize changes that have taken place within the first two decades of the Web. Warcbase will allow them to do so. This project is among the first attempts to harness data in ways that will enable present and future historians to usefully access, interpret, and curate the masses of born-digital primary sources that document our recent past.

Representación De Otras Literaturas Mexicanas En Medios Digitales

Ernesto Miranda
mirandatrigueros@gmail.com
INAH, Mexico

Introducción

Este trabajo tiene como objetivo mostrar las posibilidades que ofrecen las herramientas digitales para representar literaturas de México pertenecientes a los pueblos originarios. Estas formas literarias han sido subrepresentadas y los acercamientos a ellas siempre han estado marcados por una visión parcial sobre los procesos intrínsecos que las caracterizan y que las distinguen de las literaturas oficiales de México.

Las conclusiones se presentan en base a los resultados de dos proyectos: por un lado la edición digital *Códice Mendoza* y por otro un prototipo digital para la representación de poesía ritual. Ambos proyectos, como se verá, ilustran las ventajas de la representación digital sobre la que se ha venido haciendo por décadas en soportes impresos.

Antecedentes

México es un país con una profunda tradición intelectual que viene desde mucho tiempo atrás de la llegada de los españoles. Las culturas que habitaron lo que hoy se denomina Mesoamérica lograron un enorme desarrollo científico y cultural, que se ve reflejado en su organización política, en su esplendor arquitectónico, en la precisión de sus cálculos astronómicos y en sus expresiones artísticas y literarias.

Es importante mencionar que hoy en día ese conocimiento sigue vivo a través de más de 60 culturas que cohabitan en el territorio mexicano. Esas culturas, en mayor o menor medida, son portadoras de ese conocimiento milenario, y siguen representando y actualizando ese saber a través de sus literaturas.

El investigador británico Gordon Brotherston se ha referido a estas literaturas como los libros del "cuarto mundo", expresiones literarias que no necesariamente responden a los estándares que hemos definido durante siglos en la tradición intelectual hegemónica como literatura. (Brotherston, 1997)

Entre los ejemplos que podemos encontrar a lo largo del continente se encuentran los quipús andinos, y por supuesto los dos casos que nos ocupan: la poesía ritual y los manuscritos pictóricos mesoamericanos. Vale la pena recordar que muchas de estas culturas tenían una forma integral y holística de representar el cosmos, por lo que estas expresiones no se entienden de manera aislada de otros factores culturales como los rituales, la guerra, la caza o los fenómenos naturales.

Estos ejemplos de formas literarias no canónigas, que se multiplican por todo el continente americano, deben ser reconocidos como textos en sí mismos. Pueden ser entendidos como una modalidad enmarcada de lenguaje y todos cuentan con coherencia interna (estructura, formato y orden); codificación que le permite resistir al paso del tiempo; todas son entidades en sí mismas y cuentan con una estructura y una función comunicativa.

Es muy probable que los mecanismos de representación que hemos usado hasta ahora hayan sido poco sensibles a las necesidades formales que este tipo de expresiones exigen. Debemos reconocer que nuestros acercamientos están siempre enfocados a través de una visión binaria entre lo oral y lo escrito, irrelevante e insuficiente para las literaturas de la América Indígena.

En ese sentido hemos sido indiferentes o insensibles al ignorar todas estas categorías de representación. Si bien las hemos estudiado, y gracias a una enorme tradición de estudiosos desde fray Bernardino de Sahagún, pasando por el Padre Ángel María Garibay hasta llegar a Miguel León Portilla y Alfredo López Austin, las pudimos conocer, no hemos resuelto aún como adecuarlas para que su representación formal responda a la complejidad de su esencia.

Es necesario que entendamos que estos textos mesoaméricanos son mucho más complejos de lo que hoy leemos como medios escritos. Son indisociables de todos los elementos que lo integran: material, oral y ritual. Son diacrónicos y dialógicos y al mismo tiempo multimediáticos.

Por último es necesario tener en cuenta que las dos formas expresivas de las que nos ocupamos, tienen origen en el México prehispánico, y en algunos casos han sobrevivido a los procesos de aculturación. También, estas dos expresiones resultan únicas por sus características y, hasta el momento en que estas líneas se escriben, el autor no ha podido conocer otros proyectos que aborden desde una perspectiva holística el problema de representación de estas literaturas o expresiones culturales mexicanas en otro tipo de medios.

Representación de códices mexicanos en medios digitales

El primer proyecto que se abordará es la edición digital del *Códice Mendoza* esfuerzo histórico por ofrecer en plataformas digitales un nuevo acercamiento a estos manuscritos históricos. Estos documentos pictográficos son considerados objetos culturales complejos que representaban el conocimiento histórico, simbólico, calendárico, económico y ritual de los antiguos mexicanos. Fueron creados en diferentes tipos de soportes como el papel amate, el papel de maguey o el papel europeo, después de la llegada de los españoles.

La escritura de los códices mexicanos no es fonética salvo en el caso de los códices mayas. En el caso de los códices zapotecos y mexicas la relación entre las imágenes es lo que determina el significado. Este tipo de escritura no alfabética ha sido definida como semasiográfica (Boone Hill, 1994, 20). Asimismo, integran en un todo holístico lo que nosotros podríamos considerar como elementos separados. En ese sentido, los podemos considerar como textos multimedia ya que echan mano de imágenes, oralidad, memoria, ritual e incluso elementos no directa o físicamente asociados como esculturas, sitios sagrados o algún corpus de inscripciones. De igual manera, la lectura de estos documentos era un acto performático y ritual, sólo ejecutado por quien Jerome Rothenberg llamaría un técnico de lo sagrado.

En síntesis podemos decir que los códices son soportes abiertos, dinámicos, participativos, interactivos y 'suceden' en tiempo real. Por estas características resulta muy difícil imaginar que podamos representarlos en un soporte plano bidimensional como una edición en papel.

El especialista Miguel León-Portilla ha considerado que es insuficiente traducir un códice a una edición en papel. Quizá lo mismo se puede decir de cualquier traducción y transliteración, aunque por las características descritas arriba, se acentúa la complejidad en el caso de los códices. León-Portilla también estableció una interesante analogía, muy adecuada para nuestro tema, donde compara a los CR-ROMs con los códices. Enfatiza que ambos tienen varias formas de lectura, los dos son multimedia al combinar imágenes, texto y sonido, al tiempo que ambos tiene un afán totalizados de diversas facetas del conocimiento. (León-Portilla, 2003)

Hoy, el equivalente a un CD-ROM sería una aplicación web o una aplicación nativa para algún dispositivo móvil.

En este sentido, la edición digital del *Códice Mendoza* demostró que la representación digital es óptima para los códices mexicanos. Su complejidad semántica y también su carácter multimedial se representan de manera más holística en medios digitales. En este sentido vale la pena recordar las palabras de Willard McCarty cuando señala que toda traducción de un medio textual a un medio digital, conlleva una importante pérdida de sentido (McCarty, 2008). Sin embargo, en este caso la pérdida es mucho menor ya que lo que estamos trasladando es un medio dinámico a otro medio dinámico.

Del mismo modo, consideramos que el resultado funciona de manera doble en varios sentidos: permite un acercamiento al público en general y también un acercamiento a los académicos especializados. Al mismo tiempo, permite una representación más completa pero también las herramientas tecnológicas nos permiten un estudio más profundo de estos documentos, principalmente por su accesibilidad.

Representación de poesía ritual en medios digitales

Dentro del territorio mexicano existen más de sesenta lenguas indígenas, que con sus variaciones dialectales son más de trescientas. Como en todas las lenguas del mundo, son complejísimas las expresiones literarias verbales que residen dentro de estas lenguas y estas culturas.

Estas expresiones son consideradas como patrimonio intangible, inmaterial o vivo y pese a que existe una buena cantidad de registros, son escasos los que recaen en su valor literario, y en muchas ocasiones se desdeña este tipo de acercamientos frente a los de las ciencias sociales.

Al igual que los códices, estas expresiones son dinámicas, abiertas, multimodales, participativas e interactivas. Dentro de la enorme diversidad de expresiones, se encuentran los cantos chamánicos o rituales, que por sus características son aún más complejos. En ellos, también inciden aspectos rituales, estados de trance y otros elementos contextuales difíciles de representar como pintura facial, eructos o incluso convulsiones.

Hasta hace poco tiempo estas expresiones se representaban y se estudiaban a través de ediciones impresas. En palabras del teórico John Miles Foley, esta forma de trabajar con las formas verbales aplana o diseca su expresividad. Asimismo, los acercamientos académicos han mostrado poco interés por las características poéticas de estas expresiones[1]. Fue gracias a enfoques novedosos y propositivos como la etnopoética, que se logró un cambio de actitud hacia cómo trabajar estos materiales. (Miranda Trigueros, 2007).

Al igual que en el caso de los códices, los medios digitales parecen mucho más adecuados para representar estas expresiones orales. Podemos ser más fieles en la representación, incluir un mayor número de canales de significado, mayor contexto y ser más transparentes con la enunciación original.

En respuesta a estas necesidades el que escribe estas líneas creó el prototipo DARP (Digital Archive of Ritual Poetry) como tesis de maestría en 2013, para obtener el grado de maestro en humanidades digitales en el King's College de Londres. . El prototipo está basado en un fragmento del canto chamánico de la reconocida sanadora mazateca María Sabina.

El resultado que nos ofreció el prototipo es un medio digital que nos permite representar de una mejor manera este tipo de expresiones. A diferencia de esfuerzos anteriores, donde, por ejemplo, se representaban en papel acompañados de un CD de audio (Miranda Trigueros, 2007), la integración total de la representación aural con el texto lo hace que funcione mucho mejor. El uso de una aplicación simple basada en Javascript y JQuery permitió sincronizar el audio al texto en una lectura interactiva. Asimismo se integraron otros elementos hipermediales que amplían la comprensión del texto y su significado.

Por otro lado, la creación del prototipo permitió comprobar que la codificación del texto permite un acercamiento totalmente novedoso al contenido, obligando al investigador a hacerse preguntas hasta ese momento inéditas (Sperberg-McQueen, 2009, 35). La codificación con TEI y XLST permitió la creación de índices automatizados que estructuran el contenido textual y ofrecen herramientas al investigador para hacer un análisis mucho más ágil y certero que si lo pensáramos en términos manuales.

El prototipo busca convertirse en un recurso más sólido para lo cual se plantean dar los siguientes pasos:

- definir una ontología básica de los elementos que pueden encontrarse dentro de este tipo de expresiones.
- Integrar un corpus de diferentes expresiones que se encuentren a lo largo del territorio nacional
- Creación de una base de datos consultable para poder encontrar elementos comunes y desde allí establecer una poética de los cantos rituales mexicanos.

Conclusiones

Las herramientas digitales nos permiten representar de mejor manera los llamados libros del cuarto mundo.

Podemos crear ediciones más holísticas, precisas, fieles y con un mayor grado de contexto que permite una mejor comprensión del objeto representado.

Se puede decir también que después de haber trabajado en dos casos disímiles en su formato, pero análogos en su origen y en su complejidad, la representación de un medio dinámico siempre debe de ser representada en un medio dinámico.

Tanto en el caso de la poesía oral ritual como en el caso de los códices se hace patente que la complejidad de las expresiones culturales prehispánicas encuentra una representación más rica y transparente a través de las herramientas digitales. Sus características dinámicas, abiertas, procesuales, interactivas y multimediales obligan a pensar en los medios digitales como óptimos para la representación y estudio de este tipo de literaturas. Los recursos digitales son más fieles al original, abren más canales semánticos, ofrecen más contexto, y una forma más holística y transparente de presentación.

Asimismo, en ambos casos encontramos enormes posibilidades para los interesados en el estudio de la cultura mexicana, para entender mejor este enorme patrimonio, esta literatura sumergida, donde creemos que es necesario profundizar en las ventajas y virtudes que nos ofrecen las herramientas digitales para un replanteamiento total en el estudio de ellas.

Notes

[1] Hay varios factores que inciden en la falta de preocupación por representar de manera más completa estas expresiones, principalmente hay poco interés de parte de los antropólogos por las características meramente poéticas de este tipo de literaturas En general, las consideran como un accesorio para conocer otros aspectos de la cultura a la cual pertenecen, una fuente más para el estudio del otro. (Rothenberg and Tedlock, 1970).

Toward A Use-Value Paradigm For The Sustainability Of Digital Research

What is Sustainability?

Sustaining the results of digital humanities research projects remains an ongoing challenge within the wider DH ecosystem. This is particularly the case for research infrastructure developments, where the scale, complexity and indeed the overarching aim of the project to serve a potentially still emerging research community makes their continued accessibility even more important, and even more difficult.

Like any enduring challenge, sustainability of complex digital resources has been subjected to a certain amount of scholarly investigation (though less overall than one might expect). What a survey of this literature shows, however, is that the perspectives on how to face the challenge of sustainability are highly dependent on how a project or infrastructure views itself: for example, when viewed primarily as a *form of organisation or institution*, the sustainability model proposed will likely focus on the necessary 'business model' for maintaining the services created (Maron et al., 2009). The Archives Portal Europe (APE[1]), for example, established itself as a Foundation after the end of the project, in order to maintain the vital functions of the infrastructure and to further connect with other projects and similar initiatives.

Alternatively, when project outputs are viewed as a *tool or technical platform*, a sustainability proposal will primarily take into consideration issues and practices such as migration and curation of elements such as the repositories where the data are stored and continued maintenance of work environments and specific tools. The TextGrid project[2], for example, has been hugely successful in rolling its activities forward over a long period, continuing to make its services available to users. At its best, this approach results in a broad focus on software durability, documentation of processes and the modularity of services (Buddenbohm et al., 2015).

But to understand sustainability thoroughly we must also engage a second huge and unresolved issue in digital humanities, that is the reuse of project outputs and data. In particular, the "Log Analysis of Digital Resources in the

Arts and Humanities, or the LAIRAH project (Warwick et al., 2008) has contributed significantly to our understanding of what factors enable digital projects and tools to be found and adopted by users. From the results of this project we can see another model for the sustainable project to emerge, in which the *communication and branding* of the project is a key element of its success.

The CENDARI Project and its Approach to Sustainability

This presentation brings forward the hypothesis that a successful approach to sustainability for Research Infrastructures needs to be comprehensive; an approach that doesn't just consider data or technology, community, communications or processes, but in fact all of them simultaneously. In addition, it should focus not only on a project as a collection of tangible and intangible assets, but also on the potential user base for these assets, and what these users consider valuable about them.

Discussion of this user-centred approach to sustainability will be based on the experiences of the Collaborative Digital Archival Research Infrastructure (CENDARI[3]) project's year-long sustainability planning exercise, conducted from January 2014-January 2015. This exercise, which built upon previous work in the project and a strong link to the Digital Research Infrastructure for the Arts and Humanities (DARIAH ERIC[4]), resulted in a set of principles and processes for mapping and sustaining user value from the project for the medium and long terms. Although both the generic process (which will be released as a sustainability toolkit at the end of the project) and the specific actions implemented by the project match on some level the specifics of the CENDARI development, they also reflect the reality, identified by Joris Van Zundert, of the "fluidity" of research infrastructure, caught up in both the digital information lifecycle and the creation of knowledge by end users, as well as the software components (Van Zundert, 2012).

The Sustainability Planning Cycle

The CENDARI sustainability planning process was comprised of a series of 4 stages, from pre-planning to closure and post-project actions, each of which contributed to the overall, holistic sustainability strategy. This cycle was intended to counteract a natural impetus within projects to view sustainability as a concern only for the final phase of the project, rather than one to be integrated into the project's development and even its conception.

The CENDARI Assets and Multilevel Sustainability Action Plan

As a key component of the second and third phases of the CENDARI project sustainability planning process, the project carried out a thorough audit (including a stakeholder validation meeting) to refine its understanding of what assets the project had generated and how they could be maintained, shared and indeed passed on to its key users for further development. This process identified 7 categories of assets as most likely to find future usage, each of which posed unique challenges in how they could be captured, made visible and sustained. It has been one of the greatest challenges of the CENDARI sustainability planning process to ensure that for each of these areas we could find a solution, as we would for our personal work data, to make them findable and reusable in a contextualised manner, and preserve them in 'multiple formats and multiple locations.' For each asset type, the audience for potential future use is different, and therefore the solution proposed is as well.

The CENDARI **portal** is the most visible of its assets, representing the final synthesis of the project's activities and its main point of access. For many projects, this would be where sustainability planning would not only begin, but end. CENDARI approached this sustainability challenge via a three pronged strategy, guaranteeing 3 years of access through the German arm of DARIAH but also ensuring new communities and new approaches would be recruited to continue development.

But the portal is not only useful in its complete final form, but also as a collection of unique **services, tools and components** optimised to support DH research. This possible reuse of the project outcomes was foreseen from the beginning, and a very modular, service oriented architecture was adopted for the project. The tools therefore require a sustainable pathway outside of the portal. That said, however, connecting tools with potential user bases is a constant challenge. The software community practice of using GitHub to share software was adopted, but further awareness raising was also required to ensure the maximal future use for the tools.

CENDARI holds a lot of **data** from different sources, some unique to the project, others well signposted elsewhere, and with different requirements and expectations for sustainability. This has been its legacy as a project seeking to reuse archival data for historical research, where the culture and ability to share data is unevenly developed. The CENDARI data portal gives access to this data, and the project's data agreement and license have been developed with DARIAH as a co-signatory, so in many ways DARIAH had already agreed from an early point in the project to sustain this data. But DARIAH is not well-known as a data provider or source, and this solution alone may not maximise visibility and reuse. Therefore a redeposit protocol for unique data with an external trusted source has also been facilitated.

The **Archival Research Guides** exist as a particular subset of the data unique to CENDARI, but their status as both primary and secondary research sources justifies their consideration as an asset class in themselves, in particular because of the manner in which they challenge existing norms of publication, communication and evaluation in the discipline of history. As extended and enhanced publications, incorporating analysis, links to data sources, multimedia objects, and links to project ontologies, these guides need to be delivered within the project portal. But to sustain these unique works of scholarship only in that format would again potentially limit their visibility. They will therefore be offered in one or more export formats, as well as becoming the focus of both a review publication and a research paper to be submitted to a mainstream (not digital) historical journal. In this way, their contributions to scholarship can be recognised as independent from the format in which they have been delivered.

Given how particular many of the project experiences in building for the DH community had been, a specific audit of CENDARI's **tacit knowledge** was also undertaken, and several white papers and process oriented toolkits have emerged from the project on the foot of this (including, for example, a 'White Book of Archives' documenting the project's experience of federating highly heterogenous data from traditional collection holding institutions). As a related issue, some of the project's **management assets** may also have a future utility for others.

Perhaps the least easily defined and sustained aspects of the CENDARI project will be the **communities** - mixed and homogenous groups of historians and other humanistic scholars, collections experts and technologists - it has brought together and formed. Interconnectivity between cognate projects will be a key resource for this, as some communities will have interests across these projects, and networks can and should be shared. But some of the community aspects are very unique to CENDARI, and will have a specific role in guiding the future use of the portal and its components: for this reason, the project will use another DARIAH mechanism, the working group, to provide a structure for continued development of project concerns and assets.

As can be seen from this description, CENDARI has made both its own sustainability and the potential future role of the DARIAH ERIC in the sustainability of medium-to large-scale digital projects in Europe into key areas of applied research and development. The resulting tool-kit for sustainability will hopefully assist future projects in extending both their sustainability planning and strategies in the future.

If You Build It Will They Come? Digital Infrastructure And Disciplinary Practice In Language Documentation

Simon Musgrave
simon.musgrave@monash.edu
Monash University, Australia

Nick Thieberger
thien@unimelb.edu.au
University of Melbourne

Digital scholarship depends on the availability of data in forms which are tractable to computational techniques, implying storage of data in sustainable archives. This is perhaps even more true of research in the humanities than in science. As the ESF observed in their 2011 report on research infrastructure: "in the hard sciences, datasets tend to be generated rather than collected and tend to be homogeneous in nature .... In Humanities, data tends to be collected and to be heterogeneous in content and format" (European Science Foundation, 2011:5). It is both the possibility of storing the data and the stored data itself which makes up critical infrastructure in many disciplines and innovative scholarly practices may not develop in the absence of such infrastructure. Here, we discuss the development of digital infrastructure in the field of language documentation (within the discipline of linguistics) and try to assess the extent to which the provision of well-funded (by the standards of the discipline) infrastructure is changing scholarly practice.

Language documentation as a field in linguistics dates from the publication of the seminal paper 'Documentary and descriptive linguistics' (Himmelmann, 1998). It is in large part a reaction by linguists to the challenge of language endangerment (see Hale et al., 1992; and Musgrave, 2015 for a recent survey) and it emphasises the collection of large bodies of data of languages in use. Language documentation began at the same time that it was becoming feasible to make high quality digital recordings, both audio and video, on reasonably priced equipment. Archiving of documentary material was a core component of the program as conceived by Himmelmann, and this was immediately seen to mean digital archiving. Indeed, it can be argued that the whole enterprise of documentary linguistics falls comfortably within the digital humanities (Thieberger, 2014).

Two projects began in the first decade of the century to fund researchers to make collections of documentary materials. One was based at the Max Planck Institute for Psycholinguistics (Nijmegen, The Netherlands) and funded by the Volkswagen Stiftung;[1] the other was based at the School of Oriental and African Studies (London, UK), funded by Arcadia.[2] MPI Nijmegen had a well-resourced technical department which took responsibility for developing the archiving stream of the DoBeS project. HRELP had to build their archive from scratch; no existing resources at SOAS were available to support their work. For both projects, it was a requirement of funded research that data were deposited in the relevant archive. Both archives, however, are open to deposits from non-funded researchers.

The DoBeS archive is subsumed under a larger archive called The Language Archive[3] which also holds language data from other MPI activities and from other institutions and projects. Figure 1 shows the cumulative deposits in TLA for DoBeS material and for material classified as donated. The figures here represent the number of files retrieved from the catalogue based on their 'Last modified' field. This does not reflect the accession date of the file in all cases, but it is a reasonable proxy.[4]

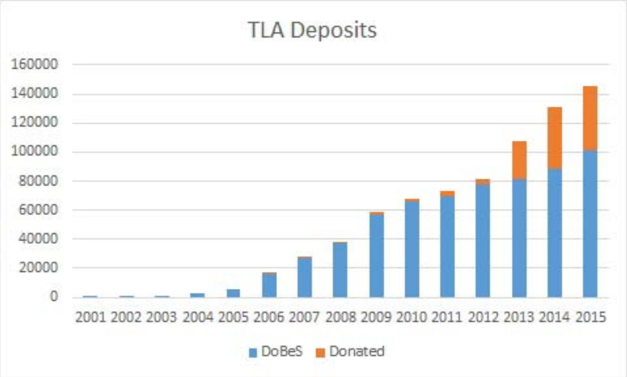

Figure 1. Cumulative deposits in TLA

The archive at SOAS is known as ELAR. Figure 2 shows cumulative deposits in that archive; figures are drawn from information provided by ELAR in the annual reports of HRELP and represent bundles of data deposited rather than individual data files.

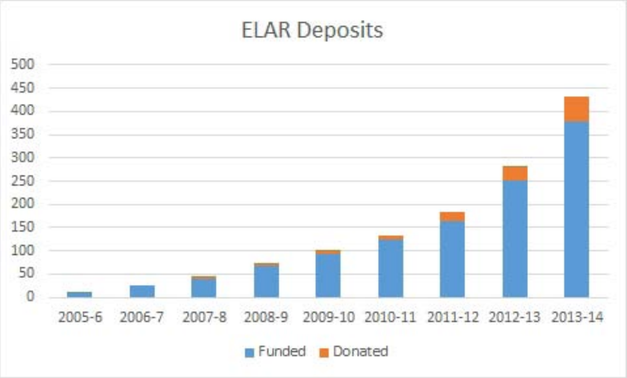

Figure 2. Cumulative deposits in ELAR

Although both archives have grown over the periods shown, the patterns are different, with a flattening out in the DoBeS deposits starting around 2011. There was no funding round in 2010. Projects were funded in 2011 and 2012 but 2012 was the final round and while the archive still expects to receive deposits from the last two funding rounds, such deposits will continue to decrease.

Figure 3 shows the percentage of donated deposits based on the cumulative figures for each archive.

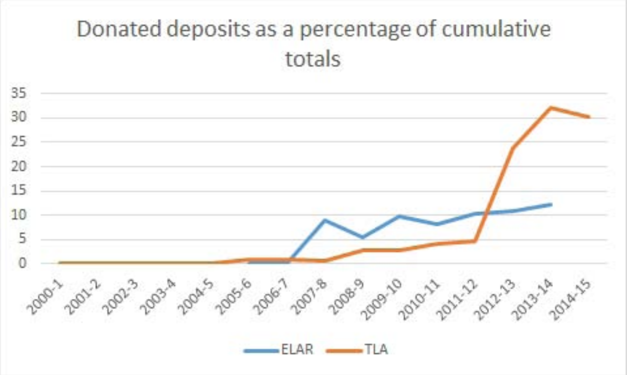

Figure 3. Comparison of the percentage of donated material in the two archives

For both archives, once the infrastructure was established, non-funded deposits make up an increasing proportion of the archive. TLA has added large amounts of donated material in recent years, in part a conscious effort by the archive to expand its activities beyond the DoBeS project by taking responsibility for existing data sets. One barrier to archiving data is meeting an archive's requirements particularly in the area of metadata. ELAR uses a more flexible metadata system than TLA (which uses the IMDI scheme, https://tla.mpi.nl/imdi-metadata/). We might therefore expect more voluntary deposits in ELAR than in TLA, but this is not the case in these data. The different proxies we are using to assess these trends here make it difficult to compare the two exactly, but we can see a clear trend over the last decade which suggests that archiving data is increasingly a part of scholarly practice in this area of linguistics and that there has been progress since the rather gloomy summary provided by Thieberger (2011).

One question raised by this data is the extent to which the donated data is coming from researchers who have also been funded by the relevant program. Both projects provide training to funded researchers and it is possible that the practices learned there are continued when researchers collect data in other projects. In the case of TLA, 36 data sets have been deposited which were not the result of DoBeS funding and in six cases the researcher(s) had been funded by DoBeS for other work. ELAR has material not associated with funded projects deposited by 37 researchers of whom eight had been funded by ELDP for other work. These figures suggest that acquiring experience of the archiving process is a factor in future work practices, and that this factor has had very similar levels of effect in both archives.

The data which we have used in this paper are limited and important questions remain unanswered. The most obvious is how and to what extent are these resources being used. ELAR provide some usage statistics; based on logs for the month of November 2013, estimated traffic on the catalogue and the archive portal is around 680 users per day with an estimated 1.66 million pages served per year. These numbers suggest that the archive is being used a lot, but it is not possible to tell who the users are or what they are doing on the site. More fine-grained data are needed to tell us whether the availability of resources such as ELAR and TLA is changing scholarly practice in accessing language data.

The data we present here indicates that, in the field of documentary linguistics, the availability of good infrastructure for digital archiving has had an impact on scholarship. Data is being deposited in the archives beyond the requirements of the relevant funding bodies, and in the case of the archive for which usage statistics are available, it seems that the level of activity is substantial. These changes may in part be due to the level of training provided to funded researchers; but such training should, we suggest, be considered an essential part of the research infrastructure of digital scholarship. Another reason for the changes may be that linguistic scholarship is moving towards recognising primary data as scholarly output (Thieberger et al., 2016). This process is only possible when primary data can be cited using persistent identifiers provided by a repository (cf. NSF (Task Force on Data Policies), 2011:9 (Recommendation 2)). There is therefore the possibility of a virtuous circle here: adoption of best practice in data management will lead to more robust research methods in the field as well as career benefits for researchers.

The Dialogic Turn and the Performance of Gender: the English Canon 1782-2011

Understanding how the spoken language is represented in novels over time, and how this relates to gender and other characteristics of the represented speaker and the author is a key question in the Digital Humanities. Previous work has explored such questions lexically, focusing for example on differences in word choice between male and female authors. Yet while such lexical stylistic approaches have been computationally sound (Argamon 2003, Olsen 2005, Yu 2014, Rybicki 2015), a purely lexical approach is known to have serious methodological dangers. Individual lexical items are highly conflated with topic, genre, author idiosyncrasies, and era, making it difficult to draw general conclusions, particularly over long time periods. An even greater problem is that this approach essentializes gender a priori (Bing & Bergvall 1996), neglecting how the complex interplay between an author and the characters they portray creates the performance of linguistically gendered writing.

We propose to draw from methods in social psychology (Newman 2008), network analysis (Schwartz 2013), and corpus linguistics (Biber 1991) to offer two innovations in the analysis of novels. The first is a new metric for characterizing dialogue, called *dialogism*, that references Bakhtin's theories of novels and dialogue (1935). This measurement uses abstract grammatical features in the text to characterize the extent to which it is dialogic. By using categories like parts of speech, our method avoids the genre-specific and era-specific problems of individual words. Our second innovation is a computational analysis of the performance of gender within dialogue. We explore the relationship between the gender of the characters portrayed in novels and their language, which illuminates the performative aspects of gender.

Although we do not entirely escape the entrapments of gender as a defining authorship trait in our analysis, we do use it to develop deeper understanding of dialogue as a whole rather than simply a tool of reifying stereotypes. From our innovations, we propose to answer three important questions: 1) what is the composition of the dialogic landscape in fiction? 2) what characterizes dialogue linguistically? and 3) how is author gender and the gender performed by characters reflected in the language of dialogue?

Data and Dialogue Extraction

Using three corpora of novels from the beginning of the romantic period to the present day, we construct a corpus that contains 1,106 novels from 1782 until 2011. This corpus is largely composed of the standard English canon, with the pre-1900 portion drawn from Chadwyck-Healey, and therefore exhibits the bias present in canonical authorship, containing 851 male-authored novels and 255 female-authored novels.

We introduce and use a new dialogue extraction system to locate quoted text based on a series of rules and regular expressions.Then, using a number of high-precision patterns such as <QUOTE>-<PRONOUN>-<VERB>, we assign speaker gender to quotes associated with gender-disambiguating pronouns (*he, she,* etc.) or proper names that can be reliably distinguished from gendered namelists. We evaluate our system on texts hand-labeled for quotes and speaker identity (Austen's *Pride and Prejudice* (He 2013), Cooper's *The Spy*, and Fitzgerald's *The Great Gatsby*), resulting in average quote extraction of 94.5% of quotes at 95.4% precision and gender attribution of an average of 44.4% of the extracted quotes at 93.1% precision.

The Dialogic Landscape

We first statistically evaluate the distributions of extracted dialogue to see whether novels have become more dialogue driven over time. Controlling for novel length (Figure 1), we measure mean quotes per thousand words per decade, finding a steady increase over time regardless of author gender (Figure 2). Overall, male authors add roughly 1 quote per 20 years (r^2 =.80); female authors 1 quote every 30 years (r^2 = .64).

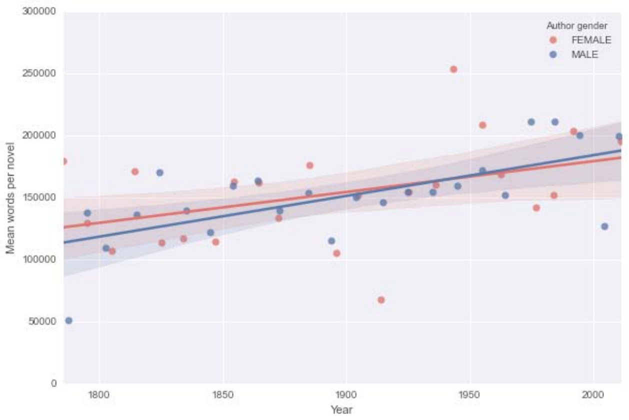

Figure 1: Average novel length over time

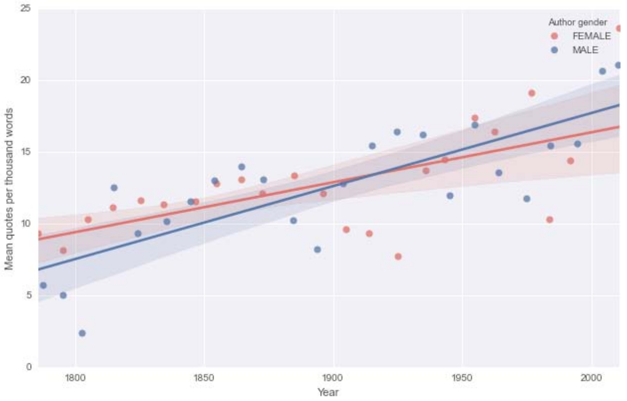

Figure 2: Quotes per thousand words by author gender over time

Next, we examine the relative attention that authors pay to characters and gender, using dialogue as our lens. From the extracted speaker-assigned quotes we calculate the proportion of male- to female-spoken dialogue per novel. This allows us to understand the gender of the characters portrayed in our texts and how this composition has changed over time.

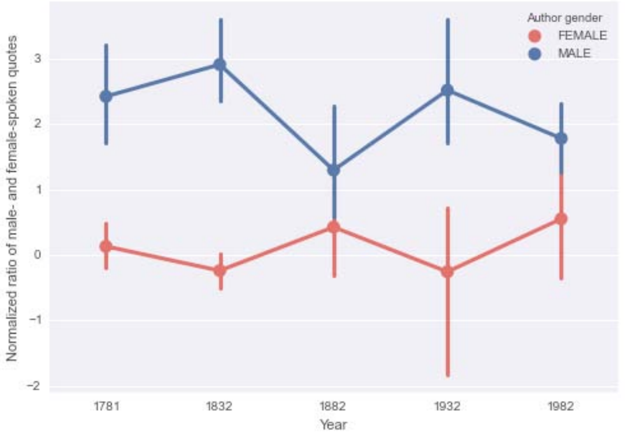

Figure 3: Mean normalized ratio of male- and female-spoken quotes by novel over time by author gender, bucketed by 50 year intervals

We compute the mean of a normalized ratio of words spoken by male versus female characters per novel, bucketed by 50 year intervals (Figure 3). This ratio is normalized such that it forms a continuous spectrum centered at 0, with +1 signifying that male characters spoke twice as often; -1 that female characters did.

Here, we see that male authors tend to write male-spoken dialogue and female authors female-spoken dialogue, but that overall, female-authored dialogue tends to be close to balanced (mean = -.04) while male-authored dialogue is far from it (mean = 2.5). An interesting leap towards balanced portrayal happens among male authors at the beginning of the 20th century, influenced largely by authors such as Henry James, E.M. Forster, and Booth Tarkington.

Linguistic Characterization of Dialogue

To discover the underlying linguistic differences between narration and dialogue, we perform Multi-Dimensional Analysis (MDA) on the dialogue in our corpus, using a slightly modified set of Penn Treebank part-of-speech tags as distinguishing features. While it is not a classification algorithm, MDA isolates factors such that data with similar features are grouped together. These factors contain features that are positively or negatively correlated with one another. Effectively, even though no class labels are used, these factors reveal strong feature relationships for dialogic text.

Based on this analysis we propose a new dialogue metric, *dialogism*, that is robust to lexical choice and transportable across corpora. The new metric is constructed from the ten factors (out of 16) with $r^2 > 0.5$ when used to separate narration from dialogue and considers both positive indicators and negative indicators of dialogue, shown in Table 1. Figure 4 shows the high overall separation between narration and dialogue that our metric achieves (Kolmogorov-Smirnov value = 0.89).

+	-
Present tense verbs, bare verbs, modals, 1st/2nd/"it" pronouns, Wh-pronouns, interjections, existential there, adverbs	past tense verbs, 3rd person pronouns, gerunds, particles, nominalizations, determiners, Wh-determiners, prepositions and subordinating conjunctions, adjectives

Table 1: Positive and negative contributors to dialogism score

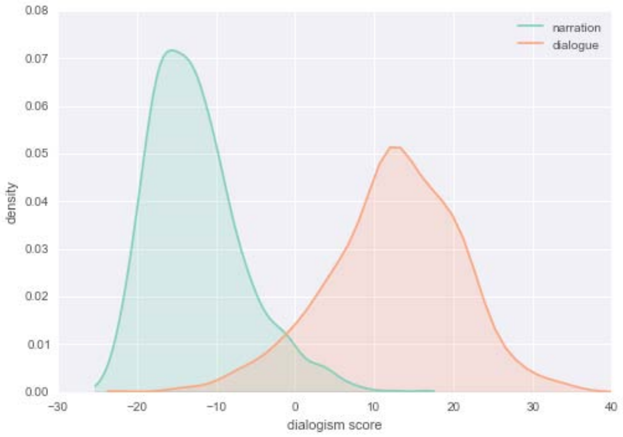

Figure 4: dialogism scores for narration and dialogue

Examing dialogism over time, we find that the distance between narration and dialogue has increased since the 18th century, and that, as a whole, novels are becoming more dialogic. At the same time, visualizing the outlying data quantifies the effects that shifts in literary style, for instance, modernism in the early 20th century, had in terms of dialogism.

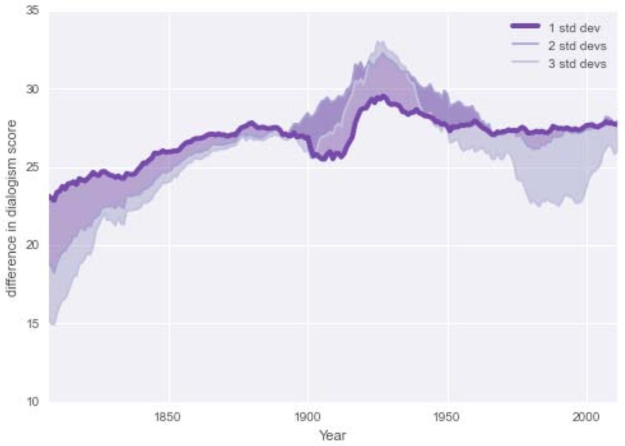

Figure 5: Difference in dialogism scores for dialogue and narration over time for texts within 1 (73.1%), 2 (93.5%), and 3 (99.5%) standard deviations of the mean difference.

Gender in Dialogue: Performance and Authorship

We finally turn to the performative aspects of gender: how do authors perform gender through the speech of their gendered characters? Which authors most significantly differentiate their male and female characters through dialogue?

Using the same corpus, but subsampling to balance for speaker gender, we isolate author gender effects and use these results combined with the original data to isolate speaker gender effects. This analysis reveals that the differences between male- and female-authored dialogue cannot be accounted for solely based on either author gender or on the genders of the speakers they portray. Author gender accounts for 64% of the variation between male- and female-authored dialogue while other speaker gender effects account for 36%. However, because the standard deviation of this ratio is so high (23%), this is an indication that some authors are more heavily influenced by their own genders and some more by the characters they portray.

Digging deeper into the question of which authors are better than others at differentiating male and female characters through dialogue, we perform t-tests on the male- versus female-spoken quotes for each author. Shown in Figure 6 are the authors who differentiate their male and female characters through dialogue at $p < .0005$. Notably, while most authors portray female characters as more dialogic in speech, a small minority do the opposite (above, Maria Cummins), a trend that also holds at higher p thresholds.

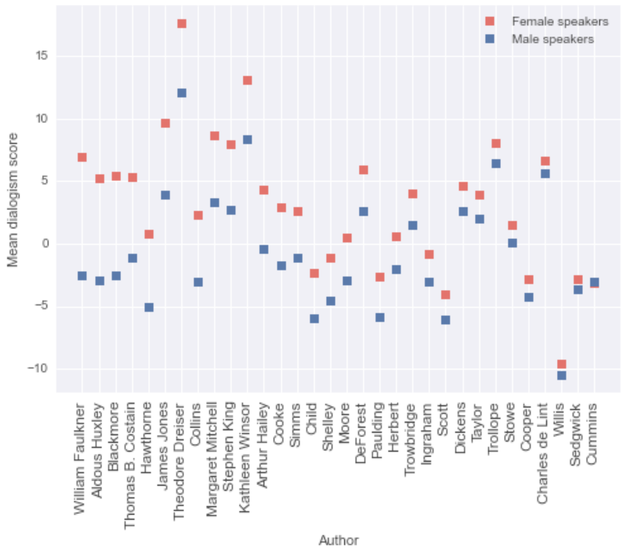

Figure 6: Authors whose male and female characters are significantly differentiated by dialogism score at p < .0005

Conclusion

The development of the novel is marked by an increased use of dialogue over time. This suggests that the deepening of characters was accompanied by, or may be an effect of, a shift of attention towards performative modes of characterization. Moreover, this transformation to a more dialoguedriven structure bears a gendered dimension, suggesting that the depiction of sociality by female novelists favored a more realistic gender balance than the predominately male social models favored in maleauthored texts. Our work suggests that the presence of any gendered language in the text may be contingent upon the mode of performance adopted by the author, regardless of gender, an observation supported by the variation in both dialogue cast composition and dialogism at the beginning of the 20th century, when a shift in literary style occurred. Further, the strict delineation of midnineteenth century sociality into the gendered public and private spheres, as represented by the novel, is itself a deeply gendered understanding of sociocultural codes more true of maleauthored texts than femaleauthored ones. The substantial effects that speaker gender has on dialogue indicates that perhaps not only are novels intrinsically dialogic, but that dialogue itself is intrinsically performative. Thus, the performative nature of a novel is itself deepened by the degree to which its' author differentiates the characters through a gendered performance of dialogue.

As most of modern and pre-modern western writing systems explicitly represent division of the words in a sentence by spaces or breaks, it has been easy to use computers to analyze texts based on each word and its meanings. However, there are several modern and pre-modern writing systems that do not explicitly indicate word separation in texts; that is, all words in a sentence are contiguous. A major contemporary representative of this kind of writing is seen in the language system of East Asia. Moreover, a popular Japanese pre-modern writing system called kuzushi-ji (cursive style characters) had often been presented with undivided characters even in typesetting until the late nineteenth century (Fig. 1, Fig. 2). As the lack of word-separation has been evoking not only ambiguity but also multiple interpretations, it has formed an aspect of cultural richness in Japanese culture. However, as a result, Japanese texts have intrinsically presented difficulties: not only in the case of textual analysis but also in both manual and automatic transcription in the digital era. This presentation will discuss problems in these writing systems and the current situation of attempts to resolve them through the methods of digital humanities.

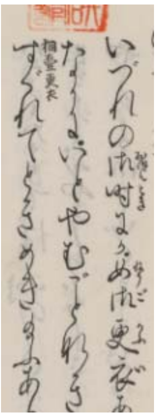

Fig.1: Typesetting printing (*Ise-monogatari* (Tales in Ise). Saga-bon. 1608. http://dl.ndl.go.jp/info:ndljp/pid/ 1287963/6)

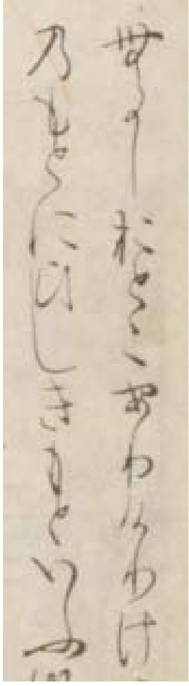

Fig. 2: Woodcut printing (Yamamoto Shunsho ed. *Eiri-Genji-Monogatari* (Pictorial tales of Genji. 1654. http://base1.nijl.ac.jp/~anthologyfulltext/)

Difficulties of transcription

Recent Japanese texts do not have serious problem in case of OCR due not only to the separation of each character but also accuracy and clarify of its printing. However, it is difficult to OCR books printed even ten decades ago because of two points: most of them uses relatively complicated characters for OCR and parallel embedded small-font size texts (called ruby in HTML5) which explain pronunciation of a word, and are too close to the explained word to OCR (Fig. 3), even though they were printed by metal typesetting. More three decades ago characters were sometimes connected, and the writing style of characters were partially cursive (Fig. 4). Recently, some researchers are attempting to develop tools for recognition of kuzushi-ji not based on the shape of individual characters but by continuous shapes of characters. They have not yet reached the stage where they are able to transcribe all characters accurately, for both technical and intrinsic reasons, but the technology can nonetheless assist in reading such texts by showing candidates of characters (Fig. 5)[1]. One of reasons why such kind of image recognition of a series of characters by machine is available in many cases is that many resources written by kuzushi-ji are woodcut printing, in which case the continuous cursive characters are more or less normalized within a single book.

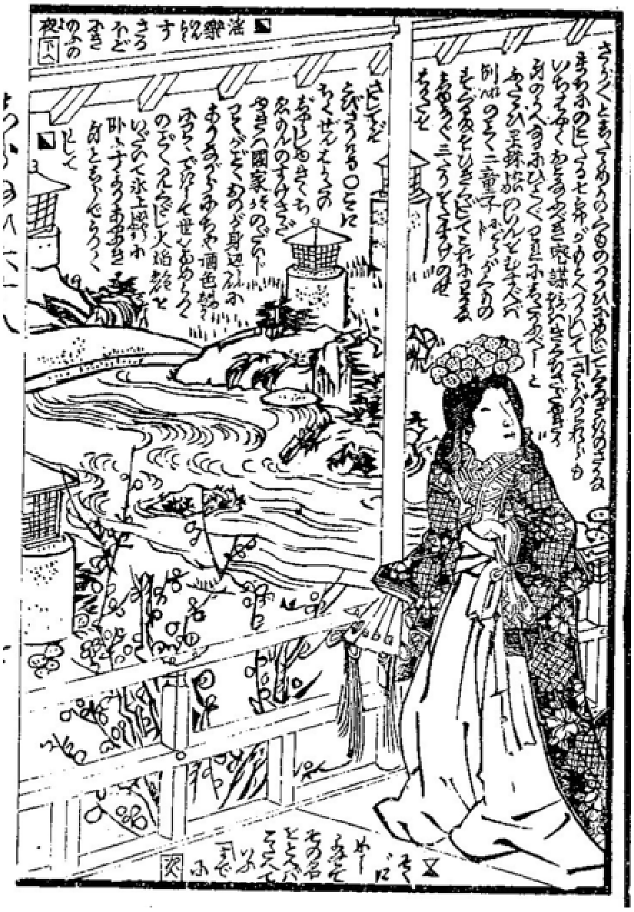

Fig. 4: Continuous characters (Ryusuitei Tanekiyo ed. *Shiranui-monogatari* (Tales of Shiranui). Vol. 68a. Enju-dou. 1885. http://dl.ndl.go.jp/info:ndljp/pid/ 884924/8)

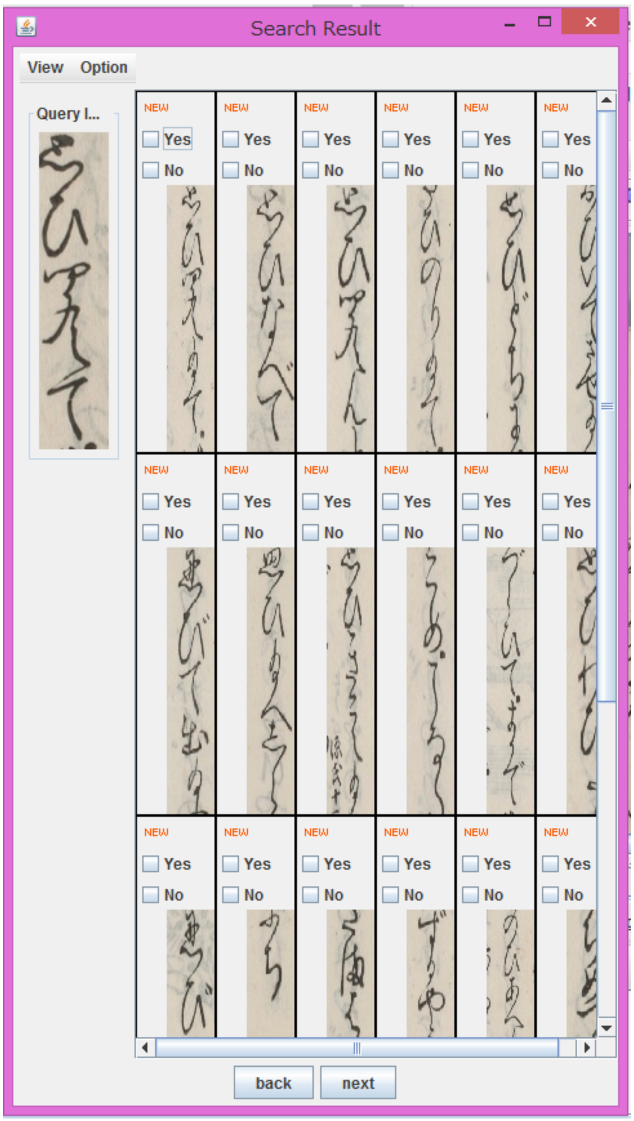

Fig. 5: A result of image search in SMART-GS

However, there are special difficulties presented when a needed character is not encoded in Unicode. It seems to be similar with the case of Medieval Unicode Font Initiative[2], but the number of unencoded characters would be much more in the Japanese case included in East Asia culture. Especially, as Japanese culture has been involved with foreign cultures and developing them in its contexts, several writing systems are preserved in its cultural resources, including Kanji, Hiragana, Katakana, Hentaigana, and Siddham scripts. Siddham scripts were encoded in Unicode 8.0 with its variant characters by efforts of Script Encoding Initiative, international experts, and SAT project[3]. There are already 80,000 Kanji (CJK unified characters) registered, but thus number will continue to increase. Hentaigana (including over 200 glyph shapes) was proposed to the ISO committee on October 2015[4]. In order to make easy-use digital scholarly edition for Japanese texts, especially classics, this process will be continued.

While efforts of transcription, due to commoditization of digitizing textual materials in hi-resolution, digital image databases have also been grown in Japan. Especially, the National Diet Library in Japan has been addressing the publication of digitized collection including over 300,000 books--since over decades ago and recently stated that most of them are to be released in the public domain[5]. And some institutes such as Kyoto Prefectural Library and Archives[6] and the University of Tokyo Library[7] are publishing their digitized collections under open license. The Art Research Center in Ritsumeikan University and the National Institute of Japanese Literature[8] have released many digitized textual resources under academic license. The latter institute plans to distribute parts of their contents under open license in this year in its new comprehensive digitization project[9]. Needless to say, these are useful to enhance the convenience of humanities research. Especially, in Japanese contexts, many humanities researchers mention that validation of research results has been made much more efficient by the increased use of the digitized images.

Crowd sourcing transcription has recently emerged also in Japan. Transcribe JP project has been conducted as a SIG of the Japanese Association for Digital Humanities. It provides a Web service[10] for transcription with Omeka and Scripto plugin. Moreover, it started a micro task crowd sourcing project on[11] October 2015 in cooperation with Crowd4U project[12]. Contributors can determine whether a character is exactly OCRed or not, comparing a candidate character with a piece of an image only by one click. The first experiment was finished in a much shorter time than we expected. Further results will be reported at the DH2016.

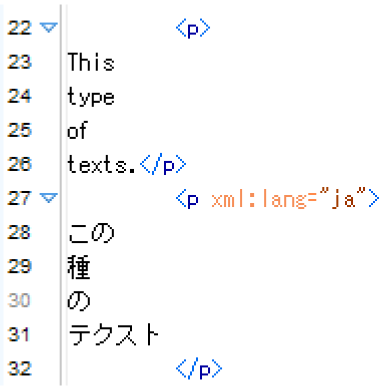
Difficulties in Word Separation

In spite of the difficulties of transcription, there are many digitized texts in Japanese. Aozora-Bunko[13], a public domain Japanese texts repository similar to the Gutenberg Project, provides over 10,000 texts on its Web site and GitHub. The National Institute of Japanese Language and Linguistics (NINJAL)[14] publishes several encoded historical Japanese texts with POS tags on Web and Web services of textual analysis on modern Japanese texts including 100 million words with POS tags each word in its original format. The SAT project[15] also provides digital texts of Buddhist scriptures consists of 100 million characters mainly in Chinese and Japanese with some philological tags on Web.

The texts of NINJAL consists of separated words with POS tags, but most of the others do not use this method. Then, methods for textual analysis are common in Japan: The one is n-gram analysis regarded a character as one "n". The other is developing tools for automatic separation of words sometimes with POS tagger, such as Mecab[16], Chasen[17], and Kuromoji[18]. These tools realize a high degree of precision, but sometimes produce erros. In this case, one has to manually correct the result of the tools if sharing exactly-processed texts is necessary. Moreover, even if a separation is not mistaken, it might support an interpretation in some cases. Such kinds of cases can also be occurred in word-separated corpora. This type of writing system includes such kinds of issues.

Rendering of texts

In XML-formatted texts, suc has those maintained in TEI, JATS[19], and so on representation of breaks in source XML files seems to be regarded a space as a separation between words in popular stylesheets. But in the case of non-separated texts, it causes problems such as unnecessary separation. The XSLT-processed Japanese text in fig.7 must exclude spaces between characters in spite of line-breaks in the XML source (fig.6). Conversely, as a Japanese semi-governmental open access journal system adopting JATS ignores line breaks even in English, the words are connected in the case of Fig. 6 and Fig.7. This problem seems to be recognized in ePub with solution in CSS according to the target language[20]. While it must already be discussed even in contexts of DH because non-spacing texts have been generated in various time and place, the differences of treatment of the line-breaks in XML source files should be carefully treated regarding not only representation but also analysis of texts.



```

こ の 種 の テクスト

Fig. 7 An example for a result of XSL Transformation of the Fig. 6

In contexts of current DH, huge humanities resources have still been dormant. According to their awakening, these kind of issues should be gradually revealed and needed to be solved from both practical and abstract viewpoints. Through solving them earnestly under global communication, DH will come to better fruition.

Player-Driven Content: Analysing Textual Communications in Online Roleplay

Introduction

The purpose of this study is to determine the extent to which online roleplayers[1] make use of language in the construction of narrative. Using computational approaches to text analysis, we compare in-game chatlogs of roleplayers with those of non-roleplayers. In doing so, we identify the particularities of the language of roleplay. Our findings are significant in that they macro-analytically demonstrate the differences between the narrative language of roleplayers and the objective-driven language of traditional players. While these differences have already been analyzed by other researchers, this study is the first to offer a thorough account of them using quantitative methods.

Roleplay is both a historic and present practice, dating as far back as ancient Greece (Corsini, Shaw and Blake, 1961). Throughout the 1970s and 80s, face-to-face roleplay surged in popularity with the advent of renaissance fairs and tabletop games such as *Dungeons and Dragons* (Barton, 2008). Today, MMORPGs (Massive Multiplayer Online Roleplaying Games)[2] are believed to enjoy over 47 million collective subscriptions. Research on the communication habits of online roleplayers provides insight into the contemporary refiguring of this long-running narrative and representational practice. The existing research on roleplay in video games relies on qualitative methods and focuses on games that have since waned in popularity. Our game of choice is *World of Warcraft*, commercially one of the world's most popular MMORPGs (Bainbridge, 2015), and thus a rich and legitimate source of data. We approach the analysis of this dataset using a range of computer-assisted methods.

Methodology and Results

For the purposes of this study, we gathered two sets of data:

- Chatlogs volunteered by *World of Warcraft* roleplayers

- Guild A donated strictly-roleplay chatlogs and non-roleplay chatlogsGuild B donated strictly-roleplay chatlogs
- Chatlogs volunteered by *World of Warcraft* non-roleplayers
- Guild C donated non-roleplay chatlogs from a server without background roleplayNon-RP RP server consisted of the study authors' chatlogs, from a server with background roleplay mixed with non-roleplay (task-oriented gameplay and casual chat)
- this sample provided a middle ground between strictly-roleplay and strictly non-roleplay samples

We applied a variety of Digital Humanities methodologies to our dataset in an effort to extrapolate the differences in language of interest to this study. Our experiments included:

- Most frequent (uncommon) word analyses to determine if any dominant themes differ across roleplayers and non-roleplayers.

As can be seen (see Fig. 1), the majority of words in the non-roleplay sets are related to objective-based gameplay, whereas in the roleplay sets, there is a dominance of emotive and descriptive words relating to interactions between characters.

- Delta analysis to determine if chatlogs clustered by style depending on whether they were taken from roleplay or standard play.

We were able to obtain both roleplay and non-roleplay chatlogs from the same group of players (Guild A), allowing us to perform a valid stylometric analysis (see Fig. 2) to determine if there is a stylistic separation between the language used in roleplay and non-roleplay. We conduct the Delta analysis using R, which shows that the linguistic styles of these player groups are distinct.

- Zeta analysis to establish words that were distinctive to each player group.

Our Zeta analysis reveals those words which are distinct to each group. Words particular to the non-roleplayers include objective-based terms such as "dps" (damage per second), and slang terms such as "nerf" (overkill). Meanwhile, the roleplayers tend to use descriptors of body language (e.g. "looks", "nods","stares", "glares" and "grins") and otherwise emotive terms (e.g. "cheers", "breath", "growls").

- Topic modelling to determine any discursive trends across roleplayers and non-roleplayers.

Using non-negative matrix factorization, we ran topic models for a non-roleplay guild and two roleplay guilds (see Table 1). The topic models reinforce the previous findings, demonstrating that the focus of roleplayers is largely on narrative content, whereas non-roleplayers are predominantly concerned with game objectives.

- Sentiment analysis to determine the extent to which roleplayers and non-roleplayers make use of emotive language.

Sentiment analyses of the non-roleplay chatlogs reveals that the language of non-roleplayers, as would be expected, remains, from the perspective of sentimentality, consistent throughout. The results of the analysis of the roleplayers (see Fig. 3) are interesting in that the sentiment oscillates to a significant degree, demonstrating a high degree of verbosity in the language that they use.

Significance

While a difference between the play styles of roleplayers and non-roleplayers has often been assumed by researchers based on players' self-identification, our study confirms a real distinction between roleplay and non-roleplay in terms of language. We have shown quantitatively that the language of roleplay is more emotive, narrative, and verbose than that of non-roleplay. MMORPGs can provide a platform not only for interactive play, but also for interactive storytelling or group narrative construction.

Of particular significance is our finding that roleplayers frequently describe their avatars' body language. Through use of descriptors such as "looks", "nods", "stares", "glares", "grins", etc., roleplayers adapt to limitations in the control of their avatars by verbally recreating non-verbal cues. Analyzing the complex interplay of roleplayers' chat descriptions and the actual movements of their avatars can help us to better understand the challenges and potential of virtual forms of embodiment. It can also assist game designers in better accommodating the needs of a dedicated subpopulation of players.

Methodologically, our choice to seek chatlogs from roleplay and non-roleplay guilds, rather than rely solely on our own in-game chatlogs, is a strategy that can be of use to other researchers. Guilds in *World of Warcraft* frequently store—and, in the case of roleplay, even clean—their own chatlogs, which can provide a focused dataset.

Figure 1

Overall, this research demonstrates the potential for increased intersection between games studies and critical DH methods. Our study provides the statistical evidence necessary to further extrapolate how roleplayers use language to create their own storylines, invent character personalities, and develop meaning in the context of a game's fictional world. In this paper, we will further detail the outcomes of our analyses, and offer a number of interpretations founded upon our results.

Notes

[1] Roleplay in videogames refers to users remaining "in-character" while playing the game. While roleplaying, users use performative communication, interacting in a manner suited to their character's personalities, and remaining constrained within the established limits of the game's backstory.

[2] A Massively Multiplayer Online Role-Playing Game, or

MMORPG, is a roleplaying videogame that takes place in a persistent Web-based world. This world is shared by a large player base interacting within a common environment for the purposes of socialising and playing the game in both an individual and collective manner.

Digital Annotation Tooling for Opera Performance Studies

Background

In opera and music theatre, the realisation of a work in performance differs significantly from the abstract concept that is captured in the score. The scenic interpretation, with its own characteristics and specific perspective on the work, is created afresh in every new staging – thus a performance and its experience cannot be determined from the score alone (Cook, 2013).

Comparing a mere three stagings of Richard Wagner's *Der Ring des Nibelungen* illustrates this point: the Bayreuth premiere in 1876, Boulez'/Cherau's *"centennial Ring"* in Bayreuth 1976, and the *Ring* Cycle in Birmingham in 2014 (which is the subject of our digital annotation capture in this paper). Not only are costumes and decorations entirely different, but also the setting and staging of the action, interpretation and presentation of the characters, visual and scenic aesthetics, and the perspective on and attitude towards the work.

For studies of the reception and perception of an operatic work, keeping a record of a particular performance – the characteristics of individual stagings – is an important requirement. This poses the question of how best to document the ephemeral phenomenon of an opera. Audio-visual recordings appear to provide an answer, but they are neither neither objective nor exhaustive; live annotation by a musicologist in the audience can thereby provide an additional or alternative resource.

Musical Score Annotation Kit

We developed the Musical Score Annotation Kit (MuSAK) to capture these musicological annotations, designing it to meet the requirements – and technical compromises – of operating in the environment and timescales of a live production in a working theatre, and providing an interface of sufficient responsiveness and adaptability to meet the needs of a working musicologist. The kit comprises:

- A touchscreen tablet device, running a bespoke web-based client through which each individual page of a score can be annotated and pages can be turned;
- A server based on the Union platform which gathers annotation keystrokes from the tablet client;
- A second "score following" page-turn annotation interface, capturing timings of the realisation (performance) of the material on a particular score page;
- A Livescribe Echo digital smart pen, used to take notes beyond those described in the annotation key (see below);
- Capture of audio and video, potentially recording both the staged performance and the musicologist using MuSAK.

Technical details of the MuSAK infrastructure are fully described elsewhere (Page et al., 2015). In this paper we report upon the utility of the toolkit: both in relation to the needs of the musicologist during the annotation event; and in relating the quantitative temporal data captured to the qualitative consideration of its potential musicological interpretation. Particularly with regard to the latter data-derived investigations, a key functionality of the kit for post-performance analysis is the temporal reconciling of the constituent digital media and annotations into a coherent metadata hyperstructure, enabling navigation of the information-dense digital captures (Nurmikko-Fuller et al., 2015).

Annotation workflow and enactment

The first full deployment of MuSAK captured annotations during a complete staging of Richard Wagner's *Ring*, performed on four nights over five days by the Mariinsky Opera at the Birmingham Hippodrome in November 2014 (Figure 1).

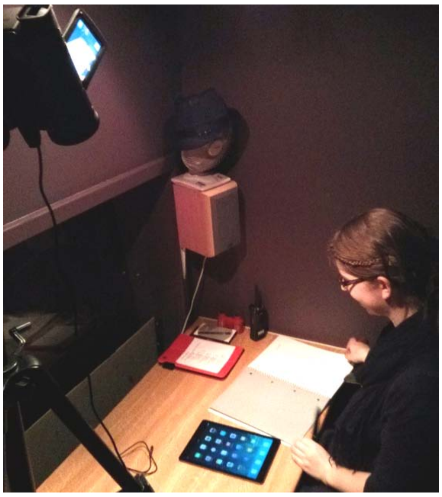

Figure 1: The musicologist and MuSAK in position from her viewpoint at the back of the stalls before curtains up

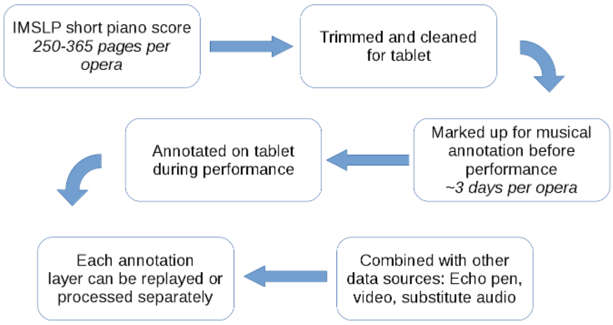
This multi-stage process is summarised in Figure 2. Digital images were generated from short piano scores of the operas obtained from IMSLP[1], then formatted and cleaned for viewing on the MuSAK tablet. The musicologist spent considerable time before the performance annotating printed copies of these scores which were subsequently re-digitised. These pre-performance notes highlighted musical elements determined directly from the score; these also served as "signposts" for potential points of interest which would be revisited during the live performance.



IMSLP short piano score
250-365 pages per opera
Trimmed and cleaned for tablet
Marked up for musical annotation before performance
~3 days per opera
Annotated on tablet during performance
Combined with other data sources: Echo pen, video, substitute audio
Each annotation layer can be replayed or processed separately

Figure 2: Annotation workflowscore_workflow.png

This necessitated the development of a symbolic key (Figure 3) which allowed annotations to be made at sufficient speed during the live performance, and which was trialled before deployment during co-development of the technical system. During the Birmingham staging the musicologist annotated the tablet-based score image directly using a stylus to draw symbols from the key (Figure 4), allowing for adaptation of the key between the nightly performances, based on experience during fieldwork.

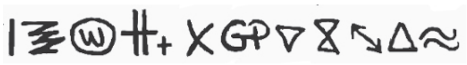


Figure 3: Examples of symbols from the musicologist's keykey_image.jpg

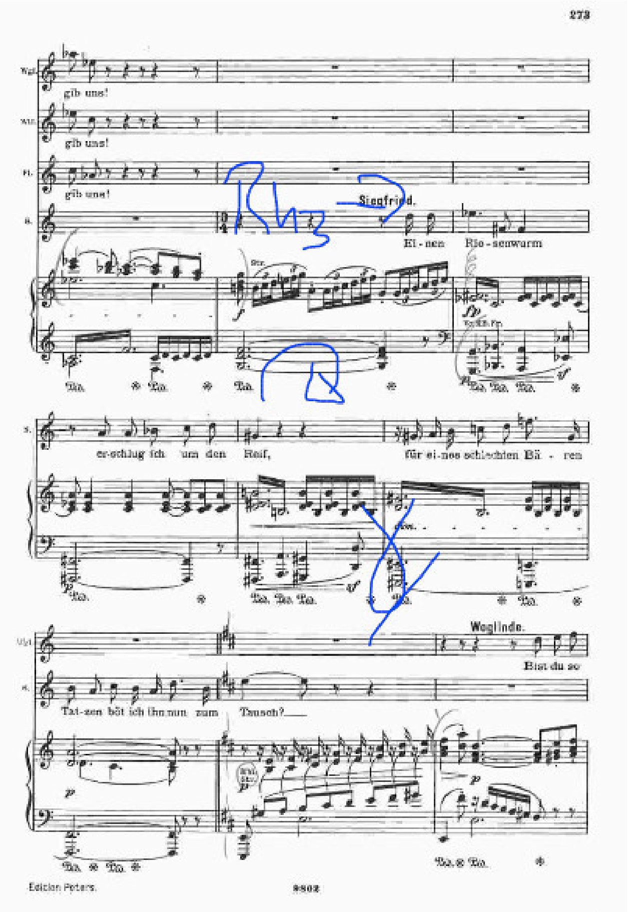

Figure 4: An annotated score pagescore_page.jpg

A significant volume of annotation and related data was gathered: 15 hours of video footage; over 100,000 tablet strokes encoding 8,216 annotations; 1,300 performance based page turns; 1,316 digital score images; and 104 pages of writing producing 13 hours of digital pen replay.

Toolkit Assessment

The usability attributes of MuSAK were assessed in interviews with the musicologist after the Birmingham performances according to learnability, efficiency, memorability, and satisfaction, as defined by Ferre (Ferre et al., 2001).

Learnability was evaluated through the musicologist's experience of acquiring the skills necessary to complete the annotation process. She found the system comparable to existing musicological annotation pragmatics, minimising the need for training:

> Using MuSAK [is] very similar to the process that I as a musicologist used to do regularly...I think it worked very well because [it repeated existing] processes [...and] fitted in with actions I was very well adapted to...the tools were very non-invasive.

On satisfactory functionality and performance, the musicologist felt "quite" able to *keep up with the pace of the* *opera*, although believed that the time necessary to make additional freehand annotations and cognitively process observations made the page turn annotations inaccurate:

> I was quite well able to keep up with the pace... I have been able to capture...a pretty good picture of...the profile of the performance... an important realisation is that making these scenic [and musical] annotations … which are particular about this performance... requires a lot of time to think and... process even if it is only [around] 10 seconds or 5 seconds...if we want to also capture a detailed and accurate time profile of the performance it would be necessary to have two people…

However, an analysis of the page turn data (below) indicates an ability to at least turn pages at a pace highly correlated with the performance. (MuSAK can also be configured to support multiple annotation devices and annotators simultaneously, although this was not done during the *Ring* capture.)

The musicologist reported an ability to *capture the idiosyncratic profile of each specific performance*, including deviations from the score or expectations based on it, as well as staging, lighting, and the behaviour of the actors:

> ...the performance details: are the musical details particular in any places, is something particular loud ...[or]... fast, are any mistakes made ... scenic specifics of the performance, what happens on stage... are people moving a lot, are they using a lot of gestures, are there significant lighting changes, are there changes of scenes...

MuSAK was described as *supportive of traditional annotation paradigms*, because new skills were not necessary for effective and efficient annotation using the touchpad screen and stylus:

> ...intuitive to use because it was mainly very similar to just using pen and paper which everyone who is concerned with analysing music is very used to... so it's very similar to the process that I as a musicologist used to do regularly anyway and ... it worked very well because it took up processes that were there anyway and tried to fit in with actions I was very well adapted to [...] very similar to [...] if you eventually get used to the touch screen which didn't take such a long time...

The additional affordances of a digital system were noted, including the automatic *capture of the temporal profile of the performance and the benefit of being able to easily make corrections:*

> ...they actually help because with using a pen and paper you wouldn't be able to undo things if you make mistakes, ...[nor]... be able to afterwards see the timings [...] with pen and paper doesn't give such an accurate profile of this particular performance [...] you're capturing the timings [of] not only the music but also the timings of the annotations because afterwards you can look at how dense are the annotations.

Data Interpretation

In addition to recording the musicologist's (subjective) annotations, MuSAK can be used to produce statistics about the acts of annotation to supplement our understanding of the technical system and our interpretation of the musicological context.

For example, Figure 5 shows comparative plots of what is, effectively, the rate of performance of each page (from the score-following annotations) compared to the musicologist, indicating an overall ability to "keep up" with the pace of the staging.

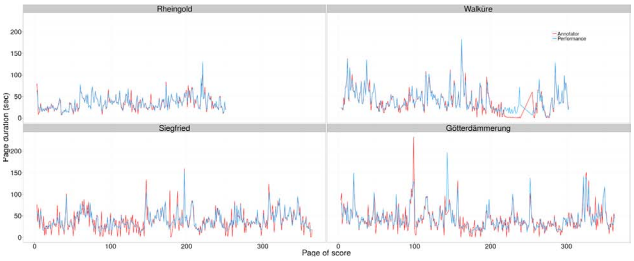

Figure 5: Comparative plots of performance and annotator

Figure 6 shows the rate of annotations over the course of the four operas, indicating what might be considered as a crude measure of "music information density".

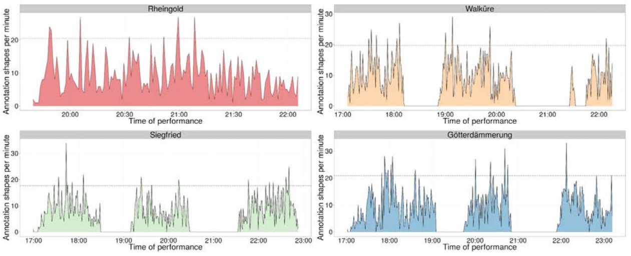

Figure 6: Rates of annotation over time during the Ring Cycle performance

Moments which pass a higher threshold of annotation rate have been identified to relate to significant music-dramatic instances in several places, which involve highly concentrated activity on stage (e.g. Hagen killing Gunther in Götterdämmerung).

Institut des sciences de l'Homme de Lyon (FRE 3768) / CNRS

S'appuyer sur le sensible pour valoriser le patrimoine est une demande récente des musées. En effet, à une époque où le multimédia modifie chaque activité de découverte, agissant notamment sur la perception, il devient nécessaire d'intégrer cette dimension du sensible lors des présentations touchant au patrimonial. *Bretez* est un projet multimédia, associant des acteurs de sciences humaines et sociales et ceux de sciences de l'ingénieur. Il est conçu pour répondre à ces problématiques.

Le projet tire son nom du géographe (Louis Bretez) qui leva, en 1739, le plan pour le prévôt des marchands Turgot en utilisant l'axonométrie – une technique de projection révolutionnaire pour l'époque.

Le projet *Bretez* relève de la recherche empirique, exploratoire et d'une méthodologie expérimentale ayant pour objectif la mise au point d'un modèle. Sa conception s'appuie sur les techniques de virtualité. Comme tout modèle virtuel, *Bretez* n'incarne pas une vérité scientifique figée mais une proposition représentant l'état de la science à l'instant de sa création et qui est voué à évoluer. Dans notre cas, c'est un média (la maquette crée sur une plateforme de jeu) qui sert de départ pour le dialogue entre différents membres d'une communauté scientifique, mais aussi un public large.

Deux grands axes se dégagent dès le début des réflexions portant sur l'élaboration du projet *Bretez*. D'une part, comment intégrer la dimension sensible, d'autre part, comment répondre à cette demande de multimédia tout en respectant les besoins des musées.

L'archéologie du paysage sonore répond à la première de ces demandes spécifiques. L'écologie du sonore et son ouvrage référent *Le paysage sonore – le monde comme musique* de R. Murray Schafer (1977, réédition 2010), est la première étape d'une prise de conscience des spécificités de cet environnement qui forment un paysage sonore. Puis les études d'A. Corbin (*Les cloches de la terre* – 1994) et de J.-P. Gutton (*Bruits et sons dans notre histoire* – 2000) ouvrent un chemin vers les aspects sonores du passé. Mais ces études restent au stade du théorique. L'archéologie du paysage sonore permet de passer à l'étape expérimentale.

Que ce soit dans le cadre d'une restitution de paysages urbains, d'ambiances d'intérieur, ou autres, les problématiques restent identiques. La restitution ou création de visuels et de paysages sonores historiques pose, d'entrée, des questions fondamentales: pourquoi restituer, dans notre cas, ce Paris des Lumières? Peut-on « voir/entendre » ce passé? Comment le restituer, le faire entendre? Quelles sont les difficultés, les limites d'une telle restitution? Quels sont les matériaux? Où s'arrête l'acte du créateur, celui du chercheur? Comment dépasser le concept d'habillage sonore et aboutir la restitution d'un véritable paysage historique? Comment intégrer ces notions relevant du sensible, les porter au public? Pour quel public?

La demande muséographique (dans notre cas) place le concepteur aux confins de la composition, de la musicologie et de l'histoire. Un « simple » habillage sonore (*sound design*) ne peut, en effet, satisfaire cette demande très spécifique qui entre, également, dans les cadres de la sauvegarde du patrimoine immatériel.

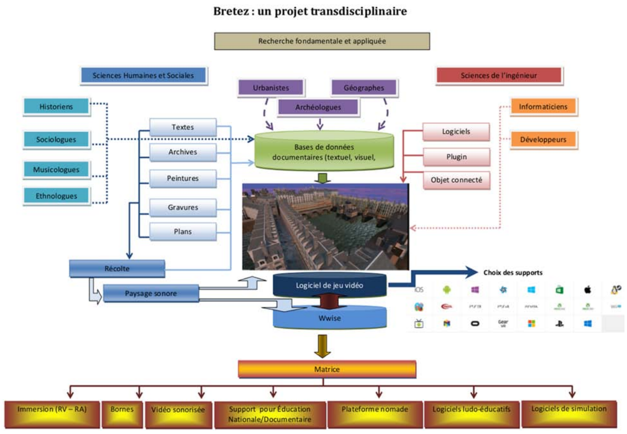
En effet, pour le musicologue, pour le metteur en sons, ce travail est inhabituel. Les matériaux ordinaires sont *quasi* inexistants: pas d'enregistrements disponibles pour les années antérieures à 1870. Entendre le passé implique donc qu'il faut en chercher les traces dans l'ensemble du corpus littéraire (livres, journaux, etc.) ou graphiques. Puis, tenter de le pister dans le temps d'aujourd'hui afin d'en faire une captation. Il faut également solliciter l'imaginaire lors de la restitution pour mieux servir l'Histoire.

Pour le visiteur, l'ambiance sonore ainsi (re)créée doit également exciter son imaginaire pour l'aider à mieux percevoir, recontextualiser des situations historiques, tout en préservant la réalité historique et non jouer sur les émotions. Trouver le juste milieu dans la sollicitation de cet imaginaire pour mieux servir le patrimoine et le mettre en valeur sera le fil conducteur de cette première partie.

D'autre part, ainsi que nous l'avons mentionné plus haut, dès nos premières observations sur et autour du Projet *Bretez*, il est apparu que de nombreuses contraintes techniques étaient présentes, notamment des contraintes matérielles et logicielles. Parmi celles-ci, l'obsolescence présente un réel frein pour les musées car elle représente un coût financier important. Il devint dont évident que mettre au service des musées, des historiens ou des archivistes une représentation visuelle, spatiale et audio qui respecte et témoigne d'une réalité du quotidien était un enjeu majeur, ceci afin de faciliter sa communication à un public de plus en plus friand de multimédia. Il était également incontestable que nous pouvions y répondre grâce, notamment, à l'utilisation d'un moteur de jeu.

Ce détournement d'utilisation de logiciel de conception de jeux vidéo soulève, à son niveau, de nombreux problèmes épistémologiques et éthiques. Comment développer une telle plateforme à des fins pédagogiques et scientifiques? Comment utiliser l'outil? Quelle stratégie de conception et de scénarisation? Quelles en sont les avantages, mais aussi les limites? Pour quel public? Ces réflexions structureront cette seconde partie.

La présentation de mes travaux s'appuie sur la maquette qui sert de matrice à la recherche et s'attardera plus particulièrement sur l'élaboration d'une maquette historique sonore, en s'articulant autour de cette réflexion: comment voir et ouïr le passé pour réjouir nos sens sans trahir l'Histoire?



Bretez est un projet restitution de Paris au XVIIIe siècle. La maquette virtuelle, résultat d'une coopération scientifique, associe des équipes de sciences humaines et celles des sciences de l'ingénieur (Humanités Numériques). Sa destination première est orientée muséographique. Son objectif, la valorisation patrimoniale par sa restitution numérique tridimensionnelle et sonore spatialisée, se dénote par une nouvelle approche de la restitution du passé en 5 D (la combinaison du visuel – la 3D –, le déplacement et la dimension sensoriel – le sonore). Fruit d'un travail collectif, *Bretez* présente une très forte dimension sonore qui rend le passé disponible et tangible pour un très large public. Il met ainsi en valeur une vision méconnue et scientifiquement valide de la ville lumière.

À terme, ce projet vise la conception d'une plateforme générique pour la génération procédurale de villes virtuelles, tant sonore que visuelle, qui permet de s'affranchir des contraintes technologiques liées à la diversité des supports et leur obsolescence. Projet innovant, ses spécificités porte sur:

- L'inter et la transdisciplinarité (association étroite entre les Sciences Humaines et Sociales et les Sciences de l'ingénieur);
- La valorisation du patrimoine par le sensible;
- La construction autour du son et une élaboration concomitante visuel/son.
- La création d'un nouveau concept: la 5D.

Un tel projet permet d'élargir au maximum sa sphère de rayonnement. Pensé pour la muséographie, il s'est orienté vers la recherche sur demande d'équipes de chercheurs historiens ou archéologues (notamment LaDéHiS/EHESS). Il n'entre pas dans la catégorie jeu ou purement artistique car répond à des critères scientifiques. Toutes les sources sont primaires (archives de police, notariales, témoignages d'époque…). Nous assumons les « vides » : S'il n'y a pas de sources (ou ne pouvant être validées par la communauté scientifique), nous n'inventons pas – tant sur le plan visuel que celui des ambiances sonores. Chaque information est recoupée et validée par des historiens, sociologues... Le tout forme autant de contraintes à tout acte compositionnel « traditionnel ». Les questions de temporalités, au sein du logiciel, sont réétudiées afin de répondre aux critères historiques et scientifiques et non ludiques.

L'élaboration de la maquette initiale sur une plateforme de jeu vidéo est un véritable atout. Ce type de logiciel permet de répondre à des demandes diverses et ouvre la porte à l'élaboration de toute sorte de produits finalisés : ceux touchant à la réalité virtuelle, à la réalité augmentée, à la création de supports immersif ou non, à ceux nomades (pour les principaux)... Le projet entre en phase de prototypage. Les premiers essais et retours sont programmés à partir de juin 2016. Dans un premier temps, il est prévu la mise en test *in situ*, Place du Châtelet à Paris, d'une application en réalité augmentée en partenariat avec Labo-M (chef de projet: Pierre Girard) et le musée Carnavalet.

Ce projet soutenu et accompagné par la SATT PULSALYS pour une mise en chantier au 01/01/2016 https://sites.google.com/site/louisbretez/home

Chronological corpora: Challenges and opportunities of sequential analysis. The example of ChronoPress corpus of Polish

Adam Tomasz Pawłowski
adam.pawlowski@uwr.edu.pl
University of Wrocław, Poland

Chronological corpus – definition

The notion of chronological corpus has appeared so far only in publications of limited circulation (cf. Pawłowski, 2006), whereas it is practically absent from mainstream literature on corpus linguistics and digital humanities. This is somewhat surprising given that the research of so called "lexical series" has been conducted in the past (cf. Brunet, 1981; Salem, 1987) and that Google has been for some years developing the tools *Ngram Viewer* and *Google Trends*, which allow sequential analysis of Google Books resources and of users' Internet queries (cf. Michel et al. 2011).

In order to understand what chronological corpus is one must grasp the basic distinction between synchrony and diachrony at the heart of structural linguistics. Synchrony is a study of language at a certain moment in time, where "moment" can last even several decades, provided there are no apparent changes in grammar, vocabulary and pronunciation. As for diachrony, it exposes evolution of language taking place in the process of its development, usually over long periods, spanning even several centuries. However, corpus research supported by NLP tools enables a far more flexible approach to the time variable, since text samples consistent in terms of their typography, spelling and grammar can be annotated with their exact publication dates. Scientific description then focusses on the dynamics of the frequency change of specific lexemes (or other segments) in time, rather than on the evolution of word forms beginning with a hypothetical proto–language until the present state.

An important issue to be resolved is that of naming such an approach, whereby the chosen term would instate it in the domain of corpus linguistics. While social sciences and psychology use the term of "longitudinal" research, its equivalent in linguistics could be 'microdiachrony'. Having said that, the term's association with traditional diachrony and history of language could prove misleading. This is why it is more advisable to speak of **chronological analysis** and **chronological corpora**, where, similarly to diachrony, both terms contain a reference to time – gr. *chronos*.

Consequently, **chronological corpus should be understood as a sequence of text samples consistent in terms of their spelling and grammar, corresponding to subsequent points on the axis of time** (e.g. weeks, months etc.). Such a corpus would make it possible to explore the dynamics of the change of lexeme frequencies in successive periods using the method of time series analysis (cf. Gottman, 1981; Cryer, 1981; Pawłowski, 1998, 2001). A chronological corpus would differ from a diachronic one in that in the former texts are evenly spread in time and word forms remain unchanged, while in the latter it is the opposite: word forms must evolve to become object of interest and time spans between measurements may be of any length. It needs to be emphasised that the annotation of the time variable may be ignored (if such is the premise of the conducted research); a chronological corpus would then be treated as a synchronic one.

Chronological corpora

There exist corpora that are intrinsically arranged with regard to the time variable, e.g. literary outputs of some authors presented as Shakespearean Corpus, Corpus Thomisticum or Corpus Platonicum. If the date of creation of every piece of data in the corpus is known, the development of the text's stylostatistical properties over time can be established. If text chronology remains partly unknown, stylometric research can help to put undated works in the correct order (cf. Lutosławski, 1897).

But there is also another set of text corpora that seem to be naturally predestined to sequential analysis. Contrary to other genres or functional styles, **press and media texts** necessarily incorporate the date or even the time of their creation. This is of course little surprising, since media must comment upon actual events. Publication dates in the headers or footers of printed newspapers may be thus regarded as "time markup" that is invaluable as a Gutenberg era contribution to the sequential corpus research in the digital universe.

ChronoPress – features and origin

At present ChronoPress corpus contains texts representing Polish press of the post-war totalitarian period (1945-1954). Future extensions are planned to cover the entire period of the country's sovereignty (1918–2018). As the flow of press information was abundant even in the early post-war period, representative method of sampling has been applied. It has also been assumed that the minimum time spans, visible from the user level, are limited to subsequent months (the volume of text corresponding to weeks was too small to guarantee a sufficient level of representativeness). Apart from that it should be pointed out that the pace of public discourse in the times of printed press was slower than it has been in the digital world, so that months as time units can be regarded as sufficient to trace relevant events or processes.

In order to obtain reliable values of lexeme frequencies the number of words per month has been established as ca 120.000-140.000. Since sample size has been fixed to ca 250-300 words of continuous text, every month is represented by 480 samples and every year by 5760 samples (ca 1,5 million words per year). Equal numbers of words per month are important to guarantee that time series and other parameters generated from ChronoPress remain statistically unbiased with regard to the sample size. Selected newspapers represent a relatively broad spectrum of public post-war discourse of the totalitarian state. Particular titles to be included in the corpus have been selected according to two criteria: newspaper circulation (only titles with the highest values and national range have been considered) and target groups, as defined by the ideology of the time (first of all the working class, peasantry, army, youth, and, to a lesser extent, "intelligentsia"). The corpus is freely available through an interactive user interface.

Data have been thoroughly sampled from Polish dailies and weeklies. Preparatory stages of analysis consist of: sample selection, scanning, OCR, markup with metainformation (XML scheme) and text curation. The corpus has been annotated morphosyntactically using Morfeusz tool which had been designed for the Polish National Corpus. Metadata (Fig.1) include newspapers' titles, articles' titles, authors' names, exposition, and data support.

Fig. 1 Example of sample annotation with metadata

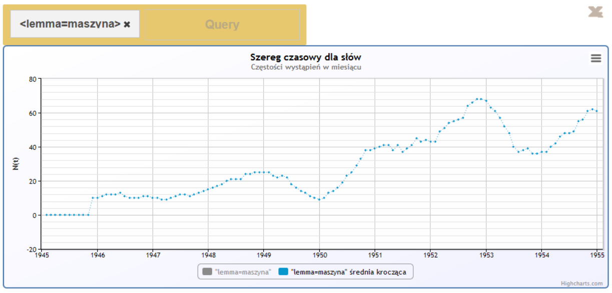

Fig. 2 Moving average of the frequency of the lexeme *machine* (maszyna). It supports the view that despite the systemic inefficiency of communist economy technological progress was promoted in post-war Poland.

ChronoPress offers a variety of online linguistic and exploratory tools, such as concordances, frequency lists, word profiles and word maps. Its specific feature is, however, the possibility to generate time series. The analysis of lexeme frequency values displayed on an axis of time allows users to discover and explore the dynamics of events and phenomena represented in daily press over long periods of time.

Goals of the presentation

ChronoPress allows to conduct a wide range of research in linguistics, contemporary history, cultural anthropology, media studies and communication science. The perspective adopted here is oriented towards the analysis of dynamic processes occurring in time rather than towards static states of language reflecting extralinguistic reality. The goal of the presentation is to provide an overview of the available exploratory techniques for chronological corpora, highlighting their explanatory power and limitations. In particular the following issues will be addressed and exemplified with empirical evidence from the ChronoPress corpus:

Manual and automated trend detection, modelling and interpretation

Long-term change in frequency of selected lexemes will be analysed as the expression of dominating topics of interest in public discourse, but also of social change imperceptible from the point of view on an average. Illustration material will include salient and informative examples generated from the ChronoPress database (*inter alia* lexemes from the semantic fields *war*, *health*, *technology*). Since trend analysis requires some conceptualisation of time, various approaches to time will be presented and discussed (linear or circular, anthropological, political and astronomical).

Detection of events

Events are understood here as sudden changes, such as natural or technological catastrophes, wars, accidents etc. They manifest themselves as sudden rises in the lexeme frequency. This task will be illustrated with some examples generated from the ChronoPress corpus and from other online sources.

Testing the efficiency of statistical tools

The utility of the autocorrelation function (for univariate series) and of the cross-correlation function (for multivariate series) in the analysis of chronological corpora will be verified.

Comparison of ChronoPress and online resources

Informational potential and functionalities of the ChronoPress corpus will be compared with other online research tools, such as Google Ngram Viewer, Hansard Corpus and Polish National Corpus.

Word profiles analyses

Collocations and semantic profiles of selected lexemes in subsequent years will be generated (using Log Likelihood Ratio) and compared.

Automatic detection and annotation of named entities

Proper names and other named entities in Polish can be detected and annotated using Liner 2. Spatial distribution of toponyms identified by Liner 2 will be automatically displayed on a map and further analysed. Both tools have been created in the framework of the Clarin-PL project (http://clarin-pl.eu/en/home-page/).

Social Networks and Archival Context: People and Cultural Heritage

Daniel Pitti
dpitti@Virginia.edu
Institute for Advanced Technology in the Humanities, University of Virginia, United States of America

Worthy Martin
wnm@eservices.virginia.edu
Institute for Advanced Technology in the Humanities, University of Virginia, United States of America

Overview

Social Networks and Archival Context (SNAC), initiated in 2010 as a R&D project, is now being transformed into an international cooperative. SNAC's original research objective was to demonstrate that descriptions of people, embedded in the descriptions of historical records that document their lives, could be extracted and used to reveal the social networks within which their lives were lived *and* provide integrated access to geographically dispersed historical records. SNAC's early success led to plans to establish a sustainable international cooperative to maintain and expand these descriptions of people. The long-term technological objective is a platform to support a continuously expanding, curated corpus of reliable biographical descriptions of people linked to, and providing contextual understanding of, the historical records that function as primary evidence for understanding their lives and work. The SNAC Cooperative will benefit librarians, archivists, and researchers, and will provide traditional historical researchers integrated access to distributed historical records and the social contexts within which the records were created and used. It will provide prosopographic researchers with methods for reconciling and establishing reliable social networks, and will enable archivists and librarians to share descriptive data while also making descriptions more effective.

The Archival Description Source Data

Archival description source data encompasses both descriptions of historical records as well as authority data for corporate bodies, persons, and families documented in historical records. OCLC WorldCat, sixteen archival consortia (representing hundreds of individual repositories), over thirty repositories, and two digital humanities research projects contributed their source data to SNAC. The holdings of over 4000 repositories are represented:

- 190,000 finding aids, contributed by fifteen consortia and over thirty repositories in the U.S., the ArchivesHub in the U.K., and the Bibliothèque nationale de France (Catalogue Collectif de France (CCFr) and BnF archives et manuscrits)

- 2.25 million OCLC WorldCat archival descriptions
- 400,000 authority records contributed by NARA (93,051), the British Library (297,731) the Smithsonian Institution Archives (2,083), the New York State Archives (258); and the Archives nationales, France (2,350)
- 30,000 correspondent names from the Joseph Henry Papers Project, Smithsonian Institution Archives
- 2,332 correspondents from The Walt Whitman Archive
- 1,200 names associated with the Chaco Research Archive

Data Processing

During SNAC's R&D phase (2010-2015), this source data was processed in three distinct steps.

- Biographical and historical data was extracted or migrated from existing archival descriptions and assembled into standardized descriptions that identify and document organizations, persons, and families based on an international archival communication standard, Encoded Archival Context – Corporate Bodies, Persons, and Families (EAC-CPF). Each EAC-CPF identity description includes the description of the entity as such (names, life dates, biographical information, etc.), links to descriptions of the historical records from which the data was derived, and links to other identities found in the same source. These links provide the foundation for assembling a vast social-document network or graph.
- The EAC-CPF identity descriptions were matched (identity reconciliation) against one another and against descriptions in the Virtual International Authority File, combining records that identify the same entity, to produce a set of unique EAC-CPF records.
- We developed a prototype access system, based on Extensible Text Framework (XTF), open source software from the California Digital Library. It has three major functional components: 1) display of the EAC-CPF records; 2) sophisticated searching and exploration of the EAC-CPF records; and 3) exposing the data to enable third-parties to access and use it in other applications.

Extracted or Migrated Data

The first step resulted in 6,719,064 Encoded Archival Context – Corporate Bodies, Persons, Families (EAC-CPF: an archival encoding standard hosted by the Society of American Archivists and developed in collaboration with the international archival community).

- 4,653,365 Persons
- 1,868,448 Corporate Bodies
- 197,251 Families

Merged Data

After performing identity resolution processing (match and merging), we had:

- 3,741,262 EAC-CPF records
- 2,466,425 persons1,077,588 corporate bodies197,249 families[1]
- 7,966,737 links between the 3,741,262 persons, corporate bodies, and families
- 15,031,209 links to 2,079,504 unique resource descriptions

Prototype History Research Tool

The prototype history research tool (http://socialarchive.iath.virginia.edu/snac/search) allows researchers to find persons, organizations, and families; to read biographic information about them; to explore the social networks within which they existed; to locate historical records that document their lives, related resources, and external links associated with that name. Associated links are provided for ArchivesGrid and Digital Public Library of America, as well as "sameAs" links to Wikipedia, VIAF, WorldCat Identities, and others.

Significance for Researchers

Researchers have welcomed SNAC for its research economies: SNAC's History Research Tool provides integrated access to distributed primary (archival) and secondary (published) resources, eliminating or at least substantially ameliorating the need to track down resources in multiple archival catalogs. Painstakingly locating these resources is a labor-intensive, time-consuming activity in the current research environment, with successful discovery and assembling of the data highly dependent on persistence and serendipity. Indeed it is likely that some of the information found in the SNAC records might never be discovered using current methods. SNAC also makes explicit what has been, at best, implicit in archival description: the social-professional-intellectual networks within which the lives and work of the people documented in historical resources took place. It exposes the vast global social-document network that connects the past to the present. Ed Ayers, President of the University of Richmond and a Civil War historian, wrote that:

> SNAC promises to change the way history is imagined and written! For all that the digital revolution has revolutionized, the heart of research lies within the primary record embedded in archives large and small. The pioneering work of SNAC will unlock that record, revealing connections and patterns invisible to us now.

Alan Liu, Professor of English, University of California, Santa Barbara and Director of Research Oriented Social Environment (RoSE), describes SNAC's potential:

> SNAC employs state-of-the-art computational techniques to do three things very well: 1) unlock information originally recorded for specific purposes in library and other archival finding aids to make them usable in new contexts; 2) connect widely-distributed information of this sort from around the world; and 3) marry the "library" or "archive" model of knowledge to a whole other model of social networks that both humanizes our understanding of the way knowledge emerges from communities of knowledge creators and seekers, and speaks powerfully to today's "social network" generation.

Significance for Prosopographical Research

SNAC is building a humanities resource that benefits humanities researchers, but ongoing development and refinement of identity reconciliation techniques are of further benefit to humanists engaged in prosopographical research. Names alone are weak identifiers: multiple people can have the same name and one person may have multiple names. A number of factors influence our ability to reliably identify people. Indeed, the larger the domain from which names are drawn, the higher the likelihood that a name is shared by several people.

Though each step in the processing described above presents intellectual and technical challenges, the most challenging is identity reconciliation. A fundamental human activity in the development of knowledge involves the identification of a unique "real world" entity (e.g., a person or book) and recording facts that, when taken together, uniquely distinguish that entity. Establishing the identity of a person, for example, involves examining available evidence, including the existing knowledge base, and recording facts associated with him or her (such as names, dates and places of birth and death, occupation, etc.). This is an ongoing, cumulative activity that both leverages existing established identities and establishes new identities. Identity reconciliation is the process by which an encountered identity is compared against established identities, and if not matched, is itself contributed to the established base of identities. The networked computing environment presents opportunities for using algorithm-based inference methods to compare newly encountered entities with established identities to determine the probability that a new entity represents the same person or thing as an established identity. This ongoing expansion of the base of reliable identities is an interplay of human research, knowledge recording, and computational methods.

Transforming SNAC into an International Cooperative

It became clear early on that the biographical data extracted and assembled from archival resource description constituted a valuable independent resource that could (and should) be maintained and further developed cooperatively. Development of a cooperative began back in 2011 and it recently entered its pilot phase with a group of fourteen inaugural institutional members that support the potential benefits of aggregated description and access demonstrated to date in SNAC, and, further, embrace the idea that the resources amassed should be cooperatively built and maintained in order to fully realize these benefits. The initial members represent research archives, libraries, museums (art and natural history), government archives, and institutional archives. The U.S. National Archives and Records Administration (NARA) serves as the secretariat for the Cooperative, while the Institute for Advanced Technology in the Humanities (IATH), University of Virginia, hosts the technological infrastructure. SNAC is led by IATH, working collaboratively with NARA, the California Digital Library, and the iSchool at UC Berkeley. The National Endowment for the Humanities (2010-2012), the Institute for Museum and Library Services (2011-2013), and the Andrew W. Mellon Foundation (2012-2017) have provided funding for SNAC.

Notes

[1] Because family names, as traditionally formed, lack sufficient qualifying information and thus commonly result in false positives, no matching was done against family names. In the final production, two family names were rejected as malformed.

Early English Books in Context: Towards a History of the Technological Humanities

Daniel James Powell
djpowell@uvic.ca
University of Victoria, Canada

Writing in *Literary and Linguistic Computing*, Julianne Nyhan et al argue that "without a better understanding—a more appropriate term might be "body of interpretations"—of the near and distant history of computing in the humanities, we are condemned to repeat the revolutionary trope *ad infinitum*." (Nyhan, Flinn, and Welsh, 2013). Willard McCarty, amplifying this, writes that "rather than hypnotizing ourselves with supposedly unprecedented marvels, we must learn to see computing in its historical and social contexts, and so be able to ground modelling in something larger than itself. For computing to be *of* the humanities as well as *in* them, we must get beyond catalogues, chronologies, and heroic firsts to a genuine history. There are none yet." (McCarty, 2008).

Susan Hockey wrote in *Companion to Digital*

Humanities that "humanities computing has a very well-known beginning," by which she means the decades-long collaboration between Father Roberto Busa and IBM to create a concordance of the work of Thomas Aquinas (Hockey, 2004). This is the heroic first, which Busa, writing in the forward of that same volume, summed up with admirable brevity: "During the World War II, between 1941 and 1946, I began to look for machines for the automation of the linguistic analysis of written texts. I found them, in 1949, at IBM in New York City."– This narrative is familiar to many of those working in digital humanities today, and has become openly accepted as the standard historical background for, first, humanities computing and, subsequently, the digital humanities writ large.

This presentation aims to upset this easy narrative by re-situating the history of one type of digital humanities project—Early English Books Online—as one chapter in an overall history of a technological humanities. That history—the history of a technological humanities—the story of how academics have deployed technology to better understand human creations, especially in textual form—or to understand and explore texts—did not begin in 1949. The creation of digital humanities, radiating outward from those early years, is surely part of the larger story of how technology and text have come together and drifted apart over many centuries. I claim that there is a great deal more continuity in the apparatuses, in the knowledge infrastructure of the humanities than we put forward in our "official" histories. In our search for a neat disciplinary history, we elide technology as a whole with the digital electronic computer. Busa's project likely does represent the beginning of one type of computational textual processing. It bears remembering, however, that his goal was to create a concordance, a type of reference tool and interface in existence in Western Europe since at least the 13th century. What is the history of *this* type of textual processing in the intervening six hundred years?

Instead of a history of tools for textual work beginning with the rise of humanities computing and moving forward to the present day, I hope to juxtapose a different narrative, one that troubles the rhetoric of a textual digital humanities that arises from a clear break with what came before. I hope to, perhaps polemically, test the boundaries of histories of digital humanities by considering an equally technologically sophisticated pre-digital humanities. Such a reframing opens many avenues of inquiry, including a consideration of Linked Open Data in the context of cooperative cataloguing practices from the 19th & 20th centuries, or contemporary textual analysis tools such as Voyant alongside the imposing machinery of an electro-mechanical Hinman Collator. This presentation, however, will highlight particularly those technologies of textual reproduction developed prior to the oft-quoted originary moment of 1949. Drawing on the history of Early English Books Online (EEBO), I argue that while a *computational* humanities may indeed be limited to the last half-century, the *technological* humanities—in both materialist and cultural senses—have a much longer history.

ProQuest introduces the resource on their front page:

> From the first book printed in English by William Caxton, through the age of Spenser and Shakespeare and the tumult of the English Civil War, Early English Books Online (EEBO) will contain over 125,000 titles listed in Pollard and Redgrave's Short-Title Catalogue (1475-1640), Wing's Short-Title Catalogue (1641-1700), the Thomason Tracts (1640-1661), and the Early English Tract Supplement - all in full digital facsimile from the Early English Books microfilm collection.[1]

In practice, this means that users are able to view the metadata for a given text; view page images of the original, early modern books in TIFF or PDF format; and, where available, view a full text transcription of the volume that are derived from the EEBO - Text Creation Partnership. Efforts to microfilm early English books began in 1931, intensified as World War II loomed, and continue today. Digital images of these microfilmed documents were made (and are still being made) available online first in 1998. The printed *Short Title Catalogue* (itself published in 1926) has determined what objects were photographed and, subsequently, scanned and put online–(EEBO).

The history of EEBO crosses multiple media, was directly impacted by global war, involves private companies and public universities, and is both analog and digital. To bracket EEBO (or EEBO-TCP) as a only a digital project impoverishes our understanding of how digital technologies have impacted the reproduction, preservation, and use of texts in humanistic scholarship. To write the full history of the early English books project, Early English Books Online, the Early English Books Online Text Creation Partnership is to engage in an act of disciplinary archaeology, one that forces digital humanists to grapple with the pre-digital origins and ideologies that inflect contemporary digital resources undergirding scholarship. EEBO is a microcosm through which one body of interpretations of digital humanities might be seen.

As much as it is a history, this presentation is also engaged in answering claims by Alan Liu and Tara McPherson, amongst others, that digital humanities has chosen disciplinarily to disengage from socio-critical questions.–[2] Thinking through the history of EEBO is one way to approach the digital humanities as a discipline tied to war-driven technological development; the uneasy relationships between private-sector providers and our shared cultural heritage; or the many varieties of labour that are imbricated within the knowledge infrastructures humanists use day in and day out.–[3] Blending media analysis, historical perspectives, and in-depth knowledge of humanities research tools, I hope to question the boundaries of what we consider digital humanities to be, how we write our histories, and how we move forward.

Notes

[1] This text was current as of summer 2015 and is available in cached form. Since that time, Proquest has altered the front page description of EEBO to the following: Early English Books Online (EEBO) contains digital facsimile page images of virtually every work printed in England, Ireland, Scotland, Wales and British North America and works in English printed elsewhere from 1473-1700 - from the first book printed in English by William Caxton, through the age of Spenser and Shakespeare and the tumult of the English Civil War. Strangely, this newer version eliminates reference to the Early English Books microfilm Collection, as well as collapsing a number of distinct early modern collections of content into what might be called the EEBO brand. See the current version of <http://eebo.chadwyck.com/home> and a cached version <https://web.archive.org/web/20150905141338/http://eebo.chadwyck.com/home> from September 2015.

[2] For work by Liu on this topic, see "Where is the Cultural Criticism in the Digital Humanites?," published in *Debates in the Digital Humaniteies*, ed Matthew K. Gold <http://dhdebates.gc.cuny.edu/debates/text/20>. For McPherson work on UNIX and ideologies of race, see "Why are the Digital Humanities So White? or Thinking the Histories of Race and Computation" in the same volume <http://dhdebates.gc.cuny.edu/debates/text/29>.

[3] It is worth noting that one of the very few publications to deal with the EEBO set of projects in this way was published in *Literary and Linguistic Computing* (now *Digital Scholarship in the Humanities*). See Diana Kichuk, "Metamorphosis: Remediation in *Early English Books Online (EEBO)*" (2007) 22 (3): 291-303. DOI: http://dx.doi.org/10.1093/llc/fqm018. Kichuk's efforts have helped establish a historical framework for this discussion; this presentation seeks to contextualise the facts she has brought together and extend their relevance into discourses about DH as a whole.

Projet Odysseus, Outil d'Etudes Comparatives Du Traductologue

CLASP, Gothenburg University, Sweden

Introduction

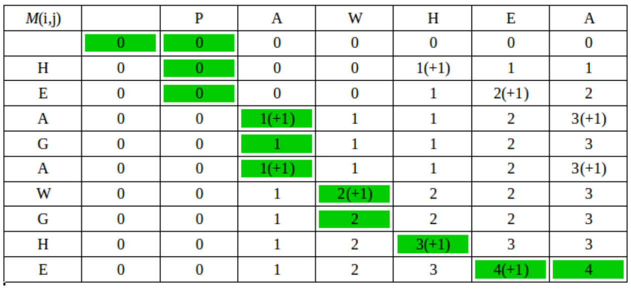
Le programme Projet Odysseus permet de voir immédiatement des différences et similitudes entre diverses traductions de l' Odyssée d'Homère. Nous appliquons ce programme à un corpus français d'une centaine de traductions françaises allant de 1584 à 1934, afin de déceler les évolutions diachroniques dans les pratiques traductives. Nous constituons un corpus italien similaire, et avons aussi effectué des essais sur des traductions espagnoles, anglaises et allemandes de l' Odyssée. Le protocole est applicable à tout corpus de traductions (Callison-Burch, 2008).

Notre programme permet donc de comparer un nombre indéfini de traductions d'un même texte source, sans dépendre des particularités linguistiques de chacune des langues cible.

Preprocessing: l'alignement

Pour comparer les différentes traductions entre elles, nous déterminons leurs similarités sémantiques et associons le texte source avec chaque texte cible. Nous établissons des points d'ancrage en grec et en français, qui permettent de découper les textes en séquences ayant potentiellement le même sens (Feng et Manmath, 2006) : les noms propres. Ils présentent deux avantages: ils peuvent être de très basse fréquence et sont majoritairement traduits par l'ensemble des traducteurs. Le texte grec pivot comprend toutes les leçons éditoriales établies à ce jour, afin d'assurer un alignement optimal tant avec les traductions anciennes que modernes. Le texte source pivot est découpé en séquences fixes : le programme découpe une nouvelle séquence dont le premier mot est le nom propre. Nous obtenons une série fixe de séquences. Nous appliquons le même processus aux textes cibles. Sont ainsi déterminés un ensemble de séquences sources et un ensemble de séquences cibles de nombre inégal.

Le programme aligne les séquences cibles aux séquences sources grâce à l'algorithme de Needleman-Wunsch (Needleman et Wunsch, 19 70). Il remplit une matrice de scores de similarité en comparant chaque séquence source avec chaque séquence cible. Un dictionnaire de noms propres augmente ou diminue le score. Un transformateur phonétique, transcrivant le grec en alphabet latin, augmente le score si le nom source phonétique se trouve dans la séquence cible. Le score tient compte la différence de longueur entre la source et la cible. Nous établissons dictionnaire de fréquence : si le nom pivot est à fréquence équivalente entre la source et la cible, le score augmente. Lorsque la matrice de scores est remplie, l'algorithme établit le chemin le plus probable depuis les deux dernières séquences source et cible jusqu'aux deux premières (Fig.1).



M(i,j)		P	A	W	H	E	A
	0	0	0	0	0	0	0
H	0	0	0	0	1(+1)	1	1
E	0	0	0	0	1	2(+1)	2
A	0	0	1(+1)	1	1	2	3(+1)
G	0	0	1	1	1	2	3
A	0	0	1(+1)	1	1	2	3(+1)
W	0	0	1	2(+1)	2	2	3
G	0	0	1	2	2	2	3
H	0	0	1	2	3(+1)	3	3
E	0	0	1	2	3	4(+1)	4

Fig. 1: Parcours de l'algorithmeTableauNW.png

Nous constituons ensuite un dictionnaire basé sur la distribution sémantique des mots. Chaque mot est caractérisé par un vecteur de cooccurrence : sur l'ensemble des séquences, lorsque un mot apparaît dans une fenêtre constituée d'une séquence source et de sa séquence cible, la valeur du vecteur à l'indice de la fenêtre augmente. Statistiquement, des mots à usage similaire se trouvent à la fois dans les séquences sources et cibles aux mêmes indices. La similarité des vecteurs est établie avec la similarité cosinus (Ye, 2011). Si un mot source obtient un vecteur similaire à celui d'un mot cible, la source-clé et la cible-valeur sont ajoutés au dictionnaire. Un second alignement est produit, tenant compte des scores obtenus grâce au dictionnaire de distribution. Lorsque nous effectuons plusieurs alignements en même temps, nous fusionnons les dictionnaires. Chaque séquence source comporte alors un identifiant unique auquel un identifiant cible est associé.

Classes comparatives

Nous pouvons comparer chacune des traductions alignées au texte source pivot, dans une interface faisant figurer autant de traductions que l'utilisateur le souhaite.

Lorsque des vides sont laissés par l'algorithme, deux interprétations sont possibles : le traducteur est extrêmement loin du texte source, ou il ne traduit pas le texte source. Dans les deux cas, cela nous renseigne sur ses pratiques traductives.

Nous comparons ensuite statistiquement les séquences alignées. Pour chaque séquence dans l'ensemble du corpus, nous déterminons la fréquence de chaque mot. Nous pouvons voir le taux d'usage d'un mot pour chaque séquence. Il est ainsi possible de visualiser les hapax produits par chaque traducteur. Il est aussi possible de déceler si un traducteur se base sur la même source que les autres : si le nombre d'hapax sur une séquence se multiplie, le traducteur ajoute probablement une séquence par rapport à ses homologues. Nous identifions les étoffements et réductions : si le nombre de mots employé par un traducteur pour une séquence est largement inférieur ou supérieur au nombre médian de mots employés dans le corpus pour cette séquence, le traducteur étoffe ou réduit le texte source. Nous décelons enfin un littéralisme fréquentiel de chaque séquence par rapport à sa source (lorsque le nombre de mots grecs est équivalent au nombre de mots français pour une même séquence), ainsi qu'un littéralisme phonétique (lemme grec retranscrit phonétiquement proche d'un mot cible).

Nous nous appuyons sur les travaux d'Henri Meschonnic (Meschonnic, 1997) et d'Antoine Berman (Berman, 1984) pour définir des critères de comparaison entre la source et les cibles. Nous déterminons d'abord s'il y a, entre les deux, un allongement ou un appauvrissement quantitatif, en définissant une fenêtre de mots au-delà ou en deçà de laquelle nous considérons que la différence dans le nombre de mots est signifiante. Nous visualisons la tendance à la « rationalisation » : nous repérons, en comparant les patrons syntaxiques, l'inversion de la linéarisation des arborescences syntaxiques. Nous visualisons enfin la « destruction des rythmes », en recherchant la similarité entre les patrons de ponctuation ou les patrons de syntaxe profonde (juxtaposition, coordination, subordination) entre la source et la cible.

Pour comparer les traductions entre elles, l'utilisateur peut considérer dans l'étude statistique soit les traductions à l'écran, soit l'ensemble du corpus.

Nous intégrons un graphique permettant de visualiser les tendances décrites des auteurs dans la diachronie. Si un auteur a une forte tendance à l'emploi d'hapax, et que cette tendance se poursuit chez ses successeurs, cela est immédiatement visible.

Cas d'étude

Voici deux exemples: une utilisation unilingue dans l'interface de comparaison automatique, et une utilisation multilingue avec les résultats d'un dictionnaire de distribution. Le premier exemple est basé sur le chant I de vingt traductions françaises, de 1584 à 1935.

Fig. 2: Une des fenêtres du programmescreen2.png

chunk 131 Ulysse n ' est pas le seul qui au pays de | chunk 131 Ulysse n ' est point le seul qui , dans la ville de | chunk 131 Ulysse , tu le sais , ne fut pas seul à perdre la journée du

Fig. 3: Trois séquenceszoom1.png

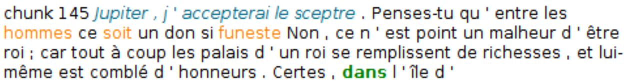
Dans la Fig.3, la première version est de Médéric Dufour et Jeanne Raison (Dufour et Raison, 1935), la deuxième celle d'Eugène Bareste (Bareste, 1842), la troisième celle de Victor Bérard (Bérard, >1924). Les termes en vert sont utilisés pour chaque tronçon par une grande majorité de traducteurs, ceux en orange sont fréquents, et ceux en rouge sont des hapax (utilisés une seule fois dans cette séquence par un traducteur). Le programme permet de visualiser ces captures sur une grande échelle, avec autant de traducteurs que nécessaire. En comparant le « chunk 131 » de Victor Bérard, par exemple, avec l'ensemble des « chunk 131 » du corpus, nous distinguons, toute proportion gardée, une tendance de Bérard à se démarquer de ses prédécesseurs par emploi de termes rares, phonétiquement ou syntaxiquement proches du grec.

chunk 134 Athénè aux yeux ballants versa sur ses paupières le doux sommeil . Les prétendants criaient dans la salle envahie par l ' ombre tous avaient senti le désir d ' être couchés près d ' elle . / Et , s ` adressant à eux , le prudent

chunk 134 Minerve répand un doux sommeil sur ses paupières . Pendant ce temps les prétendants s ` agitent dans les salles obscurcies par les ombres du soir , et tous désirent partager la couche de Pénélope . Alors

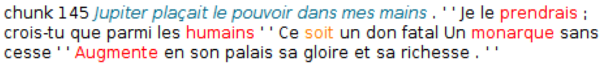
Fig. 4: Comparaison, zoom

Dans la Fig. 4 Dufour et Raison (premier texte) optent pour un terme rarement associé aux yeux d'Athéna (« ballants »), produisant un hypallage, tandis que les autres termes sont consensuels. Bareste privilégie les présents d'hypotypose et de juxtaposition temporelle. Certaines expressions homériques sont rendues unanimement par les traducteurs, comme « ὕπνος ἡδύς », « le doux sommeil ».



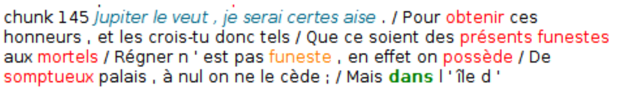
chunk 145 *Jupiter , j ' accepterai le sceptre* . Penses-tu qu ' entre les
hommes ce soit un don si funeste Non , ce n ' est point un malheur d ' être
roi ; car tout à coup les palais d ' un roi se remplissent de richesses , et lui-
même est comblé d ' honneurs . Certes , dans l ' île d '

Fig. 5: Traduction de Bareste (1842)



chunk 145 *Jupiter plaçait le pouvoir dans mes mains* . ' ' Je le prendrais ;
crois-tu que parmi les humains ' ' Ce soit un don fatal Un monarque sans
cesse ' ' Augmente en son palais sa gloire et sa richesse . ' '

Fig. 6: Traduction de Bignan (1853)

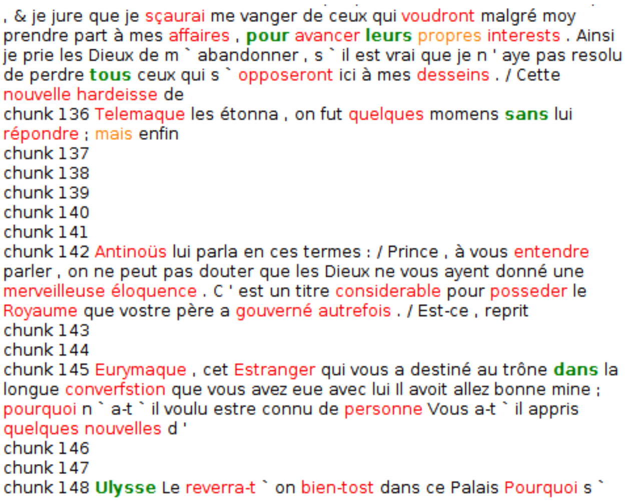


chunk 145 *Jupiter le veut , je serai certes aise* . / Pour obtenir ces
honneurs , et les crois-tu donc tels / Que ce soient des présents funestes
aux mortels / Régner n ' est pas funeste , en effet on possède / De
somptueux palais , à nul on ne le cède ; / Mais dans l ' île d '

Fig. 7: Traduction de Froment (1883)

Les Fig. 5, Fig. 6 et Fig. 7 sont des traductions d'une portion de texte qui tend à se traduire selon le même mode au XIXe siècle. Dans plus de vingt textes, pour l'expression « καὶ κεν τοῦτ' ἐθέλοιμι Διός γε διδόντος ἀρέσθαι », les traducteurs imitent la ponctuation du texte source (italique), mais aussi sa syntaxe (couleur bleue).

Le programme permet de déceler les portions de texte omises par le traducteur. Par exemple, Achille de La Valterie disait traduire l' Odyssée sans connaître le grec (à partir du latin) : sa traduction s'aligne, mais le nombre d'hapax et d'omissions est sans précédent (Fig. 8).



, & je jure que je sçaurai me vanger de ceux qui voudront malgré moy
prendre part à mes affaires , pour avancer leurs propres interests . Ainsi
je prie les Dieux de m ` abandonner , s ` il est vrai que je n ' aye pas resolu
de perdre tous ceux qui s ` opposeront ici à mes desseins . / Cette
nouvelle hardeisse de

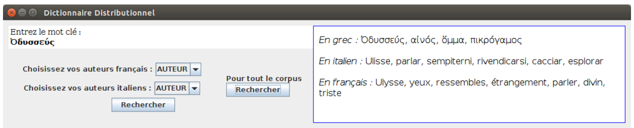
quelques nouvelles d '
chunk 146
chunk 147
chunk 148 Ulysse Le reverra-t ` on bien-tost dans ce Palais Pourquoi s `

Fig. 8: Traduction de La ValterieValterie

Dans cet extrait, les blancs laissés par le programme ne sont pas des erreurs d'alignement, mais des omissions du traducteur, qui choisit de ne pas traduire.



Dictionnaire Distributionnel
Choisissez vos auteurs français : AUTEUR
Choisissez vos auteurs italiens : AUTEUR
Rechercher
Pour tout le corpus
Rechercher

Entrez le mot clé :
Ὀδυσσεύς

En grec : Ὀδυσσεύς, αἰνός, ὄμμα, πικρόγαμος

En italien : Ulisse, parlar, sempiterni, rivendicarsi, cacciar, esplorar

En français : Ulysse, yeux, ressembles, étrangement, parler, divin, triste

Fig. 9: Dictionnaire

Pour une utilisation multilingue, nous pouvons mener les mêmes expériences que pour un corpus unilingue. Nous pouvons aussi visualiser le dictionnaire de distribution, qui permet de voir comment chaque langue traduit, pour l'ensemble de son corpus, chaque notion. En Fig. 9, nous comparons comment chaque langue traduit « Ὀδυσσεύς » dans le chant I et quels en sont les termes sémantiquement proches, tous auteurs confondus. Nous pouvons ne choisir que certains auteurs, afin par exemple de voir l'évolution de l'emploi d'un terme en France et en Italie pour une période définie. Nous pouvons générer des dictionnaires multilingues dont le degré de sévérité dans la sélection est modifiable.

Conclusion

Ce programme a pour but de proposer aux comparatistes une façon simple de repérer les grandes tendances et les phénomènes notables d'une traduction à une autre, indépendamment de la langue du traducteur. Mais le programme ouvre aussi la voie à la création d'autres outils pour l'étude de corpus multilingues (dictionnaires, détection automatique de paraphrases interlinguistiques), à de nombreuses analyses statistiques (fréquence des mots, « type / token ratio », etc.) qui représenteront un apport substantiel à l'étude de l'Histoire des traductions.

For more than 20 years, researchers at Matrix, the Center for Digital Humanites and Social Science have been working on digital projects in several countries in Africa. While the technologies are critical parts of the digital humanities, ethical considerations also need to be part of any project that involves multiple projects. This is particularly true of Digital African Studies Projects because of the long and bloody history of colonialism, exploitation, and cultural theft. This long paper will explore through the context of two ongoing projects -- "Archive of Malian Photography" and the "Gorée Island Archaeological Digital Repository" — strategies to be deployed to develop sustainable, equitable, and ethical projects. While neither project is a perfect model, the strategies deployed set against the everyday frustrations of multiple partner projects, long distance project management, and problematic working conditions does help to expose what works and what still needs to be changed or augmented.

Mali has remained the international nexus of African photography for nearly twenty years. Since 1994, its capital, Bamako, has been home to the only biennial festival of photography from Africa and has produced the continent's most globally renowned professional photographers. Matrix in collaboration with the Maison Africaine de la Photographie in Mali, is digitizing and rendering globally accessible the archives of the nation's most important photographers, dating from the 1940s to the present. The

"Archive of Malian Photography" addresses the following significant needs for scholarship and teaching in the humanities as well as the preservation of Mali's cultural heritage:

- Although commercial, popular, and scholarly interest in African photography has flourished over the past twenty years, access to photographers' studio archives is extremely limited and published materials are minimal;

- Retained in private archives, these materials are not catalogued, appropriately preserved, or internationally accessible for research and education;

- Due to the high commercial value of these archives in global markets, these materials are vulnerable to mistreatment, theft, and exploitation;

- Moreover, stored in harsh climactic conditions, the physical integrity of these collections is in serious jeopardy.

Photography was introduced to present-day Mali during the 1880s by French military officers and, later, colonial administrators, missionaries, and French expatriates. By the 1940s, an African market for photography developed in the French Sudan, as Mali was then known, and its professional photographers maintained a monopoly over the medium. As a result, their archives contain rare visual documentation of social, cultural, and political life as well as processes of urban development in the country, and in French West Africa more broadly. Spanning the eras of French colonialism, political independence, socialism, and democracy, their archives record important sociopolitical transformations of present-day Mali, its capital, and smaller towns along the Niger River such as Mopti and Ségu during the twentieth century. Employed by colonial and national governments, while operating private studio enterprises, each photographer's collection houses unique African perspectives on local histories and practices, including personal and family portraiture, military activities, visits of foreign dignitaries, and images of the coup d'états that toppled the socialist regime of the nation's first president, Modibo Keïta (1968), and the dictatorial rule of his successor, Moussa Traoré (1991). They also feature the construction of national monuments, governmental structures, bridges, dams, roadways, as well as prominent religious leaders, political figures, cultural ceremonies, and fluctuating trends in personal adornment, popular culture, and photographic practices from the 1940s to the present.

In addition to promoting the global accessibility of these materials, the project is designed to protect the physical integrity of the original archives, safeguarding the negatives from further damage and theft. After the popularization of Malian photographers' images in exhibitions and publications around the world since the 1990s, their archives have become increasingly vulnerable to pilfering and misuse due to their high commercial value in the international art market. Underscoring the severity of this issue, today, some images from the archives of El Hadj Tijani Sitou and Abdourahmane Sakaly are illegally featured for sale online (http://www.african-collection.dk/english/sakaly-1.htm) by a dealer in Denmark who obtained the photographers' original negatives, along with those from Mamadou Cissé's archives, from an administrator at the National Museum in Bamako who had been charged with their protection. To date, the dealer refuses to repatriate the negatives. In another case, prints from twelve of Sitou's negatives appeared on the cover of African Arts in 2008, without his family's permission. Such pervasive pilfering of negative archives by foreign collectors, dealers, curators, and scholars, as well as by the leaders of local cultural institutions (museums, galleries, libraries), has prevented these rare collections from entering formal, public archives in Mali.

The Gorée Island Archaeological Digital Repository seeks is creating virtual 3D representations of cultural heritage materials excavated from archaeological sites in and around Gorée Island, Senegal and share those representations in an open-access, online digital repository. This work answers at least three needs in the scholarly community. First, it enables cultural heritage institutions in Africa to digital preserve archaeological materials in a way that is unobtrusive, relatively inexpensive. The project makes use of photogrammetry, a process wherein a series of images are taken of an object and run through point-recognition software to create a virtual 3D image. This process inexpensive, portable, and relatively easy to complete, making it the jointly sustainable choice for African cultural heritage institutions. Second, the repository allows scholars both within Africa and around the world to have access to these cultural heritage materials without the restrictions and inconveniences of analog-based preservation. Finally, the Gorée Island Digital Repository builds capacity amongst Senegalese students, scholars, and organizations to continue documenting and preserving cultural heritage materials using industry best standards and practices.

The project is being developed through the collaboration of the Université Cheikh Anta Diop de Dakar – Sénégal (UCAD), Institut Fondamental d'Afrique Noire, the Smithsonian National Museum of African American History and Culture, Michigan State University, Matrix with the support of the Centre de Researche Ouest Africain.

Documenting, safeguarding, preserving, interpreting/reinterpreting, and making accessible the myriad expressions of Africa's many cultures is vitally important for Africa's diverse constituent communities as well as for the rest of the world. Museums, libraries, and archives in Africa and around the world face an enormous challenge as Africa's diverse and rich cultural heritage has been scattered by history and put at risk by wars, illicit trafficking, overwhelming economic challenges, and destruction or erosion due to human and environmental impacts. As pioneering efforts have demonstrated, the digital revolution opens up significant possibilities for long-term preservation and meaningful access that have proven unattainable in an analog world. However, to do so requires thoughtful, ethical, equitable, and sustainable strategies. These considerations need to be built into the very structure of digital humanities projects.

Significant barriers remain, however, that severely limit efforts to move beyond these individual projects and fully utilize digital technologies within Africa and with African cultural materials around the world. While we are at a moment of opportunity with digital technologies, this is also a period of crisis where invaluable cultural resources are at risk to be lost forever. This paper also calls for the need for major international leadership initiatives to tackle these barriers in coordinated fashion and chart a path forward for museums, libraries, archives, universities and other heritage preservation institutions to construct equitable international partnerships that can harness this powerful opportunity.

Addressing Torture in Iraq through Critical Digital Media Art—Hearts and Minds: The Interrogations Project

Scott Rettberg
scott.rettberg@uib.no
University of Bergen, Norway

Roderick Coover
roderickcoover@gmail.com
Temple University

Hearts and Minds: the Interrogations Project is an interactive virtual reality artwork developed by an interdisciplinary team including humanists, social scientists, artists, and computer scientists from four different universities. The project attempts to extend and make accessible difficult narratives of war and abusive violence based on actual accounts from soldiers involved. The work offers models for engaging with testimony and oral history. It uses visualization to build new discourse around challenging topics and to bridge concepts that enable storytelling. While many uses of visualization technologies are focused on providing accessible representation of "big data," in this case, the technologies are being used as a narrative platform to represent a complex contemporary issue and to provide a platform for discussion and debate of military interrogation methods and their effects on detainees, soldiers, and society.

Hearts and Minds makes use of the CAVE2^{TM} environment for a multisensory artwork addressing a complex contemporary problem: as American soldiers are returning from wars in Iraq and Afghanistan, it is becoming increasingly clear that some of them participated in interrogation practices and acts of abusive violence with detainees for which they were not properly trained or psychologically prepared. This has in turn left many soldiers dealing with Post-Traumatic Stress Disorder after their return home. More than 1.8 million US troops have served in Iraq and Afghanistan, with 37% having been deployed at least twice (Litz, 2009) The mental health impact of these wars is still under research as many veterans are at risk for chronic PTSD. American soldiers and citizens are left with many unresolved questions about the moral calculus of using torture as an interrogation strategy in American military operations.

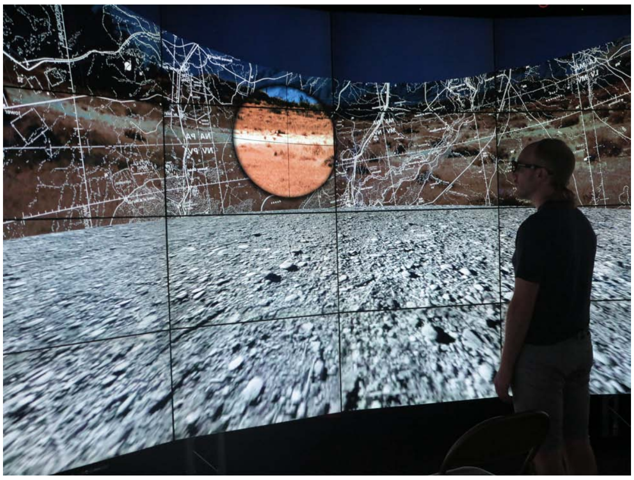

Fig 1. A performer interacts with the CAVE2 version of *Hearts and Minds* at the EVL in Chicago

Development

Hearts and Minds bridges art, computer science, and social science research. Artist Roderick Coover (Temple University) and writer Scott Rettberg (University of Bergen) worked with the research scholars John Tsukayama and Jeffrey Stevenson Murer (St. Andrews University) to distill central themes and stories from the significant and extensive research project—based on hundreds of hours of original interviews with veterans—carried out by Tsukayama (Tsukayama, 2014). These interviews include revelations of a highly sensitive nature, including narratives of participation in acts of abusive violence that entailed violations of human rights. The interviewees granted Tsukayama the right to use their stories in his dissertation and in subsequent research outcomes derived from it, provided that their identities remained anonymous. The tapes of recorded interviews were destroyed after transcription, except for short samples to prove their authenticity, and Tsukayama did not retain any personal contact information for the soldiers he interviewed. The text was condensed into an accessible and coherent set of stories that would preserve the accuracy of the testimonies while voice actors would perform the roles of veterans, further assuring their anonymity.

Coover and Rettberg worked with artist Daria Tsoupikova and scientist Arthur Nishimoto at the Electronic Visualization Lab (University of Illinois at Chicag, 2014) to transform this controversial and challenging research into an accessible form through visualization and dramatization. Together they developed an interactive virtual environment with imagery, 3D models and panoramic photographic backgrounds to bring story elements together. Working across these environments allowed new kinds of connections to be made between home spaces and battlefields, and between domestic objects and the memories they become attached to.

The voice recordings performed by Philadelphia-based actors were integrated with interactive media elements in a peformative interactive environment. Objects, 3D environments, textures, and some animations were developed in Maya (Autodesk Inc., CA). Maya speeds up the production process through its rich selection of tools supporting all stages of modeling, including surface creation and manipulation, texturing, lighting, rigging, and animation. The visual, auditory and narrative elements were brought together in the Unity platform (Unity Technologies Inc., CA), software that is typically used by computer game developers. The getReal3D plugin for Unity developed by Mechdyne Corporation is used to run Unity across the CAVE2™ cluster (Mechdyne Corporation, 2014). User interaction was scripted using the Omicron (Electronic Visualization Lab, 2014) input abstraction library developed by EVL.

CAVE2 Performance

In its first iteration, *Hearts and Minds* was presented as public performances at the University of Illinois Chicago Electronic Visualization Lab in June and July 2014 (Galatzer-Levy, 2014). Chicago-based performance artist Mark Jeffrey led a performance of the interactive work. As the audience entered the space, they found themselves in a temple environment listening to each of the four soldier character's stories of enlistment—why they originally chose to become soldiers and what motivated their perspectives on the purpose for military service.

Jeffery then led the audience to the boy's room, where activating four individual objects launches stories of first encounters with abusive violence in military experience, such as in hazing rituals during basic training, or after first arriving in Iraq. When each trigger object is selected within the 3D visual space, the domestic space falls away and a surreal desert landscape is revealed. This transition serves as a metaphor for the interior state of the individual solider, as it is coherent with accounts of soldiers experiencing Post-Traumatic Stress. It is also intended to bring audience members into a "listening state" where they can focus on the individual voices and the issues they raise. Objects in a living room space and a suburban backyard move us further into the field of battle, and there we encounter harrowing stories of interrogation, torture, and moral conflicts confronted differently by each of the characters.

An important component of the performances of *Hearts and Minds* is that the experience of the artwork is followed by audience discussion. The ultimate purpose of this work is to promote dialogue and debate about the contexts and circumstances of the use of torture in battlefield torture in recent history. In this sense the project shares an aim with Augosto Boal's Theatre of the Oppressed, in that attempts to offer audiences "the aesthetic means to analyze their past, in the context of their present, and subsequently to invent their future, without waiting for it." (International Theatre of the Oppressed Organization, 2014) During a 2015 presentation of the project at the Oslo Human Rights Film Festival (Coover et al., 2015), discussion participants included both a veteran police interrogator, who shared his experience that more humane methods of interrogation than torture were universally more effective, and a number of prisoners of conscience who had themselves been subjec to abusive violence and felt provoked by the work to share their own experiences as victims of torture.

Accessible Versions and Alternative Platforms

One of the challenge for makers of immersive virtual reality artworks, particularly those developed in CAVEs and other custom-built VR environments is that these artworks tend to be more often read about in the literature of the field than experienced first-hand. The CAVE2™ at the EVL for example is an active research lab facility with keycard access at the center of a large engineering building on the UIC campus. *Hearts and Minds* has been shown there at several special events and on specially arranged tours, but it is not the ideal accessiblity situation to reach a broader audience. Because *Hearts and Minds* was developed in Unity, it is possible to port the application to other environments. In order to make the work more accessible for new audiences, the *Hearts and Minds* team is developing new versions of the work: a Mac OS standalone application suitable for cinematic performance or installation (Coover et al., 2014), a Unity web-player version which will be published on the World Wide Web and will be accessible freely to the public, a version suitable for iPads and other tablet computers, and a version for Oculus Rift. The stand-alone application version has been used for performances in cinema enivronments in Paris, Bergen, Oslo, Krakow, Michigan, and elsewhere, and the other application versions will be publically released in 2016.

Fig. 2 Presentation of the interactive cinematic version of *Hearts and Minds* at the 2015 Oslo Human Rights / Human Wrongs festival

Completing *Hearts and Minds* as Critical Digital Media and Digital Humanities Project

The *Hearts and Minds* team is currently developing the tablet version of the work, which will include both the tablet (iPad and Android) application, and a package of contextualizing essays, interviews and commentaries both specific to the work and that provide more detailed treatments of the issues the work raises. These essays and interviews will for example contributions by political scientists and social scientists about the situations out of which abusive interrogations practice emerged, contributions by digital humanists considering interactive media artworks as a mode of critically and socially engaged research, and contributions by designers and computer scientists considering the history and technologies involved in virtual reality art. Coover and Rettberg's long paper for DH 2016 will include a presentation of this new version of the project, and will further situate *Hearts and Minds* in an emergent corpus of critically engaged new media art.

An Iterative 3DGIS Analysis of the Role of Visibility in Ancient Landscapes

Heather Richards-Rissetto
richards-rissetto@unl.edu
University of Nebraska-Lincoln, United States of America

Introduction

Through the spatial arrangements of temples, houses, roads, and more, the built environment provides a window to human interaction (Lawrence and Low, 1990). Spatial configurations influence how people negotiate their surroundings. People "read environmental cues, make judgments…and then act accordingly" (Rapoport, 1990: 139), and these decisions in turn, affect the frequency and intensity of interaction (Fletcher 1981). While many factors influence interaction within landscapes, in this paper I focus on visibility.

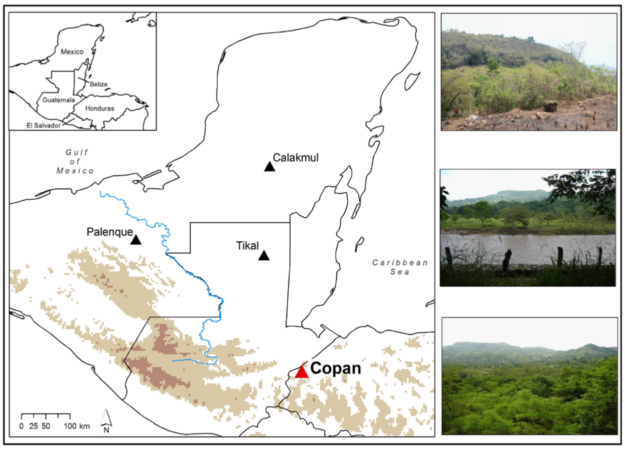

Figure 1: Map of Copan's location at southeastern periphery of Maya region (Map: H. Richards-Rissetto)

The visibility, intervisibility, and invisibility of features communicate information that guides pedestrian movement, and consequently, structures social interaction and community organization (Llobera, 2003, 2006; Gillings, 2015). Building on these ideas, this paper uses Geographic Information Systems (GIS) and 3D visualization to explore the role of visibility in ancient landscapes asking: *How might visibility influence where people went, what they did, who interacted with whom, and how did these interactions shape their daily experiences?*

Case Study: Copan, Honduras

The case study is the ancient Maya polity of Copan (Figure 1) ruled for over four-hundred years by a line of dynastic kings who by the late eighth century were facing mounting sociopolitical and environmental problems (Fash, 2001). Copan's final dynastic ruler, *Yax Pasaj*, like the rulers of many other Maya polities, was coping with strenuous environmental, demographic, and sociopolitical circumstances that would ultimately lead to the kingdom's demise. Yet during this time of stress, it seems that *Yax Pasaj* carried out a major urban renewal project commissioning several new temples in the city center that elevated Copan's skyline. Given the changes to Copan's urban fabric, *Yax Pasaj's* reign is an ideal case study to investigate the role visibility may have played in the production or reproduction of social interaction among the ancient Maya.

At Copan, as at other Maya centers, imagery on ceramics, murals, and freestanding monuments depicted deities floating over lords who subsequently looked down over lower-ranking persons. Maya architecture replicated this vertical succession by elevating royal compounds above other architecture, and in essence linking Maya rulers to the heavens (Messenger, 1987). In terms of visibility, epigraphic decipherments indicate that "seeing" afforded high status, and sight had an authorizing gaze and witnessing function—similar to Foucault's (1995) Panoptic gaze—where those who were all-seeing were all-knowing (Houston et al. 2006: 173). In order to be all-seeing or to give such an impression, however, Maya rulers needed to be seen, and so often located themselves in physically high and easily visible places or built tall temples that dominated the landscape.

While we know that Maya kings typically constructed highly visible temples, we actually know very little about the role visibility may have played in structuring social connections and daily interactions among social groups. To do this we need to broaden our view from civic-ceremonial precincts to encapsulate the broader landscape (Doyle et al., 2012; Richards-Rissetto 2010; Landau, 2015).

Background: GIS & 3D Visualization

Early visibility studies in the Maya region focused on astronomical alignments among structures, freestanding monuments, and the sky (Aveni and Hartung, 1986). Later, ethnographic studies showing that contemporary Maya often use sight lines to mark out spaces (Hanks, 1990) inspired researchers to investigate whether non-astronomical lines-of-sight also existed at ancient sites; and in fact, archaeologists identified sight lines between a major temple and outlying stelae at the site of La Milpa, Belize (Hammond and Tourtellot, 1999). Recent research has moved away from lines-of-sight between two objects to study the relationships that an object may have to the many objects or features found within a landscape, referred to as a visualscape (Llobera, 2003). Simple line-of-sight measurements cannot provide data on the relationships among multiple objects because they are done along a fixed line; however, visualscapes can be measured using viewsheds that calculate an object's entire 360° field-of-view using GIS.

A GIS links mapped features to attributes stored in a database and overlays different data layers such as land usage, elevation, and buildings to help reveal complex patterns, relationships, and trends that are not readily apparent using other tools such as traditional databases not linked to maps.

Pros: In regard to visibility analysis, GIS allows archaeologists to move beyond line-of-sight analysis to viewshed analysis. A viewshed uses raster data (pixels) to identify all cells visible from one or more viewpoints in a landscape; all non-visible cells are assigned a 0 and all visible cells are assigned a 1. This basic binary schema allows for complex mathematical calculations, for example, Boolean operations or map algebra, to calculate topographic prominence of individual features (or classes of features) and percentage of intervisibility among features.

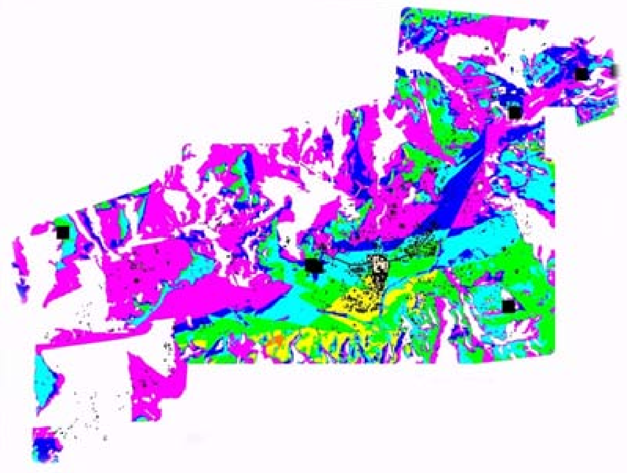

Figure 2: Cumulative viewshed illustrating number of valley stelae visible at locations at Copan

Cons: "Viewsheds depicted in a GIS map bear little resemblance to what people experience on the ground" (Conolly and Lake, 2006: 233). This limitation occurs because viewshed data are 2.5D. In other words, viewsheds store heights and elevation, but they are not actually 3D models (Figure 2). For digital humanists, these flat maps lack a sense of mass, scale, and aesthetics integral to human perception and experience, and the numerical outputs fail to differentiate visibility of a building's façade versus its sides or back—essential for close reading interpretation. Technically, data resolution (i.e., ratio of pixel size to earth's surface) can dramatically affect viewshed results—low spatial resolution often masking variation and too high a spatial resolution underestimating visibility (King et al., 2015).

3D technologies offer an alternative to GIS. 3D data acquisition (e.g., airborne LiDAR, terrestrial laser scanning, and photogrammetry), 3D modeling (e.g., SketchUp, 3D StudioMax, Agisoft), and interactive 3D visualization (e.g., Unity, Oculus Rift) are transforming archaeological practice. But, what impact are such 3D technologies having on visibility analysis across ancient landscapes? Airborne LiDAR, for example, rapidly collects 3D data for archaeological sites across vast areas (Thompson and Prufer, 2015). Most LiDAR data are of unexcavated mounds requiring subsequent 3D modeling of architecture and proper alignment within terrains in order to perform visibility analysis—traditionally time-consuming tasks (Richards-Rissetto, 2013).

While most visibility analyses of archaeological landscapes use traditional 2.5D GIS, recently archaeologists have been exploring the potential of 3D approaches for visibility analysis in archaeology. Paliou (2014) developed a computational visibility approach to analyze the visual range of paintings first using 3D modeling programs (3DStudioMax and AutoCAD) and then converting the results into raster maps to be analyzed in a GIS. Dell' Unto and colleagues (2015) bring georeferenced 3D architectural models (using laser scanning and photogrammetry) into a GIS to calculate visibility of building interiors at Pompeii. While Saldana and Johanson (2015) also use 3DGIS, they employ procedural modeling to rapidly generate alternative 3D building reconstructions based on a set of architectural rules and attributes stored in a GIS to explore visibility in Ancient Rome (Saldana, 2015).

Methods

Building on this scholarship, I employ an iterative 3DGIS approach to explore the role of visibility at the ancient Maya site of Copan—today a UNESCO World Heritage Site in Honduras. The approach is twofold: computational and experiential. In the computational approach, I employ traditional 2.5D viewshed analysis in GIS to establish a baseline for comparative analysis with viewshed results in 3DGIS.

First, I use ArcGIS 10.3 (standard GIS software) to assign known building heights and interpolate building heights of unexcavated mounds and run viewsheds to calculate topographic prominence and percent visibility in relation to settlement of major temples and classes of architecture (Richards-Rissetto, 2013). Recent acquisition of airborne LiDAR data has generated a 1m resolution terrain allowing for greater accuracy than earlier visibility analyses (Richards-Rissetto, 2010; von Schwerin et al., 2016). Second, I employ CityEngine—a procedural modeling program that convert GIS data to 3D models—to generate 3D models for Copan's 3,000+ buildings with the LiDAR terrain using the GIS data and a set of architectural rules as well as laser scanned and photogrammetric models of some standing monuments at Copan (Figure 3) (Muller et al., 2006; Richards-Rissetto and Plessing, 2015; von Schwerin et al., 2013). These procedurally-generated 3D models are then returned to ArcScene (a 3D viewer for ArcGIS) and the viewshed analysis is rerun for comparative analysis of 2.5DGIS vs. 3DGIS of visibility at ancient Copan.

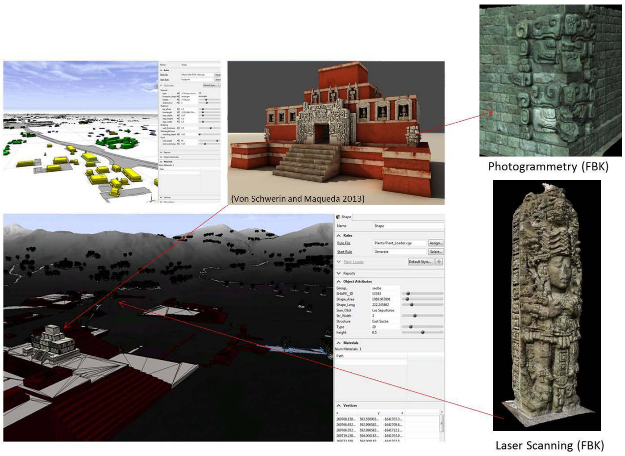

Figure 3: Illustrating procedurally-generated models and various data types imported into CityEngine

In the experiential approach, I export the 3D models and terrain from CityEngine into Unity 5—a gaming engine—to interactively explore the 3D models. In this model, vegetation is added to the landscape and avatars proceed along set paths generated from a combined cost surface and visibility analysis (Figure 4) (Richards-Rissetto, 2013; Richards-Rissetto and Landau, 2014). Oculus Rift—a head-mounted virtual reality display—is employed to create an immersive experience for ancient Copan as a means to more intuitively interact with archaeological data (Bartolo et al., 2000; Frisher and Dakouri-Hild, 2008).

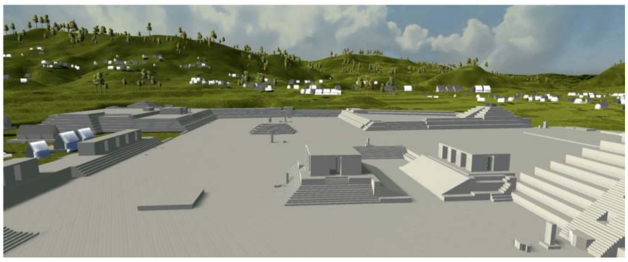

Figure 4: 3D Models (from SketchUp using GIS data) visualization in Unity 5 (Richards-Rissetto and Day)

Discussion

Strongly embedded in the Digital Humanities, this 3DGIS iterative approach tacks back and forth between

2.5D and 3D data to compare results and potentially derive new methods and interpretations for visibility analysis of ancient landscapes—analyses that would not be possible without taking advantage of the digital to cross-cut the computational and experiential.

Acknowledgements

The Layman Award, University of Nebraska-Lincoln provided a seed grant to carry out initial procedural modeling tests. This research would not be possible without permission and assistance from the Honduran Institute of Anthropology and History (IHAH). The MayaArch3D Project has generously providing the airborne LiDAR data and the laser scanned and photogrammetric models for this research. I want to thank UNL students Zachary Day, Stephanie Sterling, and Rachel Plessing for their important work on the visualizations.

The Trajectories Tool: Amplifying Network Visualization Complexity

Alexandre Rigal

Loup Cellard
loup.cellard@epfl.ch
EPFL, Switzerland

Introduction

Network visualizations are the most complex visualizations possible, but sometimes they are not capable of describing system-complexity. Even if they are the most widely employed visualization techniques, they still have limitations. Indeed a) their relations are not sufficient to analyse complexity and b) networks do not distinguish between qualitative differences of represented entities.

Starting from the actual network model, how could one manipulate this visualization to improve complexity comprehension? In this paper, we propose a solution called *trajectory*. The trajectory has two major points of difference compared to the network: the trajectory a) represents not only distances, but also durations, and b) it displays kinetic entities according to their evolution with time.

The discourse is articulated around these four points. Considering that networks are tools widely used by digital humanists, we propose a new language to improve the quality of represented data: a new network based on a vertical timeline. Complexification of the network visualization is not just a new language, but also a tool that would give the field of Digital Humanities the most complex of all possible visualizations.

Networks

How could one improve the visualization of complexity? To answer this question, we need to investigate the qualities and defects of network visualizations. A network is a wonderful way to visualize complexity: in this model, limitless relations and entities can be mapped. A network neither draws frontiers nor imposes quantitative limits to relations and entities. How does one imagine an even more complex visualization? In other words, how does one draw a "greater infinity" of relations and entities? It seems impossible indeed; the network could possess interminable relations and entities. But a trick is still possible – to enrich entities by adding a temporal dimension.

Conventionally, network visualizations are created considering the interdependence between distance and attraction, i.e. the spatial relationship. In fact, network visualizations are stable images, keeping each entity immobile, without possible evolutions. Changes in connections and disconnections of entities happen because of temporal events taking place in reality. So, if we want to achieve an even more detailed representation of complexity, we need to introduce another dimension for relations and entities – the dimension of time.

Figure 1. Umberto Boccioni, *Spiral Expansion of Muscles in Action*, 191

Time and space are intimately linked through movement. To enhance the richness of the visual language, we need to visualize the movement of entities through static simulation, as done in *Spiral Expansion of Muscles in Action* by Umberto Boccioni, the Futurist artist who introduced the art of depicting sculpture in movement (Figure 1). We do not need to draw more actors or relations, it is enough to improve their representation with a more elaborated shape. In this way, complexity will be managed not only in terms of infinite spatial entities and relations, but also in terms of infinite time-based entities and relations.

Movement and complexity

If network visualization is to represent movement, it needs the fluidity through a new dimension of reality. This is the reason why relations and entities have to be both spatial and time-based. Movement lends a continuity to time and space, and is the key to better understand the representation. Consequently, the aim is to visualize the evolution of entities through a sequence of time-based networks.

Formerly, Kandinsky had noticed that nodes are fixed (1947, 32-35). To create dynamic visualizations, these nodes should progress. Now, network visualizations enriched by time could be said to be in motion. Visually speaking, network entities are represented by points; giving them a movement signifies that the points have to be represented through lines (Kandinsky 1947, 57; Ingold 2007). This solution allows us to lend more complexity to the basic point representation. Moreover, Kandinsky claims: “Considered in terms of substance, it [the point] equals zero” (1947, 25). The contrast between the point and the line in network visualizations finds another analogy in the Kandinsky’s thoughts, who considers the line as the antithesis to the point: “The line is, therefore, the greatest antithesis to the pictorial proto-element – the point” (Kandinsky, 1947: 57).

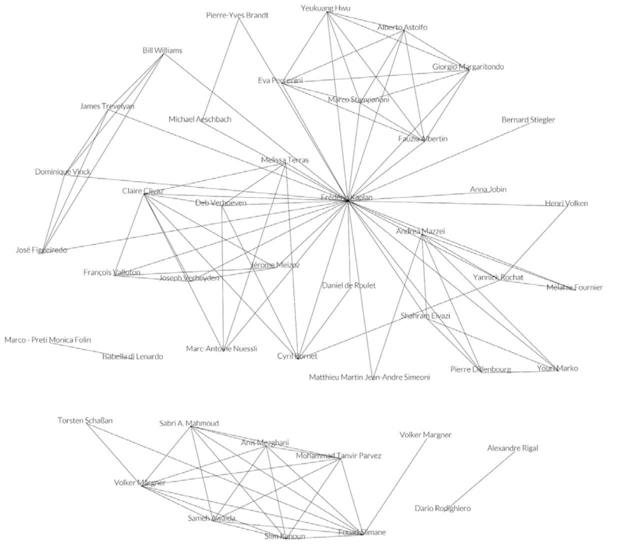

Figure 2. The DHLAB network is created by co-authoring: each node is an author and each edge a collaboration for a paper. Nodes represent also external collaborators

Thanks to the line representation, continuity enters the complexity of representation as the fabric stitching together the narrativity of several network sequences. Moreover, continuity implies an inherent relationship between both distance *and* duration. If the network visualization tends to be infinite in terms of spatial relations and entities, it is fairly weak to highlight time, another infinite dimension. The introduction of the trajectory brings another dimension to the visualization: the infinity of durations of relations and entities.

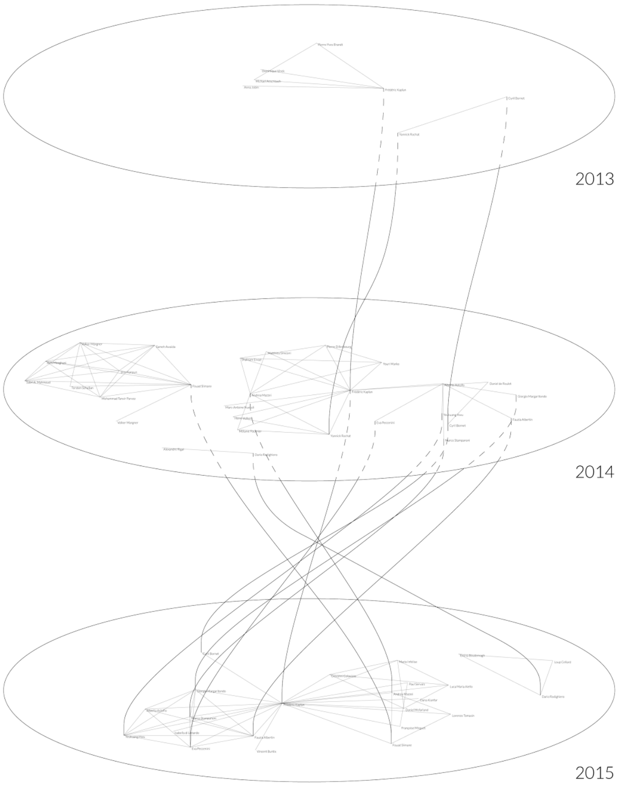

Figure 3. The DHLAB network is divided into years. Each trajectory represents an author who published during the years, tracing his continuity

The visualizations in practice

Data are extracted from Infoscience, EPFL’s publication repository. This repository is public, and everyone can access it and obtain the data presented in this paper. Technically speaking, we queried all publications associated with the DHLAB.

This article has two figures representing the DHLAB in Lausanne. Both visualizations present the same information in two different ways: the first shows collaborations on a plain surface – this figure is a classical network visualization (Figure 2); the second is based on the trajectory idea:

points previously arranged on a flat surface are transformed into lines reifying the continuity of people (Figure 3).

If we affirm that complexity representation has indeed been "complexified", how this could help digital humanists?

The first figure shows how the laboratory professor is placed at the center – the network would probably be very different without him and would be divided in parts. So, he is the core of the laboratory with good reason. The networks consists of two big clusters, which means that the professor is not included in all the publications of the laboratory (a rule that is compulsory in some labs).

The second figure immediately displays the literary production year by year. For example in 2013, the laboratory was relatively young to widely publish scientific works, collaborations have a greater size in 2014 and 2015. Compared to the network visualization, the trajectories depict the variability of links with time quite well by splitting the network into a sequence of networks.

The trajectories also describe the centrality of the professor better. For example in 2014, he basically worked with a group of people (shown at his left) and a colleague (at his right). In the same year, this colleague had a group of authors with whom he collaborated. Following the trajectories of that group, we can easily see that in 2014, it was not directly linked to the professor whereas in 2015, they all worked together. This is a detail revealed by trajectories that was not visible with classical network visualization.

The tool (conclusion)

Gyorgys Kepes wrote: "each new visual environment demands [...] new way of measuring" (1995, 13). This phrase introduces two concepts that would be of interest to the communities of Digital Humanities and Data Visualization: context and method. We could suppose that the context is given by humanists and the method by designers, but DH is the result of a blend between the two. Designers can not think of methods out of context, the opposite is true for humanists.

As Johanna Drucker says, we are experiencing "a momentary blindness among practitioners" (2011, 5). To overcome this blindness, we put together the efforts of designers and humanists: the visualization here described represents interdisciplinarity – the context and the method at the same time. For this reason, we think that trajectories are a good example. The DH community is close to having the sensibility to solve the interdisciplinarity issue.

For this reason, theory has to be combined with practice to produce solid research tools for the DH community. Trajectories are not simply a theoretical concept but also a tool that will be presented at the DH 2016 conference and which will be available to digital humanists for decomposing their networks, or, in other words, to lend representations their complexity.

À la Croisée des Discours Littéraire et Scientifique : La Comparaison comme Haute Figure Dialogique

Marine Riguet
marineriguet@gmail.com
Université Paris-Sorbonne, France

Suzanne Mpouli
mpouli@acasa.lip6.fr
Université Pierre et Marie Curie, France

Introduction

S'intéresser à la comparaison, à l'échelle du discours, c'est interroger sa fonction d'amarrage, de point charnière, entre plusieurs champs énonciatifs distincts ; c'est questionner la façon dont deux discours entrent en interaction et s'activent l'un l'autre sur le plan structurel, à travers un nouveau réseau de ressemblances/différenciations qui participe de leur affirmation singulière.

Cette étude exploratoire se concentre sur le dialogue particulièrement riche qu'entretiennent les discours scientifique et littéraire entre 1860 et 1928, et plus précisément sur la convocation, au sein de la critique littéraire, de tout un champ notionnel emprunté aux sciences dites exactes (biologie, physique, chimie, botanique…). À une époque où émergent la biologie moderne, la médecine expérimentale, les principes de thermodynamique, ou encore l'évolutionnisme de Darwin et Spencer, le discours scientifique ne se cantonne plus à une sphère dévolue aux spécialistes, mais nourrit au contraire des mutations sociales, éthiques et esthétiques, au travers desquelles la littérature redéfinit sa place.

Au vu de la dimension analogique de la comparaison, on pourrait supposer qu'elle tient un rôle central dans cet appareillement des discours littéraire et scientifique, captant et catalysant en quelque sorte le « dialogisme discursif » (Adam, 2005) au niveau microscopique. Il s'agit donc de déterminer ses différentes fonctions et manifestations au cœur de cette intertextualité qu'elle crée.

Méthode automatisée

Le besoin d'une méthode automatisée et le recours à des outils informatiques nous ont paru incontournables afin de pouvoir traiter un corpus à la fois signifiant et vaste. Nous avons donc cherché à identifier et à extraire automatiquement les comparaisons concernées au sein d'un corpus numérisé homogène, comprenant 49 auteurs pour un total de 140 ouvrages de critique littéraire française. Pour ce faire, deux outils ont été utilisés :

- un algorithme permettant d'identifier des comparaisons potentielles construites autour de différents types de marqueurs de la comparaison ainsi que les termes qu'elles mettent en parallèle (Mpouli & Ganascia, 2015) ;

- le Dictionnaire électronique des mots (Dubois & Dubois-Charlier, 2010), un dictionnaire au format XML qui fournit pour chaque entrée un champ lexical et une sous-classe sémantique (cf. Figure 1), offrant ainsi la possibilité de ne retenir que les comparaisons dans lesquelles le comparant ou le comparé relève exclusivement du champ lexical de l'une des sciences exactes prédéfinies (chimie, chirurgie, médecine, physiologie, physique, mathématiques, astronomie, biologie, géologie, zoologie et botanique).

Précisons cependant que le terme « espèce », qui occupe une place importante dans le vocabulaire scientifique de l'époque, a dû être ajouté manuellement car le dictionnaire ne le plaçait dans aucun des domaines scientifiques concernés.

Figure 1. Exemple de deux entrées dans le Dictionnaire électronique des mots

Les termes ainsi recueillis peuvent être regroupés en trois grands ensembles : les disciplines scientifiques, les métiers et les concepts qui leur sont rattachés. Si on ne considère que les termes scientifiques utilisés comme comparant, on se rend compte que le domaine de la zoologie, contenant entre autres les termes « espèce » et « animal », est le plus fortement représenté (42 % des occurrences). La fréquence de ces comparants permet en outre de dégager des groupes d'auteurs bien distincts (cf. Figure 2).

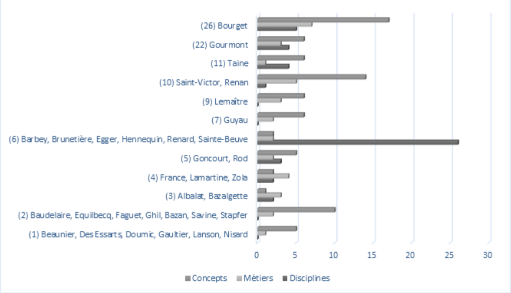

Figure 2. Répartition des auteurs en fonction de leur fréquence d'utilisation de termes scientifiques comme comparant. Seuls ont été considérés les concepts comptant au moins 5 occurrences dans le corpus

Activation d'un dialogue interdisciplinaire

De fait, une lecture plus poussée des résultats confirme deux positionnements antagonistes de la critique face au discours scientifique. D'une part, tout un pan de la critique dénigre l'aridité ou l'arrogance d'un discours scientifique qui permet, par contraste, de valoriser une vision romantique et symboliste de la littérature. La comparaison introduit en ce sens un rapport de supériorité au bénéfice du discours littéraire.

Livre	Comparaison extraite	Marqueur	Comparé	Comparant
P. de Saint-Victor, Le Théâtre contemporain.	Depuis quelques années déjà, l'auteur de l'Ami des femmes exerce la morale comme une chirurgie ; il lui prête l'impudeur tranchante d'une science expérimentale qui a le droit de tout éventrer et de tout décrire.	Comme	morale	chirurgie
A. de Lamartine, Cours familier de littérature, t. 5.	[Les psychologues] n'arrivent qu'à s'embrouiller dans leurs définitions, à se contredire dans leurs distinctions, à se perdre dans leur analyse; et, comme les chimistes, leurs émules, quand ils veulent retirer de leur creuset les principes de l'âme humaine et dire : La voilà ! ils ne tiennent sous leur plume ou sous leurs doigts qu'une pincée de cendre…	comme	[psychologues]	chimistes

De l'autre, une critique littéraire dite « scientifique », regroupant entre autres Sainte-Beuve, Brunetière, Guyau, Bourget, Taine, Renan, Hennequin, Lemaître, Goncourt, Zola ou Renard, instaure au contraire un rapport d'égalité avec un discours scientifique apte à enrichir le discours littéraire.

J.-M. Guyau L'Art au point de vue sociologique.	Dans la composition des caractères, par exemple, l'art combine, comme les chimistes dans la synthèse des corps, des éléments empruntés à la réalité.	Comme	art.	chimistes
E. Zola cité par L. Bazalgette, L'Esprit nouveau dans la vie artistique, sociale et religieuse.	Nous devons opérer sur les caractères, sur les passions, sur les faits humains et sociaux, comme le chimiste et le physicien opèrent sur les corps bruts, comme le physiologiste opère sur les corps vivants.	Comme	nous	chimiste, physicien, physiologiste

Au sein de ce second type de critique, la comparaison apparaît comme une figure de premier plan par son aptitude à cimenter un rapport de type analogique entre les discours.

Le système analogique d'une critique littéraire « scientifique »

En rhétorique, la comparaison contribue souvent, de par sa fonction évocatrice, à donner plus de poids à une argumentation. Si plusieurs usages de la comparaison peuvent ici être analysés, tous semblent néanmoins obéir à une même stratégie discursive : l'image provoquée par le rapprochement de l'objet littéraire avec un élément exogène, puisé dans le domaine scientifique, vient servir le discours critique sur un plan rhétorique immédiat. Agrandir le champ notionnel par un rapprochement analogique, c'est par là-même généraliser la portée d'un énoncé qui devient exportable à d'autres domaines. En ce sens, la comparaison est mise au service d'un processus de valorisation, dans la mesure où le discours littéraire, trouvant un pied d'égalité avec le discours scientifique, reçoit simultanément une légitimité qui lui est extérieure – sans compter la forte caution institutionnelle dont bénéficie à cette époque le discours scientifique.

Cette mise en place d'un système analogique peut ainsi s'observer autour de « concepts nomades » (Stengers, 1987) que la comparaison rend nettement identifiables, telle que la notion d'espèce, dont la circulation et la réappropriation par le discours littéraire sont ici particulièrement remarquables.

P. Bourget Études et Portraits, t. I.	Des espèces littéraires existent, analogues aux espèces vivantes, constituées par des caractères propres et irréductibles les unes aux autres, malgré l'unité de composition de notre monde intellectuel.	analogue à	Espèces littéraires	Espèces vivantes

Cette égalité introduite par la comparaison entre domaines littéraire et scientifique n'est jamais stricte, mais structurelle, comme le montre les exemples repris ci-dessous. La comparaison pose donc une ressemblance entre des rapports, de sorte que la critique littéraire peut traiter la littérature comme la science traite son objet : la littérature, l'art, deviennent par la force de l'analogie champs de savoir. En servant de « modèle analogue » (Black, 1962), non seulement la science légitime le projet de la critique littéraire, mais elle opère consécutivement un renversement axiologique en imposant la valeur de vérité, à laquelle les valeurs esthétiques et éthiques se retrouvent subordonnées.

E. Renan, Discours et conférences.	Car il y a une logique dans une tragédie en cinq actes comme dans un mémoire de physiologie, et la règle des ouvrages de l'esprit est toujours la même : être égal à la vérité, ne pas l'affaiblir en s'y mêlant, se mettre tout entier à son service, s'immoler à elle pour la montrer seule, dans sa haute et sereine beauté.	Comme	tragedie	mémoire de physiologie

A. Albalat Le Mal d'écrire et le roman contemporain.	L'étude comparative des procédés de composition dans les œuvres écrites démontre au contraire qu'il y a en art des lois d'examen invariables, des vérités esthétiques démontrables comme les mathématiques, des principes fixes, une évidence positive et irrésistible, une certitude enfin de filiation et de descendance commune à toutes les écoles et élucidant toutes les productions.	Comme	vérités	mathématiques

Enfin, la comparaison, autant qu'elle rassemble, se fait lieu de confrontation entre les discours. L'identité même du discours se voit ainsi mise en jeu, dans la mesure où le rapprochement analogique sert aussi, pour la critique littéraire, de mise en rivalité avec un discours scientifique dont elle cherche à la fois à emprunter des structures et à rejeter l'ascendant. Par la comparaison, qui contrairement à la métaphore ne « fusionne » pas, le dialogisme discursif participe finalement de la construction identitaire du discours littéraire, dans ce sens où « l'Autre n'est pas seulement la contrepartie du Même, mais appartient à la constitution intime de son sens » (Ricœur, 1990). En ce sens, on pourrait se demander dans quelle mesure et sous quelle forme la métaphore contribue elle aussi à la construction de ce nouveau discours critique.

Modelling Music Reception: An Ontology For Representing Interpretations of Richard Wagner's Leitmotifs

Carolin Rindfleisch
carolin.rindfleisch@music.ox.ac.uk
University of Oxford, United Kingdom

1. Background

Richard Wagner's leitmotifs (Whittall, 2003), the compositional technique and its aesthetic implications as well as the individual motives, their musical characteristics, meanings, and transformations through the works, have been subjected to a wide variety of interpretations throughout different cultural and historical situations. The popular Wagner discourse in particular – in work introductions, guidebooks, programme notes, commentaries and motivic annotations in libretti and piano scores – focused on the extraction, description and presentation of leitmotifs in order to convey their interpretation of Wagner's work. Thus, the phenomenon 'leitmotif' cannot only be defined as a compositional technique, but also as a reception practice (Grey, 1996; Rümenapp, 2002; Thorau, 2003). This study aims at a large-scale comparison of these reception practices that reaches across cultures and time periods and is able to not only describe general characteristics of sources, but to compare interpretations down to conceptions of individual motives. Semantic Web technologies (Berners-Lee et al., 2001; Bizer et al., 2011), with the enhanced capabilities of linking, searching and structuring of data they provide, may facilitate this undertaking. This paper describes an ontology that models the structure and content of leitmotif interpretations, which shall enable the semantic annotation of sources and the structured representation of the interpretations they contain. A particular focus lies thereby on the methodological considerations and design decisions that stand behind it.

2. Methodological Considerations

Semantic Web Research and Musicology are two distinct domains, each with their own conventions, terminologies, and patterns of thought and discourse. Attempts to integrate them thus have to deal with the following questions: "How do [musicological] methods translate into methods of Semantic Web Research?" (Kummer, 2011) Can we conceive of a musicological ontology, which not only forms the basis to represent discourse in novel ways, but also works as an analytical device? How can we take advantage of the commonalities and accommodate the differences between methodologies and ways of thinking, such as different approaches to the presentation of knowledge and the construction of complexity, and the confrontation of different values of flexibility, ambiguity, and metaphoricity on the one hand and explicit definitions and taxonomies on the other? There are several key strategies by which the described ontology aims to achieve compliance with both domains: 1) a historical, critical and philosophical 'awareness' within the terminology and its specifications, as well as the connection to a shared vocabulary in the form of musicological encyclopaedias; 2) the incorporation of flexibility, ambiguity and nuance into the explicit model; 3) a direct correspondence between the ontology and both the document and "thought structure" of the interpretations it models.

3. Related Work

Existing approaches that apply Semantic Web technologies to music or musicology are mostly concerned with organising and retrieving musical data. The Music Ontology aims at modelling the "music production workflow", and focuses on managing "music-related data" of recorded and foremost popular music (Raimond, 2007). Since this domain specification also shapes the terminology and definitions it employs, its application in the scholarly context of music history can be problematic: it does not comply with the terminological standards and conventions of musicology, and does not provide sufficient concepts to describe the variety of data that contextualises music and that is vital for music-historical study. The "musicSpace" project (Bretherton et al., 2009) aimed at enhancing the possibilities of musicological research by "integrating access to many of musicology's leading data sources", gathering factual information from this data and metadata and making this information accessible and searchable via a single interface. While sharing common goals and objectives, the project at hand aims at going beyond factual information and at analysing the structure and content of a specific type of musicological discourse, modelling assignments people attribute to a musical work throughout the history of its interpretation. Related approaches can also be found in different disciplines, such as Cultural Heritage and Museology (Doerr, 2003): Traditional approaches in musicology tended to treat works as self-contained conceptual objects; therefore, the reception or interpretation history of a musical work can, to a certain extent, be seen in correspondence to the provenance of an object. Relevant are furthermore ontologies that aim at modelling narratives or, more general, the content or structure of sources in different contexts, such as the OntoMedia ontology (Jewell et al., 2005), Story Fountain (Mulholland et al., 2004), or Curate (Mulholland et al, 2012).

4. Structure and Design

Analyses and interpretations of musical works, even though their content, analytical approach etc. might be completely different, on a basic level often rely on similar structures and constituent elements. These commonalities increase within the "specialised" analytic or interpretative discourse that is concerned with, for instance, a particular composer, a particular form, style or genre, which shares patterns and conventions of discourse and a specified vocabulary. This ontology, therefore, aims to model leitmotif interpretation as a special case of musicological discourse: its design is based on an analysis of representative source documents, and its structure and scope is informed by the structure and content of these interpretations and their presentation principles.

The ontology negotiates between several layers that model different dimensions. The first contains bibliographical metadata on the source documents, while the second concerns the source type and the corresponding internal document structure. The third level comprises the content structure, and is most significant for the comparisons of the different leitmotif interpretations.

Guidebooks, such as Hans von Wolzogen's *Thematischer Leitfaden* (Wolzogen, 1876), are already highly structured documents: They follow the chronology of the work, and "narrate" the music by extracting leitmotifs and describing their appearances, interactions and transformations through the course of the work. This interpretational concept of a leitmotif is, however, not the same as the compositional concept: they are integrated, self-contained constructs, abstractions from the musical context that tie together a musical phenomenon and its interpretation. They are represented as a collection of several constituent elements, such as a notation example fixing the motive's shape, and a descriptive name defining its semantic reference (see figure 1). Which constituent elements exactly form a leitmotif concept differs between sources, and is characteristic for the source type or the interpretation approach. However, whereas within one guide, leitmotif concepts are stable and easily identifiable, the comparison between a large number of sources undermines permanent constructions: the same name can be found applied to different musical phenomena, or the same musical shape can be assigned different names; and even seemingly small nuances can point to significant differences in interpretations and aesthetic attitudes: the names 'Schicksalsmotiv'

(Wolzogen, 1876) and 'Schicksalsfrage' (Porges, 1882), for instance, imply a completely different relationship between the name and the musical phenomenon: while the former establishes a denoting connection, with the motive acting as a sign for its semantic reference, the second establishes a metaphoric connection between the musical structure and the name, as the rhetoric characteristics of the 'Frage' ('question') parallel the musical characteristics of the motive. The varied combinations of constituent elements in different sources further complicate a comparison: how can we compare leitmotif concepts that don't share any features? The ontology applies several strategies in order to cope with these difficulties: 1) Rather than providing a fixed definition of an interpretational leitmotif concept and its structure, the notion of a leitmotif concept is defined through its relationship to its constituent elements. Thus, the ontology does not prescribe a particular structure in which the actual instances have to be fitted, but stays flexible and can accommodate varying interpretational approaches. 2) The ontology introduces three meta-constituents, that are assigned in the analytic process and that shall introduce a common basis for comparison: the reference to a point in the work, the reference to a semantic sphere, and the reference to a basic musical shape (see figure 1). 3) Within these three categories, there is a set of relationships that aims at expressing a differentiated spectrum of influence and independence, identity and contrast, similarity and difference. In addition to the described structural features, the ontology also introduces different levels of abstraction, so that leitmotif interpretation is modelled as a special case of musicological discourse in general and the ontology remains potentially extensible to accommodate other forms of music interpretation and discourse.

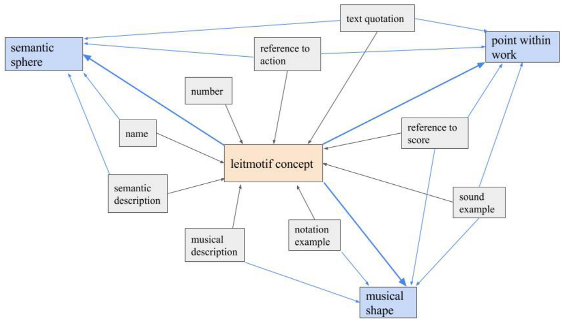

Figure: Possible constituents of a leitmotif concept

5. Conclusion

The described ontology forms the basis of a semantic annotation of the digitised sources, which shall facilitate the systematic comparison of a wide variety of leitmotif interpretations and enable to answer questions such as the following: Which musical shapes have been associated with a certain semantic sphere? How has a certain set of musical characteristics been classified in different interpretations and reception contexts? Being able to reorganise and query the reservoir of leitmotif concepts according to such questions can provide insights about larger contexts, patterns and constellations and form the starting point of more detailed investigations. Furthermore, beyond this particular analysis, it forms a first step towards a new structure of musicological discourse, as it allows to link elements of musical analyses, interpretations or reception documents together in novel ways.

Digging into ECCO: Identifying Commonplaces and other Forms of Text Reuse at Scale

Background

Commonplaces are a particular instance of historical text reuse (Dacome, 2004; Allan 2010; Blair, 2011). This paper describes our efforts at identifying commonplaces in the Gale-Cengage *Eighteenth Century Collections Online* (ECCO) database. Given the size of this collection, as well as the state of the data in terms of its OCR output, identifying shared passages that exhibit the textual characteristics of commonplaces – e.g., are relatively short, repeated, and rhetorically significant – is a non-trivial computational task. In our previous work on text reuse, we came across numerous examples of textual borrowings and shared passages that we considered possible commonplaces (Allen et al., 2010; Horton et al., 2010; Roe, 2012). We expanded this work into a Digging into Data Round 3 project using similar methods to explore the more than 200,000 works contained in ECCO, a dataset that represents most of the printed literary and scientific output in Britain from 1700 to 1799[1].

Previously we developed a sequence alignment algorithm for the identification of large-scale text reuse[2]. This algorithm, called PhiloLine, generates a list of similar passages (based on a set of flexible matching parameters) shared between any two texts. This simple approach allows us to find borrowings and other instances of text reuse, from quotations to uncited passages and paraphrases, over large heterogeneous corpora (Edelstein et al., 2013). Historical text reuse detection is a burgeoning field within the digital humanities, whether focussed on literary allusion (Coffee et al., 2012; Coffee et al., 2014), paraphrase (Büchler et al., 2011), influence (Büchler et al., 2014), or networks of reprinting (Smith et al., 2015). While all these projects address text reuse in slightly different ways, the flexibility and scalability offered by PhiloLine, coupled with our familiarity with the system, offered significant advantages over other approaches. We thus aimed to use PhiloLine to compare the ECCO corpus to itself, compile a list of the most frequent shared passages, and from there evaluate these passages in order to build a database of potential commonplaces.

Eliminating duplicates

The scope and scale of the ECCO dataset represented a major hurdle both in terms of computational expense and evaluation of the matching algorithm. Faced with more than 32 million pages of text, any manipulation of the data takes on significant proportions. To put this in perspective, comparing ECCO's 200,000 documents to each other means making some 40 billion pairwise comparisons and then storing and evaluating the output. Fortunately, our focus on commonplaces requires us to dramatically reduce the number of comparisons. We needed, for instance, to eliminate duplicate or near-similar texts in order to reduce the number of documents for comparison. The most obvious method would be to compare all the words in each work, and define a similarity threshold beyond which we consider two works to be the same. But, given the unequal quality of the OCR in the ECCO dataset, the reliability of any algorithm meant to detect similarity between two texts is very low. Two identical texts, for instance, can potentially only share 20% of individual tokens due to the quality of the OCR. As a result, we decided to focus our efforts on comparing document metadata instead, as it is of excellent quality.

Our methodology consisted in comparing titles in the dataset using a cosine similarity algorithm (Singhal, 2011). For our purposes, we determined a minimal similarity index to automatically determine whether two texts were the same, that is to say a re-edition of the same work. Beyond a certain threshold score, the newest document in terms of date of publication is automatically flagged as a duplicate. If it so happens that the minimal score is not reached, but still remains high, we compare authors, and if these are the same, we similarly flag the most recent document as a duplicate:

```
Psuedocode for title matching algorithm

if score >= 0.8:
   return True
elif score > 0.6 and score < 0.8:
   if author == other_author:
       return True
   else:
       return False
```

The document with the oldest publication date serves as the "source" text. Using this method, we were able to reduce the size of the corpus by 43%, eliminating 88,850 documents. We were thus left with 116,700 unique texts on which to run our matching algorithm.

Detecting similar passages

Similar passage detection requires a one-to-one document comparison. Rather than compare all 116,700 texts to one another, we decided to leverage Gale's thematic divisions, and limit the comparison task to individual modules[3]. While PhiloLine's matching capacity is powerful, it is necessary to understand its underlying algorithm in order to configure the tool properly. Briefly, PhiloLine's operational logic is to compare sequences of words, or n-grams, and determine the presence of a shared passage according to the number of common contiguous n-grams between two sequences. For example, the following text from Shakespeare's *The Tempest* is rendered by as a set of overlapping n-grams (where n = 3):

The cloud-capped towers, the gorgeous palaces,
The solemn temples, the great globe itself—
Yea, all which it inherit—shall dissolve
- Shakespeare, *The Tempest*, Act 4, Scene 1 ca. 1611

```
Trigrams: cloud_capped_towers, capped_towers_gorgeous, towers_gorgeous_palaces,
gorgeous_palaces_solemn, palaces_solemn_temples, solemn_temples_globe,
temples_globe_itself, globe_itself_yea, itself_yea_inherit, yea_inherit_shall,
inherit_shall_dissolve
```

Trigram generation and stopword removal are thus the main parameters we apply to transform texts prior to the sequence alignment process. Once this is done, we proceed with the text-sequence comparisons. Below is an example of just such an alignment of sequences drawn from the Literature and Language module:

an Hour of virtuous Liberty, Is worth a whole Eternity in Bondage
- Joseph Addison

```
Trigrams: hour_virtuous_liberty, virtuous_liberty_eternity, liberty_eternity_bondage
```

an hour, of virtuous liberty Is worth a whole eternity in bondage
- James Thomson

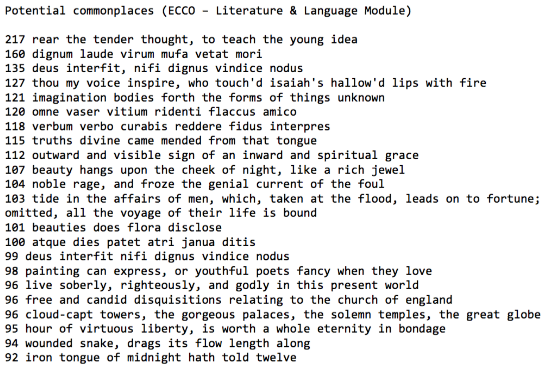
```
Trigrams: hour_virtuous_liberty, virtuous_liberty_eternity, liberty_eternity_bondage
```

In this case, we note the perfect alignment, which PhiloLine detected because there are at least three contiguous trigrams in common between both passages.

Using these base parameters (overlapping trigrams with stopwords removed), we compared the ECCO corpus to itself on a module-by-module basis. The output of this comparison ranged from 3.5 million common passages in the Literature and Language module, to almost 17 million possible commonplaces in Religion and Philosophy. Identifying these common passages is thus only a first step. Even after significant duplicate reduction, the sheer scale of the passages that require post-processing evaluation is daunting.

From similar passages to commonplaces

To attack this problem, we treat commonplaces generically as the repeated use of the same passage - more or less similar - in a minimum number of different authors. We began by grouping all source passages that were identical in order of frequency. Given that commonplaces are normally short expressions, at the most no longer than several sentences, we restricted our search to passages containing a minimum of five words and a maximum of 75:



```
Potential commonplaces (ECCO - Literature & Language Module)

217 rear the tender thought, to teach the young idea
160 dignum laude virum mufa vetat mori
135 deus interfit, nifi dignus vindice nodus
127 thou my voice inspire, who touch'd isaiah's hallow'd lips with fire
121 imagination bodies forth the forms of things unknown
120 omne vaser vitium ridenti flaccus amico
118 verbum verbo curabis reddere fidus interpres
115 truths divine came mended from that tongue
112 outward and visible sign of an inward and spiritual grace
107 beauty hangs upon the cheek of night, like a rich jewel
104 noble rage, and froze the genial current of the foul
103 tide in the affairs of men, which, taken at the flood, leads on to fortune;
omitted, all the voyage of their life is bound
101 beauties does flora disclose
100 atque dies patet atri janua ditis
99 deus interfit nifi dignus vindice nodus
98 painting can express, or youthful poets fancy when they love
96 live soberly, righteously, and godly in this present world
96 free and candid disquisitions relating to the church of england
96 cloud-capt towers, the gorgeous palaces, the solemn temples, the great globe
95 hour of virtuous liberty, is worth a whole eternity in bondage
94 wounded snake, drags its flow length along
92 iron tongue of midnight hath told twelve
```

A cursory glance at this list reveals several variants of the same passage that need to be merged in order to better represent a single commonplace. If we take the following passage from the Scottish poet James Thomson, for instance:

Then infant reason grows apace, and calls For the kind hand of an assiduous care. Delightful talk! to rear the tender thought, To teach the young idea how to shoot, To pour the freft infiruAion o'er the mind, 1150 To breathe enlivening spirit, and to fix The generous purpose in the glowing breast.

We notice that the reuse of this passage in other authors can vary significantly.

Gentleman of the Middle Temple (1775):

How glorious would her matron employments be, to hear the tender thought, to teach the young idea how to Jhoot; to be at once the precept and example to her family of every thing that was good, every thing that was virtuous.

Mrs Lovechild (1790):

Happy the Mother "Distilling knowledge through the lips of "love !"- ' Delightful talk! to rear the tender thought, "To teach the young idea how to shoot", To pour the fresh inltrution o'er the mind !'Lines which will never cease to be quoted...

Given the variability in the reuse of any given passage, as well as the approximate quality of the OCR, we developed a new algorithm that could match similar passages in a way that was both precise, and yet more flexible than PhiloLine. The algorithm uses the same n-grams as PhiloLine, though they are constructed differently. Rather than use overlapping trigrams, as we do for sequence matching, here we use alternating bigrams for increased flexibility:

Then infant reason grows apace, and calls For the kind hand of an assiduous care.

```
Bigrams: infant_grows, reason_apace, grows_calls, apace_kind, calls_hand,
kind_assiduous, hand_care
```

By skipping a word in the creation of these bigrams, we create n-grams that are both rarer than in-sequence bigrams, but also more common than in-sequence trigrams. In essence, these bigrams are flexible trigrams where the middle word is ignored. In this manner we can alleviate some of the issues that come from the dirty OCR. As there is a higher probability for a regular trigram to contain a wrongly identified letter, it has a higher chance of being unique, therefore making it less reliable for similarity matching than our flexible trigrams.

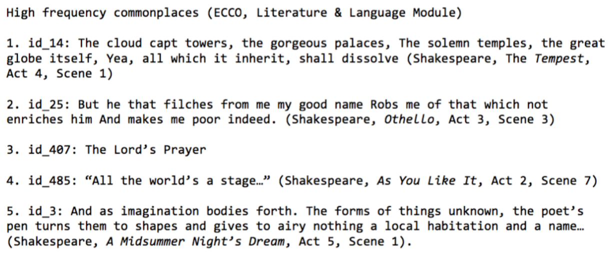
Finally, we needed to take into account the different lengths of these passages, as some are much longer than others. This variability led to the introduction of a coefficient that accounts for varying lengths, and allows us to automatically determine the minimum number of matching n-grams needed to establish similarity between two passages. For instance, if two passages of 30 words must share 4 bigrams, a passage of 30 words and another of 50 should share more bigrams to retain the same level of similarity.

Using the above methods, we were able to merge various uses of a single source passage and assign them a unique identifier. We can therefore now identify the highest frequency commonplaces in the Language and Literature module (see Appendix 1), as well as the most 'highly commonplaced' authors, i.e., those that generated the most shared passages (see Appendix 2). These preliminary results suggest that commonplacing, as an intertextual reading/writing practice, was alive and well in 18th-century England. Digging into a dataset such as ECCO can thus offer us new perspectives from which to view and understand 18th-century print culture, provided we unearth more than we cover up.

Future Work

We aim to release an interactive database of possible commonplaces in early 2016. The database will allow users to navigate the ECCO dataset via the commonplaces, most commonly cited authors and works, and visualize commonplace use and practices over time. We will also introduce several curated datasets that pre-date the 18th century, and that can act as a control on sources that fall outside the date boundaries of our data. These possible datasets include the King James Bible, Classical Latin texts, and EEBO-TCP[4]. Further goals for this project include merging the module-specific results into one large pool of potential commonplaces that reach across disciplinary boundaries; developing a user interface that allows for commonplace curation as a form of crowdsourcing; and introducing non-English datasets for comparison in order to find instances of multi-lingual commonplace practices.

Appendix 1



High frequency commonplaces (ECCO, Literature & Language Module)

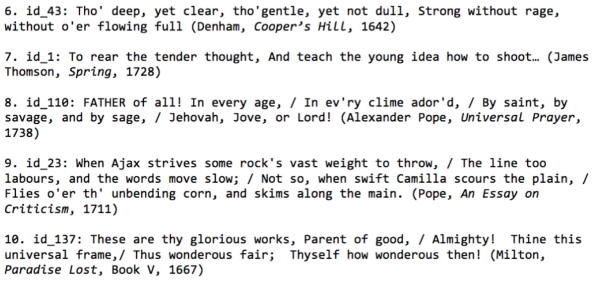
1. id_14: The cloud capt towers, the gorgeous palaces, The solemn temples, the great globe itself, Yea, all which it inherit, shall dissolve (Shakespeare, The *Tempest*, Act 4, Scene 1)

2. id_25: But he that filches from me my good name Robs me of that which not enriches him And makes me poor indeed. (Shakespeare, *Othello*, Act 3, Scene 3)

3. id_407: The Lord's Prayer

4. id_485: "All the world's a stage…" (Shakespeare, *As You Like It*, Act 2, Scene 7)

5. id_3: And as imagination bodies forth. The forms of things unknown, the poet's pen turns them to shapes and gives to airy nothing a local habitation and a name… (Shakespeare, *A Midsummer Night's Dream*, Act 5, Scene 1).



6. id_43: Tho' deep, yet clear, tho'gentle, yet not dull, Strong without rage, without o'er flowing full (Denham, *Cooper's Hill*, 1642)

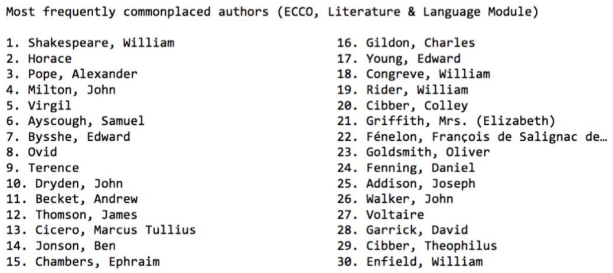
7. id_1: To rear the tender thought, And teach the young idea how to shoot… (James Thomson, *Spring*, 1728)

8. id_110: FATHER of all! In every age, / In ev'ry clime ador'd, / By saint, by savage, and by sage, / Jehovah, Jove, or Lord! (Alexander Pope, *Universal Prayer*, 1738)

9. id_23: When Ajax strives some rock's vast weight to throw, / The line too labours, and the words move slow; / Not so, when swift Camilla scours the plain, / Flies o'er th' unbending corn, and skims along the main. (Pope, *An Essay on Criticism*, 1711)

10. id_137: These are thy glorious works, Parent of good, / Almighty! Thine this universal frame,/ Thus wonderous fair; Thyself how wonderous then! (Milton, *Paradise Lost*, Book V, 1667)

Appendix 2



Most frequently commonplaced authors (ECCO, Literature & Language Module)

1. Shakespeare, William
2. Horace
3. Pope, Alexander
4. Milton, John
5. Virgil
6. Ayscough, Samuel
7. Bysshe, Edward
8. Ovid
9. Terence
10. Dryden, John
11. Becket, Andrew
12. Thomson, James
13. Cicero, Marcus Tullius
14. Jonson, Ben
15. Chambers, Ephraim
16. Gildon, Charles
17. Young, Edward
18. Congreve, William
19. Rider, William
20. Cibber, Colley
21. Griffith, Mrs. (Elizabeth)
22. Fénelon, François de Salignac de…
23. Goldsmith, Oliver
24. Fenning, Daniel
25. Addison, Joseph
26. Walker, John
27. Voltaire
28. Garrick, David
29. Cibber, Theophilus
30. Enfield, William

Introduction

Up-to-date research in the humanities today depends as much on digital methods and digital data. However, the use of computer-based methods and online sources in the humanities still faces several challenges, including the difficulty of ensuring the longevity of research data, the lack of common basic services, inadequate standardisation of data formats, insufficient training in digital methods and best practices, and weak international Digital Humanities networks. Digital documents are accumulated, organised and annotated using electronic databases. However, the necessary infrastructure is most often established in a project- specific way and is not designed for the long-term preservation of data. After the completion of a research project, these digital resources quickly become unavailable if they, and the software and hardware they rely on, are not properly maintained. Keeping digital data accessible after the end of a project is costly in terms of money and labour and is usually not included in the project funding.

While the digitisation of analogue sources produces large numbers of digital documents, these documents usually have a simple structure. By contrast, the data produced during the research process is much more complex, consisting of interlinked information (databases, annotations etc.). Because of the complexity of this research data, it is very difficult to make it permanently available. However, there are several reasons for doing so:

Transparency:

As research data is the foundation on which published results are based, it be- comes necessary to have access to this data in order to evaluate the results.

Reuse:

New research projects can reuse existing research data to propose different answers to the same questions, or to ask entirely new questions, especially if the datasets from different projects can be linked.

Citability:

Digital sources may only be referenced in scientific texts if they can be accessed permanently without modification. The long-term accessibility of arbitrary digital objects (together with permanent links and unique object identifiers) is usually not possible.

Organisational form

The Swiss Academy of Humanites and Social Sciences (SAHSS) therefore decided to establish in collaboration with the Digital Humanities Lab (DHLab) of the University of Basel a new "national research infrastructure" (Data- and Service Center for the Humanities, DaSCH) which takes this kind of digital research data into custody and preserves the direct online access. The primary goals are:

- Long-term curation of research data
- Permanent access and reuse
- Services for researchers to support data life-cycle management

The secondary goals are:

- Promoting the digital networking of databases created in Switzerland or in other countries
- Carrying out a pilot project in close proximity to humanities research

- Collaboration and networking with other institutions on developing digital literacy

During a pilot phase lasting two years that ended in July 2015, the data of about 25 different research projects ranging from ancient history to musicology have been passed to new institution for preserving long term accessibility. In order to copy with such heterogeneous data, the platform has to be extremely flexible and versatile.

Since Switzerland is a highly federalist country, a balance between a central/decentral approach had to be chosen. We decided to form of a network that currently consists of several "satellite" nodes and a central office which acts as coordinator, main provider of technology and software development. The individual locations have a great deal of freedom to take local decisions (e.g. which research projects are considered important to be included in the platform). At each satellite location, it is necessary to have both a broad knowledge and experience available in humanities research as well as in IT and software development skills. The central office provides second-level support.

Technological issues

Our daily experience seems to suggest that digital data is quite volatile and unstable. Everybody who works with computers on any scale has suffered the unfortunate experience of data loss. In a recent interview, Vincent Cerf, often regarded as one of the "fathers of the internet", says he is worried that all the images and documents we have been saving on computers will eventually be lost: "Our life, our memories, our most cherished family photographs increasingly exist as bits of information – on our hard drives or in "the cloud". But as technology moves on, they risk being lost in the wake of an accelerating digital revolution." (Cerf, 2015) Thus, it appears that "long-term archival" and "digital" are diametrically opposed concepts. However, the digital domain offers some unique characteristics that allow the long-term preservation of digital data. However, guaranteeing long-term access to digital information remains a tedious and difficult process.

There are only a few fundamental methods for long-term preservation of digital data:

*Emulation*The software and to some extent the hardware of obsolete computer system can be emulated ("simulated") on modern computers. Thus data can be rendered using vintage software.

*«Eternal» media*The «eternal» media approach requires the digital data to be recorded onto the most robust and durable media available.

*Migration*In the context of long term archiving, migration is defined as the process of periodically copying digital data onto new, up-to-date storage media and, if required, converting the file formats to new, well-documented standard formats.

The OAIS reference model for a digital archive is based on the migration model. In addition to a formal process description, it also covers the ingest of data into the archive and the dissemination of archived data to a user. An important aspect of the OAIS reference model is the systematic approach to metadata that is distinguished between the metadata required to identify and find a «document», and the technical metadata required for the management of the migration processes. The OAIS approach can be adapted for complex «objects» such as relational databases or NoSQL-databases (e.g. using the SIARD-suite (Ohnesorge, 2015), a standard adopted by European PLANETS project and as Swiss eGovernment Standard eCH-0165), however in order to browse or use the data, the whole dataset has to be retrieved from the archive and converted back into a working RDBMS using the SIARD-Suite – a «quick overview» is not possible.

Complementary to the OAIS archival process model, *keep-alive archiving* keeps a system of data, data management and access methods online and permanently up-to-date. Whenever the technology evolves (e.g. a new stable version of the data management software or a new version of a file format is released), the whole system is migrated to conform to the new environment. The keep-alive archives are especially well suited to complex data such as databases which are accessed very frequently. However, there two fundamental problems with keep-alive archives:

If the data management system does not offer a method to record all changes, the history will be lost.

It is virtually impossible to keep each projects IT-infrastructure – especially the software – running forever. Each project uses its own software (Filemaker Version XY, MySQL, PHP, ruby, Excel, etc.) and data models. The adaption to the evolving technology would overwhelm each institution.

The DaSCH implements a modified keep-alive concept. It has chosen to use the Resource Description Framework (RDF, standardised by the W3C) as a common ground for representing the data. It provides a very simple but highly flexible representation of digital information. RDF allows the definition of ontologies which formalise the semantic relationship of digital objects. We defined a base ontology which implements some required basic concepts (e.g. time-stamp based versioning, annotations, access rights etc.). Starting from this base ontology, for each research project taken into custody a specific ontology is being derived. On delivery of the data, the original data structure is translated into this ontology preserving the important features and relationships of the data. This technological framework thus allows the «simulation» of almost any data models (relational databases, XML hierarchies, TEI-encoded texts, graph networks etc.) in a common infrastructure using open standards such as RDF, RDFS[1] and OWL[2].

The pilot phase has made it clear that project-specific access applications (such as online graph- ical user interfaces) have to be preserved. While this approach does not make it possible to directly reuse the original applications, it has been shown that is easy to re-implement their basic functionality as well as their look and feel.

Using the common platform, it is straightforward to create new tools and applications that reuse existing data by combining information from different datasets. Thus, new research methods can be implemented, e.g. using methods of «big data» analysis

Due to the success of the pilot phase where about 25 projects have been integrated, some with individual user interfaces, the Academy has decided to ask for funding. The request is awaiting the approval of the swiss national parliament.

Digicraft and 'Systemic' Thinking in Digital Humanities

Enrica Salvatori
enrica.salvatori@unipi.it
University of Pisa, Italy

In the AIUCD (*Associazione per l'Informatica Umanistica e la Cultura Digitale*) conference held in Bologna in September 2014 Manfred Thaller wondered "Are the Humanities an endangered or dominant species in the digital ecosystem?" (Thaller, 2014, also Thaller, 2012). The answer was not simple nor linear and directly involved the Digital Humanities (DH from now on) as a disciplinary and research field that was still poorly defined, DH hold the promise to bring out the Humanities from the Indian reserve where they are now confined, provided certain conditions will be met. In particular DH specialists should:

1. conceive of themselves as researchers and not as conversationalists;
2. strive for a vision;
3. change the epistemology of the Humanities;
4. drive technology and not be driven by it.

A few months after the conference Serge Noiret wrote on Digital History (one of my fields of investigation) trying to clarify what actually characterizes this subject within the wider field of DH, and - within the Digital History itself - what is the specific task of the Digital Public History (Noiret, 2015; see also Robertson, 2014). We could place Noiret's article completely under the first point of Thaller's list: Digital History and Digital Public History are clearly seen as areas of research and not merely as new forms of communication of old disciplines. Moreover he answered to items 2 and 3 too, essentially proposing a more accurate taxonomy of DH. In a way, he seems to answer Thaller's question with an accurate definition of some components of the meta-discipline itself.

I do not want to linger in this paper on the definition of DH as a whole nor of its components: so many authors in recent years have-debated to define what someone thinks to be (or could be) a discipline and others a research or work field (McCarty, 2005; Svensson, 2010). Every exercise of definition of a "new" area of research is, of course, useful, but at the same time it is potentially frustrating and risky. Frustrating because, as many authors and research centers have declared, despite its now long history, the DH is still an emerging field, and as well as an open, multifaceted, ever-changing one; risky, because each taxonomy of knowledge unavoidably builds walls and fences that encase the knowledge itself in a series of sterile boxes. This could be, in my modest opinion, the risk in Noiret's essay. It's more important to go beyond a possible but also difficult definition of DH and their several sub-disciplines, focusing our attention on items 2 and 3 of the Thaller list instead, namely on the need to have our own vision and on the importance to characterize DH in terms of the emerging changes of method in our daily research.

In particular I will try to connect the concepts expressed by both scholars, looking on the one hand to the recent history of DH in Italy (i.e. degree courses, associations, meetings) and on the other hand to my own research projects at the University of Pisa, especially inside the DH course degree (https://www.unipi.it/index.php/ects/ects?ects_id=IFU-L) and within the Digital Culture Laboratory (http://labcd.humnet.unipi.it/). Starting from some specific cases I wish to reason on the possible vision of the DH.

I will focus very briefly on some projects.

1. For what concerns *Epigraphical Studies, Public History and Education*:

- Epigrapisa: A re-reading partly driven and partly spontaneous of the epigraphic messages left over time in a city. Competence/knowledge at work: history, public history, epigraphy, paleography, writing, dramatize, processing images, audio and video, web design.
- Teaching (Digital) Epigraphy: a novel education

experience in teaching students to transcribe and interpret Roman inscribed lead tags, using a Digital Autoptic Process (DAP) in a Web environment. Competence/knowledge at work: history, education, epigraphy, paleography, writing, manipulating images, collaborative tools.
  - Pisa e l'Islam and Pisan Romanesque meets Contemporary America: two examples of historical web dissemination with a reasoning about both the potential and the limits of the medium to involve the audience. Competence/ knowledge at work: history, arts, archaeology, public history & archaeology, epigraphy, GIS, writing, dramatize, processing images audio and video, web design.
2. In the area of *Digital Public History*:
  - Tramonti. Itinerari tra generazioni lungo i crinali della Val di Vara a complex project aimed at enhancing the cultural heritage of an Italian rural valley through the active participation of residents. Competence/knowledge at work: history & archaeology, public history & archaeology, invented archives, education, writing, dramatize, GIS, manipulating images and videos, libraries, collaborative tools, web design, project management.
3. In the field of Digital Editions:
  - Codice Pelavicino Digitale: the digital edition of a medieval manuscript built to provide all services of the digital world and to invite the readers to actively participate. Competence/knowledge at work: history & public history, text encoding, philology, paleography, codicology, writing, manipulating images, collaborative tools, web design, project management.

By shortly describing these project I will not try to figure out what distinguishes them from each other, but, on the contrary, what characterizes all of them as Digital Culture projects and what they tell us about a possible vision of DH:

1. they are digital;
2. they are inevitably and necessarily interdisciplinary;
3. they are open;
4. they were built in a kind of new Renaissance workshop, a digital craft (DIGICRAFT).

- They are digital. This may seem trivial but it is not. These are projects "born digital" not because the digital world offers the most useful tools to achieve the same purpose in relation with the "real" world, but because they could not exist outside the incredible interaction between real and digital world that it is now our life. They are digital because they might not otherwise exist.
- Interdisciplinarity is compulsory. DH is a field unavoidably and profoundly interdisciplinary and we have to deal with each project as a complex set of activities and skills that crosses, by its true nature, several fields; this change of practice and approach implies by itself a methodological revolution, because it requires an organization of work similar to a Renaissance workshop (a DIGICRAFT), with an articulated division of labor in relation to several levels of skills, where education and training could be provided by the same learners, coordinated by a strong and mature central idea.
- Openness is a result and a choice. Working in a multidisciplinary team built upon research and with different tools, sustainability requires using open source tools, sharing data between individuals and giving everything to the public. Then Openness is a natural result, even it is also an ethical, political and philosophical choice as the Digital Manifesto 2.0 says: "the digital is the realm of the open, open source, open resources".
- A DIGICRAFT. In a Renaissance workshop it was possible to produce different objects: statues, paintings, goldsmith or less valuable coroplastic objects. Each handwork was a "project" that included on the one hand a strong artistic and cultural vision (meaning, style, function, purpose, style) and on the other hand a complex set of different techniques made by different workers with different levels of capacity. The owner of the shop (or the head-artist) had not necessarily to know each technique as an expert, but his employees could in many ways be superior and the various members of the workshop could learn from each other. The owner had to keep the team together with a well clear idea of the work itself.
- Likewise a DIGICRAFT could work (and actually does in our LabCD in Pisa) in the same way: each project is taken over as an interdisciplinary complex object that requires specific skills and different but profoundly related competences. The basis (first phases) of the work are often composed by students of the Bachelor and Master's degree in DH, who work, in the labCD, as interns or undergraduates. The work is directed by one "manager" but followed at various stages by experts, who assign specific tasks to the students, always ensuring an active connection among everyone in the team through the usual or more useful collaborative tools. While the work goes on, often happens that some student acquire, in a particular technique or phase, a greater capacity and knowledge than the others and then he/she becomes able to propose substantial changes in the work chain. The manager is not required - nor humanly could - to know every aspect in depth, nor to be fully aware of all the problems related to it, or to master each technique: however, he/she must be able:
  - to see always clearly the aim and the nature of the work;
  - to communicate effectively with everyone in the team.
- A "digicraft" is anywhere on a DH project teachers and students exchange knowledge and leverage this interaction to offer innovative and effective solutions, combining

the theoretical reasoning with practices and skills. This is possible only if the manager and the team share a common strong vision of what a DH project is, embracing a "systemic" or "organic" or "holistic" thinking of DH itself.

The core of DH is unitary and lies in the conviction that the digital turn has permeated every aspect of our lives as people and scholars modifying them deeply.

In the 70s of XXth century has increasingly gained ground a vision of Humanities Computing that kept almost unchanged the traditional disciplines within their rigid internal divisions and distinguished the humanist from the expert in information technology, hoping and promoting a dialogue between the two main areas (still in Fusi 2011, I, p. 1-2). Today this position is no longer sustainable. The web in first place and the web 2.0 in the second (but also the Big Data emerging field as well as the Data Visualization tools) have slowly but surely changed the research landscape especially demolishing the barrier between tools, methods and ways of sharing. We are obviously still in a transitional phase. Highly specialized sub-areas remain (and also in the future will exist) and obviously several scholars strive to better define the old / new digital disciplines (digital history, digital philology and so on), but there is also a complementary phenomenon pointing to an inclusive and unitary vision of DH.

From the perhaps limited but interesting Italian observatory I believe this change has affected both the terminology used in the establishment of centers, associations and degree programs (AIUCD, Digital Humanities degree, Digital Cultural Heritage, Arts and Humanities School), both the organisation of courses and meetings.

It 's more and more widespread the awareness that we are a new type of scholar (and graduate, and PhD), the digital humanist, someone who has a mixed formation, an open mind, is able to master both languages and the main methodological issues of the two areas without considering one serving the other.

In doing so, we need to maintain the epistemological strictness that each discipline involved in the DH has developed over time: commingling does not mean carelessness or inaccuracy; but in the same time we have to claim the change or the changes in each methodology in order to build a new global epistemology.

In order to do this the digital humanist has to embrace a "systemic" or "organic" or "holistic" thinking of the humanities, leave the enclosure of the academic fields and get away from the temptation to create an old-new rigid taxonomy.

Speaking of "systemic" or "organic" or "holistic" thinking / view (I'm sorry for the repetition but the adjectives organic and holistic mean different things not only in different languages but mainly in different subjects), I refer to the epistemological approach that has emerged in some areas of the research over the past thirty years and which tends to oppose the reductionist approach flourished since the seventeenth century onwards and imposed in almost all sectors of the so-called "hard sciences" (Capra-Luisi 2014). As we know reductionism believes that studying in depth a peculiarity of a phenomenon and understanding it completely it will be possible, by progressive addition of discoveries, illuminate the entire system. The reductionist approach has been, as we know, the basis for the scientific revolution of the modern age, but it also led in the eighteenth and nineteenth century to an exasperate

fragmentation of the fields of scientific research. This phenomenon has also heavily influenced the Humanities,often creating absurd barriers and hyperspecialized languages, that have closed researches in several walled gardens. I believe that this long wave has exhausted its strength and that precisely the DH can reverse the trend. Now a new methodological approach have arisen alongside the reductionist thinking, considering the "system", the "whole", something more and different than the sum of its components. The "systemic thinking" reasons in terms of relationships, networks, patterns of organizations and processes; it proposes a change of paradigms: from the vision of the world as a machine to the world as a network; it takes account of the fundamental interdependence of all phenomena.

This change of paradigms could and should affect the DH as well for the reasons listed above, promoting a systemic view of this meta-discipline and therefore pushing Digital Humanists to deeply transform the old practice of work.

Using Computer Numerical Control Techniques to Prototype Media History

Jentery Sayers

University of Victoria, Canada

New technologies can now be used to fabricate old ones. With rapid prototyping techniques, a nineteenth-century mechanism can be downloaded from an online library, translated into code, fed to a 3-D printer, and used to repair a watch, all in about an hour. While such 3-D fabrication techniques tend to fetishize objects, this talk proposes an alternative: "prototyping the past," or remaking technologies that no longer function, no longer exist, or may have only existed as fictions, illustrations, or one-offs. Conceptually, prototyping the past explains why technologies matter by approaching them as representations *and* agents of history. Practically, it creates media that function simultaneously as evidence *and* arguments for interpreting the past. Yet most important, it does more than re-contextualize media history in the present. It integrates that history into the trajectories of design practice.

This full circuit through digital and analog manufacturing corresponds rather provocatively with a "materialist turn" in media studies, where, since at least the late 1990s, scholars have stressed the importance of media as physical entities that resist or diffract interpretations as often as they facilitate them.[1] Writing about phonography, Lisa Gitelman asserts, "At certain levels, media are very influential, and their material properties do (literally and figuratively) *matter*, determining some of the local conditions of communications amid the broader circulations that at once express and constitute social relations" (2006, p. 10). Somewhere between technological determinism[2] and social constructivism,[3] this assertion accounts for how—as both representations *and* agents of history—media play an active role in reproducing the past. Following Gitelman, in the following paragraphs I situate media history in rapid prototyping research, looking specifically at the effects of fabricating tactile models to "prototype the past." While instrumental uses of rapid prototyping tend to fetishize objects, encourage commodification, foster nostalgia, or ignore the political dimensions of material culture, I argue that rapid prototyping can help researchers demonstrate how social and cultural complexity is intricately entangled with the historical particulars of design.[4] Ultimately, what distinguishes rapid prototyping from most other approaches to media history is its investment in not only translating between 2-D and 3-D modes of trial-and-error production but also communicating across a spectrum of media that operate simultaneously as evidence and arguments for future work. Put simply, prototyping the past is more than re-contextualizing media history in the present. It is an opportunity to meaningfully integrate that history into the social, cultural, and ethical trajectories of design practice.

More common in engineering and architecture than the humanities, rapid prototyping entails producing materials through a combination of computer numerical control (CNC) machines—such as 3-D printers (additive manufacturing) and routers (subtractive manufacturing)—with manual approaches to wood, paper, clay, etc. The aim is to subject a 3-D model to repeated feedback throughout the development process. In this sense, the design cycles are small, not grand. Also, the models are versioned. Instead of working toward a single model, multiple models are maintained throughout production. This approach is steeped in "design-in-use," which privileges situated activity over some ideal model or user (Botero, 2013). Through design-in-use, a prototype is treated like a congealed dialogue between interested groups.

With the above in mind, this talk explains why scholars of media history may wish to prototype the past. It builds on especiwork by Kraus (2009), Balsamo (2011), Ratto (2011), Buechley (2012), Perner-Wilson (2012), Ames (2014), Hjorth (2014), Jungnickel (2014), and Rosner (2014)., and It also they in part corresponds with arguments published in "New Old Things" (2012), by Elliott, MacDougall, and Turkel. There, Elliott *et al.* argue that "matter [is] a new medium for historical research. Working with actual, physical stuff offers the historian new opportunities to explore the interactions of people and things" (2012, p. 122). Also, rapid prototyping may frame prototypes may be understood as *situations* for interpretation, without creating exact reproductions of historical artefacts (127). By extension, using matter as a medium for historical research need notneed not fetishize the past. Instead, itt becomes a time and space to interpret the material intricacies of technological design, both now and then.

Perhaps most important, prototyping the past allows scholars to remake technologies that no longer function, no longer exist, or may have only existed as illustrations, fictions, patents, or—fittingly enough—prototypes. TheseOne appeal of prototyping the past is that remade technologiesremade technologies may be circulated as tangible reminders of what was forgotten or destroyed. Yet prototyping the past also affords critiques of what is ready to hand. That is, *it refuses to take historical materials at face value*. Through trial and error, it tests the plausibility of historical claims. After all, what is depicted in a text may contain redactions, deliberate omissions, purposeful obfuscations, or accidental occlusions. Using historical materials to prototype a technology amplifies the meaningfulness of these absences.

Put this way, prototyping the past is intertwined with close reading. However, its emphasis on physically remaking historical technologies expands hermeneutics to include the centrality of translation and tacit knowledge toin media history. By re-contextualizing historical technologies in the present, prototyping also accentuates differences across time. What was once an innovation in the 1860s becomes a relic in 2015. Alternatively, these differences across time may turn things of the past into the stuff of present-day current curiosity., thus complicating distinctions between old and new.

Rather than transcending such differences, prototyping the past grounds media history in a particular thing and the interpretations it affords. Following the work of Karen Barad, such grounding posits prototypes as entanglements of meaning with matter by attending to the substance of "fine-grained details" (Barad , 2007, p. 90). Here, neither meaning nor matter can be relegated to a concept or abstraction. Again, situations are significant. And prototyping reminds scholars of that significance. It is an embodied process involving frustration and surprise, trial, and error, and it highlights how technologies do not emerge effortlessly from the brilliant minds of inventors or makers. Prototyping also reminds scholars that 1) the sources of meaning are forever unstable and under dispute, 2) historical materials are not complete"total" works but rather compositions of parts that change—degrade, rot, morph, warp, break, or swell—over time, 3) prototypes can be de- and remanufactured without significant material consequence, and 36), as noted earlier, materials resist or diffuse as many interpretations as they facilitate.

Example Application: Kits for Cultural History

Based at the Maker Lab in the Humanities ("Lab") at the University of Victoria, the Kits for Cultural History ("Kits") remake technologies from the past, package them in bespoke containers, contextualize them with historical materials, and encourage people to experiment with them. Comparable to Heathkits, the Kits include components and guides for assembly. However, the guides are steeped in cultural history and do not assume a single approach to assembly. By design, this resistance to uniformity is essential, since the Kits focus on technologies that are inaccessible today. These technologies are not found in galleries, libraries, archives, or museums; they no longer function as they once did; or they were never actually built or mass-manufactured. Such inaccessibility necessarily entails a degree of uncertainty where research is concerned. Rather than approaching this uncertainty at a remove, *the Kits prototype absences in the historical record and prompt audiences to examine the contingencies of that record*. Anchored in design-in-use, this method approach presents prototypes as negotiations or situations for interpretation, not replicas.

The Kits' design cycle may be visualized as follows:

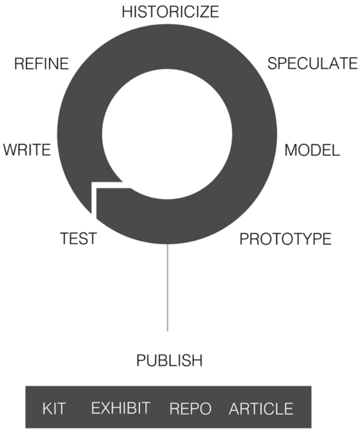

Figure 1: Design Cycle for the Kits

Once the Lab selects a technology for remaking, we historicize it through archival materials. Informed by existing theoriesy, we then speculate about absences in the record and determine how those absences might manifest in tactile form. Next, we model, fabricate, and assemble the technology's component parts into prototypes, which we test and share with other researchers. After feedback, the Lab writes about the process and related history. When bundled together, the writing, prototyping, and testing refine ourthe research, and the cycle is repeated until we deem a Kit persuasive. Once a Kit is ready for circulation, we publish it in tactile form, as a repository of digital files, and through an exhibit. With these, the Lab also authors articles about the Kit's contribution to media history, theorhistory, and design. We treat these publications—the tactile Kit, repository, exhibit, and article—equally as elements of scholarly communication.

Throughout this cycle, we ask several questions of what we are prototyping: 1) Who made it? For whom? When? 2) How was it made? How did it work? How was it used? 3) Do any instances of it exist? If so, where are they? Can they be handled? 4) Under what assumptions was it made and used? 5) How might prototyping it shape design in the future?

We have used this process to produce three Kits thus far: an Early Wearable Kit (for an electro-mobile skull stick-pin from 1867), an Early Magnetic Recording Kit (for experiments involving steel wire, telephones, and carriages during the late 1890s), and an Early Optophonics Kits (for a reading aid patented in 1919).

Findings: Rapid Prototyping and Media History, Together

The Kits support the following observations about the articulation of CNC techniques with media history: 1) prototyping the past demands methods from the humanities, engineering, and fine arts; 2) prototyping is not always futurist or restricted to forecasting; 3) 3-D media such as tactile models are not more persuasive than 2-D media such as illustrations; both include exaggeration and omission; 4) history remains inaccessible even with access to physical materials, which neither resolve issues of absence nor guarantee certainty about the past; 5) prototyping the past may actually resist nostalgia; 6) as with any research method, prototyping is not immediate and cannot access "real history"; 7) prototyping may be premised on *not* replicating history—on what we should *not* repeat; 8) prototyping tests suspicions of history by grounding them in fine-grained details of matter and meaning; and 9) prototyping the past need not aim for a rational history without remainders. Instead, it can recognize how the technologies we use to reproduce history exceed our control and understanding. Indeed, the speculative elements of prototyping can be anchored in the specificities surrounding historical absences—of what we cannot prove or do not know for sure but certainly shapes us.

Introduction

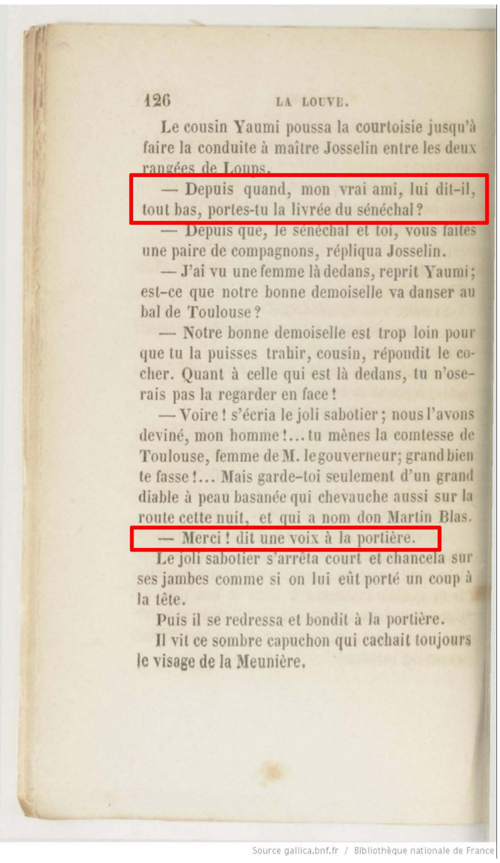
In fictional prose narrative such as novels and short stories, various forms of speech, thought, and writing representation are ubiquitous and have been studied in great detail in linguistics and literary studies. However, beyond quotation marks, what are linguistic markers of direct speech? And just how ubiquitous is direct speech really? Is there systematic variation in the amount of direct speech over time or across genres? Especially for the field of French literary history, where typography is not a reliable guide, we really don't know.

This is regrettable, because being able to quickly and automatically detect direct speech in large collections of literary narrative texts is highly desireable for many areas in literary studies. In the history of literary genres, this allows to observe distributions and evolutions of a fundamental, formal aspect of the novel on a large scale. In narratology, differentiating narrator from character speech is a precondition for more detailed analyses of narrator speech, e.g. with regard to text type (descriptive, narrative, argumentative text). And in authorship attribution, it hereby becomes possible to discard character speech from a set of novels and perform authorship attribution on the narrator speech only, something which may improve attribution.

Against this background, the work presented here addresses both the question of how to identify direct speech in French prose fiction and that of how prevalent direct speech is in different subgenres of the nineteenth-century French novel.

Aims and hypotheses

Our first aim has been to use machine learning to automatically identify direct character speech in a small collection of French-language fictional prose. This is less trivial than it seems to be since in the French typographical tradition, direct speech is usually not marked with opening and closing quotation marks (figure 1). Rather, a long hyphen usually indicates the beginning of direct speech, whereas the end is left unmarked. In figure 1, the first highlighted direct speech continues after the insertion revealing who has just spoken ("lui dit-il, tout bas,"; *he quietly said to him*). In the second example, the direct speech ends after the speaker has been indicated ("dit une voix à la portière"; *said a voice at the door*). Our hypothesis is that there are enough linguistic markers of direct speech to make it possible to identify it automatically and reliably (for an overview of such markers, see Durrer, 1994).



126 LA LOUVE.

Le cousin Yaumi poussa la courtoisie jusqu'à faire la conduite à maître Josselin entre les deux rangées de Loups.

— Depuis quand, mon vrai ami, lui dit-il, tout bas, portes-tu la livrée du sénéchal ?

— Depuis que, le sénéchal et toi, vous faites une paire de compagnons, répliqua Josselin.

— J'ai vu une femme là dedans, reprit Yaumi ; est-ce que notre bonne demoiselle va danser au bal de Toulouse ?

— Notre bonne demoiselle est trop loin pour que tu la puisses trahir, cousin, répondit le cocher. Quant à celle qui est là dedans, tu n'oserais pas la regarder en face !

— Voire ! s'écria le joli sabotier ; nous l'avons deviné, mon homme !... tu mènes la comtesse de Toulouse, femme de M. le gouverneur ; grand bien te fasse !... Mais garde-toi seulement d'un grand diable à peau basanée qui chevauche aussi sur la route cette nuit, et qui a nom don Martin Blas.

— Merci ! dit une voix à la portière.

Le joli sabotier s'arrêta court et chancela sur ses jambes comme si on lui eût porté un coup à la tête.

Puis il se redressa et bondit à la portière.

Il vit ce sombre capuchon qui cachait toujours le visage de la Meunière.

Source gallica.bnf.fr / Bibliothèque nationale de France

Figure 1: Detail from Paul Féval, La Louve, 1857, p. 126 (Source: http://gallica.bnf.fr/ark:/12148/bpt6k6366934b)

Our second aim has been to use the best-performing algorithm to identify direct speech in a larger collection of French nineteenth-century novels and to study its distribution. Here, we hope to detect significant differences in the proportion of direct speech found in different novelistic subgenres. Research about other literary traditions supports this hypothesis (e.g. Allison et al., 2011).

State of the Art

Speech, thought and writing representation are common topics in narratology and stylistics (Genette, 2008, Leech/Short, 2007). Semino and Short's 2004 quantitative study finds that direct representation is clearly the most frequent type in their English fiction sub-corpus. Brunner 2015 confirms this trend for her corpus of German short narratives. Here, the percentage of sentences containing direct speech is about 35% and varies widely over different texts (2%-72%).

Frequently, speech representation recognition is an auxiliary step to other tasks, e.g. knowledge extraction or speaker recognition (Krestel at al., 2008, Elson and McKeown, 2010, Iosif and Mishra, 2014, Sarmento/Nunes, 2009). Weiser and Watrin 2012 used a rule-based approach to extract unmarked quotations in French newspaper texts with success rates of 0.745-0.789. Brunner 2015 focuses on speech, thought and writing representation in German short literary narratives. Using machine learning with random forests, she reports an F1 score of 0.87 for direct speech in a sentence-based cross-validation.

Data

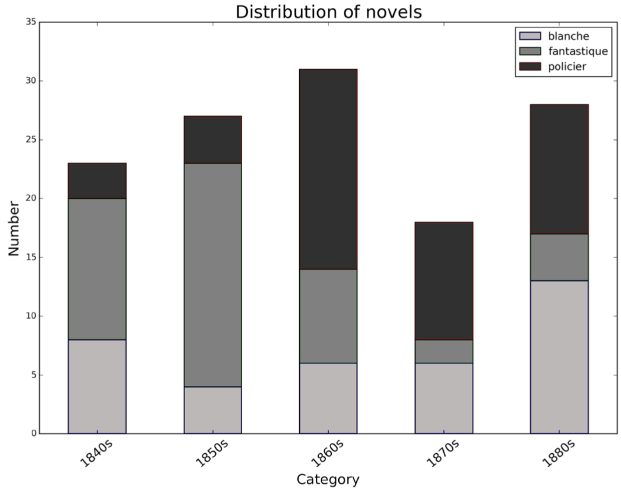


Figure 2: Distribution of novels per subgenre and decade

Our text collection contains 127 French novels published between 1840 and 1889. Three generic subsets can be distinguished, each of which is represented by approximately 40 texts: general novelistic fiction (so-called 'littérature blanche') is contrasted with specific subgenres, crime fiction ('policier') and fantastic novels (see figure 2). The narrative perspective is largely heterodiegetic.

Methods

Manual Annotation

To obtain a gold standard, 40 chapters from 20 different novels were randomly chosen from the collection and annotated manually. 5734 sentences were marked as either containing direct speech or not containing any direct speech; the former also include mixed sentences.

Preprocessing

To prepare feature generation, preprocessing was performed, the pipeline consisting of the Stanford CoreNLP-Tokenizer and Sentence-Splitter, as well as the TreeTagger for POS-Tagging and Lemmatization.

Feature generation

We modeled 81 features which we believed to be useful cues for the classification task (see the annex for a ranked list). Features are generated on a sentence-based level and can be divided into different categories:

- Character-based: e.g. long hyphen marks, exclamation marks, question marks.
- Lexical: e.g. deictic expressions, interjections.
- Semantic: categories of verbs, from WordNet and the French equivalent WOLF: e.g. verbs of motion or perception.
- Morphological: e.g. part-of-speech, verb-tense, lemma.
- Syntactic features: e.g. number of commas, sentence length.

Classification

For the binary classification task (sentences containing vs. not containing direct speech), we used an annotation and classification framework developed by Markus Krug (Würzburg) wrapping LibSVM Support-Vector-Machine (Chang and Lin, 2011), Maximum Entropy (Nigam et al., 1999) and Naïve Bayes (John and Langley, 1995) and implemented in MALLET (McCallum 2002). Random Forest (Breiman, 2001) and JRip (Cohen, 1995) were applied using Weka. All experiments were validated using 10-fold cross-validation unless otherwise stated.

Error analysis

The machine learning algorithms' incorrect assignments on the gold standard (false positives and false negatives) were manually analyzed in order to detect the errors' underlying causes.

Automatic tagging of unseen texts

Using the best-performing model, all sentences in the text collection were tagged for containing direct speech or not. The distribution of ratios of direct speech / non-direct speech was calculated for the three subgenres and five decades covered by the collection. Performance on these unseen texts was checked manually on a random sample. (We sampled 2300 sentences, i.e. 100 random sentences each from a sample of 23 novels stratified by ratio of direct speech.)

Results and Discussion

Recognition of direct speech

Table 1 depicts the performance for different conditions. Our baseline is using the speech sign (i.e. the long hyphen) as the only feature, which yields an F1 score of 0.734. Random-Forest performs best, with an F1 score of 0.939, which we consider to be an impressive result. Even when excluding the speech sign from the features, we still reach an F1 score of 0.924, much better than the hyphen alone.

	Direct speech (3222 Instances)			Non-direct speech (2512 Instances)			Weighted average (5734 instances)			Without Speechsign
	Precision	Recall	F1 Score	Precision	Recall	F1 Score	Precision	Recall	F1 Score	F1 Score
Baseline Speechsign	0.948	0.569	0.711	0.634	0.96	0.764	0.810	0.740	0.734	
N.Bayes	0.863	0.906	0.884	0.834	0.884	0.859	0.850	0.896	0.873	0.831
MaxEnt	0.894	0.887	0.89	0.856	0.865	0.861	0.877	0.877	0.877	0.847
JRip	0.881	0.912	0.896	0.882	0.842	0.861	0.881	0.881	0.881	0.849
LibSVM	0.899	0.902	0.9	0.873	0.87	0.871	0.888	0.888	0.887	0.859
Random-Forest	0.939	0.925	0.932	0.942	0.953	0.948	**0.940**	**0.937**	**0.939** *	**0.924**

Table 1: Performance (10-fold cross-validation on the gold standard)

After inspecting the models, it becomes clear that only very few features carry strong cues for direct speech, namely (and unsurprisingly) the initial long hyphen. Most other features, taken separately, carry weak signals in either direction, but become relevant in combination.

Error analysis reveals that incorrect assignments (false positives and negatives) are frequently due to imperfect sentence segmentation. Several features which have been previously used to define and recognize direct speech (question / exclamation marks, interjections, verbal tenses) also cause incorrect assignments, especially in the context of homodiegetic narration, where the narrator is somewhat involved in the plot so that his narrator speech is similar to direct speech. Finally, letters are sometimes mistaken for direct speech, which makes sense given that in most of them, one person addresses one or several other people.

Distribution of direct speech in the corpus

We applied the best-performing algorithm (Random Forest) to the entire text collection. Evaluation shows a certain drop in performance, with a weighted average success rate of 0.844, indicating less-than-perfect generalization. We noted a welcome absence of any strong bias for either direct or non-direct speech. Our results suggest that the average proportion of direct to non-direct speech across the collection is 61% sentences with direct speech (and 39% without direct speech).

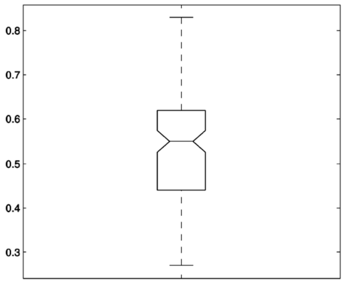

Figure 3: Ratio of direct to non-direct speech in 127 novels

While variance is considerable (see figure 3), the proportion of direct speech in French nineteenth-century novels is overall much higher than expected (and higher, for example, than the 35% reported by Brunner 2015 for German novellas).

Figure 4 shows that both fantastic novels and crime fiction have a significantly higher median for proportion of direct-speech than 'littérature blanche', but do not differ significantly from each other (for significance tests, we used the non-parametric Kruskal-Wallis test at a significance level of 1%).

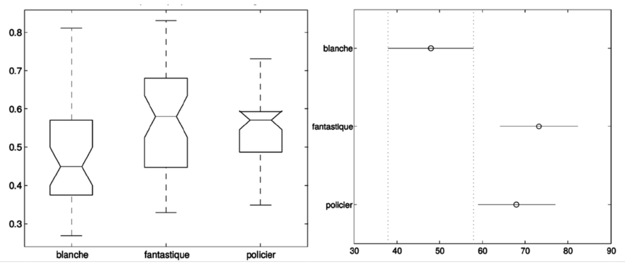

Figure 4: Distribution (left) and significance (right) of direct to non-direct speech ratios across three subgenres

Figure 5 shows that only the ratios for the 1850s and the 1880s have a significantly differing level. However, because the decades do not have perfectly balanced subgenre proportions, this is probably due to a subgenre imbalance rather than an effect of the time period.

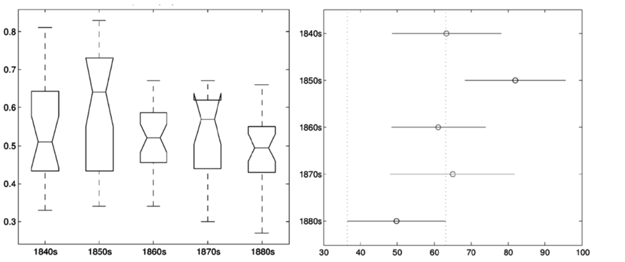

Figure 5: Distribution (left) and significance (right) of direct to non-direct speech ratios across five decades

Conclusions and Future Work

Using a wide range of linguistic markers allows the reliable identification of direct speech, even in the absence of clear typographic markers. Performance is excellent to good (F1-score of 0.94 on the gold standard, weighted average success rate of 0.844 on unseen texts). Using our method reveals that nineteenth-century French novels contain a large proportion of sentences with direct speech (61% on average). Also, there are previously unseen differences in direct speech proportion for subgenre, but not for time period.

For future work, we plan to use several strategies to improve performance. One is to add more sequential information to our set of features. Examples include the position, inside a sentence, of certain lexical or typographical features as well as linguistic cues preceding and following direct speech. Also, we plan to expand our corpus to make it more balanced in terms of genres and decades. This will allow us to discover genre-related patterns of interest to literary historians in a more reliable manner and assess their significance with more confidence.

Background

Online education has been advocated as the ultimate way of democratizing knowledge, but recent research indicates that there are reasons for concern. As the Allen & Seaman 2014 report underlines, 66% of higher education institutions report that online education remains critical to their long-term strategy while 74% of chief academic officers consider the learning outcomes for online courses to be 'as good as or better' than traditional face-to-face courses. But "despite this confidence in online education, researchers continue to report 'compromised quality in online courses' as one of the concerns of faculty, administration, and the general public" (Kidder, 2015; Selingo, 2014). In the landscape of online teaching, MOOCs (Massive Open Online Courses) have received much attention in both academic and popular publications (Bayne and Ross, 2015; Bulfin et al., 2014; Clara and Barbera, 2013) despite the fact that they are not representative of the diverse modalities of online teaching.

Siemens (2012) makes a useful distinction between xMOOCs (behaviorist MOOCs) and cMOOCs (connectivist MOOCs). The former emphasizes "a more traditional learning approach through video presentations and short quizzes and testing" with a focus on "knowledge duplication", whereas the latter focus on "knowledge creation" (Siemens, 2012). Along the same lines, Ozturk recently reported that new variations of MOOCs have emerged becoming more market oriented "aligning with instructivist, cognitive, and behaviourist pedagogy" (Ozturk, 2015). Moreover, the financial model of the MOOCs raises questions about the audience for and motivations behind this method of teaching (Ozturk, 2015; Manjoo, 2015).

Conscious of this present situation, the #dariahTeach project (funded by an Erasmus+ Strategic Partnership) is developing a network based in seven partner countries exploring the production, dissemination, and promotion of high quality, dynamic, extensible, localisable, and integrated educational materials for the digital humanities specifically tailored for third level education. It is adopting a cMOOC philosophy which focuses on 'creation, creativity, autonomy, and social networked learning' (Siemens, 2012) to provide pedagogical content that can be easily integrated into diverse teaching and learning situations.

A key consideration in the design of the platform is interoperability between courses/modules (and units within those modules) since DH draws on a wealth of methods and tools from a variety of disciplines. Moreover, it is envisioned that these modules will be used beyond the DH community as the societal impact of a culturally-driven digital transition grows opening up new ways of collaborating on productive theory and critical thinking (Hayles, 2012). Thus a goal of #dariahTeach is to develop rich educational materials that 1) instructors in the growing number of Digital Humanities programmes can use as appropriate to their own institutional settings and learning outcomes; 2) instructors in other disciplines can draw on and; 3) students who are not at institutions that have DH expertise can use to develop the skills and methods, as well as understand the theoretical basis, to engage in digital humanities and humanities research.

The project team is currently developing the infrastructure and design of the modules based on the production of five modules: Introduction to Digital Humanities, Text Encoding, AudioVisual Media and Multimodal Literacies, Retrodigitizing Dictionaries, and Ontologies and Knowledge Management. This paper will present the results of preliminary research carried out through an extensive study of user requirements, as well as desk research on module and platform design informed by a workshop in Belgrade funded by the Digital Research Infrastructure for the Arts and Humanities (DARIAH) on developing open educational materials.

Analysis of User Requirements

The design and the implementation of a successful platform-based learning environment melds concepts from psychology, education, and human-computer interaction. Poor interface design can become a serious obstacle to the learning outcome, as it may slow the process down and impose cognitive obstacles. To this end, a qualitative analysis and interpretation of online teaching practices and recommendations in the DH domain and the elicitation of corresponding user requirements was based on a series of semi-structured interviews with experienced instructors of online courses within Europe.

Findings of the user requirement process are a key component of the development of the #dariahTeach platform. These indicate that the platform needs to cater for the following needs: be adaptable to different learning methodologies; allow for persistent roles; provide an API or advanced forms of web services so that new unforeseen components can be added to the environment; support ad hoc groupings and grouping of materials across modules and units; allow for both synchronous and asynchronous collaboration and communication and enable user customization.

Module Design

#dariahTeach modules are designed as building blocks tailored to the exigencies of teaching situations in different educational and cultural contexts, allowing for localization and adaptation (via translation, subtitles, domain-specific examples etc.). By offering examples of and encouraging further adaptation of training materials to specific linguistic/cultural contexts, #dariahTeach will dispel any notion that the use of ICT methods leads to abstract representations of culturally impoverished outputs.

It is important to stress two levels of translatability of module design: 1) translatability and adaptability of the language of instruction; and b) selectability, translatability and adaptability of primary sources and materials that are used in instruction. This means that an English-language module on Text Encoding, for instance, is localizable both in terms of the instructional narrative, as well as the kind of texts that are used to exemplify the taught principles and methods of text modeling: different genres (poetry, prose, drama) but also language (Latin, Greek, Serbian, Dutch etc.)

Our "Introduction to DH" module will also not attempt to impose a single pedagogical narrative on what is a constantly evolving and highly diverse, interdisciplinary field. Instead, our Introduction to DH is based on a micromodular, polycentric approach: a collection of mutually-linked, cross-referenced, metadata-rich short videos that shed light on DH as a community of practice from multiple perspectives without creating a false sense of uniformity.

Platform Design

Modules will be made available via an online portal/web application based on existing solutions. This paper will explore the decision tree in adopting a solution including whether to use a well-established Content Management Systems (eg Drupal, WordPress, Joomla) with Learning Management System plugins and appropriate customizations or the use of a customizable Learning Management System (such as Moodle or Blackboard). Considerations feeding into the decision tree include the platform being open source, freely available, well documented and customizable with plugin development support; support for multilinguality; an embedded xml editor; collaboration and interaction functionalities (eg chats, forums and wikis); test and assessment functionalities; extended search functionalities for available metadata (mapped to Dublin Core and LOM to facilitate sharing and support interoperability and reusability (Roy et al., 2010); and copyright attribution and licence management functionalities.

Conclusion

The paper will conclude with longer-term prospects for the project. Oversight of #dariahTeach will be maintained after the grant has ended by a General Editor and Editorial Board under the oversight of the DARAH's Research and Education Competency Centre.

Introduction

Three-dimensional digital visualisations have been used in the last three decades to engage and educate by making complex data more comprehensible. These have been used across a wide range of fields including military, medicine, cultural heritage, archaeology, and history. In cultural heritage contexts, the potential of these technologies as tools in the process of knowledge production has been well demonstrated (see for example Sundstedt et al., 2004; Papadopoulos et al., 2015). Contested Memories: The Battle of Mount Street Bridge project has been exploring how to integrate a 3D visualisation as the primary text of a digital scholarly edition, raising issues of how the phenomenology of place and space can be used to design a new language of scholarly editions, one that has the ability to model experience lost because of technological and evidentiary constraints. This edition, like traditional DSEs, also brings together documentary evidence in the form of apparatus, reimagining digital textuality (see Snyder, 2015).

The project focuses on a battle that took place on Wednesday 26th April 1916 during the week of the Easter uprising in Dublin. This particular battle, between a small group of Irish rebels (members of the Irish Volunteers) and the British army sent to Dublin to put down the rebellion is used here to investigate to what extent a networked virtual world can be accommodated into a scholarly editing paradigm developed for print (and more recently digital) to enable alternative forms of research, help in the interpretive process, and assist knowledge production for both general audiences and specialists.

The development of the primary text in a gaming platform posed significant challenges, many of which have been ameliorated when creating digital editions of print or manuscript sources through such methods and standards as XML, The Text Encoding Initiative, and XML-aware databases. This case study will explore these challenges, the project's accomplishments, and future directions.

Contested Memories: The Battle of Mount Street Bridge is one of the four projects developed under the Humanities Virtual World Consortium (HVWC) and is funded by The Andrew W. Mellon Foundation. Four virtual worlds are being constructed, each released as Unity3D builds (2015), while a shared virtual world platform ensures the sustainability and interoperability of these as well as future projects.

Historical Background and Purpose of the Digital Simulation

The Battle of Mount Street Bridge has attracted much scholarly attention not only due to its significance during the Easter Rising but also because of the varied and contradictory accounts of British casualties, as well as the timeline and British strategy during the battle. Seventeen

Irish volunteers took positions at four different buildings in and around on a one block stretch along Northumberland Road in a leafy suburb of Dublin (fig. 1). They prevented two Battalions of British soldiers known as the Sherwood Foresters (some 1,750 men) for over six hours from progressing into the city centre.

Although there exists a significant amount of documentation for the battle from both British and Irish sources, some of it written in the 1920s (The Robin Hoods, 1921; Oates, 1920), with other sources given as oral histories between 1945-1955 (see the Bureau of Military History), scholars have not been able to map, both spatially and temporally, the contours of the engagement so as to understand how such a small number of rebels could inflict such heavy losses on a trained group of soldiers.

Thus, a goal of the project is to employ spatiotemporal methods in order to create a model of the environment in which the battle took place as well as simulate certain key events to enable researchers and specialists to visualise the conflict as well as to understand how the conflict unfolded.

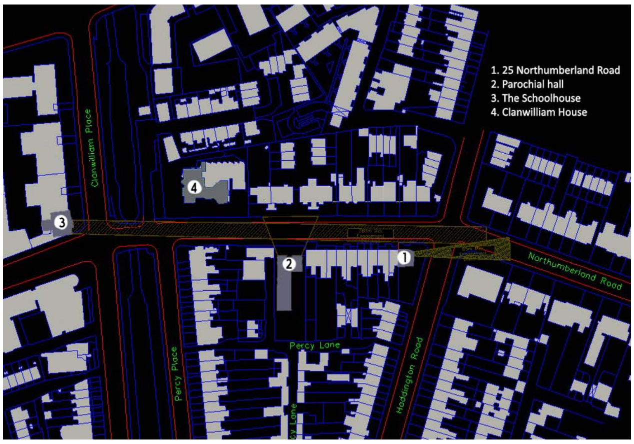

Figure 1. Location of buildings occupied by the Irish Volunteers

Methodology

This project employed a range of research methods in order to obtain relevant information for the battle and inform the decision-making process of building the virtual world. Firstly, conventional archival research and meetings with military historians were carried out to document different sources (both contradictory and fragmentary) that provide evidence for the buildings that were occupied, participant accounts, the weapons they used, as well as the events that took place during the battle. Period photographs were used for the digital (re)construction of the area, while a Lidar Scanning of Northumberland Road helped in creating a highly accurate digital model of the battle scene. Ballistic experts and experiments at the shooting range provided a well-informed recreation of bullets' trajectories and guns' sounds and reload rates.

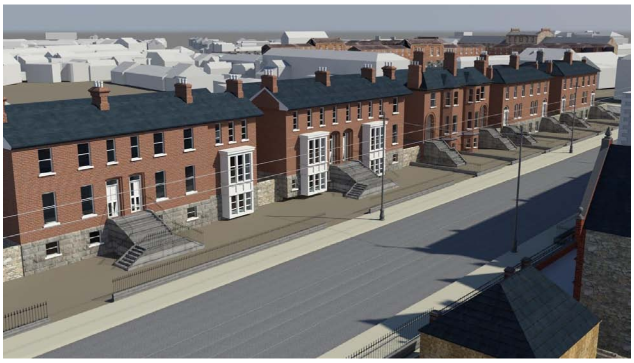

Figure 2. A 3D Model of Northumberland Road in 3ds Max 2015.

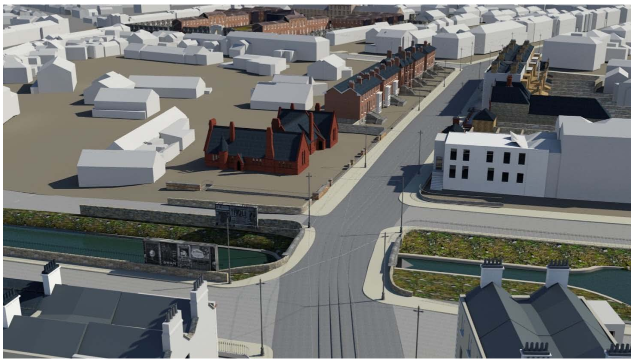

Figure 3. Rendering of the battlefield. Building and features that were significant in the conflict were modelled in more detail, while a schematic view of the broader area provides adequate context to the users.

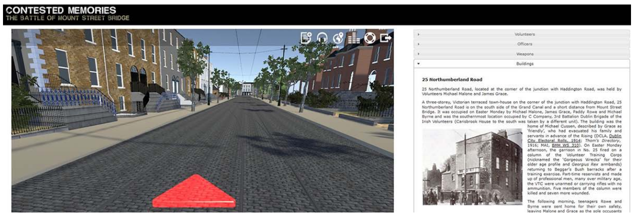
The above information was used as the basis to construct a 3D model of the battle scene, as well as annotations for the Irish Volunteers and the British forces, weapons, and buildings at Northumberland Road and the adjacent streets. The purpose of this visualisation is not to present an exact representation of the battle. Rather, it is a tool to investigate alternative interpretations, as well as provide a case study to engage in ongoing interdisciplinary debates regarding the nature of digital reconstructions (Bentkowska-Kafel et al. 2012; Clark 2010; Kensek et al. 2004). The 3D model was constructed in 3ds Max 2015 (Autodesk 2015) (fig. 2, 3) and was migrated to the game engine Unity3D (2015) in order to enable a navigable in-browser 3D world for users to explore. The first version of the virtual world (November 2015) used all the capabilities of Unity Web Player (fig. 4). However, given the limited support of NPAPI, the plugin framework that Unity Web Player uses to enable detailed and high resolution models to properly function in web browsers, the second version (February 2016) implemented WebGL technology, which at the time of writing this paper, only supports light-weight applications. Therefore, most models of the virtual world had to be optimised, while detailed models of the city that provide contextual information for the Battle had to be omitted (fig. 5). Users of the virtual environment are able to navigate the world in first person-mode, while not having in-world representation in order to avoid modern figures being visible in the battle field.



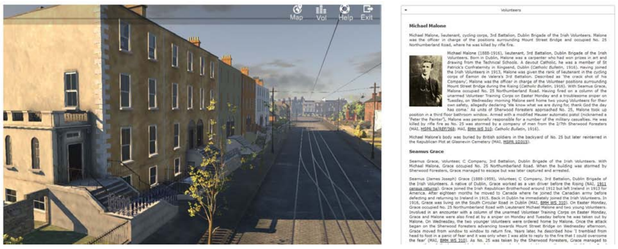
25 Northumberland Road

25 Northumberland Road, located at the corner of the junction with Haddington Road, was held by Volunteers Michael Malone and James Grace.

A three-storey, Victorian terraced town-house on the corner of the junction with Haddington Road, 25 Northumberland Road is on the south side of the Grand Canal and a short distance from Mount Street Bridge. It was occupied on Easter Monday by Michael Malone, James Grace, Paddy Rowe and Michael Byrne and was the southernmost location occupied by C Company, 3rd Battalion Dublin Brigade of the Irish Volunteers (Carisbrook House to the south was taken by a different unit). The building was the home of Michael Cussen, described by Grace as 'friendly', who had evacuated his family and servants in advance of the Rising (DCLA, Dublin City Electoral Rolls, 1914; *Thom's Directory*, 1916; MAI, BMH WS 310). On Easter Monday afternoon, the garrison in No. 25 fired on a column of the Volunteer Training Corps (nicknamed the 'Gorgeous Wrecks' for their older age profile and *Georgius Rex* armbands) returning to Beggar's Bush barracks after a training exercise. Part-time reservists and made up of professional men, many over military age, the VTC were unarmed or carrying rifles with no ammunition. Five members of the column were killed and seven more wounded.

The following morning, teenagers Rowe and Byrne were sent home for their own safety, leaving Malone and Grace as the sole occupants

Figure 4. First version of the Virtual World embedded within the digital scholarly edition



Michael Malone

Michael Malone, lieutenant, cycling corps, 3rd Battalion, Dublin Brigade of the Irish Volunteers. Malone was the officer in charge of the positions surrounding Mount Street Bridge and occupied No. 25 Northumberland Road, where he was killed by rifle fire.

Michael Malone (1888-1916), lieutenant, 3rd Battalion, Dublin Brigade of the Irish Volunteers. Born in Dublin, Malone was a carpenter who had won prizes in art and drawing from the Technical Schools. A devout Catholic, he was a member of St Patrick's Confraternity in Ringsend, Dublin (*Catholic Bulletin*, 1916). Having joined the Irish Volunteers in 1913, Malone was given the rank of lieutenant in the cycling corps of Éamon de Valera's 3rd Battalion. Described as 'the crack shot of his Company', Malone was the officer in charge of the Volunteer positions surrounding Mount Street Bridge during the Rising (*Catholic Bulletin*, 1916). With Seamus Grace, Malone occupied No. 25 Northumberland Road. Having fired on a column of the unarmed Volunteer Training Corps on Easter Monday and a troublesome sniper on Tuesday, on Wednesday morning Malone sent home two young Volunteers for their own safety, allegedly declaring 'We know what we are dying for, thank God the day has come.' As units of Sherwood Foresters approached No. 25, Malone took up position in a third floor bathroom window. Armed with a modified Mauser automatic pistol (nicknamed a 'Peter the Painter'), Malone was personally responsible for a number of the military casualties. He was killed by rifle fire as No. 25 was stormed by a company of men from the 2/7th Sherwood Foresters (MAI, MSPR 34/REF/368; MAI, BMH WS 310; *Catholic Bulletin*, 1916).

Michael Malone's body was buried by British soldiers in the backyard of No. 25 but later reinterred in the Republican Plot at Glasnevin Cemetery (MAI, MSPR 1D315).

Seamus Grace

Seamus Grace, Volunteer, C Company, 3rd Battalion, Dublin Brigade of the Irish Volunteers. With Michael Malone, Grace occupied No. 25 Northumberland Road. When the building was stormed by Sherwood Foresters, Grace managed to escape but was later captured and arrested.

Seamus (James Joseph) Grace (1888-1959), Volunteer, C Company, 3rd Battalion, Dublin Brigade of the Irish Volunteers. A native of Dublin, Grace worked as a van driver before the Rising (NAI, 1911 census returns). Grace joined the Irish Republican Brotherhood around 1912 but left Ireland in 1913 for America. After eighteen months he moved to Canada where he joined the Canadian army before defecting and returning to Ireland in 1915. Back in Dublin he immediately joined the Irish Volunteers. In 1916, Grace was living on the South Circular Road in Dublin (MAI, BMH WS 310). On Easter Monday, Grace occupied No. 25 Northumberland Road with Lieutenant Michael Malone and two young Volunteers. Involved in an encounter with a column of the unarmed Volunteer Training Corps on Easter Monday, Grace and Malone were also fired at by a sniper on Monday and Tuesday before he was taken out by Malone. On Wednesday, the two younger Volunteers were ordered home by Malone. Once the attack began on the Sherwood Foresters advancing towards Mount Street Bridge on Wednesday afternoon, Grace moved from window to window to return fire. Years later, he described how 'I trembled from head to foot in a panic of fear and it was only when I was able to reply to the fire that I could overcome the fear' (MAI, BMH WS 310). As No. 25 was taken by the Sherwood Foresters, Grace managed to

Figure 5. Second version of the Virtual World in WebGL Unity Web Player

Conclusion

The digital simulation of the Battle of Mount Street Bridge provides a novel methodology for knowledge production and understanding in historical research demonstrating how computer-based simulations can augment traditional approaches in historical datasets, enhance the interpretive process, and potentially provide answers in complicated research questions. It was the process of producing the digital simulation and not simply the end-product that provided valuable answers to our questions. Once the model was completed, however, new research questions emerged, as historians interested in the period, as well as the public, began interacting with the model.

Future development of the project includes embedding narratives about in-world objects (buildings, avatars etc.), contextual information and decisions, animations of the broad contours of the battle, an AI simulation of key events, and a Mixed-Reality application tailored to the general public and secondary school students.

The Mutual Relationship of Linguistic and Non-linguistic Elements in Breaking Down the Hierarchy of Language in Digital Narrative

Mehdy Sedaghat Payam
ms79payam@yahoo.com
SAMT Center for Research and Development in Humanities

Although there have been a handful of transmedial explorations by some novelists in the past, narrative in novels has mainly used linguistic elements in conventional print fiction. When the first generation of hypertext novelists remediated print novels in their works they only used language too. However, images, sound, movies and other non-linguistic elements in works of the second generation digital novels—called web-fiction here—have mainly challenged the hierarchy of language and have posed serious threats to the autonomy of words in novels. This challenge has worked both ways, on one hand, works of web-fiction have tried to distance themselves from works which have been merely linguistic (for instance *Afternoon* (1990)), on the other hand experimental print novelists have become media-conscious and created novels which have incorporated images, colors, innovative page design and music in their physical body (for instance *House of Leaves* (200)). Consequently these media-conscious novels, especially in digital media, have posed serious questions for novel. Some of these questions are: How much narrative in novels is dependent upon words and in what ways can it take advantage of the narrative potentials of the non-linguistic elements? In other words how can non-linguistic elements contribute to the narrative of novels in the media in which they are rendered and in what ways does this new synthesis of words and non-linguistic elements can change our understanding of the narrative in novels? Finally how these novels should be analyzed? In order to find the answers of these questions, two works of web-fiction, *Reconstructing Mayakovsky* (2011) by Illya Szilak and *Dreamaphage* (2006) by Jason Nelson, and one work of media-conscious print *S* (2013) by Doug Dorst and J.J. Abrams have been chosen and the mutual relationship between their linguistic and non-linguistic elements have been explored. All of these works have tried to break down the hierarchy of language in the narrative of the novel and in doing that have highlighted the role of non-linguistic features and have highlighted the ways these features can contribute to narrative in a novel especially in a digital medium.

Analyzing these works will help us to find the answer to a bigger question. How do these mixtures of several media justify their existences as novels? This is where pushing Bakhtin's ideas a little bit further to include works of digital fiction can become extremely useful. Bakhtin's ideas have been used as the theoretical base of my discussion because out of the three other theories of novel presented in the *Routledge Encyclopaedia of Narrative* (2005) , it is the only one which takes the materialities of the production of the text into consideration and according to Howard Mancing "seems most justified by an informed understanding of literary history and theory" (ibid, 399). According to Bakhtin "There is no specific form, technique, theme, or approach to character that makes a text a novel; rather, the distinguishing characteristics of the novel are its heteroglossia and its dialogism" (ibid, 400). Since Bakhtin does not limit dialogism to literature only and believes all language (and all thought) is dialogical, in this paper it has been tried to extend these two concepts into "modes" in both digital and media-conscious print novels. In these novels multiplicity of modes can result in novels in which the words' hold over the narrative is not as strong as it has been in conventional novels. Such novels can potentially provide a dialogical engagement between linguistic and non-linguistic elements which can eventually lead to a different understanding of what novel is (or it can be). In this way, the current proposal aims at providing a theoretical background and justification for these kinds of narratives which claim to be novels and offers a practical method to read and analyze these novels.

Historical Background

The introduction of digital media to the literary scene encouraged a number of experimental novelists—some of whom like Joyce had published novels in print—to try their hand at this medium to create works which were both written on the computer and necessarily had to be read on the screen as well. These writers who were later known as hypertext novelists experimented with the materiality of this new medium, and made its materiality an explicit part of the conception of their novels. Although some conventions of the print medium were discernible in the works of these writers, the arrival of the Internet and the developments in digital media provided a significant opportunity for these writers and the new generation of writers to experiment with new conventions for novel writing in digital media. Moreover, these experimentations with the materiality of the medium encouraged the experimental print novelists of the digital era to experiment more extensively with print as a medium.

N. Katherine Hayles is a prominent scholar who has consistently written on the "materiality of the medium" and this paper has heavily borrowed from her theoretical discussions and coinages. Hayles advocates a method of reading called Media-Specific Analysis (MSA) which involves paying particular attention to the materiality of the medium in which the work of fiction is presented. The importance of Hayles' analytical method is that it provides a practical method for thinking about text as a linguistic object, and provides a new perspective to think and write about texts. Another advantage of Hayles' approach is that it brings the medium to the foreground from the very beginning and can be applied for the analysis of both print and digital novels.

Since the novel as a specific genre and media form developed its defining characteristics and conventions in association with the evolution of print technology, the question of how narrative in novels is transformed through works of hypertext or web-fiction is a significant one. H. Porter Abbott has a useful definition of narrative and his definition will be used as a guide in the controversial subject of narrative and how it should be thought of in the works of hypertext and web-fiction. In Abbott's definition, "narrative is the representation of events, consisting of *story* and *narrative discourse.*" Story "is an event or sequence of events (the action), and narrative discourse is those events as represented" (16). The main reason that Abbott's definition has been chosen here is that it can be applied to the study of narrative in an almost any medium.

The non-linguistic elements which have been used in media-conscious novels are referred to as modes here, therefore a novel which has used several modes in its narrative is a multimodal novel. This usage of the term mode is more in line with the way Alison Gibbons has defined this term as "a system of choices used to communicate meaning." Looking at novel from the modality perspective, provides us a better understanding of how each work is created out of the different combinations of modalities of three different but related categories. A fictional text uses a specific modality of the text which is the narrative genre. It uses the modality of the medium either print or digital. The last modality which comes into play here is the modality of verbal/visual which is part of the modalities of representation. These modalities can work in different combinations, but segregating them in this way, makes them more visible and shows how each writer can create texts, by manipulating either of these so that the reading process would be affected by the way either of these modalities is brought into play.

Thus, in order to study the he fictional works discussed here, three different but interrelated dimensions of the fictional text have been identified. (1) Physical Organization and Design, (2) Narrative Strategy, and (3) Reading Process. This tripartite model can be used by other scholars for analyzing novels which incorporate linguistic and non-linguistic elements in their narrative(s). In the first dimension, Physical Organization and Design a text is analyzed from the perspective of the use of its physical resources its authorship, and design. Narrative Strategy, the second dimension, is the angle through which a text from the perspective of the use of its physical resources and signifying strategies to create a narrative is analyzed. In the third dimension, the Reading Process, the way a text shapes the experience of the reader is explored.

Novels have always been media forms which lead the reader through them to a world which is the real world or like the real world in its spatial/visual form. These worlds exist beyond the page and the language and materiality of the novel are expected to be effaced during this process. However, the digital novels and media-conscious print novels show resistance toward this self-effacement and by mixing different modes in their narrative and bringing their own materiality into the foreground. The narrative and how it is created through the interplay of different modes in a single work is analyzed in these three novels:

- *Reconstructing Mayakovsky* by Illya Szilak. This novel which claims to be the "novel of future" has been published in electronic format in the second volume of ELO in 2011. Later in 2012, a print version of the same novel was published by Revolution Nostalgia Disco Theater. Mayakovsky's believed that poetry is a mode which can disrupt a fixed narrative and this is exactly what Szilak tries to accomplish in her novel. The narrative in this novel is broken into several modes—or "mechanisms," as the writer calls them—including text, audio podcasts, video, a live Google image search, etc.
- *Dreamaphage* by Jason Nelson. The interfaces of Dreamaphage have been described as "innovative, surprising, alternately whimsical and unnerving" by ELO website and these words can be used to describe the whole narrative of novel as well. Narrative in this novel is presented through different layers of 3D text with several links to the books which the reader has to simulate the act of turning the page (which means clicking the mouse on the bottom right side of the screen where the edge of the book is and move it to the top left, so that the next page appears on screen), and move through pages filled with squares and circle to read some files which their loose connection together forms a narrative.
- *S* by Doug Dorst and J.J. Abrams. This print novel comes in a slip cover which has a book named "Ship of Theseus" which is full of handwritten comments, as well as postcards, newspaper clippings, black and white photos, even a hand-drawn map written on a napkin from a coffee shop, which together create a mysterious narrative. These non-linguistic materials play such a crucial role in the narrative, that at times it becomes impossible to follow the narrative and solve the mystery of the novel without them. *S* is described a "love letter to the written word," on its slipcover, however it is through the interaction of the linguistic and non-linguistic elements that this love letter finds its true meaning.

What Do Boy Bands Tell Us About Disasters? The Social Media Response to the Nepal Earthquake

David Lawrence Shepard

yshin@ai.u-hyogo.ac.jp
Hyogo University, Japan

When an earthquake struck Nepal in 2015, the band One Direction sent a tweet encouraging their fans to donate to relief efforts. This one tweet was retweeted a few times, but quickly lost in a flood of other tweets about One Direction's tour. Simultaneously, an Indian Hindu extremist politician flooded his Twitter stream with rumors that Christian missionaries were coercing conversions from Nepalis in exchange for humanitarian aid. Additionally, an Indian religious group mixed substantial numbers of tweets about a movie they had released with tweets about their relief efforts in Nepal. These are just a few of the users who engaged with the disaster from a distance: they had different motives for tweeting about the disaster, and different levels of engagement with it. We call these users "onlookers:" they tweet about a disaster, but are not directly affected by it.

This paper analyzes onlooker behavior: it argues that onlookers who will send a few tweets can be predicted by their interests, while onlookers who will tweet heavily about it have few, if any, shared interests. We show that onlookers who primarily tweet about entertainment topics and news topics are likely to mention the disaster, yet send few tweets about it. On the other hand, onlookers who tweet substantially about a disaster after it happens are difficult to identify before the disaster occurs because they do not share common interests aside from the disaster.

Background

Natural disasters often attract significant attention on Twitter, both by those affected and those who are distant. A substantial amount of research has explored how social media causes users to engage with political, social, and humanitarian problems; however, opinions on social media's effectiveness—whether it causes users to donate money, stay informed, or participate in campaigns—are mixed. Some argue that displaying concern in social media is more about acquiring social capital than effecting change (Shulman, 2009; Gladwell, 2011; Morozov, 2012; Morozov, 2014), while a Pew Research Center survey finds that social media does create change (Raine et al., 2016). Additionally, many have argued that social media was important though not essential to protests in Egypt (Mazaid, 2011; Tufekci and Wilson, 2012) and other nations (Raine et al., 2016; Shirky, 2011). One analysis found that charities' use of social media does not increase donations (Malcolm, 2016), while another finds that certain tweeting strategies do (Gasso Climent, 2015) although tweets may not raise awareness about the charity's causes (Bravo and Hoffman-Goetz, 2015). Where all these studies concur is that social media enable a substantial amount of discourse about crises. The question we explore is how to predict how much attention Twitter users pay to crises: social media presents the opportunity for a user to send a single retweet about a disaster—as many One Direction fans did—or to sustain interest by following other users and sending many tweets about the event over a period of time.

Additionally, there is little question that social media is useful for those directly affected by disasters. A substantial amount of research finds that social media helps first responders (Regalado et al., 2015; Dugdale et al., 2012; Omilion-Hodges and McClain, 2016; Burns, 2015; Xiao et al., 2015; Kaewkitipong et al., 2016; Meng et al., 2015; Madianou, 2015; Palen, 2008). In fact, specialized algorithms have been developed for that purpose (Pohl et al., 2013a; Pohl et al., 2013b; Platt et al., 2011). Little work examines users who tweet about disasters at a distance, however, despite the large numbers of such users. We examine these onlookers because they produce a large amount of the tweets about humanitarian crises.

Method

We use quantitative text analysis to identify tweets about the earthquake, to cluster onlookers based on shared interests, and to derive a correlation between onlookers' interests and the number of tweets they sent about the earthquake. This section outlines our methods.

To attain a broad sample of onlookers, we gathered a dataset of over 5 million tweets sent by around 15,000 users in the three weeks following the Nepal earthquake. We harvested the data from the Twitter REST API by searching for any tweets that mentioned the word "Nepal" from April 24 to May 8. We randomly selected 15,000 users from this set and harvested all of their tweets sent between April 24, 2014 and May 5, 2015. We attempted to capture only English-speaking users to increase the likelihood that we would capture users not directly affected by the earthquake, but we still captured some users who tweeted in multiple languages. This left us with roughly 11,000 onlookers.

To determine how many tweets a user had sent about the earthquake, we trained a Naive Bayesian classifier using MALLET (McCallum, 2002) on a set of 100 onlookers' tweets (totaling about 30,000 tweets), marking them as either quake-related or not. We applied the trained classifier to the remainder of the dataset to count each user's quake-related tweets. Spot checking showed this technique had acceptable accuracy.

To find shared interests, we used Latent Dirichlet Allocation (Blei et al., 2003), treating all of a user's tweets as one document. We ran LDA with MALLET with various numbers of topics, and settled on 80. These topics represented a broad span of themes: greetings, news, entertainment, technology, plus four topics directly related to the earthquake. We then looked for connections between onlookers by building an edge list of shared topics, creating a weighted edge between two onlookers if over 25% of both onlookers' tweets consisted of a shared topic. The edge weight was the product of their affinities to that topic. Using Gephi (Bastian et al., 2009), we then ran a weighted Louvian modularity algorithm (Blondel et al., 2008) over this onlooker graph to generate communities of users.

Analysis

This experiment resulted in 21 communities of onlookers being identified. The communities were labelled using the strongest topics in each.

ID	Label	Average Number of Tweets	Users	Average Quake-Related Tweets
0	Foreign language (Spanish)	419	882	9
1	Japanese Music	403	135	5
2	Greetings	326	199	5
3	Portuguese/Fifth Harmony	710	658	7
4	News Media	977	11	1
5	News Media	652	1312	22
6	News/Politics	600	1236	26
7	Indonesia	386	416	8
8	Foreign language (unknown)	495	312	5
9	Unclassified	372	589	25
10	Dera Sacha Sauda	1732	54	205
11	News about Russia	780	30	18
12	Shopping	1153	226	11
13	Greetings	476	1010	11
14	Greetings	439	1347	5
15	Science and animals	521	108	13
16	One Direction	388	1085	10
17	Foreign Language (Italian)	553	47	14
18	TV/Music	598	722	5
19	Music Videos	649	14	30
20	Nepal	393	748	125

After pruning out the foreign language communities in the dataset and some that were difficult to classify (Communities 0, 7-9, and 17), we can further group these onlookers into three broad interest groups: Casual Users (Communities 1-3, 12-14, 18, and 19), News and Pundits (4-6, and 13), and Engaged Users (20). We divided these subgroups based on the topics that were strongest in each, but these subgroups correlated with the number of quake-related tweets that each sent. They are described in the table below.

Category	Proportion	Quake-Related Tweets/ Week	Topic Affinities
Casual Onlookers	46%	3	Entertainment, greetings
News Onlookers	25%	6	News and politics
Engaged Onlookers	12%	10	Nepal

Casual Onlookers. Onlookers in these communities showed high activity but low engagement with the disaster, sending an average total of three quake-related tweets a week. Their primary topics of discussion were entertainment, or greetings and positive sentiments. This is the largest group.

News Onlookers. These accounts are either the accounts of professional news outlets or amateur pundits. We find low average quake-related tweets in this group as well: users sent an average of six relevant tweets per week. News outlets generally moved from one topic to another quickly, and pundits only sustained interest in the topics that appealed to them.

Engaged Onlookers. This group sent the most quake-related tweets of all users; the strongest LDA topics in this group were two "Nepal earthquake" topics. However, users in this community had few other topics in common with each other.

This breakdown suggests a model for predicting the number of tweets onlookers send about events. There will be roughly three categories of onlookers: Casual Onlookers, News Onlookers, and Engaged Onlookers. Casual Onlookers will consist of roughly 50% of onlookers, and will send only a few tweets over the first three weeks. Membership in this group is predicted by an interest in entertainment topics. The number of News Onlookers will be half the size of the Casual Onlookers, but they will be roughly twice as engaged. An onlookers's affinity to this group will be predicted by a general interest in news. Finally, the Engaged Onlookers will send 10-20 times as many tweets as the Casual Onlookers, and will comprise slightly over 10% of onlookers. This group sends the most tweets about an event, but membership in this group cannot be predicted from their preexisting interests.

Conclusion

We find that it is easy to predict shallow engagement with a disaster on Twitter, but difficult to anticipate sustained interest. Onlookers who tweet about entertainment are likely to pass on at least a few messages about donating money because entertainers are likely to post these messages, and fans are likely to retweet them. On the other hand, onlookers who tweet more about an event are likely to have preexisting interests that intersect with a particular aspect of the disaster, but the relevant interests are hard to predict because doing so would require knowing the nature of the disaster ahead of time. For example, to know the Hindu extremist would tweet about rumors of coerced conversions in Nepal, we would have to predict a crisis that would produce such rumors.

Additionally, we acknowledge that our model is derived from a single case study. As such, we treat it as provisional pending further experiments. We hope to confirm this model with future work.

Full Stack DH: Building a Virtual Research Environment on a Raspberry PI

James Dakin Smithies
james.smithies@protonmail.ch
King's College London, United Kingdom

Ian Hodder has recently pointed to a "return to things" in the humanities and social sciences, a mode of analysis that explores the relationships between people and the objects we use to construct and make sense of the world (Hodder, 2014, p.19). In digital humanities we can see this in Matthew Kirschenbaum's focus on the forensics of computer hard disks (Kirschenbaum, 2007), the development of platform studies to investigate the relationship between computing culture and the consoles and other hardware that enables it (Montfort and Bogost, 2009), and the appearance of maker cultures that seek to explore the humanities through practical experimentation (Dieter and Lovink, 2014). It suggests a desire to pay attention to and interact with the material world, rather than retreating to a purely digital one. Some commentators go beyond this. They propose that entanglement with material objects represents a ground of being for humans and their societies, that it presents a postphenomenological "dialectic of dependence and dependency between humans and things" worthy of deep contemplation (Hodder, 2014, p.19). People rely on the things they have created to such a degree, so the argument goes, that our identity has become inseparable from them. In Donald Ihde's original conception, it amounts to "recognition that "consciousness" is an abstraction, that experience in its deeper and broader sense entails its embeddedness in both the physical or material world and its cultural-social dimensions" (Ihde, 2009). Knowledge, art, religion, and science are entangled, in turn, with books, oil paint, churches, and laboratories: "thing theory" grounds epistemology in the myriad interactions between the physical and non-physical world (Preda, 1999).

If we apply these insights to digital infrastructure we begin to see how humanists have become entangled with complex systems, a situation that might prompt us to pause for thought. Analog books, archives, and libraries presuppose a degree of entanglement with the material world, undoubtedly, but those are relatively well understood: we have had centuries to understand and critique them. Digital infrastructure, however, is rarely "symbolically or politically construed" (Knorr-Cetina, 1992, p.119). It is merely requested in an email to a manager or Information Technology (IT) helpdesk, or held to be something humanists need to do their work. Little attempt is made to define the critical ground or, much less, to understand the object of enquiry prior to investment. Rather, in denial of the epistemological significance of things, humanities infrastructure is treated as something we should merely go to the store or work with our IT department to buy. The result has been an ongoing failure to provide the kind of infrastructure needed by humanities researchers, a misalignment of the debate, and often a rejection of the very notion of digital infrastructure itself.

As Matt Ratto points out, so-called 'critical making' provides new ways of dealing with difficult issues like this. Rather than attempting to solve complex problems in their entirety, critical making encourages the development of prototypes and basic models in the context of wider critical discourses, thus blending "practice-based engagement with pragmatic and theoretical issues" and fostering the possibility that creative solutions will be found to long-standing problems. He suggests the approach can be particularly useful in the context of so-called "wicked problems" (Ratto, 2011, p.253), defined by architectural scholar Horst Rittel in the 1960s and 1970s (Rittel and Webber, 1973). This class of problem is characterized by the existence of "many clients and decision makers with conflicting values, and where the ramifications in the whole system are thoroughly confusing" (Rittel was interested in problems associated with large-scale planning projects) (Churchman, 1967, p.B141). Significantly, he claimed there is a moral element to such problems, in that it is immoral to solve only one component of a wicked problem when such an approach will leave the larger issue unresolved. Prototyping and critical making can thus be positioned, not as inadequate tinkering, but as a mode of activity well-suited to the resolution of very complex problems. In this way we come to the intersection of critical making, cyber-infrastructure, and the humanities.

This project migrated my personal website jamessmithies.org from Wordpress.org (a free, fully hosted service) to a home server running on a Raspberry Pi 2 Model B minimal computer, a device built in the United Kingdom at Sony's manufacturing plant in Pencoed in South Wales and supported by a registered charity: the Raspberry Pi Foundation. The computer measures 85.60mm x 56mm x 21mm (or roughly 3.37″ x 2.21″ x 0.83″), has 1GB of Random Access Memory (RAM) and is powered by a 900MHz quad-core ARM Cortex-A7 Central Processing Unit (CPU). The VRE application is built using Django, a Python-based web framework designed for newspaper websites but now deployed in a wide variety of scenarios. The social media service Pinterest is one of the largest services to use it, with over 46 million unique visitors between 2011 and 2015 (Statista, 2015). The framework is thus highly adaptable, and could be used to develop almost any functionality a humanities researcher might need. The website is served by the Gunicorn application server and light-weight Nginx web server (used by NASA), with content saved in Postgres, one of the more advanced database systems available. All of these products are available free through the open source community. They require a reasonable level of technical proficiency to install and configure but there are many tutorials available online and their user communities share knowledge openly. It speaks to an interesting aspect of this project. Although there is a massive gap between jamessmithies.org and well-funded cyber-infrastructure projects, the nature of the open source software movement means there is only a small gap (if any) in terms of scalability and potential functionality.

One of the most powerful things about the project - in both technical and tactical terms - is the level of control conferred by the architecture of the 'stack'. Not only is the Pi itself accessible and configurable, but its operating system can be changed, and Gunicorn and Nginx can be configured at both an administrative level and through their core code base. Django can be programmed to support an extremely wide range of functionality. To extend the metaphor of control towards the incomprehensibly large infrastructures used by multi-national digital corporates (to escape the criticism that the Pi is a fundamentally limited device, or a mere toy), static files like CSS style sheets and images are hosted on the Amazon Web Services (AWS) cloud, integrating the Pi with a truly enormous global data infrastructure. These could have been hosted on the Pi, but it is considered best practice to deliver them separately for Django projects. It means, essentially, that much of the 'heavy-lifting' has been outsourced to a high performance computer, allowing almost limitless options for expansion of the site.

Perhaps counter-intuitively given the dominance of 'bigger is better' cyberinfrastructure discourse, the migration from Wordpress.org servers to a lowly Raspberry Pi has produced a personal VRE capable of significant further development. The intention is not necessarily to create a finished and reproducible product, but to take control of – and experiment with - all aspects of the computing architecture in order to gain a better understanding of my scholarly infrastructure needs, from the hardware the site runs on, to maintenance of the Internet domain name, the content management system that helps me organize content, and the firewalls that secure it from malicious actors. The conclusion after this phase of the project is that issues like ethical hardware, net neutrality, data sovereignty and security, and the ability to extend and configure the code that supports my research activities, are central to my work – and identity - as a humanities scholar.

SpotiBot-Turing testing Spotify

Pelle Snickars
pelle.snickars@umu.se
Umea university, Sweden

Producing and coding bot 'listeners' has today become almost as easy as automated music production has been for years. Machines can thus both 'create'—and 'listen' to 'music' (whatever we mean by these categories). In fact, such notions are capricious within the contemporary streaming music landscape. The project, "Streaming Heritage: Following Files in Digital Music Distribution" (financed by the Swedish Research Council) studies emerging streaming media cultures in general, and the music service Spotify in particular, with a bearing on the digital challenges posed by direct access to musical heritage. Rediscovering older music is key for Spotify, and the project is hence on the one hand geared towards investigating the institutional challenges of streaming musical heritage, and on the other hand—and foremost—to develop new digital research methods. Situated at HUMlab (Umeå university) part of the project is essentially about Turing testing Spotify. Building on the tradition of 'breaching experiments' in ethnomethodology, my research group seeks to break into the hidden infrastructures of digital music distribution in order to study its underlying norms and structures. The key idea is to follow files' (rather than the people making or using them) on their distributive journey through the streaming ecosystem. The setting include the distribution and aggregation of self-produced music/sounds through Spotify; the set-up of our own record label (for research purposes); the programming of bots to inform, explore, mimic, and ultimately subvert notions of usage and listening; the tracing of Spotify's history through constantly changing interfaces (web archiving and documenting these). Research questions range from various way how streaming music is commodified? What sounds are perceived as music (or not) according to Spotify and adjacent aggregating services? How is metadata generated, ordered, and valued—and what kind of metadata is actually available? What normative world views are promoted and materialized by streaming architectures? What kind of infrastructures proliferate behind the surfaces of on-demand services?

My presentation departs from the fact that one-fifth of Spotify's catalogue of 30 million songs haven't once been listened to at all. Under the computational hood of streaming services all streams are equal, and every stream thus means (potentially) increased revenue from advertisers. Spotify is hence likely to include—rather than reject—various forms of (semi-)automated music, sounds and (audio)bots. At HUMlab we therefore set up an experiment—SpotiBot—with the purpose to determine if it was possible to provoke, or even to some extent undermine, the Spotify business model (based on the 30 second royalty rule). Royalties from Spotify are only disbursed once a song is registered as a play, which happens after 30 seconds. The SpotiBot engine was be used to play a single track repeatedly (both self-produced music and Abba's ”Dancing Queen"), during less and more than 30 seconds, and with a fixed repetition scheme running from 10 to *n* times, simultaneously with different Spotify account. Based on a set of tools provided by Selenium the SpotiBot engine automated the Spotify web client by simulating user interaction within the web interface. From a computational perspective the Spotify web client appeared as black box; the logics that the Spotify application was governed by was, for example, not known in advance, and the web page structure (in HTML) and client side scripting complex. It was not doable within the short experiment to gain a fuller understanding of the dialogue between the client and the server. As a consequence, the development of the SpotiBot-experiment was (to some extent) based on 'trial and error' how the client behaved, and what kind of data was sent from the server for different user actions. Using a single virtual machine—hidden behind only one proxy IP—the results nevertheless indicate that it is possible to automatically play tracks for thousands of repetitions that exceeds the royalty rule. Even if we encountered a number of problems and deviations that interrupted the client execution, the Spotify business model can be tampered with. In other words, one might ask what happens when—not if—streaming bots approximate human listener behavior in such a way that it becomes impossible to distinguish between a human and a machine? Streaming fraud, as it has been labeled, then runs the risk of undermining the economic revenue models of streaming services as Spotify.

Reconstruction of Labour Relations in the North Sea Region in the Late Middle Ages: Spatio-Temporal Analysis Using Historical GIS, Taxation Sources, and Coin Finds

Rombert Stapel
rombert.stapel@iisg.nl
International Institute of Social History

Introduction

In this paper a range of maps, documents, data and archaeological finds are brought together in a historical GIS (Geographical Information System) to reconstruct different forms of labour and especially labour relations in existence in late medieval Northwest Europe. Starting from the Late Middle Ages, England and the Low Countries laid the groundwork for becoming two of the dominant powers in Europe and the world. The question is how this process of growth began. Often it has been coined with the rise of capitalism and the rise of wage labour as the predominant form of labour (e.g. van Bavel, 2007). The issue also touches on the Great Divergence debate. This debate centres around why and at what point in time Europe became the dominant continent in the world, surpassing the power and wealth of China, India, Japan and the Ottoman Empire (Pomeranz, 2000). England and the Low Countries play an important role in this debate and quite often the level of (real) wages is used as a determinant to study the emerging differences between Europe and other parts of the world (Allen, 2001). This opens up the question, however, how many people in a certain time and place actually worked for wages: an issue which questions the validity of real wages as (the only) measured variable (Lucassen, 2016).

Labour relations

Labour relations can be defined as "for or with whom one works and under what rules" (Hofmeester et al., 2015). In the "Global Collaboratory on the History of Labour Relations, 1500-2000", a collaboration of researchers from all over the world, study these labour relations and especially shifts between them. To effectively compare different parts of the world across time, a uniform way of entering and presenting data as well as a taxonomy has been created (Figure 1). One of the advantages of this taxonomy is that it encompasses the entire population of an area, working and non-working, forces researchers to think about female labour participation (even if it is omitted in their sources), and includes various forms of labour, from reciprocal labour to wage labour, self-employment or slavery.

Studying societies other than modern ones can be especially difficult however. Lacking anything like modern census data, one has to be more creative to study different forms of labour across time and space and bring together a wide range of data and information. One may think about information on land use, vicinity of roads, waterways or coastlines, all proving modes of transportation, the vicinity of towns and monasteries, demographic density, documents related to taxation and many other. GIS is best equipped to present such combinations of different data, and is therefore at the core of the following two areas for which the labour relations are reconstructed.

Reconstruction England/Wales

To come to a reconstruction of the labour relations in England and Wales a range of sources are combined, including the 1378-1381 Poll Tax records (Fenwick, 1998), the muster rolls of 1522, information on medieval markets (Keene et al., 2002; Keene and Letters, 2004), and GIS shapefiles of historical parish boundaries (Southall and Burton, 2004). From these sources regional variation in demography, market presence, and occupational structure can be extracted – albeit with many caveats. One of the main sources used for the reconstruction, however, are the tens of thousands of archaeological coin finds, by both amateurs and professionals. These are made available through the Portable Antiquities Scheme (PAS) website (The British Museum, 2013-2015) (Figure 2).

The principal assumption behind using the coin finds is that the presence of small denominations, valued at a day's wage or less, can function as a determinant of wage labour (Lucassen, 2014). Used in combination with figures on mint output, the coin finds can therefore be used to study the relative presence of wage labour; as well as regional differences and developments over time.

As the PAS database was formed by different people over a long period of time, various issues caused by inconsistent or erroneous data entry had to be solved. Much effort has gone into cleaning (especially place names) in the Portable Antiquities Scheme database and supplementing the numerous missing geographical coordinates. The following step is linking the coin finds to the data mentioned earlier, a complicated process that has started but for which much still has to be done in the coming months. In the end, the combination of available data provides us with an extensive toolbox to reconstruct the labour relations in late medieval England and Wales and to study the mechanisms that influence these labour relations, causing regional and temporal variation.

Reconstruction Low Countries

For the reconstruction of the labour relations on the other side of the North Sea, in the Low Countries a different approach has been chosen, although here too coin finds may be used in the end (De Nederlandsche Bank, 1997-2015). Starting point is the County of Holland. In 1494 and 1514 two sets of questionnaires were produced by the Burgundian/Habsburg rulers, intended to allocate a new round of taxes. The questionnaires had to be answered by representatives of all towns and heerlijkheden (a feudal administrative-judicial unit, precursor of modern municipalities) in Holland. They asked for information about the number of dwellings and parishioners; economic activities; how these economic activities developed in the past couple of years; land ownership; and tax-related issues. The questionnaires have been used to assess the state of the economy in Holland and study per capita growth (van Zanden, 2002).

Never before have these questionnaires been mapped, which, for instance, would allow to combine the information with land use, the vicinity of monasteries and modes of transportation, and study in more detail regional variance in the county and – because of the nature of the questionnaires – changes over time between 1477 and 1514. For this purpose, a historical GIS of the administrative-judicial boundaries in this and some neighbouring counties was created from scratch. A wide range of digitised historical maps from the sixteenth to eighteenth century were used, in combination to the historical atlas of the Netherlands drawn by Anton Beekman at the beginning of the twentieth century (Figure 3; results in Figure 4). The maps were georeferenced and combined with information on natural and/or current (sometimes unchanged) municipality borders to reconstruct the location of the historical boundaries.

One of the immediate advantages was that using this GIS map, silent omissions in the questionnaires became visible (e.g. certain heerlijkheden that were not mentioned explicitly in the sources). Moreover, the advantage of using the historical boundaries, instead of just looking at the location of the villages and creating Voronoi diagrams for instance also becomes clear, as the maps provide much more detail and display patterns more clearly: see Figure 5.

By combining the questionnaires and the newly created geographical information with assumptions on household size, child and female labour participation, information on religious houses (using Goudriaan and Stuyvenberg, 2008), and other information a tentative reconstruction is made on the full range of labour relations present in the County of Holland in the Late Middle Ages.

Conclusion

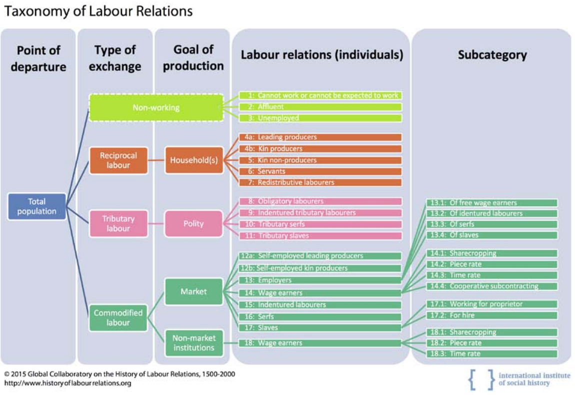

Figure 1. Taxonomy of the Global Collaboratory on the History of Labour Relations, 1500-2000.

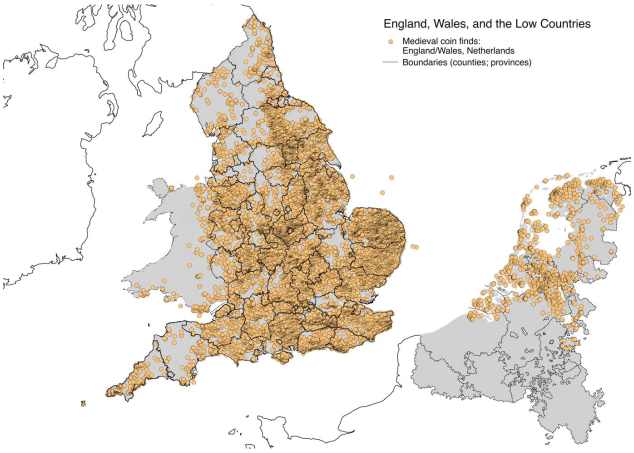
In the end, the goal is to create a map that shows the presence and absence of various forms of labour and labour relations in the North Sea region. This allows us to study this part of the world, just before two new world powers emerged from here, and the role labour plays in this development. By using GIS (instead of displaying the information in tables for instance), the full potential offered by geographical information systems is made available: e.g. easily combining different forms of information, pinpointing developments to a certain point in time and space. Large-scale regional variation can therefore become a point of study, instead of hindering or difficult to grasp principle.



England, Wales, and the Low Countries
Medieval coin finds: England/Wales, Netherlands
Boundaries (counties; provinces)

Figure 2. Archaeological coin finds in England/Wales and the Netherlands (Northern Low Countries). Note that at the moment the finds in the Netherlands and England/Wales cannot be compared easily due to national differences in registration.

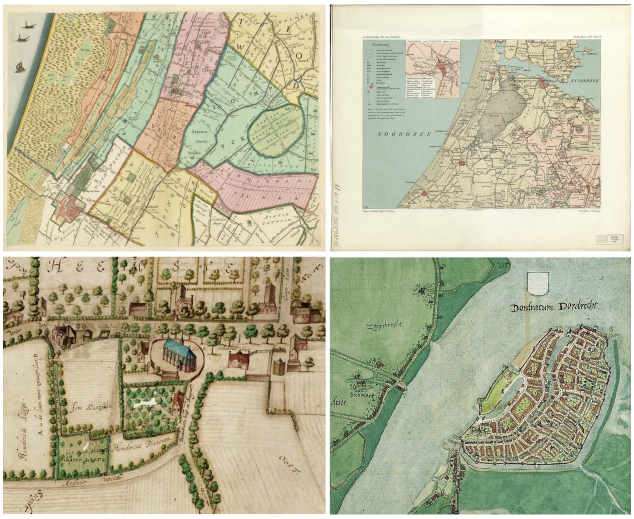


Figure 3. Excerpt of geographical sources: various 16th-18th century maps, historical atlases.

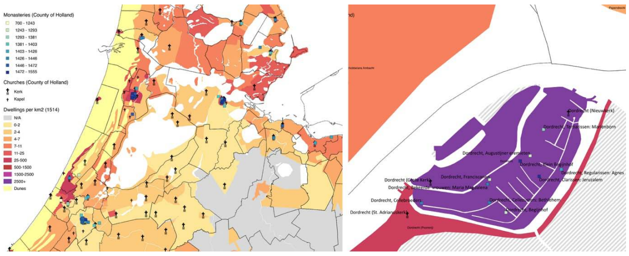

Figure 4. Result: Historical GIS of administrative-judicial units in Low Countries around 1500 (with churches; monasteries; present-day municipality boundaries).

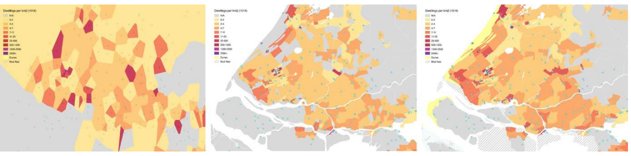

Figure 5. Thought process and development of mapping medieval tax/population records in Holland: from Voronoi diagrams surrounding the towns and villages mentioned in the sources; to mapping these towns and villages; and finally locating and assessing the areas not explicitly mentioned in the sources.

The Web is now deeply integrated into contemporary culture, and scholars interested in current phenomenon cannot afford to ignore it, however, collecting data from the web is not easy. The web is based on a mix of continually changing technical standards which make creating an archival copy of a web site for scholarly reference very difficult. Without such a copy there is no way for future scholars to question the interpretations we make today or reinterpret the phenomenon in light of new evidence tomorrow.

Researchers and organizations, such as the Internet Archive, are attempting to preserve portions of the web for future retrieval, but much of the web disappears quickly. A 2014 study of web links in scholarly papers found that 1 out 5 scholarly papers contains links to web URLs which no longer function or no longer exist (Klein et al., 2014). The need for humanists to recognize the value of web archives to historical research is especially acute. Researchers cannot engage recent cultural histories and ignore the culture of the web (Milligan, 2012).

The challenge of web archiving is especially acute for rapidly changing stories which track specific events. Discussions about controversial topics, such as GamerGate,[1] take place across multiple websites, use multiple forms of media, and occur in very different discourse communities. Underneath the different social worlds gathered around online communities there is an incredibly diverse set of technological platforms which require customized strategies for tracking and collecting data. This paper will:

- Describe the key challenges for researchers wishing to collect just-in-time archives of web based cultural phenomenon.
- Put current challenges in an historical context of differing goals between web developers and web archivists.
- Propose some social and technical solutions to improve the situation, and
- Introduce a set of tools to help researchers engaged in these areas.

Challenges

Dynamic changes in online content present one of the unique challenges for gathering contemporary web discourse. Most internet users are familiar with the constantly updating nature of Twitter and other social media platforms. Social media platforms present a challenge for web archivists because of their technological structure and commercial ownership. The speed of updates on social media requires specialized tools to download, especially in large quantities. A researcher needs deep technological knowledge of these tools and the application programming interface (API) provided by the website in order to build a reliable and useful corpus. On the legal side, the terms of service affect the types of information that can be gathered by researchers and how that data can be analyzed or shared with other researchers.

Other commercial sites, such as news media web sites, often host comment threads where internet users can post their opinions on the topics covered in the main story. It is relatively trivial to download the main content of a news story posted on the web but collecting the comment stream may present a challenge because the comments may be hosted by another website service or may be displayed dynamically as a user scrolls further through a web page. In such cases the default web archiving tools may not be sufficient. Web discussion forums present yet another technical challenge.

Researchers often frame their questions about web phenomena by describing a topic that they wish to study. But the architecture of the web is built around the key idea of a web site, a particular set of files which may include many different types of media including text, images, and video, and is hosted by a particular business, institution, or individual. These web sites are identified by the Uniform Resource Locators people type into their browsers in order to navigate to a web page.

The tools used to archive the web are built on this technical background for dealing with URLs, APIs, REST, RSS, and other interfaces which human beings do not usually interact with. In the language of web archive software the unit of research is the seed, or base URL, from which data can be harvested. For the researcher the unit of work is the topic. Negotiating between these two conceptions of how online research should work is a major social challenge for any type of internet research. Researchers and web users just want to see the content, but automating the collection of that content means reproducing a complicated software experience which has gradually been built by web developers and web browsers over the past 25 years.

Humanities researchers have traditionally relied on stable or slowly changing content. Efforts by humanities scholars have been made to adapt to the changes in digital content represented by the web. Some universities have set up web labs for collecting and analyzing web data. One key task of these labs has been building subcollections from the overall web in order to further the study of particular topics (Arms et al., 2009). One of the key insights from our work is the need to continue building strong collaborations between multiple fields. Libraries and the Internet Archive need input from digital humanists in order to understand their research questions and digital humanists need to understand the technological challenges of web archiving in order to collectively design systems which will help future researchers. The web, however, is constantly changing at multiple levels, ranging from the technology used to deliver content, the processes of creating content, commenting on content, and the distribution of information. Archiving the web for humanities research calls for changing the conceptual image of stable sources, collaborating with new communities, and adopting new technologies.

Solutions

The implication of the technological treadmill described above is that it becomes more and more difficult for a single researcher to adequately collect the web. There are two potential solutions to this problem: technological and social.

Computer scientists are working to build better web archive software which can integrate with social media in order to reduce the amount of administrative overhead needed to collect information on particular topics.[2] These tools will automate the selection of web sites to be archived, removing some of the human intervention needed to curate web materials. But simplifying the data gathering process today may make future explanations of the context of a collection more technical. For now researchers are dependent upon a mix of tools, often customized for specific uses, and mixing open source and commercial software.

In our research project we used a combination of open source tools, subscription services, and customized API calls. For gathering data from Twitter we used a program called twarc.[3] Customizations were made to improve the performance of the tool for our uses, which was tracking specific hashtags. The Twitter scraper was initially installed on a laptop belonging to a member of the research team, but when the number of tweets became too large for a laptop the program was moved to a cloud server provided by Compute Canada. The data from Twitter was stored in JSON and then transformed using standard libraries into files which could be analyzed for most frequent Twitter posters, most frequent URLs, and most frequent hashtags. Data from web pages was collected using the Archive-IT subscription service[4] provided by the Internet Archive and the wget[5] command line tool. Some specific websites, such as 4chan and 8chan, required the development of custom API interfaces to download material from relevant chat boards. Additional programs to download comments from

YouTube are currently being tested. We plan to document our recipes for using these different tools on methodi.ca,[6] the methods commons for text analysis.

Archiving the web involves many different institutions and disciplines. The largest players are the Internet Archive and various national libraries; the Internet Archive operates as a non-profit and has the most comprehensive collection of digital materials from the web. Unfortunately, the Internet Archive collections are not primarily built for researcher access and can be especially difficult to work with if you are investigating topics which cover multiple URLs or lengthy time periods. Any research project using their collections requires significant human labor. Libraries and museums can step in to fill some of the gaps by using services such as Archive-IT, which provides more curatorial control over the collection development process and also has a more robust search interface. In order to improve these tools, humanists will need to build connections with other disciplines, such as information and library science, computer science, and archival studies. Only by working together and extending our disciplinary horizons can we build the collections which current and future digital humanists can use to study our current era.

One final social issue of importance are the legal and ethical implications of gathering large amounts of data from the web. We will not discuss these issues in great depth in this paper but they do need to be acknowledged because they constrain some of the actions which can be taken in web data gathering. In our project on GamerGate we have looked closely at the ethical implications of sharing data gathered from social media. The dataset we shared online includes an appendix on ethical issues related to data sharing.[7]

Read, Play, Build: Teaching Sherlock Holmes through Digital Humanities

Joanna Elizabeth Swafford
swafforj@newpaltz.edu
SUNY New Paltz, United States of America

The nineteenth century provides a perfect setting for a digital humanities class as a result of the similarities between the industrial and digital revolutions and between the proliferation of print and periodicals and the rise of blogs and Twitter. Arthur Conan Doyle's Sherlock Holmes stories are likewise the perfect subject matter: most of Holmes's cases revolve around the technology of the day, from cabinet photographs in "A Scandal in Bohemia" to the typewriter in "A Case of Identity." These connections enable students to learn about an earlier time period and literature while also historicizing their own technological moment. The resurgence in popularity of Holmes adaptations in recent years—*Sherlock* (BBC), *Elementary*, and *Mr. Holmes*, to name just a few—emphasizes these connections and also brings students into the classroom.

"Digital Tools for the 21st Century: Sherlock Holmes's London" (taught from the Fall of 2014 through the Fall of 2015) is an introductory digital humanities class that uses Holmes stories as a corpus on which to practice a wide variety of basic digital humanities methodologies and tools, including visualizations, digital archives and editions, mapping, and distant reading. "Digital Tools" unites theory and practice with a tripartite structure for each unit, which I have dubbed "Read, Play, Build." First, students read articles from books and blog posts about the pros and cons of each methodological approach. They then examine current projects to discuss the ways that each enhances scholarly fields and poses new research questions. Each unit concludes with an in-class lab component, in which they build a small project using a well-known tool. For example, in the archives and editions unit, students examine Jerome McGann's "Radiant Textuality," discuss the importance of preservation, access, and challenging the canon, examine *The Rossetti Archive* (and many others), and use the tool *Juxta Editions* to create their own, fully transcribed digital edition of a Sherlock Holmes story of their choice, using page images of the original printing in The Strand Magazine to learn about XML, basic bibliography, and best editorial practices. Likewise, in the unit on distant reading and topic modeling, they read Franco Moretti's "The Slaughterhouse of Literature" and Ted Underwood's blog posts on topic modeling, examine *Mining the Dispatch* to see that methodology in action, and topic model all 56 Sherlock Holmes short stories and analyze the trends in a blog post.

Although this class uses Holmes stories as base texts, it also situates these stories in their historical and cultural context by examining Victorian digital humanities projects from fields other than English. Students explore the *Proceedings of the Old Bailey*, a searchable archive of all court records in the Old Bailey from 1674-1913, to learn about crime, class, and the legal system. They also examine the *David Livingstone 1871 Field Diary* to learn about empire and Charles Booth's poverty maps from 1898-1899 from the *Charles Booth Online Archive* to learn about socioeconomic conditions in London and to compare Conan Doyle's fictional London to the actual city.

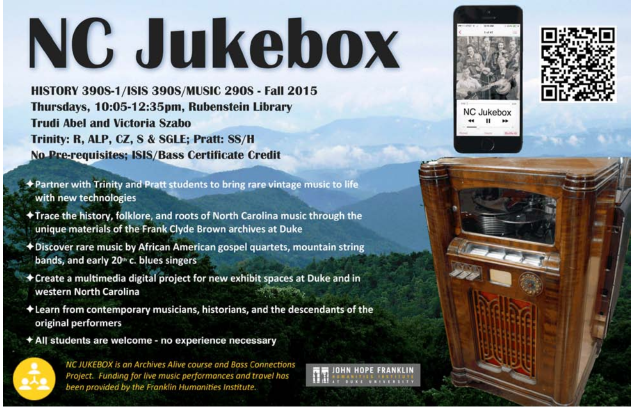
This paper will present the class in greater depth and will provide examples of the digital projects students collaboratively created—from contributing to the marginalia project *Book Traces* to making digital narrative maps of Holmes stories with Mapbox—in order to provide new models for student scholarship and their role in the future of the English departments and the humanities. It will also discuss the importance of the Holmes stories as the corpus for the class, as the character of Holmes himself provides a useful model for a digital humanist, especially when students may be unused to thinking about data in a humanities context, as he combines data science with humanities skills of close reading, archiving, and a love of literature and music.

Teaching Holmes with digital tools lets students build on the traditional humanities skills of close reading, understanding patterns, and using archives, and augments that scholarly toolkit by guiding students to a better understanding of rhetorical patterns and spatial significance, while also teaching them about collaboration, interdisciplinarity, and public humanities. In accordance with its public humanities focus, the course's materials, including the syllabus and assignments, are publicly available on the class's website (https://hawksites.newpaltz.edu/dhm293/). By melding research with project-based learning, this course enables students to engage with research and Victorian history more actively than is common at the introductory level.

The North Carolina Jukebox Project: Archives Alive and the Making of Digital Cultural Heritage

Victoria Szabo
ves4@duke.edu
Duke University, United States of America

The North Carolina (USA) Jukebox project transforms an inaccessible audio archive from the 1930s, of historic North Carolina folk music collected by Frank Clyde Brown, into a vital, publicly accessible digital archive and museum exhibition. Led by Trudi Abel, a librarian in the Rubenstein Special Collections Library at Duke University, and Victoria Szabo, a faculty member in Visual and Media Studies and Information Science + Studies at Duke, this interdisciplinary, collaborative effort also involves scholars in music and folklore, music and preservation librarians, digital media specialists, descendants of the original performers, and contemporary musicians who play this music professionally today (Archives Alive Initiative | Trinity College of Arts and` Sciences, 2016).



NC Jukebox

HISTORY 390S-1/ISIS 390S/MUSIC 290S - Fall 2015
Thursdays, 10:05-12:35pm, Rubenstein Library
Trudi Abel and Victoria Szabo
Trinity: R, ALP, CZ, S & SGLE; Pratt: SS/H
No Pre-requisites; ISIS/Bass Certificate Credit

✦Partner with Trinity and Pratt students to bring rare vintage music to life with new technologies
✦Trace the history, folklore, and roots of North Carolina music through the unique materials of the Frank Clyde Brown archives at Duke
✦Discover rare music by African American gospel quartets, mountain string bands, and early 20th c. blues singers
✦Create a multimedia digital project for new exhibit spaces at Duke and in western North Carolina
✦Learn from contemporary musicians, historians, and the descendants of the original performers
✦All students are welcome - no experience necessary

NC JUKEBOX is an Archives Alive course and Bass Connections Project. Funding for live music performances and travel has been provided by the Franklin Humanities Institute.

JOHN HOPE FRANKLIN HUMANITIES INSTITUTE AT DUKE UNIVERSITY

Figure 1. NC Jukebox Project Advertisement

As a teaching experience associated with the Library's Archives Alive initiative, the project offers opportunities for students from arts, music, computer science, and engineering programs to learn about the collection and develop an exhibition from initial concept to execution, and to do so in collaboration with a diverse set of mentors and collaborators who help them understand the histories and technologies involved, as well as stakes of their presentation choices. As a ongoing archival project, it demonstrates the challenges and opportunities inherent in working out a major library archive and preservation effort alongside a live curricular intervention and planned public exhibition. As a research project, it offers scholars in media studies a firsthand view of how material recording and playback technologies and their affordances help shape subsequent cultural histories, and affect what we can recirculate and share today. Taken together, these strands demonstrate that introducing digital cultural heritage project development as a shared objective enriches student learning, encourages library archiving and preservation projects to consider their public facing dimensions as they construct new resources, and offers digital humanities and media studies scholars meaningful opportunities to collaborate with colleagues in historically minded disciplines around new forms of scholarly production – in this case data-driven exhibitions at the Mountain Music Museum in Western NC, at the Rubenstein Special Collections Library at Duke, and online.

Our project begins with the songcatcher himself. In the 1930s Frank Clyde Brown, Duke Professor of English, and co-organizer of the North Carolina Folklore Society (1913) as Zeke Graves in our Library tells us, began recording and archiving Western North Carolina folk music (Graves, 2015). Following in the tradition of folklorist Alan Lomax, and songcatcher/musician Bascom Lunsford as chronicled by Loyal Jones, along with other famous songcatchers of the period, he drove around region capturing a range of singers and songs using the technology available in the period, a notebook and Dictaphone equipped with first wax cylinders and later aluminum cylinders (Jones and Forbes, 1984). Like us, Brown involved his students in the project as well, encouraging them to capture songs and research their origins. Today most of those recordings are still housed on wax cylinders and glass disks in the Duke Libraries, and in the Library of Congress, with about 400 songs having already been converted to digital formats. The rest are being converted as part of a substantial Council of Library and Information Resources grant.

In addition to learning about Brown, histories of the music, songcatching, and folklore practices of the period, students in a Fall 2015 NC Jukebox course began to work closely with the 400 digitized recordings we currently have available, developing metadata, transcribing songs, and organizing their materials in spreadsheet, blog, and database form. Our project also explores biographies of the singers, transcribes the songs as heard on the tapes in in comparison to other versions, and traces the Scotch-English history and contemporary analogues of the songs themselves through research in Child's *Ballads* and other key sources (Child et al., 2001). In addition, we have begun to demonstrate change over time and space through maps, patterns, flows, timelines, and networks of the music - a kind of distant listening, or viewing of its collection and presentation, with more to come. In the physical exhibits, interactive touchscreens, period photos, and hybrid analog-digital audio playback machines – a radio, a Jukebox, and perhaps a 78-playing phonograph – will invoke the historical conditions of production and reception of the music for diverse audiences.

As an historiographical research project, NC Jukebox is also offering opportunities to explore firsthand how social and material conditions affect the writing of cultural history itself. Over the course of this project we have learned about the history of songcatching and folklore as social and academic practices designed to verify expectations about a specific kind of musical heritage. Brown died before his work could be compiled into the published versions of his work. As his papers reveal, not all of the songs he collected were included in the final, posthumous collection of his work (Guide to the Frank Clyde Brown Papers, 1912-1974, 2016). His subsequent editors, like other before them who were seeking a pure musical tradition descended from that of the Scots-Irish settlers in the region, as seen in Ritchie and Orr's *Wayfaring Strangers,* for example, picked and chose songs to include in the published work (Ritchie, Orr and Parton, 2014). Their criteria are (helpfully for future researchers) sketched out in their editorial notes, which are also in the archives. Songs that were too popular, had been published, were too religious, or, perhaps most significantly, were from African American traditions, were excluded from the published collection, even if familiar from other sourdes like the Library of Congress Checklist of Recorded Songs (U.S Library of Congress, 1942). On another note, we also experienced the lingering effects of musical and cultural segregation first-hand as a class when our well-intentioned musical guest, a contemporary folksinger who is helping keep the Mountain Music traditions alive today, explained that he was going to perform a song as he had heard his "colored" neighbors sing it growing up (McKinney, 2015). This moment became part of a class conversation about representing tradition while at the same time acknowledging our contemporary perspectives upon it in how we frame the music.

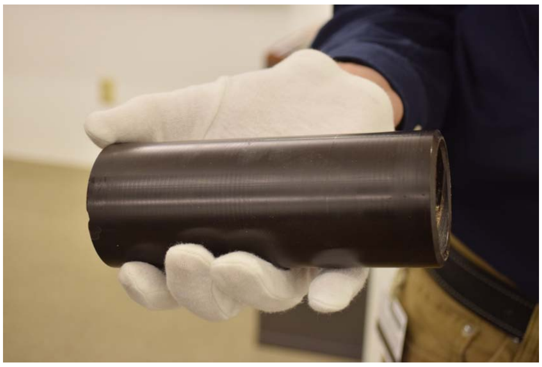


Figure 2. Wax Cylinder from the FCB collection

This project is also about the history of recording and reproduction technologies, which has deeply affected the content. Encountering recordings made from wax cylinders and glass disks, which included a white-glove visit from Special Collections as well as examining photographs of Brown and other "in the field," encouraged conversations around our continuously evolving standards and expectations for archiving and reproduction. Our students had to consider whether it was more "authentic" to leave in the hisses and crackles that had made it into the third generation audio files they were listening to, or whether they could and should attempt to clean up the sound quality so it was closer to the "original" source – the singers themselves. Were we archiving the archives, or the ur-performances? Our students also learned about and from Charles Bond, the onetime Duke undergraduate (and now lawyer in San Francisco) who serendipitously took it upon himself in the 1980s to transfer some of the existing recordings to reel-to-reel tapes, using a moog synthesizer to clean up some pops and crackles.

Further, we discovered how the limits of the recording medium itself reveal the priorities of the documentarians and archivists involved. Wax disks could only record 6-7 minutes of a song, as the *Federal Cylinder Project* editors note (Gray and Schupman, 1990). Songcatchers might record just one stanza of a song, rather then the whole performance, a fact that highlights that it was the intellectual process of abstracting data from the performance, to be converted to written notation and lyrics, rather than the performance itself, that was most valued for academic folklore purposes. The recordings were data to mine rather than songs to hear. We have also confronted challenges to our efforts in repatriation and exhibition as we began to develop our downloadable "Greatest Hits" of the FCB collection. Because of copyright restrictions on published songs, in the end we may need to limit our final song choices to the purely folkloric – putting us in some cases right back in line with Brown's purity-seeking editors! We have even begun to wonder about the NC Jukebox idea itself as a title and concept, given that the term jukebox didn't come into common parlance until the 1940s, as we learned from *Jukeboxes:An American Social History*, and the music we are sharing was most likely shared at the time either locally or over live radio, as our guest Terry McKinney told us (Segrave, 2002). Our presentism is a both a problem and an acknowledgement of our own historicity and subjectivity.

NC Jukebox is serving as a prototype for future "Archives Alive" projects at Duke University in terms of pedagogical approach, access to primary and secondary source materials from Special Collections, community engagement, and digital platform and exhibition development. As a digital heritage project designed to serve multiple audiences, the digital and onsite exhibition components are being built with an eye towards multiple display formats and locations for a single set of materials within a grown growing database of content. This includes exhibition in a regiona museum organized by McKinney himself (Neufeld, 2015). It also necessitates metadata standards and library infrastructure, a conversation that is ongoing with our Library staff. For the exhibits in Western North Carolina and at the Rubenstein Library we have websites, Omeka exhibits, and interactive web graphics, as well as the downloadable playlist and physical exhibits and listening stations. For the archive, however, we are working with Library and technology partners on a more sustainable and flexible content management system in Drupal that draws content from the more permanent institutional repository solution, which will serve as the substrate for future development as well as, we hope, drive later installations. Our hope is that subsequent generations of students, librarians, and scholars will be able to build upon what we have done in bringing the archives alive.

The Online Archive “Forced Labor 1939–1945. Memory and History”. A digital Application for Research and Education

Doris Tausendfreund
doris.tausendfreund@cedis.fu-berlin.de
Freie Universität Berlin, Germany

Research

This presentation will focus on the development of the Online-Archive “Forced Labor 1939-1945. Memory and History”.

The collection of narrative interviews was compiled in 2005 and 2006 by the Institute of History and Biography at FernUniversität Hagen. In a joint project, the Foundation “Remembrance, Responsibility and Future”, the Freie Universität Berlin, and the German Historical Museum aim to safeguard and provide easy access to these multilingual audio and video interviews and accompanying materials for research and education.

The online archive contains 583 comprehensive life story interviews with concentration camp survivors, prisoners of war, and “civilian” forced laborers. In 27 countries, mainly in Central and Eastern Europe, 192 video and 391 audio interviews were conducted in the native languages of the witnesses. Each interview is accompanied by additional material: a short biography, a transcript of the interview, a translation of the transcript into German, a table of contents showing the structure of the interview, additional photos and documents, as well as basic biographical information. All content is accessible worldwide for any users who registered with the site.

So far there are no standards on how to document and index Oral History Collections and we will show examples of different approaches which are used at the moment.

Nun, man bombardierte lange, mehrere Monate, und dann schon so ... die Ereignisse entwickelten sich schon so, dass das Werk wegen dieser Bombardierungen nicht mehr im Betrieb sein konnte.

Anmerkung (Valentina Stefanski)
Seit November 1944 stand die Stadt Völklingen unter ständigem Beschuss durch amerikanische Truppen, die sich auf dem linken Saarufer befanden. Die Bevölkerung wurde ab Anfang November evakuiert und die Produktion in der Völklinger Hütte eingestellt (wahrscheinlich am 30.11.1944).

4.16 Ein Brief nach Hause über die deutsche Feldpost - eine Nacht im Karzer - Androhung von KZ-Haft
4.17 Unterbringung in Holzbaracken - erneute Bombardierungen - medizinische Versorgung
4.18 Fluchtversuche - Arbeitsbedingungen im Winter
4.19 Zusätzliche Essensbeschaffung - Verpflegung im Lager
− 5. Das Kriegsende - Befreiung - Heimfahrt (I)
5.1 Bombardierungen durch die Allierten
5.2 Schutzbunker an der Siegfriedlinie - Luftschutzröhren auf dem Lagergelände
5.3 Flucht während einer Bombardierung - Auf einer Sammelstelle der Amerikaner
5.4 Gute Verpflegung und Lebensbedingungen auf der Sammelstelle der Amerikaner
5.5 Bei den eigenen Landsleuten: Unterbringung in deutschen Häusern und Verhör durch SMERSCH
5.6 Rücktranportin die Heimat in Viehwaggons
+ 6. Das Leben nach dem Krieg (I)
+ 7. Kindheit, Jugend und Familie in der Vorkriegszeit (II)

In this context we will describe our indexing method, with its internal working interfaces and the process involved, as well as the public online application and its functionalities. We will present the different functionalities (content-based indexing, full-text search and an interactive map application) that enable a targeted search that leads directly to individual passages of the interviews.

We will also discuss considerations involved in designing an online platform to avoid the use of the interviews as a mere quotations quarry and instead supports a comprehensive understanding of the whole testimony in its narrative structure and its biographical meaning.

An annotation function will be presented. The function is meant to benefit from the specific knowledge of users to add to the understanding of the interviews.

Finally, the archive has been designed multilingually and runs in German, English, and Russian in order to accommodate the needs of a greater international audience.

This presentation doesn´t focus on a special research problem. Instead it shows a powerful tool which enables academics to work effectively with testimonies to answer their own research questions.

Education

The online-platform aims to support education as well, and there is the option to give an overview of our approaches in this context, too.

We created an online-learning-environment for the use in the classroom which will be available from the beginning of 2016. Based on short biographical films (half an hour) and additional provided material (maps, documents, photographs, additional films) students are asked to work on a number of didactically framed tasks. Most tasks are historical in nature and working with them is useful for the teaching of history. But also for other school subjects exercises are available as for example in language education or religious instructions.

The pupils are asked to write their answers in an online-editor and combine them with selected materials which are easy to import. The results can be saved and printed individually.

- Teachers have additional options and can for example create their own questions based on the films and the materials.
- The software offers versions of the learning environment for different countries. These versions vary in language and content and are drawn up by experts in the respective countries. From the beginning of 2016 a Czech and a German version are available. A Russian version is on the way.
- The online-learning-environment is responsive and can be used with different mobile devices.

How best can humanities researchers access and analyse large-scale digital datasets available from institutions in the cultural and heritage sector? What barriers remain in place for those from the humanities wishing to use high performance computing to provide insights into historical datasets? This paper describes a pilot project that worked in collaboration with non-computationally trained humanities researchers to identify and overcome barriers to complex analysis of large-scale digital collections using institutional university frameworks that routinely support the processing of large-scale data sets for research purposes in the sciences. The project brought together humanities researchers, research software engineers, and information professionals from the British Library Digital Scholarship Department[1], UCL Centre for Digital Humanities (UCLDH)[2], UCL Centre for Advanced Spatial Analysis (UCL CASA)[3], and UCL Research IT Services (UCL RITS)[4] to analyse an open-licensed, large-scale dataset from the British Library. While useful research results were generated, undertaking this project clarified the technical and procedural barriers that exist when humanities researchers attempt to utilize computational research infrastructures in the pursuit of their own research questions.

Overview

The drive in the Gallery, Library, Archive, and Museum (GLAM) sector towards opening up collections data,[5] as well as the growth in data published by publicly-funded research projects, means humanities researchers have a wealth of large-scale digital collections available to them (Lui, 2015, Terras 2015). Many of these datasets are released under open licences that permit uninhibited use by anyone with an internet collection and modest storage capacity. A few humanities researchers have exploited these resources, and their interpretations make claims that change our understanding of cultural phenomena (for example, see Schmidt, 2014; Smith et al., 2015; Cordell et al., 2013; Huber, 2007; Leetaru, 2015). Nevertheless, there remain major barriers to the widespread uptake of these data sets, and related computational approaches, by humanities researchers, which risks diminishing the relevance of the humanities in "big data" analysis (Wynne, 2015). These barriers include:

- fragmentation of communities, resources, and tools;
- lack of interoperability;
- lack of technical skills: "mainstream researchers in the humanities and social sciences often don't know what the new possibilities are" (ibid) and seldom have the technical experience to experiment (Hughes, 2009; Mahony and Pierazzo, 2012).

A common response to this lack of awareness and computational skills is to build web-based interfaces to data[6] or federated services and infrastructures[7]. Whilst these interfaces play a positive role in introducing humanities researchers to large-scale digital collections, they rarely fulfil the complex needs of humanities research which constantly questions received approaches and results, or allow researchers to tailor analysis without being limited by shared assumptions and methods (Wynne, 2013).

Method

We explored the challenges associated with deploying and working with large-scale digital collections suitable for humanities research, using a public domain digital collection provided by the British Library[8]. This 60,000 book dataset covers publication from the 17th, 18th, and 19th centuries, or – seen as data – 224GB of compressed ALTO XML that includes both content (captured using an OCR process) and the location of that content on a page. Using UCL's centrally funded computing facilities[9] we worked from March-July 2015 with RITS and a cohort of four humanities researchers (from doctoral candidates to mid-career scholars) to ask queries that could not be satisfied by search and discovery orientated graphical user interfaces. Working in collaboration we turned their research questions into computational queries, explored ways in which the returned data could be visualised, and captured their thoughts on the process through semi-structured interviews.

Results

We successfully ran queries across the dataset tracking linguistic change, identifying core phrases, plotting and understanding the placing of illustrations, and mapping locations mentioned within core texts. We found that building queries that generate derived datasets from large-scale digital collections (small enough to be worked on locally with familiar tools) is an effective means of empowering non-computationally trained humanities researchers to develop the skill-sets required to undertake complex analysis of humanities data.[10]

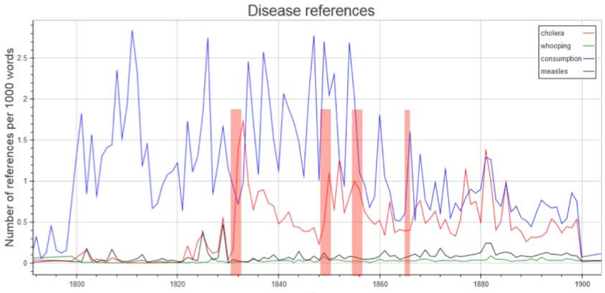

Figure 1: A search for mentions of various infectious diseases (Cholera, Whooping Cough, Consumption, and Measles) across the 60,000 book dataset. We compared the profound spikes for Cholera in the dataset with known data regarding epidemics in the UK (Chadwick, 1842; Wall, 1893) which appear as the bars on the graph, showing a relationship between the first major UK outbreak of Cholera and its appearance within the written record of the time. There are further pronounced spikes 1870s and 1880s: these are not associated with UK epidemics, but there were outbreaks in the US and elsewhere. Identifying the texts that refer to these outbreaks allows us to look more closely at these clusters and to understand the relationship between public health, epidemiology, and the published historical record.

From a technical perspective, this pilot highlighted various sticking points when using infrastructure developed predominantly for scientific research. 224GB is only moderately large by comparison to the scientific datasets UCL RITS usually encounters, but although there are shared assumptions between research infrastructures (adoption of technical standards, and the sharing of tools, approaches and research outputs (Wynne, 2015)) most of the UK's university eScience[11] infrastructure has been constructed specifically to run scientific and engineering simulations, not for search and analysis of heterogeneous datasets. Our task here had a large textual input, a simple calculation, and a small output summary. By comparison, the typical engineering simulation addresses moderately sized numerical input data, runs a long, complicated calculation, and produces a large output. Poor uptake in the arts and humanities (Atkins et al., 2010; Voss, 2010) has meant that these resources have not been optimised for these workloads. The file system and network configuration of Legion – UCL RITS's centrally funded resource for running complex and large computational scientific queries across a large number of cores – did not match the way that the dataset in question was structured (a large number of small zipped XML files).

The complexities associated with redeploying architectures designed to work with scientific data (massive yet very structured) to the processing of humanities data (not massive but more unstructured) should not be understated, and are a major finding of this project. Relevant libraries (such as an efficient XML processor) needed to be installed and optimised for the hardware. Also, the data needed to be transformed to a structure that the parallel file system (Lustre) could address efficiently (that is, fewer, larger files).

Best practice recommendations for comparable projects emerged from this work: the need to build multiple derived datasets (counts of books and words per year, words and pages per book, etc) to normalise results and maintain statistical validity; the necessity of documenting decisions taken when processing data and metadata; and the value of having fixed, definable data for researchers to explain results in relation to (and in turn, the risks associated with iterating datasets). Pointers to how to process the derived datasets were welcomed, but it was at this stage that the researchers were confident to "go it alone" without our support. We also discovered that a core set of four or five queries gave most of the humanities researchers the type of information they required to take a subset of data away to process effectively themselves: for example, keywords in context traced over time; NOT searches for a word or phrase that ignored another word or phrase, etc. As Higher Education Institution (HEI)-based subject librarians regularly handle routine research queries, we contend that training librarians to aid humanities researchers in carrying out defined computational queries via adjustable recipes would improve access to infrastructure, and cut down on the human-resource intensive nature of this approach. In turn, research computing programmers could be invoked as collaborators for their expertise, such as for developing more complex searches beyond the basic recipes.

Conclusion

We successfully mounted large-scale humanities data on high performance computing University infrastructure in an interdisciplinary project that required input from many professionals to aid the humanities scholars in their research tasks. The collaborative approach we undertook in this project is labour intensive and does not scale. Nevertheless, we found many research questions can be expressed with similar computational queries, albeit with parameters adjusted to suit. We recommend, therefore, that HEIs or HEI clusters looking to build capacity for enabling complex analysis of large-scale digital collections by their non-computationally trained humanities research should consider the following activities:

- Invest in research software engineer capacity to deploy and maintain openly licensed large-scale digital collections from across the GLAM sector in order to facilitate research in the arts, humanities and social and historical sciences,
- Invest in training library staff to run these initial queries in collaboration with humanities faculty, to support work with subsets of data that are produced, and to document and manage resulting code and derived data.

Our pilot project demonstrates that there are at present too many technical hurdles for most individuals in the arts and humanities to consider analysing large-scale open data sets. Those hurdles can be removed with initial help in ingest and deployment of the data, and the provision of specific, structured, training and support which will allow humanities researchers to get to a subset of useful data they can comfortably and more simply process themselves, without the need for extensive support.

From Order to Order Switch. Mediating between Complexity and Reproducibility in the Context of Automated Literary Annotation

Introduction

In the context of literary studies, which are mainly concerned with the hermeneutic interpretation of literary texts, narratological annotation can be helpful in at least two ways. First, the identification of narrative structures can point to peculiarities of the individual texts that are in need of interpretation, thereby advancing the generation of interpretation hypotheses. Second, since narrative structures can often be detected on the surface level of texts and described intersubjectively, narratological analyses may provide a robust and concrete backing for more comprehensive and complex interpretations.

Against this backdrop, the project heureCLÉA aims at developing a "digital heuristic": a functionality that automatically annotates specific narrative features in literary texts. To achieve this, a corpus of short stories is manually and collaboratively annotated based on a narratological tagset (cf. Gius, 2015; Gius/Jacke, 2015a). The automation is subsequently achieved in a combined approach of rule-based NLP methods and machine learning techniques (cf. Bögel et al., 2015a). However, the automation process is complicated by a specific interdisciplinary conflict: the textual phenomena literary scholars are interested in are often very complex and closely interconnected, which seems to significantly hinder the automation process.

In this paper, we present our way of addressing this problem by way of example: we introduce the basic narratological concept of *temporal order* and its theoretical prerequisites/application conditions; we show how the concept's complexity causes technical issues in the context of automation and how converting *order* to the stripped-down concept of *order switch* significantly enhances the automation results; finally, we explain in which way the new concept is still suited for literary analysis.

Collaborative manual annotation of *temporal* order

The discipline of narratology mainly deals with analyzing the (textual) features typical for narrative representation (cf. Meister, 2014). Narratological text analysis is based on often widely accepted narratological concepts or categories. The project heureCLÉA focuses on the operationalization of a subset of these categories: categories that describe temporal relations between a story and its representation. These categories are: *order* (when does an event happen? – when is it told?), *frequency* (how often does it happen? – how often is it told?), and *duration* (how long does it take to happen? – how long does it take to tell about it?) (cf. Genette, 1980). While these categories are reckoned comparably simple and straightforward in narratology, collaborative manual annotation revealed that they are not. We would like to illustrate this using the example of *order* (cf. fig. 1).

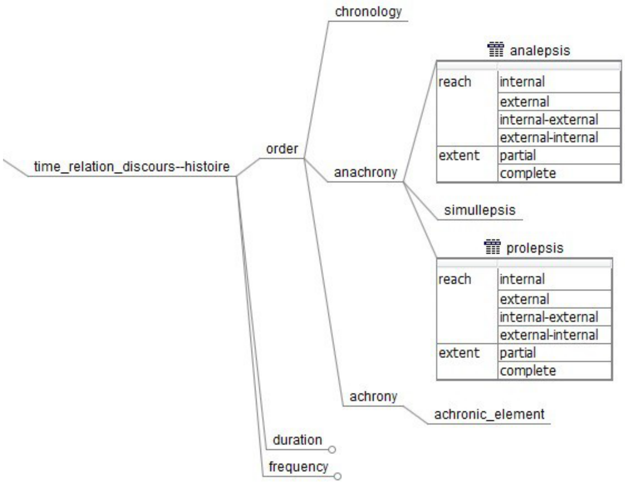

Fig. 1: Tagset order

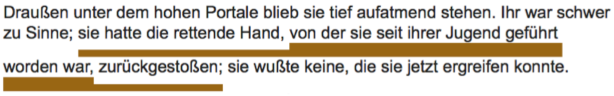
Basically, the events of a story can either be presented in chronological order or the chronology can be interrupted by "flashbacks" (*analepses* in narratological terms) or "flashforwards" (*prolepses*). Each analepsis and prolepsis can further be qualified according to their reach and extent. Whenever anachronies occur, the whole text passage constituting the anachrony is annotated as either *analepsis* or *prolepsis*. Furthermore, anachronies may be nested: they can contain further anachronies (cf. fig. 2).



Draußen unter dem hohen Portale blieb sie tief aufatmend stehen. Ihr war schwer zu Sinne; sie hatte die rettende Hand, von der sie seit ihrer Jugend geführt worden war, zurückgestoßen; sie wußte keine, die sie jetzt ergreifen konnte.

Fig. 2: Annotation of nested anachronies[1]

The complexity of *order* annotation is significantly increased by the fact that the analysis of *order* showed to be dependent on a different narrative phenomenon: that of narrative levels. Narrative texts can contain embedded narrations, i.e., narrations within narrations. This occurs whenever a character in the story starts telling a story of their own ("new speaker") or when counterfactual passages occur in a narration ("new world") (cf. Ryan, 1991). As should be immediately plausible (at least for ontologically distinct narrative levels), it does not make sense to try and analyze the temporal relation between different narrative levels, i.e., between "actual" and counterfactual events in a story. It thus became necessary to establish an additional round of annotation preceding the annotation of *order*: we first had to identify the embedded narrations in a story, so that temporal order could subsequently be analysed for each narrative level separately.

Automation: from *order* to *order switch*

From a computational linguistic perspective, modeling order phenomena imposes interesting challenges that can be grouped into two types: aspects inherent to the phenomenon and data-specific issues.

Phenomenon-inherent aspects

Regarding characteristics of order phenomena, the aforementioned aspects of nestedness of order poses interesting challenges. As order phenomena are inherently nested, they yield a tree structure of annotations with multiple parent-child relationships. While there are models to formalize and predict tree structures (e.g., in the area of grammars), the prediction is orders of magnitude more complex than the prediction of linear or independent annotations, where complexity in this sense means the amount of training data required to sufficiently model the problem.

In addition, the span of order annotations is highly heterogeneous comprising few tokens as well as multiple paragraphs. Finally, while a sequence classification approach would be suitable to annotate a sequence of tokens representing a specific order, additional aspects of the data at hand impede sequence classification. There is thus no clear annotation target that should be classified by a classifier.

Investigating the data

To assess the annotation quality and thus feasibility of automation, we investigated the primary annotations of order phenomena. Investigating the number of different annotations for the entire training set (21 documents, see below) where two annotators agree with each other – which was the case for 90% of all annotations – revealed that there is an imbalance of annotations with seven times as many analepses (696) than prolepses (98).

This imbalance poses three major problems for statistical modeling and machine learning: *sparsity*, *noise* and class- *imbalance*. Sparsity occurs for annotations that are not well reflected in the data set, such that a classifier cannot find enough evidence to integrate the annotations into its model. This issue is reinforced by noise, meaning inconsistencies in the annotations. One sequence of tokens could either represent a certain order phenomenon or just reflect a change of narrative levels, making it hard for the classifier to learn anything meaningful. Finally, class-imbalance imposes a bias on the classifier, resulting in the phenomenon that the minority class is rarely predicted or even not considered at all.

From order to order switches

Investigating the annotations revealed that sub-sentences serve as boundaries for order switches. Thus, to solve the issues mentioned above, we do not attempt to classify order phenomena directly but instead predict for each sub-sentence whether it introduces a *switch* of the order in the previous (sub-)sentence. While this is, of course, a simplification of the task, it allows us to model the task as a binary classification problem with a clear annotation target and alleviates the issue of sparsity because we do not distinguish between different types of order annotations. To generate training and test data from the original manual annotations of order, we determine all sub-sentences where the order annotation changes, and tag them as order switches.

The resulting annotation statistics are shown in table 1 and indicate that switching from order to order switch increases the number of positive instances in the training set to 1802, meaning that 1802 out of all sub-sentences introduce order changes. Note, however, that the issue of imbalanced data still exists.

Annotation	Mount	percentage
order-switch	1802	12.3%
no switch	12871	87.7%

tab. 1: New training set based on order switches

Evaluation and experiments

Our training set consists of 21 documents from various authors of the 20th century, comprising about 80,000 tokens in total (cf. Bögel et al., 2014). For evaluation, four additional documents were annotated.

Overall, we use 21 features (presented in the appendix) to model order changes. We investigate different aspects of tense (e.g., whether a sub-sentence and the previous (sub-)sentence use the same tense), direct speech, temporal signals (cf. Bögel et al., 2015b), as well as structural features, e.g., paragraph boundaries. Finally, we add features to capture whether the sub-sentence represents a change of narrative levels rather than order.

As mentioned above, the class-imbalance between positive and negative instances remains problematic. To reflect this during the evaluation, we perform randomized re-sampling (cf. Japkowicz/Shaju, 2002) with replacement on the training data which allows us to artificially adjust the spread between two classes. Table 2 contains the evaluation results for different spreads using Random Forests (Breiman, 2001) for classification. The more uniform the distribution of both classes and thus the lower the spread, the better the results. With the best setting (spread = 1:2), we are able to achieve a balanced result with a high F$_1$-score of 81.4%.

Setting	precision	recall	F1
spread=1:6	20.4	14.7	1 7.1
spread=1:3	74.9	7 7.5	76.1
spread=1:2	79.1	83.9	81.4
spread=1:1	76.2	79.5	7 7.8

tab. 2: Evaluation results for different spreads

Overall, the high performance confirms our hypothesis that breaking the complex task of predicting order phenomena into more manageable sub-steps yields promising results.

Nevertheless, we expect that even more complex narrative phenomena can be automatically annotated in the future. As simple narrative concepts have now been tackled successfully, their annotations could be exploited as features to predict more complex phenomena.

Conclusions

Our aim to automate the annotation not only of basic and rather straightforward linguistically encoded temporal aspects like tense and temporal signals (cf. Bögel et al., 2014; Bögel et al., 2015b), but also of more complex phenomena like *order* in heureCLÉA was a long shot. However, by cautiously reducing the concept's complexity in active dialogue between computer scientists and literary scholars, we were not only able to yield good annotation results, but also to end up with a concept that is still of value for literary scholars: while deviations from the chronological presentation of a story cannot be automatically predicted in as much detail as in manual annotation, the automated functionality still serves as a robust heuristic pointing to temporally interesting passages upon which literary scholars can base their in-depth analyses and interpretations. By finding a way to include consideration of narrative levels in the automation, the original *order* concept was not compromised with regards to its conceptual key features. The transformation from *order* to *order switch* is therefore yet another example of successful collaboration between literary scholars and computer scientists in heureCLÉA (cf. Gius/Jacke, 2015b): only a frequent exchange between the involved parties can yield results satisfactory to both sides. We are optimistic that this kind of collaboration has the potential to achieve a functional automated annotation of even more complex narrative phenomena – provided that the phenomena in question are of the kind that their analysis allows for a certain degree of inter-annotator agreement.[2]

Appendix: feature set for order switch prediction

Tense	**tense of target**
tense of target-1	same tense for target&target-1? target contains imperative? target-1 contains imperative
direct speech	target starts direct speech? target-1 starts direct speech? target within direct speech? target-1 within direct speech?
Structural	target occurs after paragraph boundary? target is at beginning/end of sentence? length of target relative to entire sentence
temporal signals	target contains temporal signal? target starts with temporal signal? string of temporal Signac first token of temporal Signac preposition of temporal Signac last token of temporal
Signac narrative levels	target in conjunctive mood? target-1 contains utterance verb

Notes

[1] "Outside under the high gateway she stopped, breathing deeply. Her heart grew heavy; she had [just] pushed back the helping hand by which she had been guided since her youth; she knew none she could grasp now." (Theodor Storm: Veronika).

[2] This precondition may be the critical factor in some automation attempts, e.g., the automated annotation of free indirect discourse that lacks a sufficient amount of reliable indicators (cf. Brunner, 2013). Its determination is rather interpretation-dependent and thus the phenomenon is barely qualified for high inter-annotator agreement.

Printing in a Periphery: a Quantitative Study of Finnish Knowledge Production, 1640–1828

This paper presents a transparent and quantitative analysis of the overall development of Finnish book production between 1640-1828. The work is based on automated information extraction from library catalogues, and introduces the concept of open analytical ecosystems as a novel research tool for digital humanities. This extends our earlier pilot project on the use of the English Short Title (ESTC) catalogue (https://github.com/rOpenGov/estc). In this new work we focus on Scandinavia, further demonstrating the potential of digitized library catalogues as a valuable resource for digital humanities and reproducible research. We continue our experimental analysis of paper consumption in early modern book production, and provide a practical demonstration on the importance of open-science principles for digital humanities.

Compared to our earlier British analysis (Lahti et al., 2015) we now integrate data across multiple library catalogues from Finland and Sweden. This analysis transcends national boundaries and brings forward key questions in metadata integration such as entry harmonization and duplicate identification. We propose a set of best practices for such tasks in automated large-scale analyses, and exemplify their use in the Scandinavian context. Such pilot project is crucial to later integrate data across the Heritage of the Printed Book database that eventually covers all of early modern Europe. Our emerging data analytical ecosystem supports these goals concretely.

Instead of ready-made standard software, such as Open Refine, Palladio, or similar user-friendly software, we have developed a set of custom tools in the R statistical programming environment to combine automation with full flexibility and access to state-of-the-art data analysis and visualization algorithms. An important contribution in comparison with related earlier work, for example Kalev's GDELT (http://blog.gdeltproject.org/mapping-212-years-of-history-through-books/), is that we have drastically refined the metadata, for instance by harmonizing synonymous entries and by enriching the data with external information such as name-gender mappings and geographical information. The bibliographic metadata in national library catalogues follow international standards and, as we demonstrate, the fully open source computational data analysis tools introduced within this project are immediately relevant and widely applicable in further studies based on library catalogue metadata.

We focus on the extraction and statistical analysis of library catalogue metadata to study the emergence and development of public discourse in Finland (1640–1828). The main data source for our analysis is Fennica, Finnish National Bibliography (https://github.com/rOpenGov/fennica). This is complemented with further metadata and content analysis of Finnish newspapers and journals and material from Sweden, from the Kungliga collection, Stockholm (https://github.com/rOpenGov/kungliga), and include comparisons with further library catalogue material from other countries as well. The analysis allows us to provide concrete, quantitative figures on publication activity, places, and topics and compare these to political, technological, and social ruptures. The quantitative analysis of print culture will allow us to study how the development of Finnish book, newspaper and journal production compares to European trends.

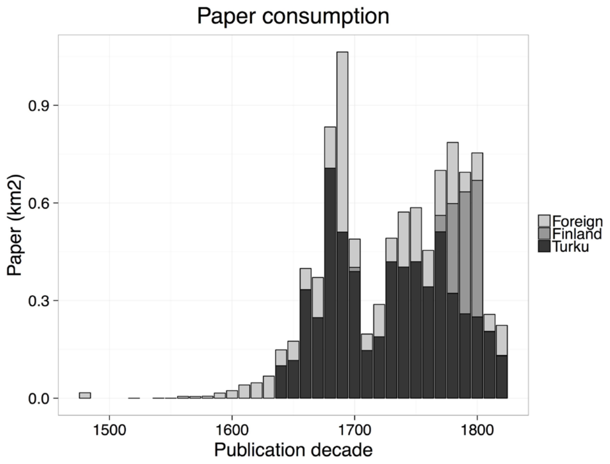

Fig. 1. Paper consumption of documents recorded in Fennica until 1828 by place of publication (Turku, other places in Finland and elsewhere including Sweden)

It is not enough, however, to see European public discourse by combining nationally organized knowledge. The hypothesis is that the European map of knowledge production will have local flavors in different corners of Europe. The aim should thus be to integrate data across library catalogues to analyze different streams of influence and varying regional perspectives and uncover potential asymmetries that may have guided intellectual life. The comparison between neighboring countries also allows for the detection of local publishing networks in the Baltic Sea region.

Our aim in this paper is particularly to study the development of publishing houses in Finland and their spread from Turku to other parts of Finland. We will also identify overlooked moments of transformation in public discourse in Finland by blending historical and computational approaches. The research undertaken will reflect on how social change and public discourse are intertwined, and how cultural, institutional, legal and technological changes are reflected both in publication metadata and the textual content of the publications. In terms of the historical timeframe, our study begins with the founding of the first Finnish press at the Academy of Turku in 1640, tracks the overall publishing history of the country until 1828 when Helsinki starts to play a major role in Finland.

Public discourse in Finland has been largely approached from the perspective of the breakthrough of the Finnish language, the role of elite discourse at the university, early Swedish-language newspapers, and book history. We combine these perspectives, and further analyze how language-barriers, elite culture and popular debate, as well as different publication channels interacted. Large-scale quantitative analysis of library catalogues opens novel opportunities to characterize the general impact of the turn from Swedish to Russian rule in early nineteenth-century regarding public discourse in Finland. Previous historical research on the development of civility in nineteenth-century Finland has lacked appropriate quantitative tools to take an objective 'bird-eye' view of these complicated and crucial transformations. Questions of how, for instance, the establishment of the university in Turku/Åbo (1640), the introduction of freedom of print (1766), the formation of a Finnish Grand Duchy in the Russian Empire (1809–1812), the changes in the enforcement of censorship, the decision to transform Helsinki into a capital city (1819), the lack of estate representation in the Grand Duchy, and the slow emergence of a Finnish written language resonated in publication practices are explored from a quantitative perspective.

Our open data analytical ecosystems provide powerful and flexible data analytical tools that can best serve the needs of genuinely data-intensive research, in contrast to traditional point-and-click interfaces that are suitable for simple query tasks but not designed for fully transparent, reproducible and automated large-scale algorithmic data mining. The open source ecosystems will also enable new collaboration models around digital data collections that are now becoming increasingly available for research and other purposes. This emphasis on transparent and collaborative methodology, already wide-spread in other fields of computational science, sets the context for our work within digital humanities. Others can benefit from the new tools and the libraries from the refined data sets. The data analytical algorithms, including data extraction, statistical analysis, summarization and reporting, will be are released in full detail within a unified open source ecosystem in Github (http://github.com/rOpenGov/fennica), where all steps from raw data to the final results can be traced back and improved further. In this sense, our emphasis on open data analytical process and collaboration model is different from Anderson's and Blanke's discussion on digital humanities ecosystems (Anderson and Blanke, 2012), which focuses on the role of the community of researchers.

This paper continues an ongoing trend of quantitative analysis of publishing history (Moretti, 2013; Towsey et al., 2015). While reuse of library catalogue data has been discussed in recent digital humanities scholarship (for example, Prescott, 2013 and Bode and Osborne, 2014), large-scale library catalogues represent a so far underestimated research resource, containing systematic information on publication activity over years, language barriers, genres, geographical regions and other variables in which the evolution of the public sphere is reflected. Moreover, our work complements the distant reading and related concepts discussed by Bode and Moretti by introducing concrete algorithms and proposing a collaborative development model. Lincoln Mullen has used a related approach to analyze historical texts (http://lincolnmullen.com/#software).

Our ultimate aim is to develop algorithms to extract, harmonize and integrate relevant metadata across the different European library catalogues, regardless of language. This research data will be further enriched by complementing it with data from auxiliary sources, such as linked data on person records, biographies of partner organizations, ontologies and other assets. The enriched information is then used to formulate statistical summaries and systematic quantitative comparisons, as well as interactive and dynamic visual representations of the publication activity, topics and geographical variation and of their evolution over time. To demonstrate the efficiency of this approach, we quantify the importance of Turku in the Finnish publication landscape during 1640-1828.

Approach

Decades ago, alongside more traditional structuralist paradigms that were largely based on linguistic theorems (Lotman 1972, Titzmann 1977), literary studies began to undertake structural analyses based on empirical sociology, in particular the social network analysis. Structure was no longer solely defined by semantic relations (such as opposition or equivalence), but by social interactions, too (Marcus 1973; Stiller, Nettle and Dunbar 2003; de Nooy 2005; Stiller and Hudson 2005; Elson, Dames and McKeown 2010; Agarwal et al., 2012). In the context of the Digital Humanities, this kind of approaches has gained a new dynamic in shape of a dedicated literary network analysis (Moretti 2011; Rydberg-Cox 2011; Park, Kim and Cho 2013; Trilcke 2013). This method is based on the analysis of bigger literary corpora (i.e., quantitative data) and promises insights into the history of literature as well as generic characteristics of literary texts. In our project, "dlina. Digital LIterary Network Analysis", we already developed a workflow for the extraction, analysis and visualisation of network data from dramatic texts built on basic TEI markup (Fischer, Kampkaspar, Göbel, Trilcke, 2015). This paper will present results of our analysis of the network data gathered so far and discuss them in the light of current theories in the field of social network analysis.

Data Collection and Analysis

Our current corpus comprises 465 German-language dramas (from 1730 to 1930), the better part of the Digitale Bibliothek corpus contained in the TextGrid repository (https://textgridrep.de/). The structural data crucial for the network analysis of these dramas (segmentation, character identification, etc.) was revised manually in a rule-based process to straighten out issues with the OCR and TEI tagging. We also had to level out philological peculiarities that would otherwise distort our results (such as different names for identical figures or groups of characters like 'Both' or 'All'). All the structural data is stored in an XML format we especially developed for that purpose (DLINA format). Network visualisation and network-value calculation has been automated (via Python and, alternatively, JavaScript to facilitate a direct embedding of our results into webpages). The scripts are fed with the data stored in DLINA files. In addition to graphs and simple network values that globally describe networks (like network size, density, average degree, average path length, clustering coefficent), we also calculate centrality values for the characters of each play (like degree, average distance, closeness centrality, betweenness centrality). In addition, we most recently implemented the calculation of random graphs based on the observed drama networks. All data and visualisations are freely available online on the project website (https://github.com/dlina and https://dlina.github.io/linas/).

Evaluation, Part I: History of Drama

The diachronic extension of our corpus over 200 years of German literary history allows the observation of larger developments in the structural composition of dramatic texts (we outlined some reflections on this in a blog post: https://dlina.github.io/200-Years-of-Literary-Network-Data/). Values referring to networks as a whole will be broached (incl. network size, density, average degree; as an example, we put average-path-length values by decades in Fig. 1), as will be character-related values for each character of each play (centrality measures, primarily) providing information on the distribution of the personae dramatis or their division into 'central' and 'less central' characters. These values will lay the groundwork for the discussion of some global hypotheses of literary history. We will discuss, firstly, the extent to which we can observe a differentiation of the structural composition of drama at the end of the 18th century on the basis of network analysis values: Such a differentiation is to be expected given the coexistence of 'closed' drama (following the doctrines of French classicism) and 'open' drama (mostly influenced by Shakespeare). Secondly, we will discuss some common literary periodising hypotheses (originating from structuralism, social history, or other directions). We will have a closer look at correlations between our network data and well-established traditional periodisations.

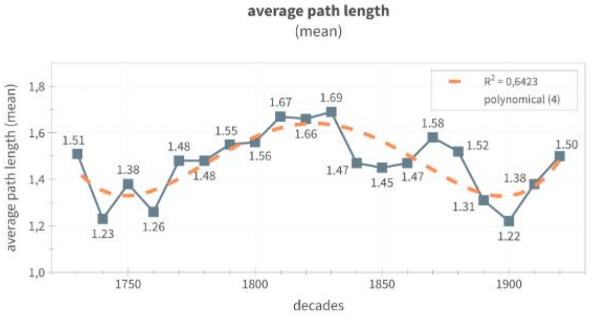

Fig. 1: Average path length by decades (mean)

Evaluation, Part II: Types of Drama

The data raised so far shows how very differently theatre plays were structured in the focal period. Traditional literary studies have developed various typologies for such different types, the most popular in German studies being Volker Klotz's subdivision into 'open' and 'closed' drama. We want to build on this kind of typological impulse and propose a method as to how certain types of structural composition can be distinguished by means of network analysis (and also placed in their historic context). With this proposal we want to take up reflections from research on so-called small-world networks. This branch of research assumes that the values of empirically collected networks often differ significantly from those of corresponding random networks (e.g., graphs generated with the Erdős–Rényi model). Following the approach of Stiller, Nettle and Dunbar 2003, but relying on a much larger set of texts, we investigate the plays in our corpus with regard to their small-world properties (clustering coefficient, average path length, node degree distribution). The results show that there are just a few plays that meet all the criteria (a total of five plays, i.e., just about one percent of the corpus) – see figs. 2.1 to 2.5.

These findings will give us a deeper understanding of different types of structural composition. We shall first direct our attention to forms of networks that – unlike dramas with small-world properties – occur much more frequently in our corpus. Eventually, we will discuss structural characteristics of drama networks exhibiting properties exactly opposite to the properties of small-world dramas (e.g., reverse power-law form in the node degree distribution). It will also be discussed in this context whether we can contrast the strong hierarchical type of small-world drama with an anti-hierarchical type.

A literary rat race

Karina van Dalen-Oskam
karina.van.dalen@huygens.knaw.nl
Huygens ING, The Netherlands / Universiteit van Amsterdam,
The Netherlands

Introduction

'A hype already', was the Friday 28 January 2011 headline on the first page of the Dutch newspaper *NRCnext*. 'It's called the literary rat race K2, the simultaneous publication of Herman Koch's *Zomerhuis met zwembad* and Kluun's *Haantjes*'. The front-page story continues with literary critic Arjen Fortuin presenting an analysis of the two novels that were published the week before, both written by well-known Dutch authors and with the amazing first print runs of 80,000 (Kluun) and 100,000 (Koch) copies. These two novels are from totally different authors, who began their careers on opposite sides of the literary spectrum. However, Fortuin states, they seem to be converging. Koch started out as a 'literary' author not selling very well, but with his last book before *Zomerhuis met zwembad* (*Summerhouse with Swimming Pool*), *Het diner* (2009, translated into English as *The Dinner*, 2012) he turned to a wider audience, thus - according to literary critics - severely damaging his literary reputation. Kluun (the one-word alias of Raymond van de Klundert) started out as writing popular fiction with no literary pretentions at all with his much read but openly despised *Komt een vrouw bij de dokter* (2003, translated as *Love Life* (2007), under the name Ray Kluun). Quite unexpectedly, on 23 January 2011, Kluun's new novel *Haantjes* (which could be translated as 'Alpha-males') got a positive review from prominent literary critic Arjan Peters in *de Volkskrant*. Fortuin found this an additional reason to compare the two novels. His conclusion is: 'It's an uneven literary match – Kluun plays in a lower league – but the commercial battle of K2 could be a close tie – although here Koch also seems to have the best chances: the Alpha-males are in fact very light-weight'.

The Riddle of Literary Quality

Both novels are on the list of 401 novels analyzed in the project *The Riddle of Literary Quality* (http://literaryquality.huygens.knaw.nl/). The aim of the project (running until 2017) is a stylistic analysis of novels in Dutch and to compare this analysis with readers' opinions. The corpus was based on a list of most sold and most lent titles in The Netherlands from 2010 to 2012, excluding titles first published in Dutch before 2007. It includes Dutch originals (such as the novels by Kluun and Koch) and translations. The list contains a lot of genre fiction such as thrillers, 'literary thrillers', and chick-lit, and many titles the publishers categorized as 'literary novels', among which the K2 titles (Koch's *Zomerhuis met zwembad* and Kluun's *Haantjes*). In 2013, in an online survey titled *Het Nationale Lezersonderzoek* ('The National Reader Survey') we asked a wide audience of readers to indicate which of the 401 novels they had read, and for a smaller set of these novels how they rated them on two scales: one on the scale of literariness, from 1 (not literary at all) to 7 (highly literary) and one on the scale of general quality, from 1 (very bad) to 7 (very good). In total, 13,782 respondents completed the survey. By combining these data with an analysis of stylistic characteristics of the novels we expect we can discover which textual features may play a role in the current Dutch conventions of literariness. In this paper I will compare the K2 novels both in an exploratory analysis of the survey results on the scale of literariness and in stylometric analysis. Do the opinions of the K2 readers agree with the stylometric picture we get?

Fig. 1

'Style is a property of texts constituted by an ensemble of formal features which can be observed quantitatively or qualitatively' (Herrmann et al. 2015). For the K2 case, I use the Stylo package in R (Eder et al. 2013). This R package is mainly used for authorship attribution. It compares texts based on the frequencies of a range of words or characters. Since words give more insight into the texts themselves than characters, Stylo can also be used for literary analysis beyond verifying authorship. In Fig. 1 I used Stylo to measure the distance between the ten 'literary' novels by male authors with the highest scores for literariness and the ten novels that got the lowest scores. The bootstrap consensus tree (a harmonization of cluster analyses) was based on the most frequent 100, 200, 300 etc. words (MFW) until 1000 MFW. There is a complete distinction between the "HIGH" and the "LOW" group.

However, the ten novels with the highest scores are all written by men and the ten with the lowest scores by women. The "HIGH" novels are labelled by the publishers as 'literary novel' and the "LOW" ones are mostly marketed as genre fiction such as chick-lit. The graph therefore probably does not distinguish literary quality but genre.

I now zoom in on the 'literary novels'. The Riddle corpus contains 96 titles labeled as 'literary novel' written by a male author or by only male co-authors, and 66 by a female author or only female co-authors. For the whole set of 401 novels, 191 are written by male and 196 by female authors or co-authors, which shows female authors are not underrepresented in the corpus. In Fig. 2 all 'literary novels' are categorized according to the mean scores for level of literariness. The general trend seems to be that the respondents see the female authors 'playing in a lower league' than the male authors. Riddle-PhD-students Corina Koolen and Kim Jautze will deal with gender issues in detail in their dissertations.

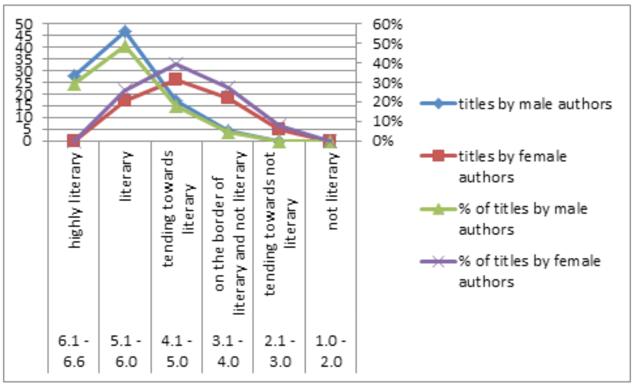

Fig. 2 Literary novels (originally Dutch and translated into Dutch)

I will leave the gender topic to my PhD-students to publish about, and I will for now limit my presentation to an analysis to novels written by male (co-)authors. The lowest score on the level of literariness was 3.1, for two titles written by the Dutch author (and sports reporter) Mart Smeets. Kluun's novel *Haantjes* is directly above these two novels, with a score of 3.5. *Zomerhuis met zwembad* clearly did better. It got a mean score of 5.1. The highest score is 6.6, for Julian Barnes' *Alsof het voorbij is* (*The sense of an ending*). Where Barnes' novel ranks first on the list of 96 novels, the new Koch ends up at rank 74 and the new Kluun at 94. The respondents of *The National Reader Survey* thus agree with Fortuin that Koch ranks higher on the scale of literariness. From the list of 96 novels I select thirty novels: ten with the highest (including Barnes), ten with the lowest (including Kluun), and ten with intermediate scores for literariness (including Koch). If we use the same settings in Stylo as above, the 30 novels end up as shown in Fig. 3.

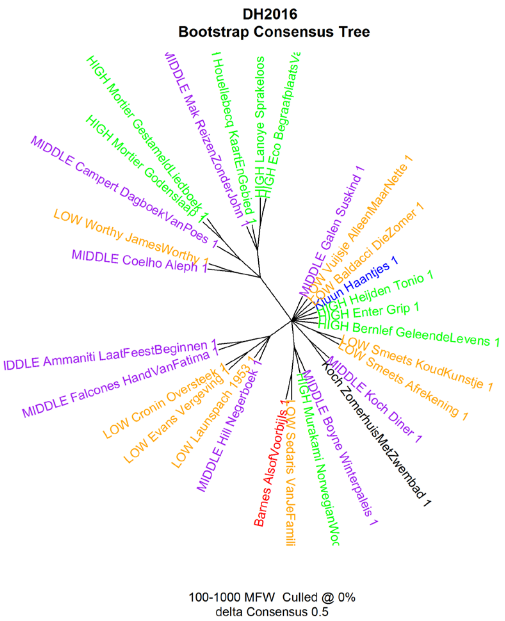

Fig. 3

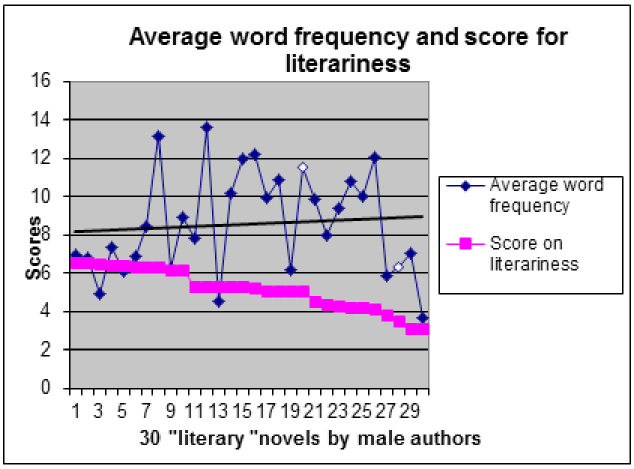

Fig. 4

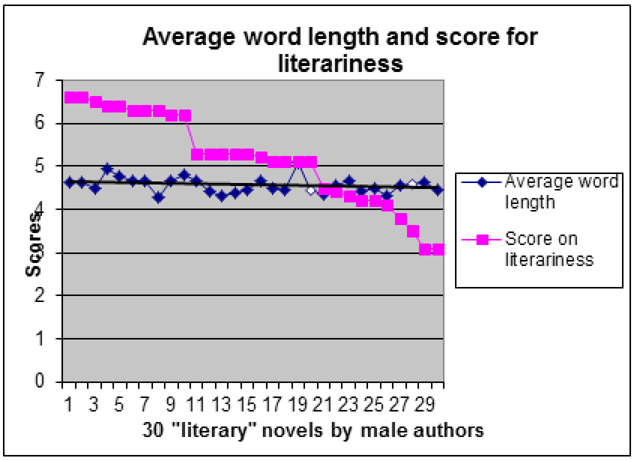

Fig. 5

The results are not very clear. The groups "HIGH", "MIDDLE", and "LOW" do not have their own specific clusters. For now, we can conclude that literary quality for this corpus does not reside in shared word frequency patterns. We are currently gathering as many measures of linguistic features as possible to apply these to the selected corpus. One of the assumptions to test is whether the scores for literariness correlate with features that relate to linguistic complexity. A suite of tools for Dutch is currently being developed. A simple test using HyperPo does show that some features normally related to the level of difficulty of a text need further inspection (Fig. 4, 5, 6) (http://tapor1.mcmaster.ca/~sgs/HyperPo/).

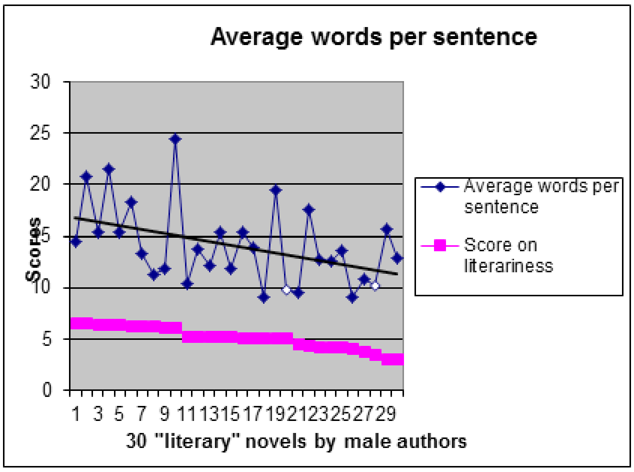

Fig. 6

In each of these figures, the 30 novels are represented on the x axis arranged from highest score for literariness to lowest. Koch is at data point 20 and Kluun at 28. Fig. 4 shows that the scores for literariness display a trend that is opposite to the average frequency of words – this suggests that for this corpus, lexical density scores perhaps play a role in what makes a novel literary or not. However, Kluun's score below the trend line is close to that of the top-5, while Koch is on the opposite side of the trend line. Fig. 5 highlights that mean word length does not resonate with scores for literary quality. Fig. 6, however, shows a clear (statistically significant) trend of literary score and average words per sentence. Here, Koch and Kluun do not differ very much. This sneak preview (which will be tested with tools finetuned for Dutch) shows a further analysis of complexity issues is promising. Riddle PhD student Andreas van Cranenburgh is working on syntactic markers of literariness, and all three PhD students have looked into topic variation in the Riddle corpus (see the abstract they have submitted for DH2016).

Conclusion

So how do the novels by Kluun and Koch compare? The match is still undecided. We need an analysis of many more linguistic features before we can draw conclusions. This analysis did show in which directions to look. For now, stylistically they are playing in the same league.

Taalportaal: A New Tool For Linguistic Research

Ton van der Wouden
ton.van.der.wouden@meertens.knaw.nl
Meertens Instituut, Netherlands, The

1 Introducing the Taalportaal

The Taalportaal project aims at the development of a comprehensive and authoritative digital scientific grammar for Dutch and Frisian, the two official (oral) languages of the Netherlands, in the form of a virtual language institute. The Taalportaal is built around an interactive knowledge base of the current grammatical knowledge of Dutch and Frisian. The Taalportaal's prime intended audience is the international scientific community, which is why the language used to describe the language facts is English.

The Taalportaal provides an (almost) exhaustive collection of the currently known data relevant for grammatical research, as well as an overview of the established insights about these data. This is an important step forward compared to presenting the same material in the traditional form of (paper) handbooks. For example, the three subdisciplines syntax, morphology and phonology are often studied in isolation, but by presenting the results of these sub-disciplines on a single digital platform and internally linking these results, the Language Portal contributes to the integration of the results reached within these disciplines.

Technically, the Taalportaal is an XML-database, organized as DITA-topics (cf. https://en.wikipedia.org/wiki/Darwin_Information_Typing_Architecture), that is accessible via the Internet using any standard internet browser. Organization and structure of the linguistic information are reminiscent of, and to a certain extend inspired by, Wikipedia and comparable online information

Sources (but without the anarchy of Wikipedia). The project is a collaboration of the Meertens Institute, the Fryske Akademy, the Institute of Dutch Lexicology and Leiden University, funded, to a large extent, by the Netherlands Organisation for Scientific Research (NWO) (Landsbergen et al. 2014).

Besides the grammar modules, the portal contains an ontology of linguistic terms (recast recently in the CLARIN Concept Registry (Schuurman (2015), cf. https://www.clarin.eu/ccr) and an extensive bibliography. As of January 2016, the first release of the Taalportaal is online via http://www.taalportaal.org.

2 Enriching the Taalportaal with links to linguistic resources

The Taalportaal database has been enriched with links to on-line linguistic resources. Links between a descriptive grammar and a linguistically annotated corpus are valuable for various reasons. Illustrating a given construction with corpus examples may help to get a better understanding of the variation of the construction and the frequency of these variants, as well as give insight into the lexical items that occur most often in the pertinent construction. Corpus data may also convince a reader that a given variant really occurs in (well-formed) text. Finally, corpus data may also yield occurrences of constructions judged ungrammatical by the authors of the descriptive grammar for reasons such as prescriptivism or theoretical bias. The possibility of enriching a grammar with links to on-line linguistic resources is thus a unique selling point of digital grammars vis-a-vis old school paper grammars (van der Wouden et al. 2015).

Luckily, there is no lack of linguistic resources for Dutch that are useful for this purpose (Frisian is a slightly different matter), e.g. the (syntactically annotated part of the) Corpus of Spoken Dutch (manually verified syntactic annotation for 1M words of speech) (van der Wouden et al. 2002b; Schuurman et al. 2003), the Lassy Small treebank (manually verified syntactic annotation for 1M words of text from various genres) and the Lassy Large treebank (700M words of text, automatic syntactic annotation by means of the Alpino parser (van Noord 2006, van Noord et al. 2013) are all suitable corpora for our project. The first two resources provide high-quality data for a limited amount of text, while the last resource provides wide-coverage, but noisy, data. All treebanks follow (with minor modifications) the same annotation standard (van der Wouden et al. 2002a).

2.1 Automatic links

We have investigated the feasibility of generating links to linguistic resources automatically (van der Wouden et al. 2015). As the Taalportaal texts are in XML format, linguistic examples, linguistic terms, etcetera are marked as such and can be "harvested" as such. Example sentences have been selected and translated into queries for corpus tools such as GrETEL (Augustinus et al. 2013), linguistic terms and lexical items that were highlighted, ended up being automatically linked to resources such as an etymological database such as the etymologiebank (van der Sijs 2010) the large (historical) dictionary WNT (De Vries & te Winkel et al. 1864–1998) or to a section in an on-line version of the Dutch reference grammar ANS (Haeseryn et al. 1997).

2.2 Intelligent links

Next to these automatic links, the linguistic data is also enriched with tailor-made links to corpus data (van der Wouden et al. 2015). For this, student assistants with a considerable linguistic schooling have read the linguistic texts, interpreted them and translated their content into queries that address the corpora that seems most fit to them, documenting their choices and considerations.

The web-based corpus query tool PaQu (Odijk 2015, http://zardoz.service.rug.nl:8067/xpath) is our first tool of choice for executing treebank queries. The PaQu interface helps the user to formulate XPATH-queries; it returns matching sentences in the selected corpus, with the option to display the matching nodes in the syntactic dependency graph. It also displays the query being executed along with a brief description. Queries are dynamic, i.e. the user can switch between treebank corpora, or substitute a given lexical item by an alternative. Furthermore, users can select up to three attributes (i.e. lemma, part of speech, dependency relation, etc.) of matching nodes to obtain a frequency distribution of the attribute values. Advanced users can also modify the XPATH query as they see fit. Integration of queries into the electronic version of the SoD will be done by adding links (in the form of an icon) to paragraphs and examples for which queries are available.

(GrETEL (Augustinus et al. 2013, http://nederbooms.ccl.kuleuven.be/eng/gretel) is another a corpus query tool that supports the same XPATH query language as PaQu, but that also provides support for example based query construction, a feature that might be particularly useful to non-expert users.)

2.3 First results

After completion of approx. 1.000 queries that cover the syntactic parts on complementation and modification of adjectives and adpositions, we have learned that creating suitable queries for a given fragment from the SoD requires creativity and careful experimentation, tuning, and documentation (cf. van Engeland & Meertens 2016). Construction of queries is far from deterministic, that is, different annotators have different opinions concerning the most suitable query for a given example or phenomenon. In a surprisingly high number of cases, there are mismatches (in constituent structure, in part-of-speech) between the presentation in the grammar and the treebank annotation. While this makes the development of queries harder, it also underlines the value of the current project: by systematically exploring the way various linguistic examples are annotated in the treebank, we provide a starting point for further corpus exploration for users that have a general linguistic interest but who are not necessarily experts on Dutch treebank annotation.

The manually verified treebanks almost always provide sufficient examples of basic word order patterns for queries that are not restricted to a specific adjective or preposition. For queries that search for a specific lexical head or for less frequent word order patterns, the Lassy Large treebank usually has to be used. In that case, users must be prepared to see also a certain number of false hits. However, there are also examples in the Taalportaal descriptions that cannot be found even in a 700M word corpus. The conclusion that such word orders are not found in the language would be too strong, but it might be a starting point for further research (e.g. does this construction occur only in certain registers or discourse settings?) or for an alternative analysis (e.g. do these cases really involve adjectives?).

3 Extending the Taalportaal: Afrikaans

Only recently, South Afrika has started building a virtual language institute Viva! (http://viva-afrikaans.org/) that aims at developing a digital infrastructure for Afrikaans. Among its goals are study and description of the Afrikaans language and development of comprehensive tools and resources for written and spoken Afrikaans, including digital dictionaries and corpora; language advice is also supplied. Part of the Viva portal is a comprehensive grammar of Afrikaans, which is based on the Taalportaal architecture, and will be part of the Taalportaal infrastructure.

Stylochronometry and the Periodization of Samuel Beckett's Prose

Dirk van Hulle
dirk.vanhulle@uantwerp.be
University of Antwerp, Belgium

Mike Kestemont
mike.kestemont@uantwerp.be
University of Antwerp, Belgium

Introduction

Probably best known as the author of *En attendant Godot / Waiting for Godot*, Samuel Beckett was not only a bilingual playwright, but also a poet, translator, essayist and novelist. Notably his prose fiction is the focus of this contribution, in which we use quantitative methods to delineate a periodization of Beckett's œuvre. In art studies in general, there is a tradition of distinguishing an 'early' and 'late' period in an artist's work, sometimes with a distinct 'middle' period in between. The late Beethoven sonatas are a good example, or the early Rembrandt's 'smooth' style versus the rough paint surfaces of the late Rembrandt. Nevertheless, it is often difficult to determine exactly when an author's work moves from, say, the 'early' to the 'middle' stage.

In Beckett studies, we find a similar pattern of periodization, ending with the 'late style' (Gontarski, 1997). Peter Boxall (2015: 34) problematizes the idea of periodizing Beckett's œuvre, but admits that it is hard not to parcel it into a beginning, a middle and an end: an early period up to and including the novel *Watt*, written during WOII; a rich middle period up to and including *The Unnamable*; and the later, 'halting' prose after the latter text. Numerous critics have proposed alternative periodizations, resulting in almost as many different periodizations as the number of critics that devised them. We therefore investigated what a non-human 'interpreter' would come up with as a periodization by means of stylometry.

In this paper, we apply methods from stylometry to the problem of periodizing Samuel Beckett's prose. A novelty is that we restrict it to function word frequencies, which are a common object of research in stylometry, but which have hardly been considered in Beckett studies. An exception is Banfield, who suggested a four-phase evolution in Beckett's oeuvre, partially on the basis of linguistic arguments. Our approach is related to 'stylochronometry' (Stamou, 2008), in which a text's writing style is studied as a function of its date of composition, in accordance with recent research into the stylistic development of individual authors, such as Henry James (Hoover, 2014), W. B. Yeats (Forsyth, 1999) or Jack London (Juola, 2007).

Preprocessing

Here, we analyze Beckett's prose fiction, in both French and English. We removed all non-authorial paratexts and only considered lower-case, alphabetical character strings. In the software repository accompanying this contribution (https://github.com/mikekestemont/beckett), we present a tabular overview of the materials we collected, including the publication dates of the editions we used, the text's length, etc. (Note that this repository also holds high-resolution versions of our plots, which will be much more readable on screen.) In terms of chronology, we focus on the moment when Beckett started working on a text in either language (Van Hulle et al., 2015).

We defined a relevant list of function words by extracting an initial list of the 300 most frequent words (MFW) from each corpus. From this list, we have manually removed non-grammatical words, which might correlate too strongly with the topic of particular texts. We refrained from removing common auxiliary verbs or personal pronouns, because they are interestingly tied to a text's narrative perspective, as will become clear below. After this procedure, we were left with 162 function words for the English corpus and 169 for the French, the frequencies of which were scaled using *z*-scores.

Preliminary Analyses

We carried out an exploratory analysis of the material, using principal components analysis (PCA, first two dimensions plotted in Figs. 1-2 for 3,761-word slices). This unsupervised procedure does not yet integrate any chronological information in the analyses, which will help establish whether Beckett's œuvre might have a 'natural' chronological structure with respect to writing style. In Figs. 1-2, the horizontal spread is dominated by a threefold clustering, with some of Beckett's earlier works clustering in the far left. The loadings reveal that these works are characterized by a high frequency of words related to a third-person narrative perspective (*he*, *she*, *his*, *has*, etc.). To the far right, we find a tight sample cloud corresponding to some of Beckett's post-war works, such as *The Unnamable* and *Texts for Nothing*. These texts can be characterized by the use of first-person pronouns (*I*, *me*) in combination with impersonal pronouns such as *it* and *there*, which suggests that these texts focus on the relation between an 'I' and his non-personal surroundings.

Texts from the in-between period (such as *Molloy* and *Watt*) also hold the middle in the horizontal distribution of samples. In both languages, samples from later works jump out with respect to the vertical dimension – e.g. *Worstward Ho* in English, which is characterized by a rich mix of fairly abstract words, with an indeterminate semantics. Both scatterplots horizontally create an opposition between earlier and later writings in Beckett's oeuvre, focusing on an opposition between a first-person and a third-person perspective. In the vertical dimension, both analyses reveal on a vocabulary shift, in Beckett's late writings, towards a more abstract and indeterminate vocabulary.

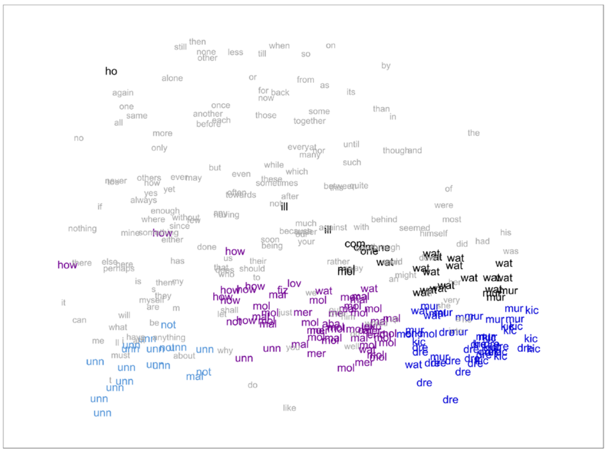

Figure 1: English corpus PCA

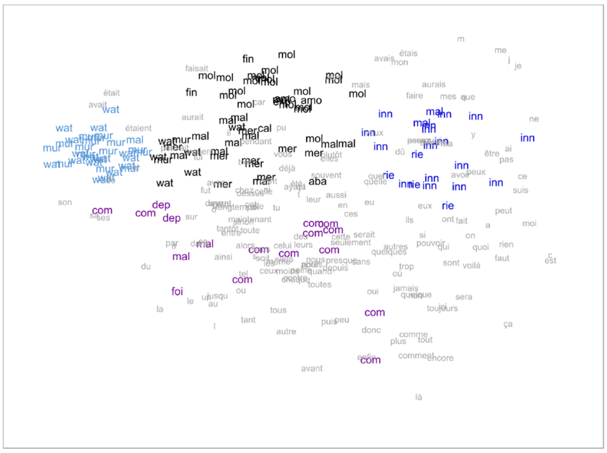

Figure 2: French corpus PCA

Chronological Analyses

The previous analyses were ignorant of the diachronic structure of the data: samples from Beckett's early works could just as easily cluster with later writings. This prevented us so far from identifying clear turning points in Beckett's career. Variability-based Nearest Neighbour Clustering or VNC (Gries et al., 2012) is a method for the diachronic analysis of corpus linguistic data. VNC aims to identify distinct temporal stages, by pinpointing the main turning points. In traditional cluster analyses, each node can be freely combined with any other node in the tree, thus potentially scrambling the original chronological order of the data. VNC adds the constraint that only consecutive nodes, immediately adjacent in time, can form new clusters. This restriction enables analyses in which the chronological structure of the data is reflected in the top branches of trees, representing the main diachronic stages in the data.

We have run VNC on our data (Figures 3-4, Euclidean distances, Ward's linkage), which resulted in clearer insight into the chronological structure of Beckett's œuvre. The English prose, displays a clear initial cluster of Beckett's earliest two novels, *More Pricks than Kicks* and *Dream of Fair to Middling Women*, which lack a French translation. Otherwise, the structures of Figs. 3-4 run remarkably parallel. *Murphy* and *Watt* constitute the second chronological cluster of works, together with the *Nouvelles*. Only at a higher level is the former group paired with the cluster consisting of *Mercier and Camier*, *Molloy* and *Malone Dies*. Interestingly, the original French versions of the *Nouvelles* are joined with the next cluster, whereas the English versions are joined with the previous cluster, which indicates a different status of this collection in both languages. The last major branch for both languages holds the tight clade representing *The Unnamable*, *Texts for Nothing*, *How It Is* and the series of shorter late works. In the English tree, *Worstward Ho* occupies a fairly pronounced position, emphasizing its special status.

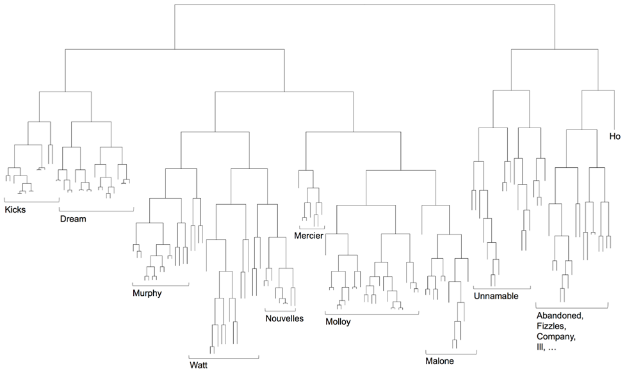

Figure 3: English corpus VNC

The VNC analysis (supplemented by a more complex, bootstrapped analysis, which we do not describe in this abstract) generally supports the periodization of Beckett's oeuvre into an early, middle and late 'cluster'. In English these periods would cover, firstly, Beckett's early works, *More Pricks than Kicks* and *Dream of Fair to Middling*

Women; secondly the mid-career works, ranging from *Murphy* to *Malone dies*; and thirdly, a series of later works starting with *The Unnamable*. From the French prose, a similar periodization arises – although it clearly reflects the absence of any translated counterparts for *More Pricks than Kicks* and *Dream of Fair to Middling Women*.

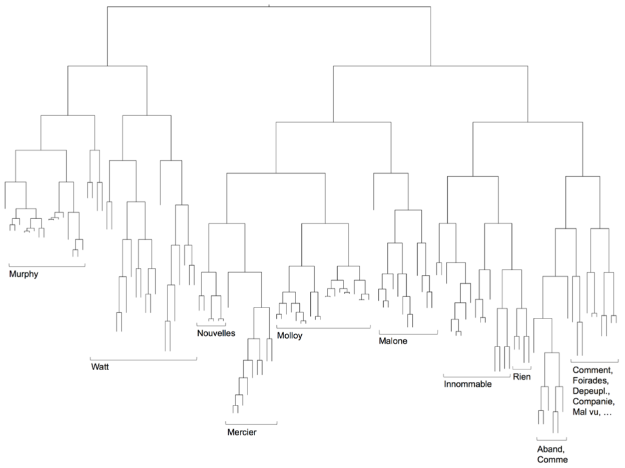

Figure 4: French corpus VNC

Interestingly, our analyses invariably point to the beginning, rather than the end, of *L'Innommable / The Unnamable* as a major stylistic turning point, thus breaking up the unity of the so-called post-war 'trilogy'. Additionally, *From an Abandoned Work / D'un ouvrage abandonné* – notwithstanding its short length – also often emerged as a major watershed. The question, however, is whether this result is to be interpreted as a turning point leading the way for Beckett's later, experimental works, or as a sort of 're-turning point', marking a temporary relapse into the idiom of the *Nouvelles* after *L'Innommable*. This might be a valuable pointer for further research, since this particular text does not seem to have played a significant role in the periodization debate so far. Additionally, it turns out to be more difficult in English than in French to model the transition from a young to a middle Beckett (also in the bootstrapped experiments). This result possibly reflects the fact that the original, English version of *Watt* was written relatively early (during the war), whereas its translation was made much later. In any case, this particular result offers grounds for a re-examination of the difference in evolution between Beckett's French and English prose production, and in particular the role of *Watt* as a transitional novel.

Qu'est-ce qu'un texte numérique? A New Rationale for the Digital Representation of Text

Joris J. Van Zundert
joris.van.zundert@huygens.knaw.nl
Huygens Institute for the History of the Netherlands - Royal Netherlands Academy of Arts and Sciences

Tara L. Andrews
tara.andrews@kps.unibe.ch
Universität Bern, Switzerland

Over half a century ago Briet (1951) famously asked "Qu'est-ce que la documentation?" She proposed a definition much more fluid than the scraps of writing on paper we usually associate with the term: any object, even an uninscribed stone, becomes a document as soon as it is used to communicate some fact (e.g. in a museum's geological collection). In a similar vein we argue in this paper for a renewed consideration of the nature of text in the digital realm, or rather the nature that has been imposed upon it both by information-technological and methodological constraints.

Text is by its nature both discrete and continuous. The glyphs of a writing system are combined into words, which are arranged into phrases, sentences, paragraphs, quotations, and so on; these discrete formations can be arbitrarily complex, but they are communicated through the atom of the glyph. On the other hand, very many elements of the meaning of a text—e.g. narratological elements such as the theme of isolation in *Do Androids Dream of Electric Sheep?*, intertextual references and referents (Miola 2000), the concept of *writerly text* (Barthes, 1974), or even the visual presentations of individual glyphs, defy discrete boundaries. Yet the technologies we have used overwhelmingly for the large-scale production of text—from the printing press to signal transmissions and thence to digital models—treat text as a code of discrete characters; moreover, once text moves from "print" to "signal" (Petzold, 2000) it becomes specifically a single stream of these discrete characters. This can already present some problems to scholars who wish to remediate texts not coded by machine, e.g. manuscripts, to the digital domain for humanistic enquiry. To date scholars who encounter these problems generally consider them an acceptable trade-off for the benefits of access, exchange, and computational tractability that the digital medium offers.

If we want our digital model of a text to extend beyond the semiotic registration of a single stream of characters, however, problems emerge. McGann (2004) summarizes this well: "Print and manuscript technology represent efforts to mark natural language so that it can be preserved and transmitted. It is a technology that constrains the shapeshiftings of language, which is itself a special-purpose system for coding human communication. Exactly the same can be said of electronic encoding systems. In each case constraints are installed in order to facilitate operations that would otherwise be difficult or impossible." Everyone who has ever worked on the remediation of a physically-inscribed text into the digital medium has implicitly conceptualized it at some point as a single stream of discrete characters, simply because this is how we have always known text, ultimately, to be represented digitally. Transcription is thus exactly the sort of constraint to which McGann refers: there is a single stream of text, and only once it exists can it be subdivided and classified as having certain descriptive, structural, or logical characteristics, or even relationships to other portions of text.

The model of text as a single stream of discrete characters also informs the concept of XML markup.[1] As Pierazzo (2011) notes, "The editor will first transcribe a primary source, thereby creating a transcription; this transcription will be corrected, proofread, annotated, and then prepared for publication." The predominant model for the process of annotation to which Pierazzo refers is TEI-XML, that is, embedded markup within the hierarchical structure required by XML. Conceptually a tree structure expressed in XML can be perfectly reorderable, and so not bound to a single valid serialization. With text encoding, however, the ordering constraint remains and must be preserved, however marked up it is and subdivided into branches. Standoff markup schemes similarly assert a single stream—each scheme relies on the stability of the range notation it uses for the underlying text stream—but the markup itself is reorderable. This reorderable property of standoff markup takes us a small step closer to our goal: to recast and represent digital text as something more than a single stream of discrete tokens.

Standoff markup essentially applies a graph model. This is the feature of standoff that makes it so valuable to its proponents—in a graph, unlike a tree, overlapping ranges of markup are easily handled. Some of these standoff markup elements might even include alternative readings to a given text range, or a reference to a different text that elucidates the contextual meaning of the range in question. From there it is only a small step to the conception of a text that is itself more complex than a single stream. Such conceptions emerge already with the different implementations of variant graphs for collations of "multi-version documents" (Schmidt and Colomb, 2009; see also Dekker et al., 2015; Andrews and Macé, 2013; Jänicke et al., 2014). While so far the variant graph has been used only for word-by-word comparisons of text versions, the concept can be extended radically farther. We will demonstrate this, building on prior work in this direction (e.g. Marcoux, Sperberg-McQueen, and Huitfeldt, 2013). We will show in our paper, for instance, how a graph-based digital text can model collections of stories preserved in manuscripts, without giving primacy to any one ordering of the story sequence; that is, it can contain both the collated text of each story and the variety of story order within the tradition. Likewise the same narrative element, inserted into multiple stories, can be represented as such.

The representation of information as entities with relationships between them—in other words: as a graph—is not a new idea. RDF works exactly this way, and the theoretical ideas behind hypertext are not dissimilar (cf. Nelson, 1993). The ease with which complex graphs can be modelled in software, however, has massively increased in the last five years. Moreover, it is now reasonably straightforward to create an initial graph representation from a TEI-encoded XML file, and nearly as straightforward to produce multiple "flavors" of TEI XML from a single graph—for example, a document-oriented representation alongside a logical-text-oriented representation, such as those created in the Faust edition project (Brüning et al., 2012).

Graph representation does not relieve us from the constraint that digital text must be formed from discrete atomic units (characters) and discrete compound digital units. What it does allow us to do, however, is to digitally model the shades of meaning, ambiguity, and uncertainty of text—the aspects of a text's meaning or interpretation that are not by their nature discrete at all. So far, uncertainty of interpretation has been all but explicitly avoided in the scholarly digital space. McGann (2004) observes: "In the case of a system like the Text Encoding Initiative (TEI), the system is designed to 'disambiguate' entirely the materials to be encoded." The 1700+ pages of the TEI guidelines bear witness to the difficulty of this task; element names and their intended usages are defined as precisely as possible, with illustrative examples.

The use of tags and attributes in a TEI-encoded file is itself an act of interpretation—it is precisely in the labelling of the elements of an encoding and of the relationships between those elements that much of the scholar's interpretation of the encoded text lies. This is equally true of a graph encoding. The prolixity of the Guidelines is in fact a result of the attempt to constrain the scholar's interpretation of a given tag to a disambiguated, and thereby discrete, set of meanings. Rather than shrinking from uncertainty of meaning, however, rather than resolving it in an occasionally misleading or (paradoxically) unhelpful attempt to ease computational analysis, how much better if the uncertainty can be retained in the model, in a manner that is nonetheless machine-parseable? Interpretation remains inherent in the labels that are chosen for the properties in a graph model; these may be taken from the TEI, or they may reflect another interest of the scholar. Either way, a graph-based text model by its nature includes computationally tractable information about how these properties relate to each other.

In representing "fuzziness" or ambiguity of interpretation, we can perhaps follow the lead of those who have struggled with similar problems of representation of time. If text can be represented as a graph, mostly-sequential but with scope for fluidity, then interpretative elements—say, picking out the theme of isolation within the text—can be represented as spanning a continuous or disjoint range of text sequences, beginning not before word A but certainly by word B, and continuing at least as far as word C but certainly not beyond word D. And so on. If scholars disagree on the correct identification of a person in a historical text, both hypotheses can be represented without innate primacy being given to one over the other, because a graph does not enforce a single ordering of its elements.

The text model we are advocating, then, amounts to a form of knowledge representation; in representing "the text", we are actually representing a collection of our knowledge, understanding, and interpretation of that text, in a form that can be analyzed and processed by a machine. The more we can encode texts as computable knowledge, the greater the power computational methods will have in textual scholarship of all forms.

Notes

[1] While this is not stated explicitly anywhere of which we are aware, the underlying assumption is plain in, e.g., Goldfarb's discussion of the roots of SGML (1996) or Renear's definition of text encoding (2004).

Music notation addressability

Raffaele Viglianti
rviglian@umd.edu
University of Maryland

Introduction

How can one virtually 'circle' some music notation as one would on a printed score? How can a machine interpret this 'circling' to select and retrieve the relevant music notation in digital format? This paper will introduce the concept of addressability for music notation, on the basis of a comparison with textual addressability as defined by Michael Witmore (2010). Additionally, the paper will report on the work of *Enhancing Music notation Addressability* (EMA), a NEH-funded one-year project that has developed methods for addressing arbitrary portions of encoded music notation on the web.

Many Digital Humanities projects are concerned with the digitization of cultural objects for varied purposes of study and dissemination. Theorists such as Willard McCarty (2005) and Julia Flanders (2009) have highlighted the fact that digitization involves the creation of a data model of a cultural object, whereby scholarly interpretation and analysis is inevitably included in the model. Editorial projects in literary studies, for example, often model sources by encoding transcription and editorial intervention with the Text Encoding Initiative (TEI) format. The ability to identify and name textual structures is a fundamental operation in the creation of such models. Michael Witmore has called text a "massively addressable object" (2010); that is, given certain abstractions and conventions, it is possible to identify areas of a text such as characters, words, as well as chapters or proper names. Reading practices influence and contribute to the development of such conventions and abstractions, but, Witmore argues, addressability is a textual condition regardless of technology. With digital texts, modes of address become more abstract, so that arbitrary taxonomies can be identified as well as more established ones. To exemplify a more abstract mode of address, Witmore suggests items "identified as a 'History' by Heminges and Condell in the First Folio". This enhanced addressability available in a digital context is the engine for textual analysis and scholarly discourse about digital text.

This idea of addressability is arguably applicable to many more kinds of "text", including music notation; indeed, addressing units of music notation (such as measures, notes, and phrases) has long been a powerful instrument in musicology for both analysis and historical narrative.[1] Music notation, however, is more complicated to represent digitally than text. Human-computer interaction has since its early days been built around the concept of character and line, which makes dealing with "plain" text a fairly straightforward matter for many basic operations; counting the number of characters in a given plain text document is trivial in any digital environment.[2] Music notation, on the other hand, requires substantial computational modelling even for the simplest musical text before any further operation is possible. This is particularly evident when music notation is represented with markup, which implies a system based on characters and lines. There are many different ways of representing a single note; some aspects are common to all representation systems, such as information about pitch and duration, but some systems will prioritize certain aspects over others. To give a simple example, one system may represent beams (ligatures between flagged notes, usually shorter in duration), while others may ignore them altogether.[3]

Nonetheless, there are simple units that are typically represented by all music notation systems for common western music notation, such as measure, staff (or instrument), and beat. The EMA project, therefore, developed a URI scheme and an Application Programming Interface (API) to make it possible to target music notation resources on the web regardless of their format. Such a scheme may facilitate (and in some cases enable) a number of activities around music notation documents published on the web. The following table gives a few basic examples of how an implementation of the URI scheme could be useful to musicological research:

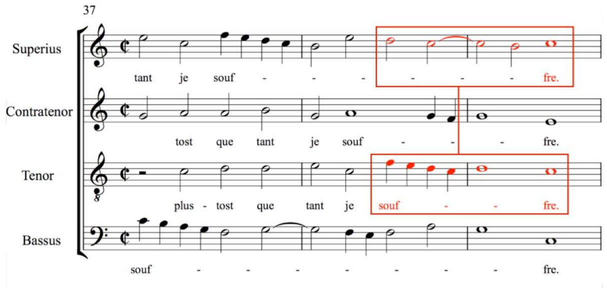
Scholarly	Visual	Procedural
Analysis: being able to address components of music notation for analytical purposes. Example: precisely identify start and end of a pedal tone in Bach's Prelude no. 6 in D Minor, BWV 851.	Rendering: rendering music notation in an interactive environment such as a browser or a tablet requires the ability to cut up a large music document. For example to show only the number of measures that fit in a given space.	Processing: extracted portions of music notation can be passed on to another process. For example, given the MEI encoding of the Overture to Mozart's Don Giovanni, extract the string instrument parts and send them to another program that will return an harmonic analysis.
Citation: quote a passage from an encoded music notation file. For example the timpani in the opening bars of the Overture to Mozart's Don Giovanni.	Highlighting: address a segment of music notation to highlight it in a visual context (e.g. with color).	

The EMA project has particularly focused on facilitating citation and attribution of credit, as is discussed in the "Evaluation" section below.

A brief overview of the specification

The specification was created to provide a web-friendly mechanism for addressing specific portions of music notation in digital format. This is not unlike the APIs often provided by image servers for retrieving specific portions of an image. Such servers typically operate on a given large image file and are able to return different zoom levels and coordinate spaces. The International Image Interoperability Framework (IIIF) has recently created an API to generalize interaction with image providers, so that it can be implemented across multiple servers and digital libraries. IIIF was used as a model for the Music Addressability API created for EMA and briefly described here.

Consider the following example,[4] and the notation highlighted in the boxes:



37
Superius
tant je souf - - - - - - - fre.
Contratenor
tost que tant je souf - - - fre.
Tenor
plus - tost que tant je souf - - fre.
Bassus
souf - - - - - - - - fre.

The highlighted notation occurs between measure 38 and 39, on the first and third staves (labelled *Superius* and *Tenor* — this is a renaissance choral piece). Measure 38, however, is not considered in full, but only starting from the third beat. This selection can be expressed according to a URI syntax:

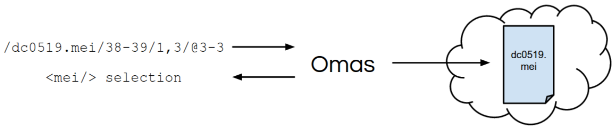
/{identifier}/{measures}/{staves}/{beats}/
/dc0519.mei/38-39/1,3/@3-3

The measure is expressed as a range (38-39), staves can be selected through a range or separately with a comma (1,3), and the beats are always relative to their measure, so @3-3 means the third beat of the starting measure to the third beat of the ending measure.[5] In this specification the beat is the primary driver of the selection: it allows for precise addressability of contiguous as well as non-contiguous areas.

Music notation, however, occasionally breaks rules in favor of flexibility. Cadenzas, for example, are ornamental passages of an improvisational nature that can be written out with notation that disregards a measure's beat, making it impossible to address subsets of the cadenza wit the syntax discussed above. While EMA's URI scheme offers the granularity sufficient to address the vast majority of western music notation, a necessary future improvement on the API is, indeed, an extension that would make it possible to address music notation with more flexible beat.

Evaluation

In order to evaluate the specification, EMA has created an implementation of the API as a web service. While the URI specification can be absolute from a specific representation, the implementation must know how to operate on specific formats. The web service that we coded operates on the The Music Encoding Initiative format and is called Open MEI Addressability Service (Omas).[6] Omas interprets a conformant URI, retrieves the specified MEI resource, applies the selection, and returns it. An additional parameter on the URI can be used to determine how "complete" the retrieved selection should be (whether it should, for example, include time and key signatures, etc.).



Similarly to an image server, Omas assumes that the information specified by the URL can be retrieved in the target MEI file. If requested, the web service can return metadata information about an MEI file, such as number of measures, staves, beats and their changes throughout the document. This can be used to facilitate the creation of URL requests able to return the selection required.

Finally, EMA partnered with the *Du Chemin: Lost Voices* project to model a number of micro-analyses addressing music notation from their existing collection of MEI documents. In a second phase of the project, the analyses have been re-modeled as Linked Open Data according to the Nanopublication guidelines.[7] Each EMA nanopublication addresses an arbitrary portion of music notation using the URL specification described here. Omas operates as a web service to connect the nanopublications with the collection of MEI files in *Du Chemin*.

Notes

[1] When talking about music in general, it is important to say that addressing written music notation is not the only instru-

ment of the musicologist. Music exists on several domains besides the written or "graphemic" one, each addressable in its own way (see Babbitt 1965). For the purpose of this paper, we focus on written Western music notation, because it shares features with written language and for its prominent role in musicological discourse.

[2] Modern computing systems are able to support complex ancient and modern writing systems, including those requiring right-to-left strings and compound symbols. The Unicode Consortium has been at the forefront of the internationalization of computing systems. Nonetheless, computationally speaking, a "string" of text remains a sequence of characters even in more complex representations. Indeed, many compound Unicode characters still retain sequentiality, i.e. one component comes after the other and the compound symbol only makes sense if they are in the correct order. Music notation is not a string of text; therefore this is not possible.

[3] By grouping notes together, beams provide important—but somewhat secondary to pitch and duration—information to the reader of a music score, such as a performer, a musicologist, or an algorithm.

In this paper we discuss our strategy for the creation and exploration of graphs based on co-occurrences of named entities using the recently developed open source version of histograph and present a live demo. histograph builds on previous work conducted in cooperation with several European partners in the FP7 funded project CUbRIK but has been further developed by the Centre Virtuel de la Connaissance sur l'Europe (CVCE) in 2015. It combines the graph-based exploration of large cultural heritage collections with crowd-based indexation. histograph opens up a new perspective on CVCE's collections which contain some 20.000 digitized text documents, photos, audio recordings and videos that document the history of European integration since 1945.

Figure 4: A query for paths between Pierre Werner, Elena Danescu and Jean-Claude Juncker reveals all relevant documents as well as an interactive graph of co-occurrences (who co-occurs with whom)

In contrast to the hierarchical, expert-curated collections, histograph enables an interest driven exploration by the users and provides them with an effective way to retrieve and explore the relations which are of interest to them. Compared with the museum-like order of the classical CVCE collections, histograph models a more or less targeted visit to an archive, which holds the promise of serendipitous discoveries.

Methods for the annotation of named entities such as persons, institutions and places have reached a very high degree of maturity and are used in different applications. For histograph we tested a variety of web services for the detection and disambiguation of entities (NER) among them TextRazor (TextRazor - The Natural Language Processing API, n.d.) and YAGO (Max-Planck-Institut für Informatik: YAGO, 2016). While these services perform well depending on the context of use (language, domain, etc.) even in a best case scenario they only allow to identify the occurrence of an entity within a logical unit such as a text but do not allow to clarify the nature of the connection between persons, places and organisations that occur together in the same unit. In our previous experiences with the detection and identification of faces in historical image sets (Wieneke et al., 2014) the format and context of the images as official photographs of specific events enabled us to understand the nature of the relationship as more easily defined: the simple working hypothesis that persons that co-occur together in a photo have some kind of connection proved to be very efficient. In the case of text however, these semantics are significantly more complex.

We therefore decided to follow two directions: first based on the nature of the text document, where letters for example constitute a relationship between the sender and the receiver and second through a mathematical modelling of the relationship based on the distance between entities in the text and their distribution within the corpus. More specifically, we work with Jaccard distances and co-occurrence frequencies weighed by tf-idf specificity. The latter step became necessary as not all of our text documents fall in the category of clearly structured formats such as letters and even if they do, a strictly format based co-occurrence approach could hide interesting relationships that would foster exploration, e.g. in our case a written exchange between two politicians where they discuss a third person.

Entities who appear within a certain distance from each other can be linked based on the assumption that their co-occurrence in the text is not arbitrary and that there is a high probability that they have *something* to do with each other. The boundaries for such relations can be defined freely, for example based on sentences, paragraphs, or documents. Alternatively, a window approach considers all entities related if they appear within *n* characters from each other. In addition, such co-occurrences can be further defined by the recognition of the semantic relationships within a sentence. We have, however, not yet systematically tested their performance and therefore limit ourselves here to a more basic approach.

Despite all efforts to further specify the significance of such relations, co-occurrences are elusive:

- It is hard to further specify what more or less connected mean
- It is hard to further specify which types of relations are at play
- It is hard to assess which relations were missed because entities were named differently

A graph representation of such data can only allow rather general statements: We can reasonably assume that entities, which co-occur often, are more connected than those who do not. We can also assume that entities, which never co-occur together, are less or not at all connected. Finally, we can assume that entities, which tend to cluster together, are more likely to have something to do with each other without further specifying their relationship.

In contrast, most social network analysis (SNA) research questions require very well defined relations given that they treat social networks as models of highly complex social interactions. Here, a graph represents a meaningful reduction of such complexity and allow insights into specific dimensions of social relations. Graphs are used to represent and/or illustrate highly complex matters, which are otherwise hard to express. Such data is typically generated and curated for the purpose of specific research questions and its value is limited to their respective context in which it was created.

CVCE and cultural heritage institutions in general however address heterogeneous user groups and wish to make available their data to different audiences including educators, researchers and interested laymen. A graph representation of relations between entities therefore will serve different purposes than in a SNA context. Here, graphs need not be meaningful models of social relations but need to be multi-purpose means for the discovery of materials and acknowledge wildly different interests. This means that it is impossible to predict, which relations a user will consider relevant.

Against this background we embrace co-occurrences despite their inherent shortcomings. In order to improve the quality of the various relations we display we need to balance a) higher quality or more meaningful relations and b) the potential to make highly unexpected, yet meaningful discoveries in the data. In order to achieve this, we decided against a rigid ontology of relationship types, which would significantly limit the chances for unexpected discoveries, beyond format based assumptions. Instead we use text synopses and full document text for the generation of relations and filters on time periods, media types and entities in order to further specify our graphs. In addition, we use a two-fold crowd-based approach: generic crowds help clean the data and report obvious mistakes; expert crowds provide high-quality annotations which required a highly domain-specific knowledge. Generic crowds perform tasks which do not require specialist knowledge, for example an answer to the question “Is ‘N.A.T.O.’ a person?” Expert crowds are identified based on past performance and are presented with tasks related to entities and documents they have worked on before.

The resulting graphs can be considered hybrids: They are inasmuch based on co-occurrences as they are on user specifications. Such graphs, we argue, have the potential to meet both the necessities for the automated generation of graphs and still provide meaningful structural information which can be the starting point for a deeper investigation of the materials. We are committed to further increase the quality of co-occurrence relationships in the future.

One of the most frustrating challenges facing practitioners of Dance is the need to use spoken/written language to reference non-verbal movement. The non-verbal to verbal, and vice versa, is not a challenge isolated to practitioners of dance, but is a frustration shared amongst researchers working to represent movement through technological means. Perhaps it is enough to allow the movement, non-verbal as it is, to speak for itself. Then again, it is often through verbal language that we can make meaning from movement. The intersection of language and movement is the point at which meaning-making enforces the mind-body connection, and it is often how embodied experience is transmitted. Two HCI research projects that have studied this connection between words and movement as a means to the classification and automatic recognition of movement, ARTeFACT and POEME, are now collaborating in a new project: Schrifttanz.

ARTeFACT seeks to enable automatic recognition, identification, annotation, and retrieval of movement-based data from streaming video. A lofty goal that has been approached through the generation and analysis of both codified and abstract movement using motion capture data collected at 120 Hz with a Vicon 8-camera motion capture system and a modified Plug-In Gait full body marker set with 38 infrared reflecting markers placed on performers. Early research included instances of iterative choreography created from accelerometer data and descriptions of movement through verbal language by observers (Coartney and Wiesner, 2009). The second phase of the project involved the capture of over 200 codified dance 'steps' in various genres, the development of an ontology, and the creation of IDMove, a tool through which we were able to automatically identify and name dance movement from single dancers (Wiesner et al., 2011, 2014). The third phase ventured into the realm of identifying abstract movement that represents the conceptual metaphor CONFLICT, as introduced by Lakoff and Johnson (2003).

This data, derived from 7 dances about conflict and 19 CONFLICT terms, 396 different sections of movement, each lasting from 2-120 seconds, were captured and categorised. Critical reviews (written) about the dance works were also collected. Through statistical analysis of written and danced texts about CONFLICT, we distinguished body parts frequently used, structural preferences (e.g. stage spacing), and choreographic time spent on the different CONFLICT terms in total and per dance (Wiesner et al., 2015). The findings were validated by a small 'crowd-sourced' experiment, and movement 'rules' were developed per term in order to enable identification of a concept through movement (terms include victim, attack, surrender, struggle, conquer, hero, victory, survive, etc.) (Wiesner and Stalnaker, 2015). Concordances and collocation studies aided in the investigation of the intersections of words and movement, through the phenomenological approach of dancers' descriptions and perceptions of viewers in the form of the reviews written by dance critics. A final step has been to align the non-verbal and verbal output with concepts used in Laban Movement Analysis (Body, Effort, Shape, and Space). ARTeFACT has collected a wealth of data from captured movement, from written descriptions and articles based on the dances, and from a broad LMA perspective. In the future, various modes of comparison (e.g. the metaphor PEACE, general language studies, etc.) will further test the system.

Other researchers have incorporated LMA into their study as a means to identify movement (including studies on rats' play) (Foroud and Pellis, 2003), yet their focus is on deconstruction. POEME and ARTeFACT coincide in that rather than provide a deconstruction of the movement they both seek to characterise the essence of that movement, an approach inspired by LMA. In the case of ARTeFACT, this is accomplished by describing the relations between parts of a movement that accompany the portrayal of abstract concepts in dance. For POEME, it means finding computational means to summarize a movement experience so that it can be studied as a whole.

Where ARTeFACT has taken a more actively analytical approach - which resulted in a set of rules that describe stereotyped motion consistent with conceptual metaphors - POEME has taken a more abstract approach, letting data collection from a large number of human responses gradually expose relationships between verse and movement. POEME (Portrayal of Ephemeral Movement Experiences) is a mobile website (http://poeme.iat.sfu.ca) that interprets movement data, captured through a MARG sensor array commonly found in smartphones, into insightful, witty and whimsical poetry. The goals of POEME are twofold: 1) to create a playful game that can inspire movement exploration and 2) to explore new methods of classifying the nuances of bodily experiences through poetry and in turn understand how bodily knowledge can more easily be transmitted and articulated through words.

POEME, inspired by the Japanese form of poetry known as *haika no renga* (comic, collaborative poetry), involves the social creation of poems through turn taking (Basho, 1998). Creating these linked poems requires participants to respond to previous stanzas with original verse creating a 'movement poem', an interleaved work of verses of words and phrases of movement. We believe, as Herbelot notes, that poetry can be "analysed along the usual dimensions of prosody, syntax, semantics, etc." (2015). In POEME, each verse follows a rigid template that follows the form of a Parts of Speech Poem (PoSP). This PoSP template allows for very simple production of verses. Each poem begins with a noun, followed by two adjectives, two verbs, and an adverb. POEME composes verses from a large dictionary of English language words, based on measurements taken from prior movement responses. In an initial study, the system was trained by collecting movement responses to human- and machine-composed verses. In a later study, training was focused on two wordlists that depict different themes of movement: the 'stillness wordlist' (75 words that relate to little or no dynamic change in movement, e.g. frozen, still, serene); and a 'motion wordlist' (250 words related to the mechanics or physics of motion, e.g. buoyant, centripetal, accelerated). Using a Naive Bayes algorithm, POEME can differentiate between stillness and motion with 97% accuracy (Cuykendall et al., 2016).

Schrifttanz is a unique project that combines the scale of data collection, which POEME offers, with the nuanced language model of ARTeFACT. In Schrifttanz we explore if POEME can recognise conceptual differences in movement, specifically concepts related to CONFLICT, which have been studied in detail during the creation of the ARTeFACT system. Three dancers train the POEME agent by recording movement based on the rules defined in ARTeFACT. These recorded movement sessions are used to model conceptual relations to movement in POEME. This allows us to generalise previous findings from ARTeFACT into a new sensor modality. Also, a Laban/Bartenieff Movement Analysis using the rules-based movements establishes a secondary set of language elements and validates distinctions between movement rules. A computational agent in POEME learns to classify these movements according to the metaphor terms and their associated movements generated by the rules. We then compare POEME's ability to classify these movement metaphors with existing capabilities in ARTeFACT to validate and generalise previous findings and establish the reliability of the POEME system.

Concurrently, POEME composes verses comprised of natural language words gathered through the written articles and reviews based on dances representing the conceptual metaphors identified in ARTeFACT. Free form responses to these verses are collected using POEME's normal training procedure. A machine learning-process associates features of movement with the words. This allows POEME to generate relevant responses to movement. We explore methods of supplementing POEME's verse generation by including the conceptual metaphor model.

Words, like movements, have layers of meaning and can be recombined to create a multitude of sentences or sequences that all vary in their underlying meaning. As philosopher Mark Johnson states, "It is true that when we read, we read words. But words have meanings, and meanings go far beyond words" (2008). In Schrifttanz, the same could be said for bodily movement. POEME's use of current mobile technology and the powerful interactive engine the POEME project has developed enables us to draw from a broader population in order to study and validate the findings of ARTeFACT. Synergistically, ARTeFACT offers to POEME the ability to advance its training mechanisms while it supports the representational nature of the data generated. The two projects are pieces of a puzzle that seeks to establish a better understanding of the relationship between movement and language through the particular and the universal.

Introduction

Many researchers, from the humanities and other domains, have a strong need to study resources in close detail. Nowadays more and more of these resources are available online. To make these resources discoverable, they are described with metadata. These metadata records are collected and made available via central catalogues. Often, resource providers want to include specific properties of the resource in the metadata. The purpose of catalogues will be more generic and addresses a broader target audience. It is hard to strike the balance between these two ends of the spectrum with one metadata schema, and mismatches can negatively impact the quality of metadata provided. The European CLARIN infrastructure (CLARIN ERIC, 2016b) was confronted with this specific problem, and designed a solution based on a flexible mechanism to build resource specific metadata schemas, potentially using domain, community or project specific terminology, out of shared components and semantics. This paper introduces this approach and the infrastructure built for it, which is applicable to any domain with the same needs.

Component Metadata

In the Component Metadata (CMD) Infrastructure (CMDI) (CLARIN ERIC, 2016c; Broeder et al., 2012) the metadata lifecycle starts with the need of a metadata modeler to create a dedicated metadata profile for a specific type of resources, e.g., speech recordings (e.g., HZSK, 2015) or historical letters (e.g., Roorda, 2013). The modeler can browse and search a registry for components and profiles that are suitable or come close to meeting the requirements at hand. A component groups together metadata elements that belong together and can be potentially reused as a group in a different context, e.g., a location or a language description. Components can also group other components, e.g., the actor component can contain the general location component. The CMDI Component Registry (CLARIN, 2016a) already contains many of these general components. And these can be reused as they are or be adapted, i.e., add or remove some metadata elements and/or components. Also completely new components can be created to model the unique properties of the resources under consideration. All the needed components are combined into one profile that is specific to the type of resources, e.g., a profile for a speech recording (see Figure 1). Components, elements and values in this profile are linked to a semantic description, e.g., a concept, to make their meaning explicit. This feature allows the use of community specific terminology, while still creating a shared semantic layer that can be exploited by generic tools. Finally, metadata creators can create records for specific resources that comply with the profile relevant for the resource type, and these records can be provided to local and global catalogues. Notice also that CMD leaves the final responsibility of how heavy a metadata description should be to the modeler: it is perfectly possible to create a lean profile, resulting in lightweight records and combine it with a full-text index of the resources for discovery.

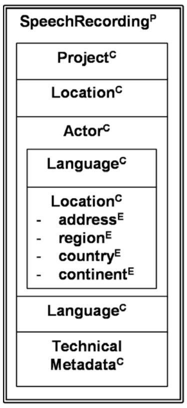

Figure 1: Example CMD profile (p), components (c) and elements (e)

The Component Metadata approach is currently being standardized by ISO Technical Committee 37. And the first part (ISO 24622-1, 2015) of this family of standards has been released and specifies the model just described.

Component Metadata Infrastructure

CLARIN built an infrastructure (see Figure 2) around the approach described in the previous section. This infrastructure is open source and provides many tools, which can readily be reused by other communities.

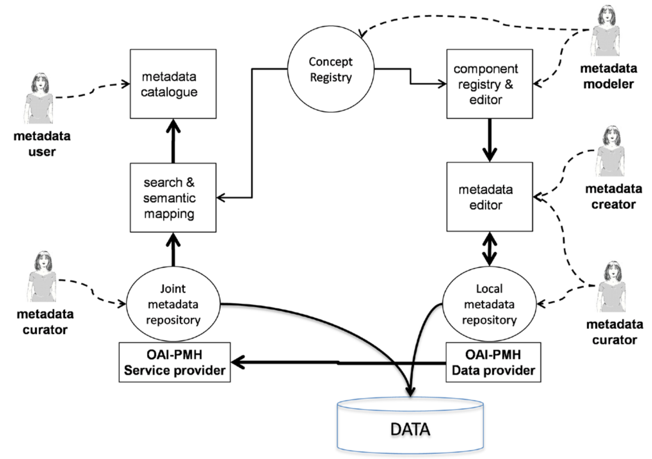

Figure 2: An overview of tools and roles in CMDI

CMDI toolkit (CLARIN, 2016b): A set of XML schemas and transformations that implement the workflow from validating component and profile specifications to conversion into profile specific XML schemas used to validate specific CMD records.

Component Registry (CLARIN, 2016b): A registry storing the profiles and components created by the community for reuse. It also provides an editor for the creation of new profiles and components and derivatives of existing ones. The backend also provides REST services based on the toolkit, i.e., serves the XML schema representation of a CMD profile.

Concept Registry (CLARIN, 2016c; Schuurman et al., 2015): A SKOS-based registry storing the communities widely accepted concepts and their relations, which form the general semantic network overlaying the specific metadata profiles (Durco and Windhouwer, 2014).

CMD editors and forms: Various general CMD editors have been developed, e.g., the desktop tool Arbil (The Language Archive, 2016a) and the online editor COMEDI (CLARINO, 2016). Also dedicated forms for specific profiles, e.g., the CMDI maker (CLARIN-D, 2016), which can be inspiring.

Repository systems: Many CLARIN centers have deployed and configured generic repository systems to store their resources accompanied by CMD records. LINDAT (UFAL, 2016) and The Language Archive (2016b) have done so as well and released their solutions as general CMD-capable repository systems.

OAI harvester (The Language Archive, 2016c): CMD records can be harvested with any OAI harvester, but this harvester is special in that has easy provisions to add transformations to CMD that enable the harvesting of other metadata formats.

Catalogues: Faceted browsing is a suitable and commonly applied method for exloring vast collections based on some key properties. The CLARIN Virtual Language Observatory (VLO) (CLARIN, 2016d) is such a browser. Although the front-end is rather CLARIN specific, the VLO importer in the back-end, which takes the harvested CMD records, determines the facets and their values and stores these in a SOLR index, is generic because the facet mapping is highly configurable and exploits the shared semantic layer. The Meertens Institute has developed an alternative faceted browser (Meertens Institute, 2016) for CLARIN-NL. The importer of this browser does not take any configuration and dynamically creates facets for any semantically different context it finds in the CMD records.

Convertors: CMDI is currently XML oriented, but other representation formats are possible. The CMD2RDF service (CLARIN-NL, 2016) provides a RDF representation to link CMD records with the world of Linked (Open) Data. Also convertors for other metadata formats, e.g., MODS or OLAC, to CMD are available.

Although this list is far from complete it shows that the CMD Infrastructure is a thriving and versatile software ecosystem. Also many parts of it are configurable, which makes it adaptable to other domains.

Lessons learned by CLARIN

When CLARIN started development on the CMD Infrastructure in its preparatory phase many things were not clear yet and a lot of flexibility was needed. Common and reusable components and concepts still had to be specified. This has lead to situations where sometimes several alternatives have coexisted for a long time in the CMD ecosystem, which can make it hard for users, especially novices, to select which one to use. It is better to prevent this kind of confusion. CLARIN advises new communities that start using the CMD Infrastructure to first setup a set of basic recommended or even obligatory components and concepts, so a stable generic core is available to the community to extend with their specific needs.

Future work

CLARIN keeps on working actively on the CMD Infrastructure, with the next version, i.e., CMDI 1.2 (Goosen et al., 2015) currently under development. The following topics will be addressed by this update:

- Lifecycle management of components and profiles.
- Connection to vocabulary services.
- Annotation of profiles and components with hints targeted at tools.

Also improvement of the metadata quality is an ongoing process. The ongoing CLARIN-PLUS project (CLARIN ERIC, 2016a) includes the design and development of tools and and a workflow that can be used used by metadata curators for quality assessment and curation of CMD records (King et al., 2015).

Conclusions

CLARIN has built a highly flexible and versatile infrastructure for metadata that is able to meet both the generic needs of catalogues and the specific needs of resource providers. The fruits of these efforts are ready to be picked by any community experiencing the same needs. CLARIN is happy to share their experiences as well as the sometimes hard learned lessons.

The Manuscripts of David Livingstone and New Frontiers for Spectral Imaging

Adrian S. Wisnicki
awisnicki2@unl.edu
University of Nebraska-Lincoln, United States of America

Ashanka Kumari
ashanka.kumari@louisville.edu
University of Louisville, United States of America

Introduction

This presentation will focus on the results of the newest phase of the NEH-funded Livingstone Spectral Imaging Project (2010-present). This project seeks to apply spectral imaging and processing techniques to the study of some of the most damaged manuscripts produced by David Livingstone (1813-73), the famous Victorian traveler, abolitionist, geographer, and missionary. Our project asks whether spectral imaging can indeed restore erased or otherwise invisible portions of Livingstone's writing. More recently, we also explore whether the technology can illuminate the specific circumstances of the production and preservation of Livingstone's manuscripts, thereby better revealing the links between these manuscripts and the unique historical events that shaped the material dimensions of these manuscripts.

Methodology

Spectral imaging, a technology beginning to make a significant impact in humanities research (see bibliography), relies on imaging an object, such as a manuscript, under multiple wavelengths of light, ranging from ultraviolet (UV) through the visible color spectrum to the near-infrared. A high-resolution monochromatic digital camera automatically photographs each illumination. Imaging scientists then manipulate this raw image data with computers by applying various processing algorithms with the goal of enhancing features of interest. Often these features are made more visible by creating pseudocolor (false-color) representations of the object that foreground or suppress other object elements.

Our previous research (Wisnicki 2011) applied spectral imaging to recover the text of a diary that Livingstone had written over newspaper pages and that had become illegible because, first, the considerable fading of Livingstone's ink (which he had concocted out of a local African clothing dye) and, second, the continuing prominence of the black newsprint over which Livingstone wrote his text. Using a combination of new and established spectral image processing techniques, our team successfully suppressed the newsprint so that it no longer interfered with Livingstone's text. By enhancing his writing so that it could be read easily, we were able to recover some 99% of Livingstone's words (up from about 40% before) and, in turn, use this technique to reveal important new information about Livingstone's strategies for representing his experiences in interacting with local populations in Central Africa.

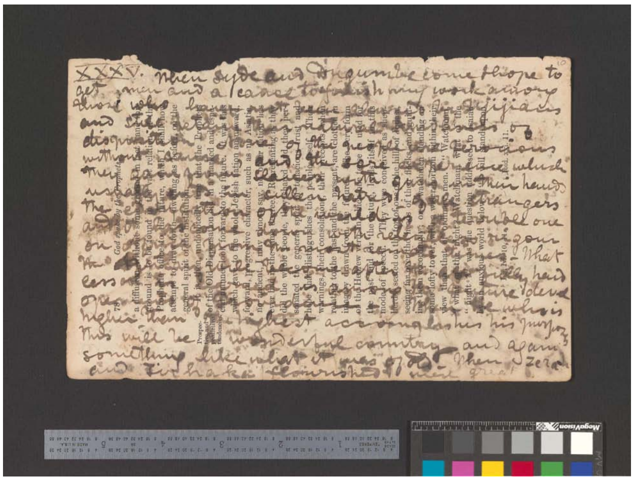

Figure 1. Page XXXV of Livingstone's 1870 Field Diary in natural light. Copyright National Library of Scotland. CC BY-NC 3.0

Our current project takes our previous research in a new direction to suggest that spectral imaging can illuminate the production and preservation history of Livingstone's fragmentary 1870 Field Diary. With spectral imaging, we have enhanced or revealed material features of this diary, such as overwriting, staining, and page topography, that are often not visible or difficult to discern with the naked eye. Our results represent an important advance in the study of manuscripts with spectral imaging, particularly because previous related research has generally focused on using of spectral imaging for the recovery of faded texts or illegible palimpsests such as the Dead Sea Scrolls (Shor 2012) and the Archimedes Palimpsest (Netz and Noel 2007).

Historical and Scholarly Implications

Livingstone wrote the 1870 Field Diary in central Africa and carried it with him to his death in 1873 in what is now Zambia. Livingstone's supporters then transported his manuscript (and his corpse) from the interior to the coast of Africa and back to Britain, where different repositories have since preserved the manuscript. The pages of the diary, therefore, bear the remnants of this complex history, from the changes and deletions that Livingstone made over time, to the marks left on the manuscript pages by the diverse local African environments through which the diary traveled, to the traces of modern curatorial methods used to preserve the diary's pages.

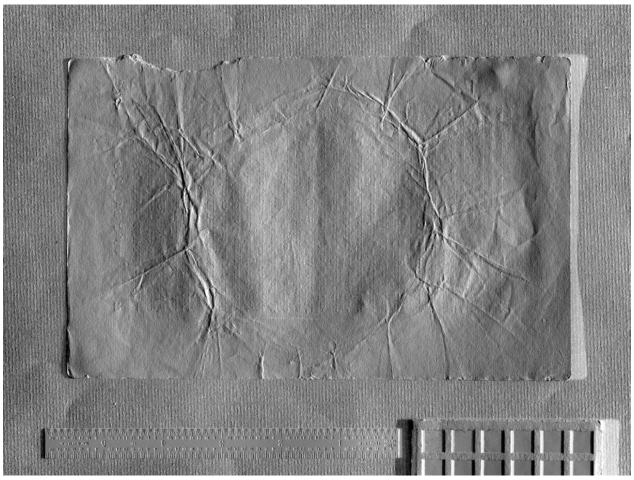

Figure 2. Page XXXV of Livingstone's 1870 Field Diary with topography illuminated by spectral image processing. Copyright National Library of Scotland. CC BY-NC 3.0

Our efforts to study the material history of Livingstone's diary with spectral imaging represent an important intervention in the field. Our work demonstrates new methods and frontiers for the use of spectral imaging in the humanities because it underscores that spectral imaging can do more than recover faded or invisible text. Spectral Imaging can provide crucial insights into the passage of a manuscript through time and into the relationship between a manuscript and the specific historical circumstances from which it emerged. By applying this technology to the 1870 Field Diary, we have gained key insights into the strategies by which Livingstone shaped his experiences and identity for public consumption and the impact of specific moments of handling in determining material features of the manuscript. These insights promise to enhance our understanding of Livingstone's biography and the history of the many African cultures in which he worked.

Moreover, the spectral image processing techniques we have developed for the 1870 Field Diary can now be applied to study other manuscripts with notable textual and material features or, indeed, other cultural objects such as paintings and sculptures whose surfaces retain their material history and bear the marks of the many people and events that have come to shape the objects we encounter today. Our project is helping us distinguish such marks, but, in our case, the project also sets the stage for future research in which we might use the spectral signatures of specific marks as a portal to defining tangible aspects of nineteenth-century African environments from which Livingstone's manuscripts emerged and through which these manuscript circulated.

Public and Private Views of Texts in Digital Editions – The Case of the Kanseki Repository

Christian Wittern
cwittern@gmail.com
Kyoto University, Japan

Introduction

The established pattern for a scholarly digital edition today is the website, which in many cases has a unique and well thought out user interface. It concentrates all information pertaining to the topic, but allows little interaction of the reader with the texts beyond what has been designed into the user interface by the developers of the site.

Although there are also many efforts to go beyond this and experiment with new forms of reading in the digital age, for example protocols for sharing annotations or reading communities, they have not yet reached a stage where they would be available to mainstream researchers.

In contrast to the polished and well advertised flagship editions of digital projects at prestigious institutions, there is also a continuing trend of making the source texts that feed into digital editions available in a way that not only allows, but actively encourages tinkering with the texts. The distribution for this latter type of texts is frequently on the site github.com, which is the world largest repository for software development[1], but as a free site for data sharing with collaborative editing it is becoming more popular for other purposes as well.

Some of the large scale text projects using Github in this way include the *Chinese Buddhist Electronic Text Association* (CBETA)[2], *gitenberg*[3] and *EEBO-TCP*[4] to name just a few.

The presentation proposed here reports on the *Kanseki Repository*, a project that tries to establish a link between these two different types of text dissemination and through this combination to achieve the best of the two worlds: The texts can still be presented through a sophisticated web interface, which uses Github as a backend storage and reads the texts from there for presentation to the user. These texts can be forked (that is, cloned and copied to the user's account) which makes it possible for the user to revise or annotate them. The system is set up in a way that it will show this private copy of the text if configured so by the user.

Methodological considerations

The goal here is not simply to upload as many texts at possible to public archives, but rather to develop a platform that allows the basic tenets of scholarly editing to co-exist and thrieve with the possibilities and affordances of the digital medium. It is therefore of paramount importance, to consider the requirements as voiced from practioners of scholarly editing and implement them as transparently as possible.

Record and interpretation

In a seminal article, the Swiss scholar Hans Zeller (1995) emphasised the fact that all scholarly editing should make a clear distinction between the record of what is transmitted and the scholarly interpretation thereof. While this distinction is blurry at times, it has informed the design of the *Kanseki Repository*, which arranges the editions of a text it represents into those that strive to faithfully reproduce a text according to some textual witness ('record') and those that critically consider the content and make alteration to the text by adding punctuation, normalizing characters, collating from other evidence etc. ('interpretation').

Additional requirements

Peter Shillingsburg (2015) outlines the following requirements of a digital edition (slightly edited for clarity):

a. Digitize images of all the documents. That will make it possible, from anywhere in the world, to see any document side-by-side with any other document without traveling from Tokyo to Marburg and New York.

b. Prepare a table of variants to show how all the documentary texts differ from one another.

c. Write a textual history that explains the relationships among the variant documents and explains why we should care–why it is important to know.

d. Transcribe at least one of the documents so that the variants list can be more easily used. Or transcribe all the documents so that readers can select and read any one. Transcribing all the documents will also make machine collation possible.

e. Edit one of the transcriptions to correct obvious errors. This will preserve the text as a historical documentary text but will help readers avoid the distractions caused by scribal or compositorial errors.

The architecture developed in this project strives to implement as much of this as seems feasible within the limits of the current funding and other constraints. The components will be further described below.

Main components of the project architecture

The architecture of the project consists conceptually of two parts: (1) the text repository and (2) clients accessing this repository. Of these clients there are currently two, both developed within the project.

Backend: Repository of texts: github.com/kanripo

Since every text has its own unique history and witnesses, every text is allocated to its own repository (in the technical sense). These repositories, currently more than 9000, are are organized according to the traditional Chinese cataloging principles and kept under the Github account @kanripo. Since the texts are publicly accessible, they can be freely downloaded and cloned even without ever touching the client interfaces. Due to the large number of texts and the Github interface, which seems foreign and intimidating to most readers of classical Chinese texts, special clients cover most needs in interfacing with the texts.

Client interfaces

Web interface at www.kanripo.org

This website provides access to the texts, including full-text search, display of transcribed text and facsimile(s) of different editions. Users can log in using their Github credentials and get access to more advanced functions such as selecting lists of text of special interest, advanced sorting functions by text category or date as well as cloning of texts to the Github user account and editing on site. The site went into testing mode in October 2015 and a first public release has taken place in March 2016.

Mandoku, a stand alone tool for further immersive reading and study

In addition to the website, an Emacs module called Mandoku (see Wittern, 2012, 2013, 2014a, 2014b) has been developed (as an extension to Orgmode, see Domnik et al., 2015), that uses the API of the website to provide the same search functions, but clones the texts of interest to the user to her local machine, thus providing advanced editing possibilities and offline access.

Towards a platform for text-based Chinese studies

All modes of interaction described above are based on the distributed version control system git, using the Github site as a 'cloud storage'. However, in addition to providing storage, Github also provides a feedback mechanism through "pull-requests", where users can flag corrections to a text for the @kanripo editors to consider for inclusion in the canonical version, thus making it available to all users.

The model outlined here is extensible and allows other developers of websites related to Chinese studies to access the same texts, and provide specialized services to the user, for example by enhancing the text through NLP processing. These enhanced versions can be saved ("committed" in git language) in the same way to the users account and are then also visible to the client programs described here.

This will open the door to a open platform of texts for Chinese studies, where the texts of interest to the users form the center of a digital archive, with different services and analytical tools interacting and enhancing it. The user, who makes a considerable investment in time and effort when close reading, researching, translating and annotating the text, never loses control of the text and does not need to worry about losing access to it when one of the websites goes offline.

By providing versioned access to the texts in question, it is also possible to make any analytical results reported in research publications reproducible (Rawal, 2015) by indicating the additional tools and processes needed, ideally also in a Github repository in the same ecosystem.

The aim is not just to provide a static, completed, definitive edition of a text, but as fertile a ground as possible for the interaction between the text and its readers, hopefully improving both through this process.

Oulipian Stylometry

Mark Wolff
wolff.mark.b@gmail.com
Hartwick College, United States of America

The Oulipo, or Ouvroir de littérature potentielle, is a group of writers in Paris who for over fifty years have experimented with algorithmic techniques for writing and reading literature. Raymond Queneau, one of the group's co-founders, proposed a method in 1964 for analyzing the syntactic structure of texts written in French, and he believed that the method, which he called matrix analysis, could provide a measure of an author's style.

What can matrix analysis contribute to stylometry? Apart from its origins as a form of computational play for play's sake (Wolff, 2007), matrix analysis offers an alternative to lexically based techniques for authorship attribution such as Burrow's Delta (2002). Rybicki and Eder reported that Delta does not work as well for texts written in French as for those in English and German (2011). Antonia, Craig and Elliott have shown that analyzing the frequencies of lexical n-grams where n > 1 does not usually yield very good results (2014). Researchers have developed syntactical methods based on bigrams of labels for a simplified parsing of texts (Hirst and Feiguina, 2007) and on correlations between semantics and the structures of dependent and independent clauses (Allison et al., 2013). In the latter study the researchers concluded that their definition of style "entailed [...] *a method for looking for it*" (28). The early Oulipo would have agreed with this approach. Recognizing that an author aware of how he or she used words syntactically might apply Queneau's matrix analysis to change his or her "manner," François Le Lionnais (the other co-founder) claimed that matrix analysis could serve as a "literary prosthesis" exemplifying the vocation of the group (Bens, 2005: 246). For Le Lionnais, the most important focus of the Oulipo should be the synthesis of new possibilities for understanding literary phenomena (Oulipo, 1973: 17). Matrix analysis enables the identification of significant syntactical patterns for further inquiry into an author's style. These patterns would be difficult to ascertain without a method like the one developed by Queneau.

Queneau devised a grammatical schema of the French language for describing the construction of word pairs using a system similar to linear algebra (1964). He began by dividing all elements of speech into two categories: signifiers, which include nouns, adjectives, and verbs (except *avoir* and *être*); and formatives, which include everything else (*avoir*, *être*, pronouns, articles, conjunctions, prepositions, adverbs, interjections, etc.). Given a sentence, one can construct two matrices where the first matrix contains all formatives and the second all signifiers:

Figure 1

$$\left\| \begin{matrix} le & a & la \end{matrix} \right\| \times \left\| \begin{matrix} chat \\ mangé \\ souris \end{matrix} \right\| = (Le \times chat) + (a \times mangé) + (la \times souris)$$

If a sentence contains two consecutive formatives or signifiers, one can use a unitary element to construct the matrices:

Figure 2

$$\left\| \begin{matrix} Le & 1 & a & bien & la & 1 \end{matrix} \right\| \times \left\| \begin{matrix} vilain \\ chat \\ 1 \\ mangé \\ belle \\ souris \end{matrix} \right\| = \begin{matrix} (Le \times vilain) + (1 \times chat) + (a \times 1) + \\ (bien \times mangé) + (la \times belle) + (1 \times souris) \end{matrix}$$

By adopting the conventions that neither (1 × 1) nor (Y × 1) + (1 × Z) are allowed within a sentence, one avoids uninteresting or redundant word pairs.

Queneau proposed observing the distribution of formatives and signifiers in a text using the relation F + Uf = S + Us, where F is the number of formatives, S the number of signifiers, Uf the number of unitary elements paired with signifiers (1 × Z), and Us the number of unitary elements paired with formatives (Y × 1). Noting that even if an author like Flaubert worked tirelessly to vary how he wrote, Queneau believed that this distribution could serve as a "potential" but unconscious indicator of the author's style (1965: 319).

In order to test Queneau's hypothesis, I applied his matrix analysis to a corpus of 328 nineteenth-century French novels from the ARTFL-FRANTEXT database using Helmut Schmidt's part-of-speech tagger (1995). Figure 3 is a biplot of a principal components analysis of scaled values for F, S and Uf (Us is excluded to avoid collinearity) and the graph shows that works by the authors Jules Barbey d'Aurevilly, Alexandre Dumas and Honoré de Balzac cluster separately whereas works by George Sand form distinct clusters.

Figure 3

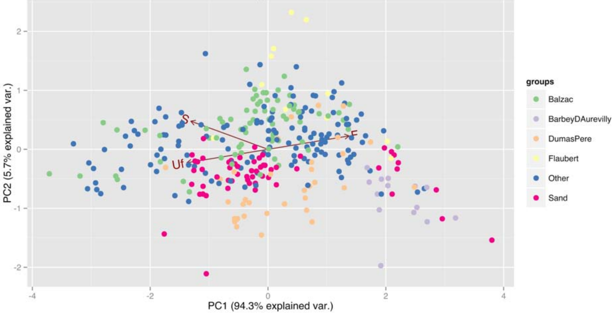

Table 1 indicates the results of using support vector machines with a radial basis function kernel to build a classification model for the texts (Kuhn, 2015). Sixty-seven percent of the corpus was used for training the model with 10-fold cross-validation. A one-against-one method was used for classifying the test set (Karatzoglou, 2004: 7-8). The results show a moderate authorial signal in the works of Barbey d'Aurevilly and weaker signals for Dumas and Balzac.

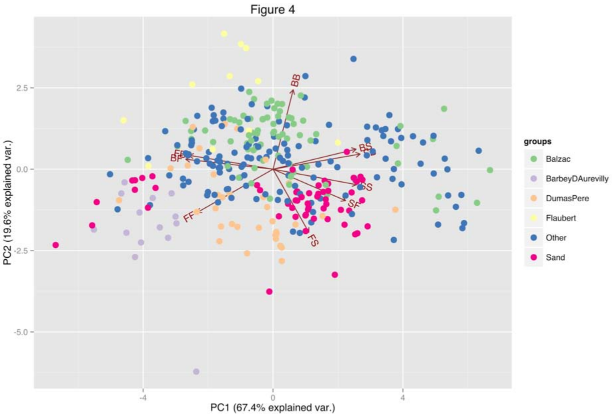
Table 1

	Sensitivity	Specificity	Prevalence	Balanced Accuracy
Class: BarbeyDAurevilly	0.750000	0.934783	0.041667	0.842391
Class: DumasPere	0.636364	0.776471	0.114583	0.706417
Class: Balzac	0.875000	0.458333	0.250000	0.666667
Class: Flaubert	0.000000	1.000000	0.031250	0.500000
Class: Sand	0.000000	1.000000	0.197917	0.500000

Figure 4



To build a better model using matrix analysis, one can observe the distribution of bigrams of matrix analysis pairs in the corpus. Given the labels **F** for (Y × 1), **S** for (1 × Z), and **B** for what Queneau called a biword (Y × Z), one can transcribe a text into a series of these letters. For instance, the sentence from George Sand's *Indiana* (1832):

> (Toute × 1) (sa × conscience), (c' × 1) (était × 1) (la × loi); (toute × 1) (sa × morale), (c' × 1) (était × 1) (son × droit).

can be represented as **FBFFBFBFFB**. With the feature set of bigrams **FF**, **FB**, **BF**, **BB**, **BS**, **SB**, **SS**, **SF**, and **FS**, one can analyze its distribution within the corpus. Figure 4 is a biplot of a principal components analysis of the corpus with the nine bigrams as variables and suggests that at least some authors do have measurable differences in style.

Table 2 shows the results of building a model with support vector machines to classify the texts by author according to the distribution of bigrams.

Table 2

	Sensitivity	Specificity	Prevalence	Balanced Accuracy
Class: BarbeyDAurevilly	1.000000	0.945652	0.041667	0.972826
Class: DumasPere	0.909091	0.894118	0.114583	0.901604
Class: Flaubert	0.666667	0.978495	0.031250	0.822581
Class: Balzac	0.833333	0.500000	0.250000	0.666667
Class: Sand	0.000000	1.000000	0.197917	0.500000

The model can identify the styles of Barbey d'Aurevilly and Dumas with very good accuracy, and it can detect authorial signals in works by Flaubert and Balzac. The model does not do well identifying works by Sand because they seem to evince two distinct styles (as suggested by Figure 4). The small cluster of works by Sand on the left side of the graph include *François le champi*, *Elle et lui*, *Le Château des désertes*, *La Mare au diable*, *Consuelo*, *Indiana*, *Lélia*, and *La Comtesse de Rudolstadt*. The predominance of formatives in this cluster is perhaps indicative of a more conversational style: such an hypothesis would require further analysis.

Compared to other classification methods based on wordlists, matrix analysis does not deliver as high a level of accuracy. Table 3 summarizes the sensitivity and specificity of several classification models with different statistical techniques for the five selected authors using the *classify()* function of the R software package *stylo* (Eder et al., 2013):

Table 3

	Matrix Analysis	Delta (Classic)	k-NN (k=3)	SVM (radial)	NSC
Class: BarbeyDAurevilly	1.000000 0.945652	1.000000 1.000000	1.000000 1.000000	0.500000 1.000000	1.000000 1.000000
Class: DumasPere	0.909091 0.894118	1.000000 0.818182	0.818182 0.363636	0.818181 1.000000	0.727273 0.181818
Class: Flaubert	0.666667 0.978495	1.000000 1.000000	0.333333 1.000000	0.666667 1.000000	1.000000 0.000000
Class: Balzac	0.833333 0.500000	0.958333 1.000000	0.958333 0.916667	0.916667 1.000000	0.916667 1.000000
Class: Sand	0.000000 1.000000	1.000000 0.947368	1.000000 0.947368	1.000000 1.000000	0.842105 0.684210
Overall Accuracy	68.5%	96.2%	85.8%	93.4%	78.3%

To minimize the effects of semantic variation, the wordlists for classification with *stylo* were culled 100% (only those words that appear at least once in every text were included).

Despite the low accuracy of matrix analysis, it is possible to identify sample sentences that exemplify an author's style with sequences of bigrams. In Figure 4 the left group of Sand's texts clusters near the vectors for **FF**, **BF** and **FB**. Scanning the texts for the highest relative frequency of these bigrams yields sentences such as this from Sand's *Consuelo* (1842):

> (Il × faut) (que × 1) (je × sache) (comment × 1) (elle × 1) (se × tient), (ce × 1) (qu' × 1) (elle × fait) (de × 1) (sa × bouche) (et × 1) (de × 1) (ses × yeux). **BFBF FBFFBFBFFB**

The syntax of this sentence as schematized by matrix analysis contains within it the syntax of the previously quoted sentence, inviting further inquiry into how Sand constructed her texts. Although Sand most likely did not think of her writing style in the terms conceived by Queneau, matrix analysis represents a method for thinking about style that not only measures how words are used but can also inform potentially the act of writing and reading. Lexically-based techniques consider texts as "bags of words" with structure-less frequencies, but matrix analysis approaches texts as objects that have undergone a process of development. As an Oulipian procedure, matrix analysis allows the reader to detect reproduced and reproducible patterns through an interactive process of textual exploration.

Queneau's matrix analysis represents an analytical method for defining style that classifies texts according to their structure. The Oulipo in the 1960s made a distinction between the quality of works of literature and the potentiality of the methods used to create works of literature (Bens, 2005: 80). Practitioners of computational text analysis can observe a similar distinction between the accuracy of text classification and the potentiality of classification methods for understanding literature. If style implies how words are used more than what words are used, stylometry should seek to better understand how words are used. The Oulipo provides us with an example of this kind of inquiry into computationally revealed text structures. Queneau performed small experiments with matrix analysis, but Le Lionnais imagined the possibility of harnessing machines to support the necessary calculations on a larger scale (Bens, 2005: 246). Following the Oulipian notion of "plagiarism by anticipation" (Oulipo, 1973: 23), we can understand matrix analysis as a precursor of stylometry in the digital humanities.

Introduction

We present an easy-to-use web-based user interface which allows scholars working on manuscripts to assess the usefulness of automatic document image analysis (DIA) methods when incorporating automatic processes into their workflows. In contrast to existing web interfaces (Clausner, Pletschacher, and Antonacopoulos, 2011; Embach et al., 2013), this interface allows the user to directly upload images of the manuscript of interest without any registration. Thus, a fast assessment of a variety of algorithms and DIA processes can be performed. DivaServices is not a specialized tool for one specific use-case, but a collection of tools for several tasks in different use cases.

With this web interface we build on our previous initiative (Würsch, Ingold, and Liwicki, 2015) to provide access to a wide range of DIA methods to the research communities in Computer Science and the Humanities. While the existing DivaServices are already useful to integrate state-of-the-art DIA methods into new research applications it is still difficult for researchers with little programming experience to estimate the capabilities of the offered methods. For example, it is not easy to know which binarization, text line segmentation, or OCR method and which parameters would work best on a given manuscript.

In order to overcome this shortcoming, we present a web application that allows interacting with all offered methods. Users are able to upload their own images, perform experiments on them and have the results visualized. With this, researchers in the Humanities should get a better understanding on what the methods developed in the Computer Science community are able to achieve. The other way round, researchers from the Computer Science will have their methods exposed to a much broader range of data and can gather feedback to further improve the methods. This feedback loop should enhance communication between the two communities such that future methods can target the respective needs even better.

DivaServices-Spotlight is built in a highly modular way, providing Graphical User Interface (GUI) blocks for various kinds of input and output parameters. The web interface is therefore automatically updated when new methods are added without the need of any further ado. Furthermore, based on our continuous open source support, this tool is available under a LGPL v2.1 license and the source code can be downloaded from github.[1]

DivaServices-Spotlight

DivaServices-Spotlight[2] is a web application that allows user to upload their own image data, perform experiments and investigate the results. This should help in deciding whether an algorithm can help solving a particular problem or not, and which parameters are best for the data at hand. Figure 1 provides an example of such an experiment where the highlighted area (left) is segmented into text lines (right) and visualized for the user.

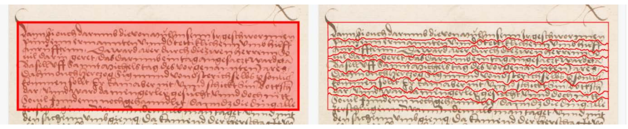

Figure 1 Example of an executed experiment using DivaServices. The highlighted region (left) is segmented into separate text lines (right) and visualized for the user.

In this part we give an overview of how the different user interface works and provide an example on how to perform a workflow.

The User Interface

From the welcome page the three main parts of DivaServices-Spotlight are available: Images, for uploading and manipulating input images; Algorithms, for executing methods; and Results, for accessing computed results.

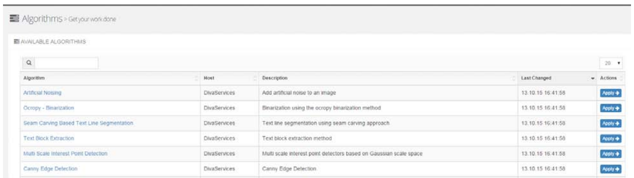
Images

Via the "Images" link the user can view his already uploaded images (Gallery) or upload new images (Upload). In its current version all uploaded images are automatically converted into the PNG format and users can upload a maximum of ten images at the same time.

Users get the possibility to apply various pre-processing steps onto their image. It is possible to crop an image to a specific size and values such as *brightness*, *contrast*, and *saturation* can be adjusted. Performing these pre-processing steps can lead to better results of varying methods.

Algorithms

On the "Algorithm" page, all currently available methods are listed (c.f. Figure 2). When selecting "Apply" on a given method, the user is asked to select one of his uploaded images.



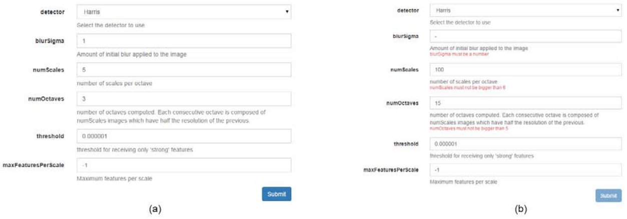
Algorithms > Get your work done

AVAILABLE ALGORITHMS

Algorithm	Host	Description	Last Changed	Actions
Artificial Noising	DivaServices	Add artificial noise to an image	13.10.15 16:41:58	Apply
Ocropy - Binarization	DivaServices	Binarization using the ocropy binarization method	13.10.15 16:41:58	Apply
Seam Carving Based Text Line Segmentation	DivaServices	Text line segmentation using seam carving approach	13.10.15 16:41:58	Apply
Text Block Extraction	DivaServices	Text block extraction method	13.10.15 16:41:58	Apply
Multi Scale Interest Point Detection	DivaServices	Multi scale interest point detectors based on Gaussian scale space	13.10.15 16:41:58	Apply
Canny Edge Detection	DivaServices	Canny Edge Detection	13.10.15 16:41:58	Apply

Figure 2 The "Algorithms" page provides an overview of all available methods with a short description of what they can be used for. Using the "Apply" button one method can be used.

On the page for a specific algorithm the user then has to specify input for this method. The input elements are created automatically based on the specifications of the method. For certain input elements a method can also specify ranges of possible values. The input of the user is validated and error messages are displayed should the input be not in a valid range.



(a)

detector: Harris
Select the detector to use

blurSigma: 1
Amount of initial blur applied to the image

numScales: 5

Figure 3 Different input types and validations. DivaServices-Spotlight offers automatic generation of input blocks for different types of inputs (a) like numbers, strings, and selection. Automatic validation (b) ensures that the user input is within ranges specified by the method.

Figure 3 (a) shows how various input blocks are generated by DivaServices-Spotlight. Currently it is possible to generate blocks for the following elements: strings (textual data), numbers, selection (one of multiple), and checkboxes. In Figure 3 (b) validation of input elements is visualized. When the user inputs data that is not valid for the given input type (e.g. text data for numbers) an error message is displayed and the user cannot execute the method.

Furthermore, an algorithm can specify that a user needs to select a region within the image. This is needed by methods which want to only work on a subset of the image and can speed up the runtime, as well as the quality of the results of a method (e.g., of text line detection). DivaServices-Spotlight allows for drawing the following selections onto an input image: rectangle, polygons, and circles. These regions are drawn using the mouse. Rectangles and circles can be created using a simple click and drag operation. Polygons are created through manually creating every point of the polygon and clicking near the start point to close it. After creating the various highlighters, they can be edited (e.g., a single point of a polygon can be moved to a new location after creation). The various highlighters are visualized in Figure 4.

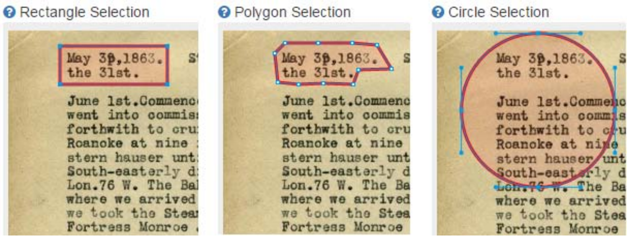

Figure 4 The different selection methods; rectangle (left), polygon (center), and circle (right).

Once the user has entered necessary parameters and selected a region on the image (if needed) the execution can be started using "Submit". The user is notified of the process at the top of the page that shows more information when clicked on with the mouse (Figure 5 (a)). Once the execution is finished, again the user is notified by a small balloon that pops up in the top right corner (Figure 5 (b)). Also, the counter behind the “Results” link in the menu navigation is increased (Figure 5 (c)).

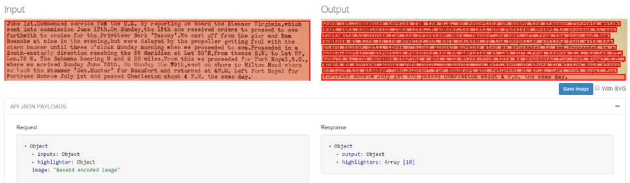
Algorithm Multi Scale Interest Point Detection is done

(a) (b) (c)

Figure 5 Notifications shown to the user about the current status of an execution (a), when an algorithm finishes (b), and the number of available results (c).

Results

The “Results” page provides the user an overview of all available results. Using the “+” button on a specific result will show him the computed result. On the left side the user sees the input image as well the used parameters and on the right side the user gets a visualization of the results.



Input

June 1st.Commenced service for the U.S. by reporting on board the Steamer Virginia,which
went into commission June 13th.On Sunday,the 15th she received orders to proceed to sea
forthwith to cruise for the Privateer Bark 'Tacony'.We cast off from the pier and Ram
Roanoke at nine in the evening,but were delayed by the propeller getting foul with the
stern hauser until three o'clock Monday morning when we proceeded to sea.Proceeded in a
South-easterly direction reaching the 68 Meridian at Lat 30'N,from thence S.W. to Lat 27,
Lon.76 W. The Bahamas bearing W and S 20 miles.From this we proceeded for Port Royal,S.C.,
where we arrived Sunday June 28th. On Monday the 29th,went on shore to Hilton Head where
we took the Steamer 'Gen.Hunter' for Beaufort and returned at 4P.M. Left Port Royal for
Fortress Monroe July 1st and passed Charleston about 4 P.M. the same day.

Figure 6 Results of a text line segmentation method. User input (left) is shown together with the computed results (right). Below the images is the JSON information a programmer would receive when calling the methods on DivaServices directly.

Figure 6 provides an example of a detailed result. The user input is shown (left) with the computed result (right). The image view can be manipulated (dragging, and zooming) to get a better view of certain areas. Below each image is the JSON information that is sent to and received from DivaServices. This information should help programmers to see with what kind of information they have to deal with should they decide to integrate that method into another application.

Using DivaServices-Spotlight for Designing DIA Workflows

We provide an example how DivaServices-Spotlight can be used to design a full workflow. The aim is to build a system that takes an input image and performs OCR on the segmented text lines. For this we need to perform three steps: binarization, text line segmentation, and OCR recognition.

Using the “Save Image” functionality on the result page we save the result image after each step. Figure 7 (a) – (d) show results at each stage using a combination of available methods. Parameters or even method could be changed at each step in order to find the best suited combination.

Figure 7 Results at different stages in the workflow. The input image (a) is binarized (b), segmented into text lines (c) and processed using an OCR algorithm, leading to its digital representation (d).

Once a researcher is satisfied with the results on a small scale, he could then integrate that workflow into his application by directly invoking the methods on DivaServices using his programming language of choice.

Conclusion

With DivaServices-Spotlight we provide a web application to interact with all available methods hosted on DivaServices. Researchers can run small scale experiments to experience the possibilities of the different algorithms. Furthermore, the application provides developers with the necessary information they would need to use the methods outside of DivaServices-Spotlight and integrate them into other applications.

Introduction

The character network of a given narrative (novel, play, film, graphic novel, etc.) models the structure formed by the relations in its character-system (Woloch, 2003). A relation between two characters symbolises their co-presence in parts of the narrative; the entire set of relations between all characters constitutes a formal model of this character-system and lends itself to display and analysis. For example, Moretti (2011) used network modelling to compare the importance of protagonists from Shakespeare's *Hamlet*, while Trilcke *et al.* (2015) created character networks for 465 German plays and used them to initiate a wider study of German Theatre.

Most applications of character network analysis have disregarded temporality, possibly because of its representational complexity. Consequently, all relations in the system are considered as happening at the same time: one cannot distinguish if a given edge symbolises a relation at the start, at the end, or in several parts of the work under study. Furthermore, because temporality is not being accounted for, there is usually no way of relating the network visualisation with the unfolding of the source narrative. While prototypes such as those discussed in Roberts-Smith *et al.* (2013) offer sophisticate ways of dynamically visualising the text of theatre plays, they do so in a way that is unrelated to character network modelling.

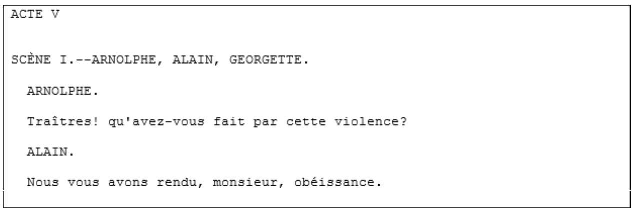
Based on these observations, we set out to develop an open source web application which models the character-system of theatre plays as a sequence of network states synchronised with the actual narrative content (https://github.com/maladesimaginaires/intnetviz). This paper proposes a high-level overview of our application , successively focusing on the underlying structure extraction process, the conception of the graphical interface, and the range of uses envisioned for it. In the conclusion, we evoke the ways in which we intend to develop it and reflect on the potential significance of this development at a more epistemological level.

Tool overview

The underlying workflow has been divided into two parts. First, the text of a play is processed using *Orange Textable* (http://langtech.ch/textable, Xanthos 2014), an open source text analysis add-on for the *Orange Canvas* (http://orange.biolab.si/) visual programming environment: in particular, the play is divided into its component parts (acts, scenes, lines) and the characters present in each scene are identified and associated with each line. These data are then imported into a web interface based on the open source *D3* JavaScript library (https://github.com/mbostock/d3, Bostock et al., 2011), which allows the user (author, researcher, teacher, etc.) to manipulate the character network without prerequisite installation.

Structure extraction

The workflow is designed to facilitate the later inclusion of new data. The play used in the initial development phase was Molière's *L'Ecole des femmes*, as found in raw text format on the Project Gutenberg website (http://www.gutenberg.org/files/43535/43535-0.txt). Theatre plays constitute a privileged input for the automatic extraction of structural information: such information is in general explicitly encoded in these data, as illustrated by the excerpt of Molière's play reproduced on Figure 1. It is worth noting that the extraction phase can be readily adapted to take advantage of cases where structural information has been formally encoded using TEI-XML annotation for instance, such as the "Théâtre classique" database used by Karsdorp *et al.* (2015). We are currently investigating the possibility of extending our approach to a large body of plays in this way.



```
ACTE V

SCÈNE I.--ARNOLPHE, ALAIN, GEORGETTE.

  ARNOLPHE.

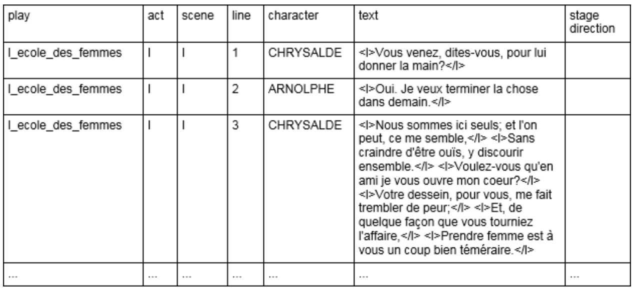
  Traîtres! qu'avez-vous fait par cette violence?

  ALAIN.

  Nous vous avons rendu, monsieur, obéissance.
```

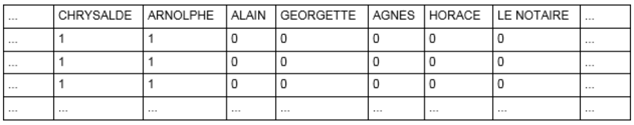
Figure 1. Excerpt of L'Ecole des femmes illustrating the explicit structuration of the data

Structure extraction is performed by a mostly linear chaining of segmentation and recoding operations based on regular expressions which gradually transform the raw text of the play into the tables that will be later used for controlling the web interface. Each table has the same number of rows, corresponding to the extracted lines of the play. The first table gives the text of each line (lightly annotated in XML) along with the associated character and stage directions (Table 1). The second table indicates the presence or absence of each character when each line is spoken (see Table 2).



play	act	scene	line	character	text	stage direction
l_ecole_des_femmes	I	I	1	CHRYSALDE	<l>Vous venez, dites-vous, pour lui donner la main?</l>	
l_ecole_des_femmes	I	I	2	ARNOLPHE	<l>Oui. Je veux terminer la chose dans demain.</l>	
l_ecole_des_femmes	I	I	3	CHRYSALDE	<l>Nous sommes ici seuls; et l'on peut, ce me semble,</l> <l>Sans craindre d'être ouïs, y discourir ensemble.</l> <l>Voulez-vous qu'en ami je vous ouvre mon coeur?</l> <l>Votre dessein, pour vous, me fait trembler de peur;</l> <l>Et, de quelque façon que vous tourniez l'affaire,</l> <l>Prendre femme est à vous un coup bien téméraire.</l>	
...	...	...	...	...	...	...

Table 1. First rows of the table containing the extracted text and stage directions



...	CHRYSALDE	ARNOLPHE	ALAIN	GEORGETTE	AGNES	HORACE	LE NOTAIRE	...
...	1	1	0	0	0	0	0	...
...	1	1	0	0	0	0	0	...
...	1	1	0	0	0	0	0	...
...	...	...	...	...	...	...	...	...

Table 2. First rows of the table indicating the presence or absence of each character when each line is spoken (the first four columns are identical to Table 1 and have been omitted, along with the last few character columns)

Applied to *L'Ecole des femmes*, the process was found to give fairly reliable results: about 98% of the lines were correctly extracted. Most errors could be fixed by determining *a priori* the set of acceptable character names in a given play. An unexpected source of errors was the assumption that characters could be consistently identified by a single string; even without taking into account situations where a character is explicitly "renamed" as part of a surprise effect, linguistic processes such as the succession of indefinite and definite articles in French discourse lead to formal variations in the designation of characters.

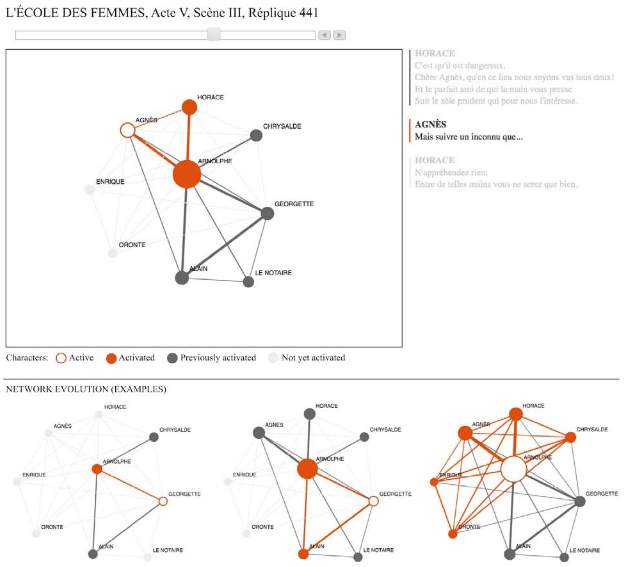
Interface

Data files are then imported into a browser and D3 is used to build an interactive visualisation of the character-system (a demo is available at http://bit.ly/network-demo) where the state of the network is synchronised with the current line (Figure 2). Character nodes are positioned using a force-based layout. Browsing the text simultaneously updates the network, line, and position indicator (act, scene, line). At each step, the weight of edges (expressed by their width) increases with the number of co-presences between the characters up to this point. Similarly, the weight of nodes (their radius) increases with the number of lines spoken by this character.

A character node can be in one of four states. It is:

- "active" when the character is speaking.
- "activated" when it is present in the scene but not active.
- "previously activated" if it was present in the play but is not currently active nor activated.
- "not yet activated" if its first appearance is in a later scene.

The latter state makes it possible to offer a view of the final network state, highlighting absences as well as presences in the earlier stages.



L'ÉCOLE DES FEMMES, Acte V, Scène III, Réplique 441

HORACE
C'est qu'il est dangereux,
Chère Agnès, qu'en ce lieu nous soyons vus tous deux!
Et le parfait ami de qui la main vous presse
Suit le zèle prudent qui pour nous l'intéresse.

AGNÈS
Mais suivre un inconnu que...

NETWORK EVOLUTION (EXAMPLES)

Figure 2. User interface. [Above] Agnès is speaking in presence of Horace and Arnolphe; all characters have already intervened except Oronte and Enrique, who will appear in the final scenes. [Below] Three moments of the unfolding character network (lines 41, 359 and 536)

Uses

We display each line in front of the matching network state for a reason: the network does not exhaust the richness of the play. Since co-presence analysis does not consider the actual content of lines, it cannot–nor aims to–account for discursive references to characters. However, by extracting an actantial model from speech turns, the tool provides a concise and dynamic representation of the enunciative structure of the play. Paired with background knowledge about theatrical narration, such a visualisation offers new ways of reading.

From a philological perspective, relating sociological variables (gender, age, social status) with structural properties of the network (dynamical statistics, centrality measures, word and line counts) helps clarifying which profiles lead the interactions, which ones merely react to them, and which ones are excluded from them, revealing potential social stigma. By expliciting not only the presence but also the absence of links between certain characters, the proposed visualisation may contribute to a visual and interactive deconstruction of the plays (Derrida, 1967).

By allowing the user to browse through successive pictures of the interactions, the interface provides a unique opportunity to "play" the play and visualise the flow of speech between characters. We believe that this playful dimension is particularly interesting for pedagogic uses, especially when discovering a new narrative work with students.

Last but not least, our method can also be applied to any text in the course of the writing process. In this context, disposing of a visualisation of existing interactions at each moment of the text may help the writer distance herself from an impressionistic representation.

Perspectives and conclusion

One of the most significant benefits of a digital humanities approach is the dialectic relation created between the development of a prototype and the verification of scientific hypotheses. Discussing seemingly trivial design issues like the number of colors requested to map the network relations has frequently led us to expliciting and fruitfully questioning differences in our epistemological backgrounds. Thus we consider the following perspectives not only as potential improvements to our tool but also, more importantly, as opportunities to challenge our own theoretical preconceptions:

- Further enriching the visualisation (e.g. by adding line count histograms or highlighting of the first intervention of a character) would benefit the back-and-forth movement between the content and the structure of a given play.
- The dynamical nature of the interface would enable us to compare the distinctive features of different plays not only in terms of the final state of character networks, but also and more importantly, of their evolution; this should help bring out "interactional styles" and discover *Familienähnlichkeit* (Wittgenstein, 1953) by author or period.
- Other kinds of texts will benefit from such a dynamical analysis: other fictional texts such as screenplays, but also linguistic transcriptions as used in conversation analysis.

By allowing the user to browse the content of a narrative and manipulate an interactive character network, our motivation is ultimately to contribute to a better integration of distant and close reading practices.

Work In A Globalised World. Allocation Algorithm To Add Labour Relations To Digitised Census Data

Richard Zijdeman
richard.zijdeman@iisg.nl
International Institute of Social History

Rombert Stapel
rombert.stapel@iisg.nl
International Institute of Social History

Contemporary studies on social inequality often focus on income or status attainment, but neglect the fundamental underlying relationship between employer and employee, referred to as a 'labour relation'. This negligence of labour relations (for and with whom one works) was for a long time of no concern, as the employer-employee relationship was predominant in the period after World War II. However, the current fierce debate on the desirability of precarious work among the rising number of freelancers and independent contractors around the world, as well as the increased media attention and consumer awareness of 'forced labour', shows that employer-employee relationship is not a universal constant, but the result of a much broader historical context. Moreover the interest in the historical context of social inequality is now bigger than ever, judging by both the academic and media impact of recent publications (e.g. Clark, 2014; Piketty and Goldhammer, 2014; van Zanden et al., 2014).

In order to describe and explain the historical context of shifts in labour relations and to recognize global connections between these shifts, a taxonomy of labour relations covering the past five centuries was devised by the participants of the Global Collaboratory on the History of Labour Relations (https://collab.iisg.nl/web/LabourRelations/; Figure 1). This collaboratory – hosted by the International Institute of Social History in Amsterdam (http://www.socialhistory.org) – has grown in the past decade to an online scholarly community of dozens of regional experts across the world and from various scholarly disciplines, such as social and economic historians, archaeologists and sociologists.

Using the taxonomy (Lucassen, 2013) (Figure 1), accompanying codebook and guidelines for data entry, the global collaboratory has gathered data on labour relations for more than twenty countries, using five temporal cross-sections (1500, 1650, 1800, 1900, [Africa: 1950], 2000) (Brown and van der Linden, 2010; Hofmeester and Moll-Murata, 2011; van der Linden, 2008; Lucassen, 2008). Databases of many more countries and regions are currently being prepared. For each country and cross-section a set of scholarly products are created that consists of a predesigned database with 1) population and demographic data and 2) details of the labour relations. A methodological paper explaining the choices made in the data collection for each country and time period accompanies the database. Both the database and methodological paper are verified before they are provided online as open access publication.

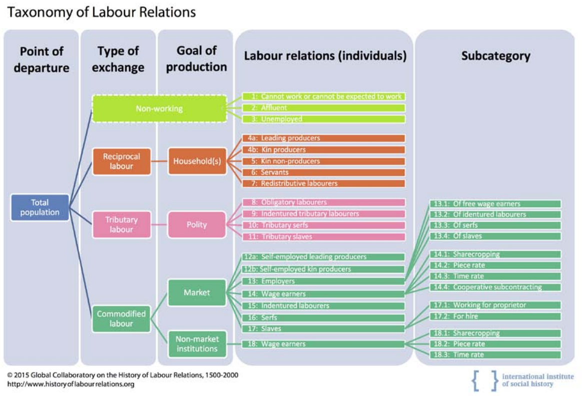

Figure 1. The taxonomy of labour relations, 2015

Until now, most of the data gathered are manually derived from aggregated sources, similar to contemporary occupational censuses, mainly for the period before 1800. The main aim of this paper is to present an alghorithm that was developed to automatically derive labour relations from digitized census materials. We therewith improve on the traditional way of working in the following ways. First, our alghorithm specifically applies to the biggest two projects that digitize census materials in the world NAPP and IPUMS, therewith providing a major contribution to the collection of labour relations for the post 1800 period and for the entire world.

A second advantage of the algorithm is that it provides the first alternative derivation of labour relations and thus can be used to test the reliability of the traditional derivation of labour relations. For many of the digitized censuses both original aggregated tables as well as the individual level data have been preserved, thus allowing for a reliability test of both methods.

The third advantage our algorithm provides is that is able to derive labour relations from individual level census data, thus allowing for more rigorous tests of hypotheses on labour relations. For until now, labour relations have just been gathered from aggregated census tables, only allowing for national comparisons and hypothesis testing. Also labour relations for the past two centuries have only been gathered for three cross-sectional years, while census data is available by decade from ca. 1850 onwards. By being able to attach labour relations to individuals, for the first time descriptive results on heterogeneity of labour relations within countries as well as over time will become available. Moreover, researchers will be much more able to zoom in on the characteristics related to changes in labour relations, such as individual characteristics (e.g. age, gender, education), household composition (e.g. extended family, sibling composition), and historical context of the municipality, region or state (e.g. level of development, political orientation) and therefore be able to provide more rigorous tests of hypotheses on changes in labour relations.

For this purpose, an algorithm is created to allocate labour relations to each of the millions of individual records that are part of the IPUMS databases. This algorithm was first tested on the censuses of the United States between 1850 and 2010. While an earlier version was written in R, the current algorithm was written in SPSS syntax, a fourth generation programming language, as SPSS proved to be better equipped for our purpose and to handle the large file sizes (4-10 GB). In the end, the algorithm will be available to all users of the IPUMS databases.

Starting from the total population, in each iterance a proportion of the records was allocated to a certain labour relation until all records were assigned. Different variables were used or combined, including age, class of worker, employment status, whether someone was considered in the labour force, their occupation, whether they lived on a farm. Here, the order of the different allocations is very important. Broadly speaking, the algorithm moves from the general to the detail. The end result is an enormous database of labour relations, both in the United States and the wider world. This allows us to study shifts in labour relations in much more detail than before (for example: Figure 2). As the census also includes numerous other information, including for instance place of residence, it is also possible to study in great detail geographical factors

(Figure 3, or the role of education, gender, age, ethnicity, household composition, migrant status, wealth, and many other things.

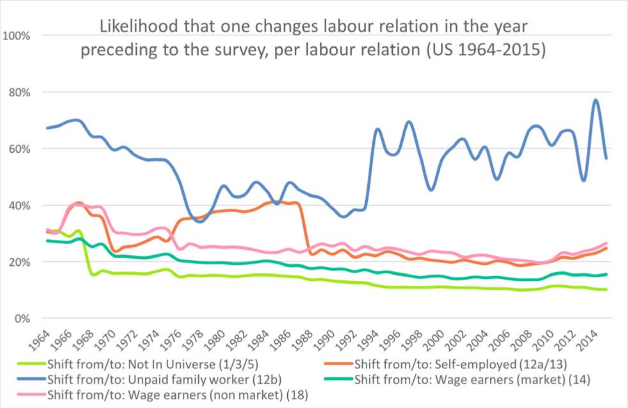

Figure 2. Likelihood that one changes labour relation

Although the IPUMS project has done much effort already to harmonise the different census data, and although historical census takers were also much aware of the need to create uniform censuses both national and trans-national, the algorithm can easily be adapted to the specifics of each of the sources used by the Collaboratory. This means that changes in categories in the census, but also changes in the meaning of census category labels can be adapted to. A future goal is to create an updated version of the algorithm, that allows not only an allocation of a labour relation, but also provides a certainty value. This update is expected in the coming months. Also, in our paper, in addition to presenting the algorithm itself, we will provide a complete research cycle for the US census data from 1850-2013. We start by deriving the labour relations for each of the census years and show our census-specific adaptations of the algorithm to account for historic changes in census taking, such as changes in instructions or the meaning of census category labels. Next, we will describes shifts in labour relations in the US for the period under study using amongst others animations as depicted in Figure 3. Finally, we will derive and test hypotheses on acts that affect self-employment in the US, such as the Midwives Act, that forced women out of self-employment.

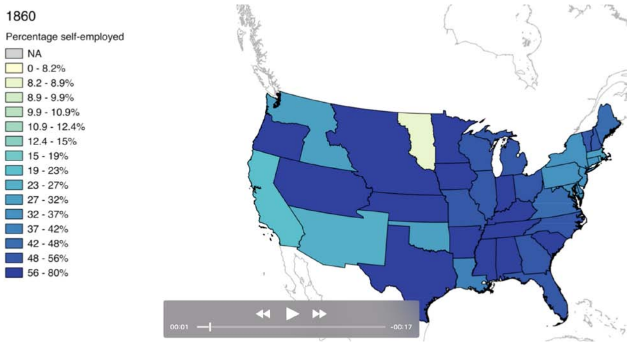

Figure 3. Still of an animation of changes in self-employment in the US, 1850-2013

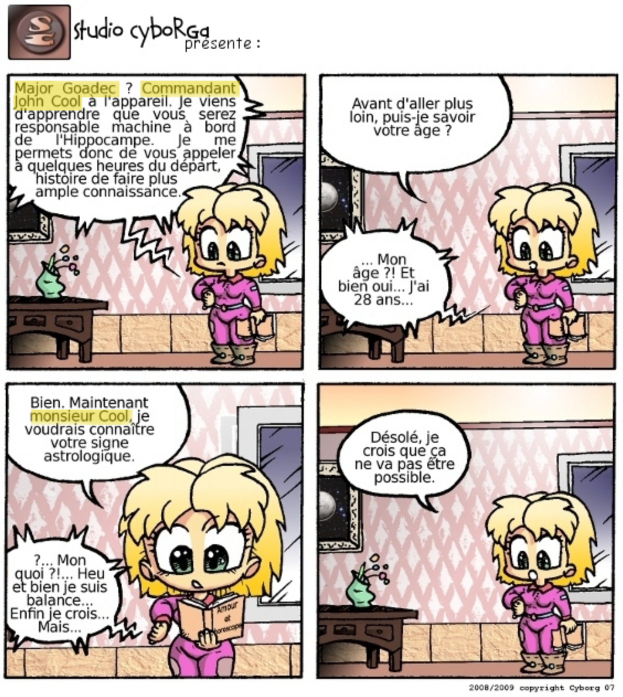
Huge amounts of comics are being published on a daily basis. However, the textual data that are circumscribed in comics' speech balloons and thought bubbles are highly unstructured, and very hard to automatically extract and digitize. Several automatic techniques have been used to automatically detect the shapes, sizes, and contents of speech balloons and thought bubbles leading to automatic text digitization and localisation in comics (Rigaud et al 2013; Ho et al 2012). Such advances open new horizons for a myriad of text mining applications to comics, namely, automatic indexing, searching, recommendation and visualization.



Studio cyboRGa présente :
Major Goadec ? Commandant John Cool à l'appareil. Je viens d'apprendre que vous serez responsable machine à bord de l'Hippocampe. Je me permets donc de vous appeler à quelques heures du départ, histoire de faire plus ample connaissance.
Avant d'aller plus loin, puis-je savoir votre âge ?
... Mon âge ?! Et bien oui... J'ai 28 ans...
Bien. Maintenant monsieur Cool, je voudrais connaître votre signe astrologique.
?... Mon quoi ?!... Heu et bien je suis balance... Enfin je crois... Mais...
Amour et horoscope
Désolé, je crois que ça ne va pas être possible.

Named Entity Recognition (NER) is a task of information extraction under text mining that aims to identify in-text references to concepts such as people, locations and organizations, mainly in unstructured natural-language text. NER is very useful for text indexing, text summarization, question answering and several other tasks that enhance the experience between humans and literature.

In a previous study, we developed a simple and original method of Unsupervised Named Entity Recognition and Disambiguation (UNERD) (Mosallem et al 2014) to automatically extract names of people, locations and organizations from French and English (Abi Haidar et al., 2016) newspapers. We then used the text coordinates in the ALTO XML format to automatically locate and highlight the named entities detected by UNERD on the scanned image of the newspaper (Abi Haidar et al 2014). Last, we used UNERD to detect and visualize named entities from French newspaper during the period of the first world war (Abi Haidar et al 2016).

The main challenges encountered in unsupervised NER have been identified and addressed with our original UNERD method when applied on English and French newspapers and French literature. These challenges include but are not limited to named entity disambiguation, named entity boundary detection, and domain-specific dictionary attribution. In comics, in addition to the aforementioned challenges, the case-insensitive text extracted from comics adds the challenge of proper noun detection that we used to handle using POS tagging. We used TreeTagger (Shmid 2005) POS tagger to detect proper nouns, however and like other POS taggers, it works only when applied on case sensitive text.

Here, we use a variation of our UNERD method to detect names of fictional characters in a database of unstructured text from comics that has been recently digitized by our partners at the L3i Labs using an active contour model for speech balloon detection (Rigaud et al 2013). Au lieu of POS tagging for proper noun extraction, we filter stop words that constitute a 5000 word list of most frequent French words. For the dictionary, we use the freebase dictionaries of fictional characters and characters in fiction novels from Freebase. The comics digitised data amounts to around 8000 case-insensitive words in the French language. We evaluate our method's precision by analysing the predicted character names.

Out of 182 predictions of character names made by UNERD, 113 names were correctly predicted. This precision of 62% cannot be compared to that obtained in our previous results with UNERD when tested on case sensitive textual data. We also did not compute the coverage since we do not have any gold standard or any annotated data. In the table below, we see the most frequent characters that were automatically detected. The terms 'FLIP' and 'HUM' could be discarded by adding a list of onomatopoeic terms to the list of stop words thus improving precision to 68%. Our precision compares well to results presented in Cornolti's meta-study of Named Entity Recognition/ Entity Linking resulting in a precision of 69% (Cornolti et al 2013).The extracted character names are then associated with page numbers to help with the automatic indexing of characters that is otherwise very costly in time and human resources. Co-occurrences of character names in the same page are used to detect dialogues or interactions between the characters. Such information, along with the mere occurrences of character names, are used by our partner, Actialuna, in order to enhance digital comics recommendation. Our method can be applied to extract entities from other case-insensitive texts by simply adapting the dictionary to the targeted text. Our results are preliminary and have been tested on a tiny database that is currently being updated.

Minimal Editions in the Classroom: A Pedagogical Proposal

Introduction

Mastering a complete workflow for creating editions when the editor works alone, or has no access to technologists, has proven challenging, leading to the creation and adoption of tools that make the final product conform to pre-determined models (Burnard et al., 2006; Pierazzo, 2015). Although having access to such tools can be very salutary in many cases, the need remains for independent scholars to be able to create their own editions based on unique visions, without recourse to grants or large teams. One of the main challenges we face to achieve these goals is our limited ability to train humanities students in the span of a semester the full stack of skills they would need in order to create digital editions according to standards (MLA, 2011). We believe that by adopting a minimal computing (http://go-dh.github.io/mincomp/) approach, we can achieve such a goal.

This paper reports on a classroom experiment done during a course entitled *Creating a Minimal Edition: From the Manuscript to the Web*, that tries to address these issues in context. The main goal of the course is to introduce students to textual scholarship in general, and to digital scholarly editing in particular (Fraistat & Flanders, 2013). Our core goal is to build a TEI-to-Jekyll workflow and a simple customizable web template to be used for small digital editions, and release it openly to scholars. Underneath our prototype, we adopt the principles of minimal computing. By minimal we understand computing done under a set of significant constraints, where we reduce the stack to the minimum needed technology to accomplish a scholarly need: in this case to produce a critical digital edition that meets standards and teach the necessary skills to students within the course of one semester.

We use our created template to publish a small-scale digital scholarly edition online of one of the most remarkable Spanish literary works, the *Lazarillo de Tormes* (16th century). The course is conceived as a combination between collaborative research and digital humanities design. At all steps of the process, instructors and students work together toward the completion of the digital edition. The course is divided into lectures and recitation sessions. The first is an opportunity for students to become familiar with central ideas in textual scholarship, while focusing on the textual situation of the Lazarillo; the second allow us to put those ideas into practice in the creation of the digital edition.

Underneath our proposal, there are three main theoretical axes of different nature: ethical, technological, and scholarly.

First, we would like to underscore some issues related to execution and interfaces. Well funded research projects may afford IT services or the creation of standalone systems or "workstations" to build and publish their edition, but this is the best case scenario which sometimes is made publicly available; but not always these interfaces are flexible enough and not usable by people with few IT knowledge. Digital scholarly edition, and specially workflow and interfaces, need to be more diffused, more used, easier to build and less expensive, inspired in what has been called the "bricks approach" (Pierazzo, 2015: 116-117). Hence, the need to offer a simple framework that begins on an XML-TEI dataset and ends in a minimal interface, customizable by the user.

Second, and tightly connected with the ethical component, is the relevance of technological choices, which deals with two main issues: the use of available standards and the open source ethos. We believe that digital scholarly edition, and DH in general, must rely on free and standards web services and technologies. Furthermore, we align our project on what it has been called "open source critical edition" (Bodard and Garcés, 2009) underscoring the need to make available all the datasets and scripts involved in the project.

Third, we are aware that for our show-case scenario the term "scholarly edition" is somewhat simplified. For our goal we understand "scholarly" in a large sense where the scholarly paradigm and a critical approach to primary sources are applied. Our work consists on the critical representation of one historical document, taking into consideration the full textual tradition (4 printed editions from the 16th century) of the literary work. The scholarly paradigm is obviously rethought from the digital perspective, giving special attention to execution and workflow, that is to say, giving room to understand concepts such as modeling and presentation. Furthermore, we wish to insist in two other main issues connected with DH discussions. On one hand, the fact that scholars need to take full control of their digital tools, as well as understand digital methods from their hermeneutical point of view. On the other one, we explore complex issues such as collaboration and authorship, in our case, wagering for a GitHub proposal.

Description of the Course

The course is divided into six main units and is conceived as a collaborative project, where each student is in charge of a main chapter of the literary work.

First, we offer a general introduction to textual scholarship and text editing, paying attention to scholarly editing trends from the 19th century to the present, through a selection of core readings in the field. We also offer a theoretical framework for digital editions, specifically to help students understand how digital editions differ from their traditional counterparts. Afterwards, students are introduced to Github and acquire the methodology needed to work collaboratively. The goal of these two sessions is to create a collaborative and robust work environment, and to ensure that all students gather the basic skills to become fully involved. In Unit 2, we present the primary source: the historical context, the argument, the literary relevance and the text of the *The Life of Lazarillo de Tormes and of His Fortunes and Adversities*. This work, published in 1554, is one of the first novellas in Iberian literature and a classic in the picaresque Spanish tradition. We then start planning the digital scholarly edition and its workflow. Students gather the basic approaches to the data modeling and conceptualize the text as a document object, starting from the analysis of the primary source. The next Unit is devoted to the eXtensible Markup Language and the Guidelines of the Text Encoding Initiative. Students gather the basic principles of the Extensible Markup Language, following the Guidelines of the Text Encoding Initiative. We also offer a general overview of the concepts of schemas (RelaxNG) and ODD documents. Each student is in charge of pursuing a textual encoding, marking up the main features: structural parts, typographic features, dates, place, and person names. They also become aware of the process of quality assurance of the text encoding of their peers.

The next steps of the process consists, on the one hand, in introducing students to the basics of Markdown, HTML and CSS, giving students the opportunity to think about data transformation, and to participate in the design and the final presentation format of the edition. On the other, we focus on inputs and outputs and textual migrations. The central node is the eXtensible Stylesheet Language Transformation, and the conversions from text encoding (XML-TEI) to the web (Markdown/HTML).

The last part of the course is devoted to web infrastructure and web publication. Students learn how to build a static website with Jekyll, dealing with the different technologies needed (HTML, CSS, Liquid, Markdown), and how to transfer their work from GitHub to GitHub Pages. We conclude with a minimal introduction to JavaScript, meant to introduce students to simple document interface: in this case the manipulation of the dates, places and person names marked up in the TEI.
