As learning goals, we want our students to be able to participate in an authentic research and editing project, engaging in all steps of the process; to become aware of the challenges and opportunities of the digital medium for scholarly research and editing. We aim to teach how to apply different methods and technologies, to grasp the value of standards, and to understand data modeling and transformation from a theoretical as well as a practical perspective (Rehbein & Fritze, 2012). As a "technical" outcome, we seek to offer the basic skills to work independently in several languages (XML – TEI, HTML and CSS, XSLT, Markdown, Liquid, JavaScript), and a basic understanding of infrastructure (Jekyll, GitHub, Github Pages). Because this course is meant for students of Spanish as well, our program allows students to improve their Spanish language skills while engaging in public-facing, task-driven scholarship.

Our presentation will give us the opportunity to present the online version of the course, the results of the collaborative edition created along the 27 lectures of the semester, and, finally, to release the first prototype for minimal editions as a Jekyll template, in the hope that can be useful to other DH courses and projects.

Testing the Doctrine of Election: A Computational Approach to Karl Barth's Church Dogmatics

Christopher Scott Bailey

Karl Barth's *Church Dogmatics* (Barth, 1969-80) is widely considered to be one of the most influential works of Christian theology since the Reformation, and within it Barth's doctrine of election is considered a decisive contribution to modern theology (Webster, 2004: 1, 88, 93; von Balthasar, 1992: 174). Briefly, the doctrine of election, as a theological topic, describes the manner of God's salvific work, particularly how God determines those who will be saved. Barth's genius was to inscribe election within the relationship of the Father and the Son, Jesus of Nazareth, so that God is both the electing God and the elected human, and the humanity of Jesus is elected even while the divinity of Jesus is condemned. Over the past two decades, theologians have engaged in a rich questioning of the significance of Barth's doctrine of election for his own theology. His elaboration of the doctrine occurs in the document sections, traditionally referred to as paragraphs,[1] numbered 32 through 35 (of a total of 73 plus a fragment), with paragraph 33 being the primary location for Barth's innovative reworking of the doctrine of election. Some scholars, such as Bruce McCormack (McCormack, 2000, 2010) and Paul Jones (Jones, 2011), contest that election is a turning point in Barth's theology, decisively shaping the remainder of the *Dogmatics* to the point that some formulations after election are incompatible with formulations made prior to the doctrine of election, particularly within the context of Barth's Trinitarian ontology. Others, such as George Hunsinger (Hunsinger, 2000, 2008) and Paul Molnar (Molnar, 2002, 2006), argue that while the doctrine of election is the heart of the *Dogmatics*, it is a part of a consistent and coherent whole, and does not mark an incompatibility between what comes before and after.

This paper engages the question of the significance of the doctrine of election, as elaborated in paragraphs 32 through 35, to the whole of the *Church Dogmatics* through algorithmic approaches. It suggests that if a portion of a corpora strongly determines the rest of the corpora after its appearance, there will be textual traces, such as changes in word frequencies and common semantic groupings, that can be detected through computational analysis. It approaches the corpora, consisting of the entire *Church Dogmatics*, including prefaces and forewords written by Barth as well as his unfinished fragments that have been published as the final volume of the *Dogmatics*, though a variety of analytic techniques.

The initial explorations are conducted through topic modeling in order to discover hidden thematic structure in texts (Blei, 2012). Using Mallet, we first run topic models on different collections of paragraphs, from 15 to 30 topics, to discern the thematic structure of the entire corpora, noting especially those topics that seem definitively about the doctrine of election. Given the hypothesis that the *Dogmatics* from paragraph 36 on is determined by the theme of election in a way that the paragraphs leading up to paragraph 32 are not, we break the corpus into paragraphs 1 through 31, 32 through 35, and 36 through 73 plus the fragment that Barth was writing before his death. We then run topic models with the number of topics ranging from 15 to 30, looking for the presence of topics indicating the doctrine of election. We also run similar models for the entire corpus minus paragraphs 32 through 35 in order to see whether election would appear as a theme in the *Dogmatics* without the presence of the paragraphs explicitly committed to explicating the doctrine. Examining the results, we find that election fails to surface as a topic at most levels of granularity when paragraphs 32 through 35 are not included. We find that at all levels of granularity in which the topics are meaningful and coherent, election does not appear as a topic in the corpus consisting of paragraphs 36 through 73, plus the fragment, and we offer an interpretation for why this is the case based on the rhetorical strategy that Barth employs throughout his lengthy work.[2]

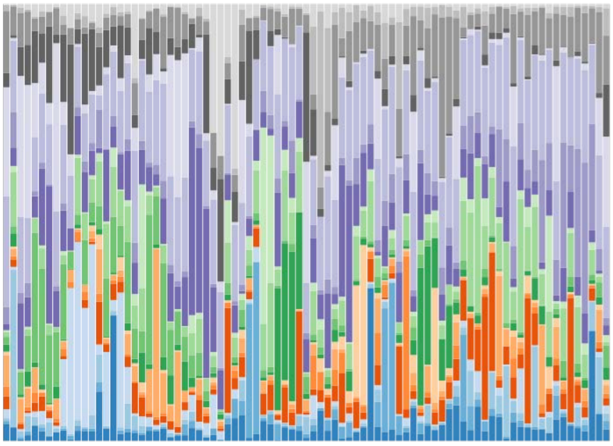

Fig. 1: Graph of topic distributions across the Church Dogmatics. Each column is one paragraph

Our topic models not only provide data for interpretation, but also supply a vocabulary for focusing further computational analysis. Based on words we determined to be distinctive to the theme of election, we examine overall frequency of key terms across the whole corpora, tracking the rise and fall of language specific to election. We also use term frequency-inverse document frequency (tf-idf) to examine which terms are particularly characteristic of individual paragraphs, paying attention to words typically associated with election (Kilgarriff, 2001; Garside, 2000). In a similar vein to that of our topic models, we determine mean tf-idf values for all features (words) in the broken down corpus, consisting of the same three chunks as determined above, at the levels of unigrams, bigrams, and ngrams (n=1-3). Looking especially at the bigram and ngram results, we do see shifts in the importance of some features that fit the hypothesis that Barth's doctrine of election determines the rest of his work. If the proponents of this thesis are correct, there should be an increase in reference to Jesus Christ due to a stronger Christological shift, and a greater sense of the humanity of Jesus due to the election-based eternal identification of the Son, the second Person of the Trinity, with the historical human Jesus of Nazareth. We do see a rise in the importance of 'jesus' in the unigram set, and in the ngram set see the bigram 'jesus christ' appear in the election and after election corpora. In the bigram set, we see 'elected man' appear in the election set, which in Barth's paragraph 33 references Jesus, and interestingly find "man jesus" as the fifth most characteristic bigram of the after election corpora. In relation to the text, we interpret this as an indication of the increased importance of the humanity of Christ in the election and after election corpora.

Based on these results, we explore two conclusions. While our analysis of frequencies and tf-idf values does seem to support the hypothesis that Barth's doctrine of election is a determining point in the *Dogmatics*, the connection between high value features and a substantial conceptual shift is difficult to determine, especially when the conceptual shift regards that ontology underlying theological developments in many doctrinal loci. Our topic models likewise were inconclusive in identifying shifts in the corpus that could be attributed to the paragraphs on election. We suggest that Barth's style of writing, which notoriously circles around and repetitively approaches topics from different angles, though with a traditional theological vocabulary, proves resistant to current algorithmic approaches in textual analysis.

Notes

[1] Barth's *Church Dogmatics* are broken down into volumes, part-volumes, paragraphs, and sections. Paragraphs are the primary organizing unit, though, and each constitutes a coherent thematic whole.

[2] In his text, *Barth*, Webster notes that Barth's, 'preferred method of exposition, especially in the *Church Dogmatics*, is frustrating for readers looking to follow a linear thread of argument. Commentators often note the musical structure of Barth's major writings: the announcement of a theme, and its further extension in a long series of developments and recapitulations, through which the reader is invited to consider the theme from a number of different angles and in a number of different relations" (13). Barth frequently circles around his topics, returning again and again to various doctrines through different paragraphs, in each case attempting to approach in such a way as to show something new.

Concept Modeling the Advertising Chinese Modern Society

Tani Barlow
barlow.tani@gmail.com
Rice University

Jing Chen
ccjj2008@gmail.com
Nanjing University

Ke Deng
kdeng@math.tsinghua.edu.cn
Tsinghua University

In the late 19th century, thousands of industrially produced consumer items flooded into extraterritorially governed, internationally regulated, Chinese, treaty port cities. Foreign commodities were products, and formed the backbone of new, urban, popular consumer culture. Consequently, the advertising industry infiltrated commodity brands and branding techniques into everyday life making commodity images a paramount symbol of civilized urban life. Advertising ephemera thus provides researchers with the conditions for thinking about modernity par excellent since it breaks data free of its origins to demonstrate how concepts embedded in ads ingratiate all consumer cultures (Barlow, 2012).

To force advertising to speak clearly, we launched the Chinese Commercial Advertisements Archive ("CCAA") and 'metadated' (Lev Manovich's term) more than ten thousand high quality images from microfilm copies of three, major, commercial, Chinese newspapers, in the period of 1880 to 1940 (Manovich, 2002). CCAA applies customized metadata schema based on the structural standard, Dublin Core, to each digital image of advertisement, entering all relevant information e.g., cartoon, brand icon, word texts and syntax, plus street names and business titles. Our metadata include: descriptive content, contextual information, bibliographical, technical and image sources of location, copyright status, and owning institution.

Scholars had already studied categories like hygienic/卫生), modern/现代, human/人类, eugenics /优生, and female/女性 in commercial/common ideas. They sampled image-based advertisements in libraries using newspapers, facsimiles and microfilm/fiche. Though more recent research projects have done a poor job of digitizing advertising, still we cannot ignore ad digitalization because historians are still generalizing from a fraction of ads that make up any potential archive. To avoid wasting time and to collaborate with other scholars developing what Franco Morreti calls 'distance reading,' we seek to connect concepts appearing in advertisements to concepts found in sociological texts employing statistical text mining of advertising copy (Hayles, 2012).

Space prevents a full literature survey here, but we have met with pioneering researchers Professor Peter Bol of 'China Biographical Database Project' at Harvard University and Professors Zheng Wenhui and Liu Zhaolin, co-PIs, 'Database for the Study of Modern Chinese Thought and Literature (1830–1930) 'at Taiwan National Chengchi University, and now have available over 30,000 annotated ad images which our proposed paper will use to augment evidences and expand analysis.

On the basis of these 30,000 annotated, newspaper, advertising images, our work is generating a text-mining model for advertising language, a language presenting historically anchored technical difficulties as follows:

1. Lack of word boundaries and punctuation. Word boundaries in Chinese are invisible; worse, ad slogans are not punctuated. Raw data is just a sequence of unsegmented Chinese characters which means text mining in Chinese is comparatively tough.

2. Lacks definitions of vocabulary. Ad texts contain lots of instable, idiosyncratic technical terms, like company names written in different ways, transliterated brand names, product names and so on that we discover during the text mining process.

3. Lack of training data. Most Chinese text mining methods depend on high quality training data, and will fail if the target texts are remarkably different from the training data. Considering that the advertisements that interest us are from regional newspapers over a long period, ad writing style is uncertain due to local linguistic differences. We cannot rely on current training data employing modern Chinese to establish models for mining 1920s syntax, vocabulary, punctuation (or lack of it) word use, semantic references, ideograph variation for 100-year-old print media.

4. Difficulties distinguishing technical and background words. Ad texts are a mixture of technical and background phrases, so it is not a trivial task to distinguish technical terms, our true interest , from noise, words rarely used a century after the ads were published.

We have overcome many of these roadblocks using statistical methods for Chinese text mining and knowledge discovery. Text mining allows us to: 1) discover potential associations among features and terms extracted from advertisements; 2) build links among these and ideological trends in the treaty port urban areas of China during our period by developing Deng Ke's statistical text mining method to establish indices of technical terms ("TT") and metadated association patterns among technical terms ("APTT") (Deng, Geng and Liu, 2014). Word Dictionary Model ("WDM") and Advanced Word Dictionary Model ("AWMD") are tools for word discovery, text segmentation and entity recognition of Chinese texts when training data are not available. WDM can be extended into an AWDM to achieve automatic recognition of TT (distinguishing technical terms from background words/phrases). In this case, technical terms mean the specific phrases we choose from datasets or metadata of images, and establish as concepts in the network.

To this purpose we are developing the following indices: 1) Bibliographical (volume, issue, page numbers, location, date) to enable statistical analysis of ad publication frequency in one or several newspapers over the course of one or many years. 2) Contextual Informational (brand, product category, company, agency, retailer's address, registered nationality) allowing users to establish a statistical picture of a commodity, in specific newspapers, geographical locations and decades. 3) Content index (sorting by drawing of male, female, elders, youth, middle age people, infant, human, animal, plant, Chinese, foreigner) meaning ad images are hybrid artifacts, mixing text and cartoons; 4) Theoretical categories (the modern, human, woman) to identify categories used aggressively in ads. Once TT in each and every advertisement have been successfully located and the indices of TT identified, we can reveal the APTT of ads, defined as subsets of technical terms that tend to co-occur in an advertisement frequently. With TDM, association pattern discovery can be converted into a statistical inference problem and solved by statistical means.

Second, we seek concept networks that connect key concepts embedded in ads to sociological theories. The Concept Network (CN) is a graph that can efficiently present domain knowledge and reasoning based on it. Each CN node is a concept corresponding to an entity or a technical term. Thus if concept A appears in the definition of concept B, we add a direct link from A to B and domain topology will eventually reflect the structure of the knowledge system: closely related concepts are direct neighbors or locate in the same neighborhood, while concepts belonging to different disciplines or areas will be far away from each other in the graph. Building CN requires indices of concepts and their descriptions. Traditional dictionaries might be a source and our period shows an efflorescence of dictionary publication. Another source is online knowledge databases, like Wikipedia. However domain knowledge of sociological theories are not represented in any language or in any period anywhere on the World Wide Web. To compensate, we are erecting an ontological knowledge database of sociological theories as these appeared in journals, books, articles and the archived documents, 'Social Thought in Modern China, 1830–1940' (STMC). With an ontological database, we can open our sharing platform to define and describe key concepts and relationships among them. Interdisciplinary by design CNMACMS users are welcome to participate by entering data into the databases to improve our model.

Notes

As for the studied have been done by schoalrs on categories like hygienic/卫生), modern/现代, human/人类, eugenics /优生, and female/女性 in commercial/common ideas, please see Jin Guantao(金观涛), Liu Qingfeng(刘青峰), *Studies in History of Idea: The Building of Basic Political Concepts in Modern China* (观念史研究:中国现代重要政治术语的形成), Falv Press, 2009; This book has investigated the origins and transformations of tern basic concepts of "gonghe" (republicanism), "minzhu" (democracy), "quanli" (rights), "geren" (individual), "geming" (revolution), "kexue" (science) in modern Chinese history by using the data of "Database for the Study of Modern Chinese Thought" (1830–1930). Huang Kewu (黄克武), "從申報醫藥廣告看民初上海的意料文化與社會生活 1912–1926" explored the idea of "disease" in advertisements published on *Shen Bao* during early 19th century. Tani Barlow's published papers and book, *In the Event of Women* (Durham: Duke University Press, 2017) establish a historical parallel connecting advertisement ephemera, social theory and the woman category.

The Great War on the Web: the Making of Citing and Referencing by Amateurs

Valérie Beaudouin
valerie.beaudouin@telecom-paristech.fr
Telecom ParisTech, France

Zeynep Pehlivan
zeynep.pehlivan@gmail.com
Telecom ParisTech, France

Over the last two decades, an important amount of work has been carried out by cultural heritage institutions to make their collections available online. How are these digitized collections discovered, discussed and shared on the Web?[1]

The digitized heritage around the First World War (WW1) is an ideal area for such analysis: many digitized collections, centenary anniversary (2014–2018) and an important activism around the Great War. Family, local and militant history are the main motivations of persons that get involved in the history of WW1 (Offenstadt, 2010).

Who are the users who publish or discuss around WW1 on the web? Are they amateurs, experts, academics? How do they publish, share and comment digitized documents? These questions matter for the development of Digital Humanities, but also to those in charge of managing the collections. We conduct an exploratory analysis to understand how the activity around the war is visible in the digital space.

Our research consists of two steps:

1. Identification and categorization of web sites dedicated to WW1 and network analysis of the links between those sources, in order to draw an overall cartography of Web activity on WW1 and to identify the position of amateurs.

2. Focus on one of the main nodes in the web cartography (a forum dedicated to WW1), to analyze the forms of circulations of digitalized documents.

We also conducted a series of semi-structured interviews with participants.

Corpus and methodology

The web is ephemeral: working on web archives allows us to rely on a stabilized corpus, which guaranties the reproducibility of the research (Brügger, 2013). Bibliothèque Nationale de France (BnF), in charge of archiving the French web, created a specific web archive collection dedicated to the centenary of the WW1, based on web sources chosen by librarians. The process of archiving is regularly repeated. Our research relies on the November 2014's archive (9 698 633 Urls for a total size of 800 Gb).

The first step of our analysis consists of generating an oriented network graph on web archives to study the relations (materialized by hyperlinks) between web sources related to WW1. We can consider a link as a pragmatic activity of citing or referencing sources (documents, web sites etc.), although in our approach we are not able to qualify the exact nature and function of the link (Saemmer, 2015).

To make the large-scale graphs readable, the nodes in the graph correspond to the *seed urls* chosen by librarians and all the data crawled from each url is agregated to it. Librarians, in charge of web archiving, qualify the producers (or authors) of the websites. Depending on this categorization, we will distinguish institutional websites (public and official, red) and personal websites (personal and associative, blue).

Mapping WW1 on the Web

The network graph allows to evaluate the place of "amateurs" websites compared to institutional sources.

Basic characteristics of our network are calculated using Gephi (Bastian et al., 2009). The network consisted of 514 nodes and 3713 edges with an average degree of 7.22. The average network distance between all pairs of nodes (average path length) is 2.78 edges with a diameter (longest distance) of 8 edges. The clustering coefficient (the degree to which they tend to cluster together) is 0.27 and the modularity index is 0.28. Overall, WW1 French network is made of highly connected pages (~2.7 edges per node) and shows small-world scale-free network properties (Humphries et al., 2008; Watts et al., 1998) with high clustering coefficient, short average path length and a degree distribution following a "power-law" (smallworldness index = 15).

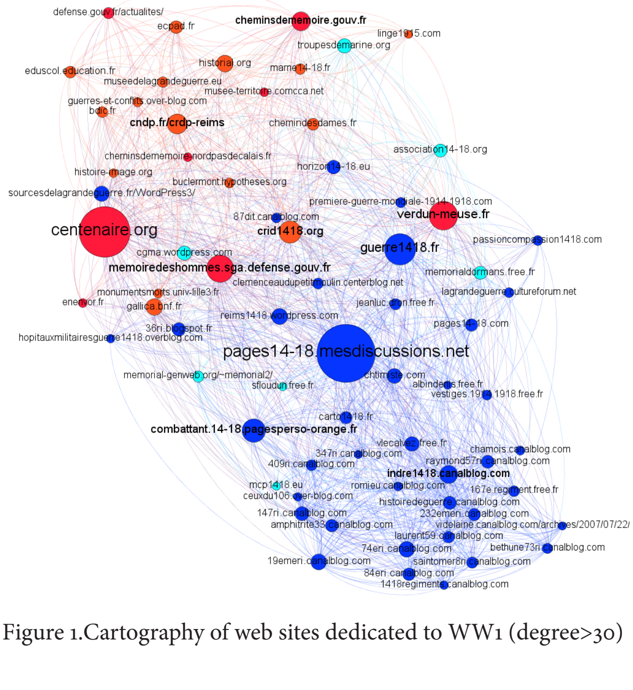

Figure 1.Cartography of web sites dedicated to WW1 (degree>30)

More than half of the sources (52%) come from personal websites that are involved in WW1 as a serious leisure, but not as a profession. The institutional sites are less present (36 %).

To detect influential actors on our network, we use the *degree centrality* which is simply the number of direct relationships that an actor has, the sum of outgoing and incoming links. The network is visualized in Figure 1 by using Gephi, Force Atlas 2 algorithm (Jacomy et al., 2014) as layout with node sizes proportional to their degree centrality. The two main actors are centenaire.org, the official site dedicated to the Centenary, on one side and pages1418.mesdiscussions.net, a web forum managed by amateurs, on the other. Around them, we can distinguish two clusters: the red gathers the institutional sites, while the blue (bottom) gathers all the personal web sites that are intensely interconnected. The forum (Pages 14-18) has a specific position: although it is immersed in the middle of the amateur sphere, it is well connected to institutional sources, because users of this forum are mediators to institutional ressources. The forum constitutes a community of practice (Lave and Wenger, 1991): questions and answers on one side and discussions on the other are two kinds of interactions that allow to share and elaborate knowledge collectively (Conein and Latapy, 2008). Thanks to the forum, a lot of personal websites emerged, each of them dedicated to a specific regiment of foot. Experts of those regiments are the authors of those website that accumate documents (public and personal documents and photographies) on each soldier, each battle, each place occupied.

Degree centrality considers only direct relationships, we also use Hubs and Authorities, known as HITS (Kleinberg, 1999) algorithm. A hub is defined as an actor that points to many other actors and an authority is defined as an actor pointed by many others. HITS algorithm calculates two scores for each actor, hub score and authority score, in a mutually reinforcing way based on the idea that a good authority must be pointed to by several good hubs while a good hub must point to several good authorities (Table 1).

Top 5 Authorities	Authority Score	Top 5 Hubs	Hub Score
memoiredeshommes.sga.defense.gouv.fr	0.0199	pages14-18.mesdiscussions.net	0.0379
centenaire.org	0.0135	centenaire.org	0.0276
crid1418.org	0.0127	guerre1418.fr	0.0251
chtimiste.com	0.0125	combattant.14-18.pagesperso-orange.fr	0.0175
gallica.bnf.fr	0.0124	verdun-meuse.fr	0.0163

Table 1 : Hubs and Authorities

Some authorities, like memoiredeshommes.sga.defense.fr and gallica.bnf.fr, have a very specific profile: as documents warehouses, they receive a lot of links but do not point to other resources. The Centenary website is at the same time a top level authority and hub. The forum, pages1418.mesdiscussions.net, and other personal websites are hubs that point to a relatively large number of authorities.

Forum activity of citations

Based on the specific position of the forum, we decided to focus on it. This forum, founded in 2004 by an amateur, has gradually become a reference site in terms of exchanges and discussions on the WW1. It is a highly active platform with about 400,000 messages in 10 years and about 18,000 subscribers.

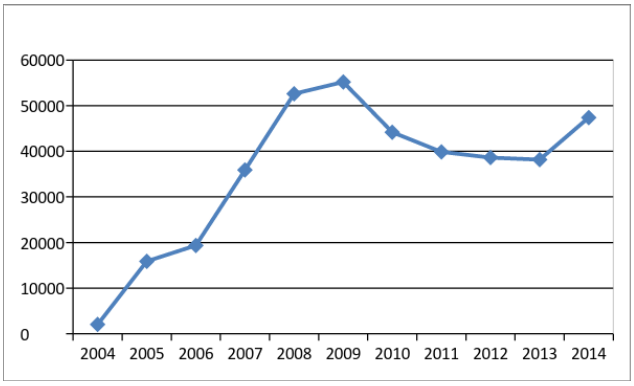

Figure 3. Number of messages published in the forum by year

This forum was archived by BnF in January 2015 and we rely on this corpus for our work. For analysing the activity of citing, we classified the citations into four categories:

- Message_Citation: using a part of previous message
- Quote: text inserted using another source
- Links: hyperlink by using 'link' tag
- Images: hyperlink by using 'img' tag

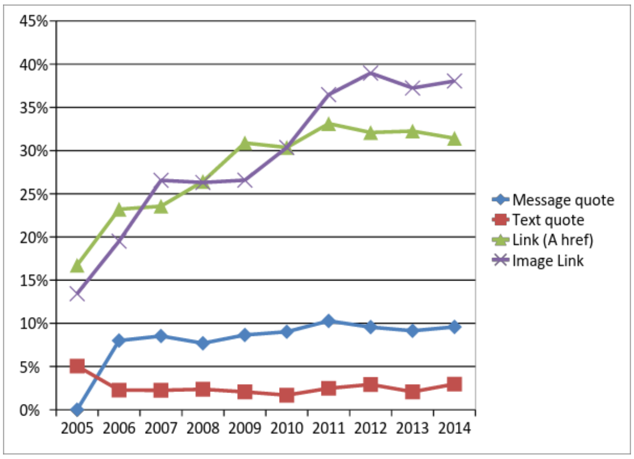

Figure 4. Citations distribution over time

As shown by Figure 4, while the usage of quote and message_citations stays stable, the usage of links and images increases over time according to the increase of digitized documents available on line.

In the corpus, we identified 255,374 image or link citations, an average of 1 citation for 2 messages. We extracted their domain name. The ten more cited domains, which represent 60% of total links, are shown in Table 2.

Netloc	Fréquence

images.imagehotel.net	1041
images4.hiboox.com	1016

Table 2. Most frequent hosts extracted from url citations

The most notable result is the importance of image hosting services. Instead of giving a direct link to an online source, people use hosting services (ex: images.mesdiscussions.net). We can estimate that more that 100 000 citations (40% of total) are of this kind where almost half of them point to images. Users are not confident with the life of web sources. They prefer to download and post the picture than to point to a link which may disappear. The image, in this case is directly available and visible into the post.

Secondly, the forum itself is the most cited website: due to his long history and intense activity, a lot of questions have already been answered. An activity of knowledge management consists in answering a question by signaling an old topic about the same topic.

Memoire des hommes and *Gallica* are the most cited institutional sites. The first one is a gold mine for genealogists who search for ancestors dead during the war and for historians interested in the battles and regiment history. Gallica is a huge warehouse (4 millions of documents): there is a need to identify what kind of documents people are looking for. We extracted the titles of the documents cited and made a content analysis with Iramuteq (Reinert, 1993) (Figure 4); we identified three kinds of documents: photographs and newspapers, official documents ("journaux officiels", "décrets") and documents related to the history of regiments ("historiques des Régiments") from the department of Defense.

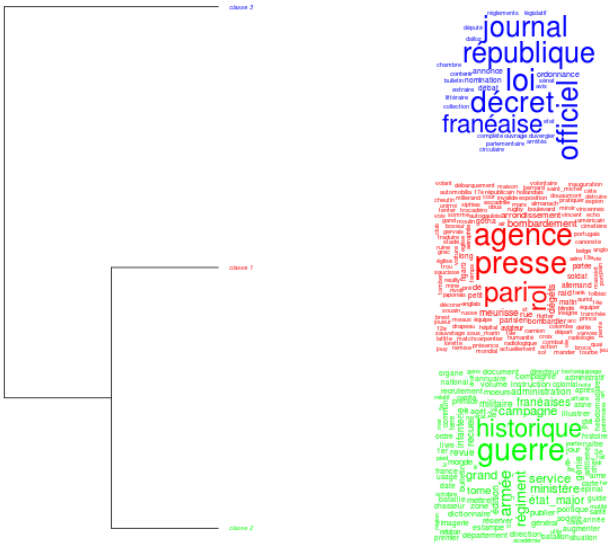

Figure 5. Text Mining clustering of title documents cited from Gallica

Users of the forum also cite a lot of personal web sites dedicated to specific aspects of the war: the history of the soldiers from a specific regiment or squadron for example.

Conclusion

To understand what internet users do with digitized archives, we explored systematically the websites discussing WW1. We developed an original methodology combining web and text mining methods applied to web archives. This method is transferrable. It includes expert advice to qualify the relevant variables for qualifying and selecting sources.

Our analysis shows a great involvment of amateurs (more than half of the websites) in the memory of WW1. They participate to a network of personal websites that gives a specific vision of WW1, more focused on soldiers, regiments, geographic places, objects, remains of war, close to micro-history. A the core of this network, we find the forum, which is the place for interactions and discussions on documents, data, interpretations.

In doing research with digitized resources, amateurs collectively increase their professionalism. Although they do not have the status of academics, they acquire methods in exploring and citing their sources, commenting and sharing with other users. Those amateurs, in doing research with digitized resources, play a major role by discovering and citing institutional heritage documents, adding to their value and creating networks and resources.

Countering Counter Mapping Methods: Constructing A Humanities GIS Methodology In the Age of Electracy

Clayton John Benjamin
claytonbenjamin@knights.ucf.edu
University of Central Florida, United States of America

Most government and business sponsored geographic information systems (GIS) are employed to manage, track, and exploit labor and production. GIS has primarily been used to regulate political economies, "the concern for life is to administer it (life) through controls and regulations so that resources might be rightly apportioned" (Crampton, 2011). Therefore, governments and businesses use GIS is to produce abstract intelligence and knowledge about people and terrains, which they use to make decisions for distributing goods. These goods can include hospitals, parks, roads, military air strikes, etc. By understanding GIS as an engine for political decision making, we can begin to understand that maps are inherently political. However, GIS, because of its ubiquitous, malleable, and slippery nature, can be used for more than simply calculating statistics to influence the distribution of goods. Instead, GIS can be used to distribute ideas, concepts, emotions, and narratives (the qualitative data of our human actions) in order to act as a counter-map.

Nancy Lee Peluso (1995) first defined counter-mapping as an effort to "appropriate the state's techniques and manner of representation to bolster the legitimacy of "customary" claims to resources" (384). In this definition of counter-mapping, counter-maps contest governmental decisions on political economies by representing location specific knowledge that challenges the abstract statistical knowledge sanctioned by the state. Researchers usually create these counter maps by using participatory GIS (PGIS) methods. PGIS is a cartographic research method that asks members of a population of a mapped geographic area to become active producers in their own mapping. It asks the population members to map their own problems, wants, and needs. For example, Sarah Elwood (2006) has used PGIS with community members from low income neighborhoods in Chicago to help community members advocate for neighborhood improvements (197-208). Though this use of counter-mapping may be helpful to advocate for the redistribution of goods, I argue, it doesn't do enough to contest the primary political functionality of GIS. GIS in these projects often simply replicates the dominant ideology of GIS - that its sole function is to be used to make decisions for the distributions of goods within political economies. This definition of counter-mapping has constrained our imaginations and the ability to play with the functions of GIS and to miss out on potential GIS poetics. The central question in consternation is: how can maps function in the age of electracy unconstrained by the ideologies of the paper map?

Instead of focusing on the political and economic functionality of GIS, which I argue is a print centric way of thinking about GIS, what would it mean to create an electronic poetic discourse of GIS? How can GIS be used to map human emotion, desire, and truth? This type of reasoning resists the temptation to define GIS as a tool for deliberate decision making and to understand GIS as a medium for invention. Invention is the counter logic of GIS hermeneutics -- GIS heuretics. Gregory Ulmer (2002) states, "The purpose of the course is to approach electracy by trying to invent it (what I call "heuretics" --the use of theory to invent forms and practices, as distinct from "hermeneutics," which uses theory to interpret existing works)" (4). How can we invent geography for the electronic apparatus? This question can be answered following the models provided by Ulmer. Ulmer invents a method for applying humanities discourse which relies "not on positivism but quantum relativity; not realism but surrealism." Surrealism, then can act as theory that counters traditional positivistic and "rational" decision making. In the Surrealist Manifesto, Andre Breton (1924) writes:

"(I)n this day and age logical methods are applicable only to solving problems of secondary interest. The absolute rationalism that is still in vogue allows us to consider only facts relating directly to our experience. Logical ends, on the contrary, escape us. It is pointless to add that experience itself has found itself increasingly circumscribed. It paces back and forth in a cage from which it is more and more difficult to make it emerge. It too leans for support on what is most immediately expedient, and it is protected by the sentinels of common sense. Under the pretense of civilization and progress, we have managed to banish from the mind everything that may rightly or wrongly be termed superstition, or fancy; forbidden is any kind of search for truth which is not in conformance with accepted practices" (2).

We can see that, just as I'm searching for a theory and method that resists hermeneutic rationalizations of GIS, so were the surrealists resisting positivist rationalism, because these rationalisms limited creativity and human experience. Therefore, surrealism allows humanities researchers to infuse creativity back into the research milieu.

Furthermore, one humanities method that may be applied to electronic map making, GIS, is psychogeography, an avant-garde method developed by the Situationists who were heavily influenced by surrealism. Guy Debord (1959) defines psychogeography as derive, meaning "to drift." He defines derive as "the study of the precise laws and specific effects of the geographical environment, consciously organized or not, on the emotions and behavior of individuals" (3). By implementing psychogeography, the researcher ignores the boundaries and zones of a city, disturbs the modern distance between researcher and space, and allows the researcher to gain the feeling of a place. By performing psychogeography, the researcher is allowed an intimacy with space and place which may change the conclusions he or she may make about a particular space had he or she relied solely on traditional GIS hermeneutics. Here, emotion has been injected into the research paradigm.

This paper then, describes a method of using GIS tracking services to record a pscyhogeography performed in Bradenton, FL. Currently, there is a heroin epidemic happening in Bradenton, FL, particularly in the South Bradenton neighborhood, and there have been several maps issued by the government and local media agencies that track heroin overdoses in Bradenton, FL. To counter map these official and popular maps, I used Debord's drifting methodology which he outlines in "Theory of the Derive," to perform three different drifts. My goal was to record the feeling of South Bradenton. These drifts were tracked using the GIS interface My Tracks mobile phone application by Google, Inc. During the drifts, My Tracks recorded my path as I drifted through South Bradenton, FL. Additionally, I used my cell phone to take images and videos of the neighborhood and I recorded notes, thoughts, and feelings into a notebook with time stamps. Once the drifts were completed, the My Tracks paths were exported to Google My Maps and the photos and notes were imported into the My Map and added to their corresponding places on the My Tracks path. This presentation will showcase these maps and contrast them to the government maps created about the heroin epidemic. My presentation then focuses on my analysis of the results, the usefulness of psychogeography for geographic research in the digital age, and further research needed for the development of a theory for electronic geographic research and methodologies.

Does Character Speech Matter? A Quantitative Approach

Peggy Bockwinkel
peggy.bockwinkel@ilw.uni-stuttgart.de
University of Stuttgart, Germany

Introduction

Character speech is an elementary part of novels. When calculating with German-speaking novels, the question arises, if there is a stylistic difference between character and narrator speech. Given the presupposition that character speech imitates authentic communication, I will answer these questions with a structured series of experiments on deictic expressions, based on statistic and linguistic knowledge.

Theoretical background

Character speech is defined here as direct or cited/ quoted speech, the words and sentences one finds between quotation marks. By drawing on these distinct punctuation markers, it can be separated automatically from the rest of the text. With the beginning of modernism, however, these formal structures have started to dissolve. Between the clear marking of character speech and no marking at all, gradual stages are possible. In these cases, a considerable effort is required to automatically separate character speech from the rest of the novel. An examination of the differences between character and narrator speech therefore can be useful to assess the necessity of such a costly separation.

Deictics are necessary in communication situations to refer to a point in time, space or to certain objects or persons like the speaker or the addressee. In the sentence

Tomorrow I will be there.

every word is deictical. Deictics are context-dependent, which means that in different situations they have different meanings. They belong to different lexical categories – but most of them are function words. The presented approach implies the following premises:

1. Different (non-fictional) texts types show a different frequency of deictic terms. These basic text types have been categorised according to three criteria of communication (dialogical, *face-to-face* and *oral* by Diewald, 1991).
2. Character speech imitates a *dialogue* – which is one of these basic text types.

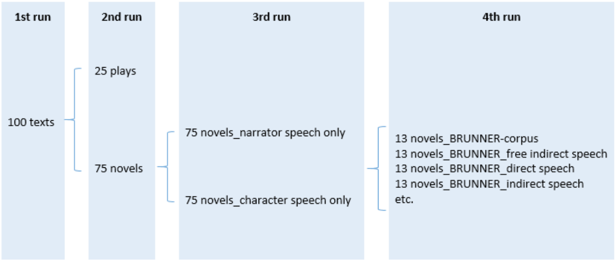
Transferring the first premise on fiction, literary genre-categorisation has to stand back: character speech in novels and plays would belong to one basic text type.

Previous Work

Previous research on character speech in the humanities shows, that it seems to be a subject mainly in the philosophy of language (see Pafel and Dirscherl, 2015). In literary studies, only one monograph on direct speech exists (Müller, 1981). Recently Brunner (2015) showed that the automated tagging of different kinds of speech in German-speaking novels with computerlinguistic methods is possible, but still has weak results – except for direct speech. Her corpus consisted of 13 different novels, which is a rather small corpus. In computational stylistics it appears that most approaches tend to use smaller corpora (e.g Burrows, 1987; van Dalen-Oskam, 2014).

Method

For the corpus, German-speaking plays and novels from the 18th to the 20th century are selected randomly. They are separated into several subcorpora consisting of 25 plays and 75 novels, including the Brunner corpus with 13 novels (Fig. 1).



1st run
2nd run
3rd run
4th run
100 texts
25 plays
75 novels
75 novels_narrator speech only
75 novels_character speech only
13 novels_BRUNNER-corpus
13 novels_BRUNNER_free indirect speech
13 novels_BRUNNER_direct speech
13 novels_BRUNNER_indirect speech
etc.

Figure 1: corpus scheme

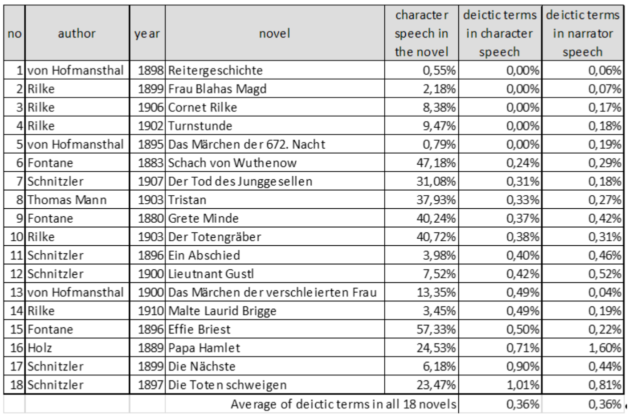
The subcorpus with the plays serves as a benchmark/ reference value: Since plays consist mostly of character speech, they can be compared with the *plays* and *novels_character speech only*-subcorpus. Gries 2008 serves for the statistical basis. Eder's structured experiments in "Does size matter?" (2013) serve as a template for the presented analyses. That means parameters are changed in a consistent and transparent way through the experiment:

The experiment – counting the deictic terms – is run several times (Fig. 1): At first, the whole corpus is tested. For the second run the novels are separated from the plays and for the third run character speech is separated from the rest of the text. Finally, the Brunner corpus is run a forth time with the other categories of speech, e.g. free indirect speech, separated as well.

Since there is no common definition of deictics, nothing like a deictic lexicon exists. In my analyses, I will use a rather straightforward approach: An expression will be regarded as deictic, if it belongs to one of the main deictic categories like time, space, or person and if the deictic reference is its main function. This definition excludes verbs, but includes all function words like temporal and spatial adverbs and a small group of personal pronouns.

Results sample corpus

As a starting point for upcoming research I will present temporary results that are generated by drawing on a small sample corpus of novels in which character speech is separated from the rest of the text and the frequency of deictic terms is analysed (Fig. 2). Then the results are compared with Diewald's results for the basic text types in non-fiction (Fig. 5).



no	author	year	novel	character speech in the novel	deictic terms in character speech	deictic terms in narrator speech
1	von Hofmansthal	1898	Reitergeschichte	0,55%	0,00%	0,06%
2	Rilke	1899	Frau Blahas Magd	2,18%	0,00%	0,07%
3	Rilke	1906	Cornet Rilke	8,38%	0,00%	0,17%
4	Rilke	1902	Turnstunde	9,47%	0,00%	0,18%
5	von Hofmansthal	1895	Das Märchen der 672. Nacht	0,79%	0,00%	0,19%
6	Fontane	1883	Schach von Wuthenow	47,18%	0,24%	0,29%
7	Schnitzler	1907	Der Tod des Junggesellen	31,08%	0,31%	0,18%
8	Thomas Mann	1903	Tristan	37,93%	0,33%	0,27%
9	Fontane	1880	Grete Minde	40,24%	0,37%	0,42%
10	Rilke	1903	Der Totengräber	40,72%	0,38%	0,31%
11	Schnitzler	1896	Ein Abschied	3,98%	0,40%	0,46%
12	Schnitzler	1900	Lieutnant Gustl	7,52%	0,42%	0,52%
13	von Hofmansthal	1900	Das Märchen der verschleierten Frau	13,35%	0,49%	0,04%
14	Rilke	1910	Malte Laurid Brigge	3,45%	0,49%	0,19%
15	Fontane	1896	Effie Briest	57,33%	0,50%	0,22%
16	Holz	1889	Papa Hamlet	24,53%	0,71%	1,60%
17	Schnitzler	1899	Die Nächste	6,18%	0,90%	0,44%
18	Schnitzler	1897	Die Toten schweigen	23,47%	1,01%	0,81%
				Average of deictic terms in all 18 novels	0,36%	0,36%

Figure 2: Percentage of deictic terms (*here*, *now*) in character speech and in the rest of the novel (narrator speech), relative frequency.

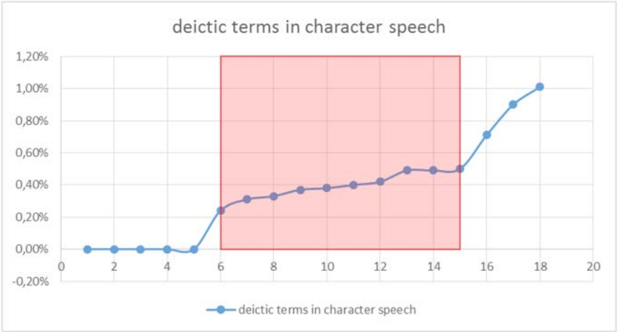


Figure 3: Frequency of deictic terms in character speech of the 18 novels of the table in fig. 2, in ascending order

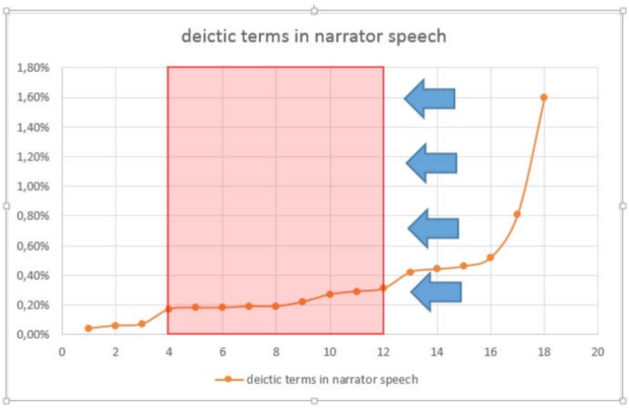

Figure 4: Frequency of deictic terms in narrator speech of the 18 novels of the table in fig. 2, in ascending order

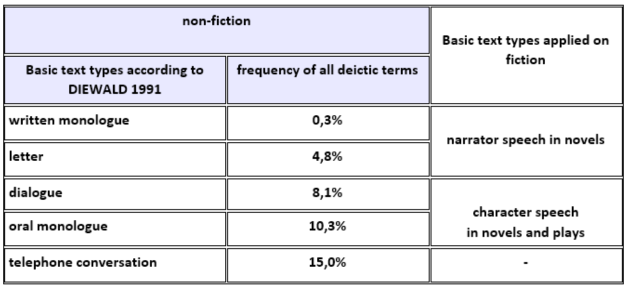
The average values for character and narrator speech (0.36% in either case) show no difference at all (Fig. 2). However, a closer look on the frequency distribution draws another picture: Figure 2 shows that most of the novels (novels 6 to 14) range around 0,4% deictic terms in character speech. In figure 3 the results seen in figure 2 are visualised: in contrast half of the deictic terms in the narrator speech of the novels range a bit higher than 0,2%. This shift is marked by the blue arrows (Fig. 3 + 4). The stability of these results will be evaluated on the complete corpus (see "Methods").

Conclusions

According to Diewald's results the deictic frequency of basic text types is lowest in *letters* and *written monologues*. *Dialogue* and *oral monologue* present a higher frequency of deictic terms, but still topped by *telephone conversation* (Fig. 5). Regarding their principle structure, character speech can be assigned to the basic text types, *dialogue* and *oral monologue*, whereas narrator speech resembles *written monologue* and *letters*.



non-fiction		Basic text types applied on fiction
Basic text types according to DIEWALD 1991	frequency of all deictic terms	
written monologue	0,3%	narrator speech in novels
letter	4,8%	
dialogue	8,1%	character speech in novels and plays
oral monologue	10,3%	
telephone conversation	15,0%	-

Figure 5: Different text types and their frequency of personal, local, temporal and objectual deictic terms, the results refer to Diewald 1991: 383.

Accordingly, the results of the sample corpus indicate a lower deictic frequency in narrator speech compared to character speech, which matches DIEWALD's results on deictic frequency in the basic text types.

Still, for the sample corpus, it is quite problematic to compare these numbers with DIEWALD's results, because in the non-fictional discourses all deictic terms are analysed instead of only two prototypic ones (*here, now*). Since it seems that there is a difference between both types of speech in novels, it nevertheless has to stand the test of the broader experiments with the bigger 100 texts corpus. In addition, for further research another series of this experiment should be run with the same corpus scheme, but set up as a stylometric analysis to see if similar patterns can be found. If the results show a significant difference between character and narrator speech, it is necessary to have character and narrator speech separated in all novels as part of the preparation for digital text analyses.

Introduction: Digital musicology

Computer-based methods in musicology have been around at least since the 1980s[1]. Besides the creation of digital editions (cf. Kepper et al., 2014; Veit, 2015), scholars in this area of study have also been interested in quantitative approaches for musicological analyses (cf. Müllensiefen and Frieler, 2004; Vigilanti, 2007). Such quantitative analyses rely on music information retrieval (MIR) systems, which can be used to search collections of songs according to different musicological parameters. There are many examples for existing MIR systems, all with specific strengths and weaknesses. Among the main downsides of such systems are:

- **Usability problems**, i.e. tools are cumbersome to use, as they oftentimes only provide a command-line interface and also require some basic programming skills to utilize them; example: Humdrum[2]
- **Restricted scope of querying**, i.e. tools can only be used to search for musical incipits; examples: RISM[3], HymnQuest[4]
- **Restricted song collection**, i.e. tools can only be used for specific collections of music files; various examples of MIR tools for specific collections are described in Typke et al. (2005)

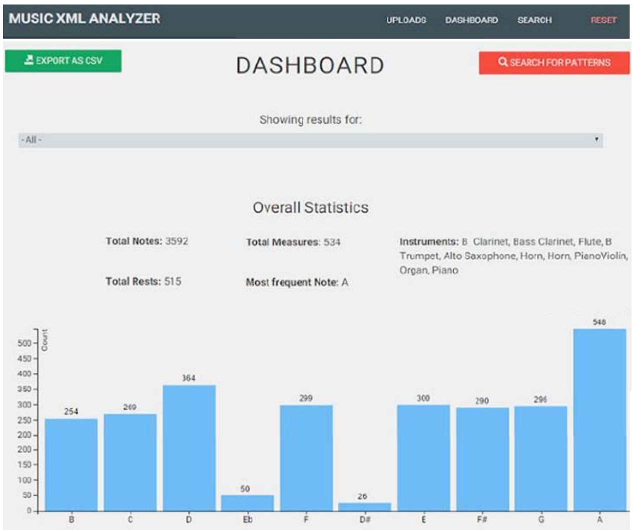
A particularly promising MIR tool can be found in Peachnote[5] (Viro, 2011), which uses optical music recognition (OMR) software to index more than one million sheets from the Petrucci Music Library[6], aiming to provide a search interface for musicology which can be seen as an analog of the Google Books Ngram Viewer[7]. Despite many existing software solutions, we believe that accurate OMR is still a major challenge in digital musicology. At the same time, there are numerous databases[8] at hand, that provide machine-readable music documents, fully annotated with MusicXML (Good, 2001) markup.

On this account, we designed MusicXML Analyzer, a generic MIR system that is trying to overcome the weaknesses of existing MIR tools, and that allows for the analysis of arbitrary documents encoded in MusicXML format.

MusicXML Analyzer: Basic functionality and implementation details

MusicXML Analyzer can be used to analyze songs in a quantitative manner, and to search for specific melodic patterns in a collection of songs. The results of the analyses are rendered as virtual scores and can be viewed in any recent web browser. In addition, the queries and the results can be played as a synthesized audio file; all analyses can also be exported as PDF or CSV files.

The tool comprises three main components: (1) the upload function, (2) the analysis function, and (3) the search function. After one or more files in MusicXML format have been uploaded via an intuitive drag-and-drop dialog, the analysis component parses the data and calculates basic frequencies; the results are stored in an SQL database and can be displayed in a dashboard view (cf. Fig. 1).



Showing results for:

- All -

Overall Statistics

Total Notes: 3592

Total Rests: 515

Total Measures: 534

Most frequent Note: A

Instruments: B Clarinet, Bass Clarinet, Flute, B Trumpet, Alto Saxophone, Horn, Horn, PianoViolin, Organ, Piano

Figure 1: Snippet from the dashboard view, showing basic frequencies for a corpus of MusicXML documents.

The dashboard displays the following information, either for an individual song, or for a corpus of multiple songs:

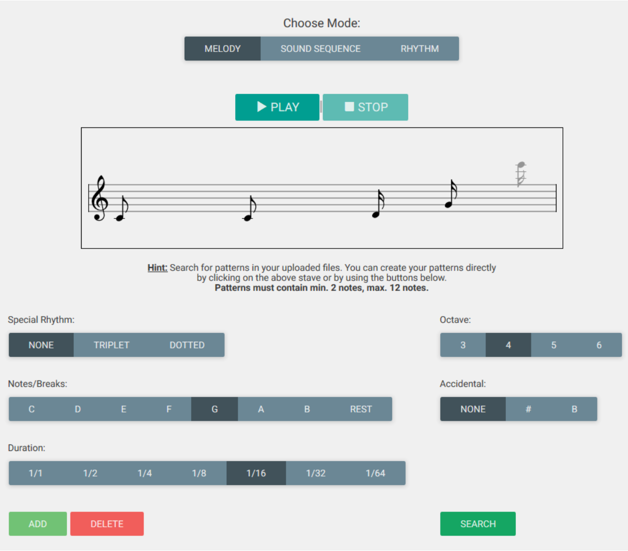
- Overall statistics for single notes, rests and measures
- Types of instruments used in the song (if described in the MusicXML data)
- Frequency distribution for single notes, intervals, keys, note durations and meters

Via a dedicated search function, a corpus of MusicXML documents can be queried for melodic patterns on different levels of information:

- Search for a sound sequence; example: c', c', g', g'
- Search for a rhythmic pattern; example: eighth note, eighth note, quarter note, quarter note
- Search for melodic patterns, i.e. a combination of sound sequence and rhythm; example: c' / eighth note, c' / eighth note, g' / quarter note, g' / quarter note

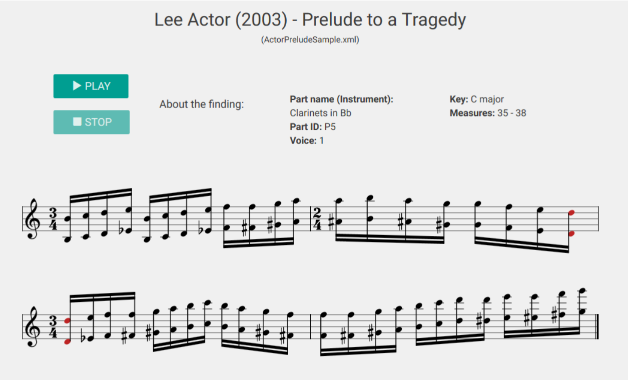
Search queries can be entered via a virtual staff that was realized with the VexFlow library[9] (cf. Fig. 2). Once a search pattern has been entered, it can also be played as a synthesized Midi sequence, which was realized with the Midi.js library[10].

After a query has been submitted, all results – i.e. the songs that contain the search pattern – are displayed in a list view. The list contains the name of the song and also the number of total occurrences of the search pattern in that song. By clicking on one of the song items in the list, a virtual score is rendered for the whole song; the search pattern is highlighted whenever it occurs in that virtual score (cf. Fig. 3). The whole song can be played directly in the web browser, or downloaded for further analyses as a PDF (realized with the jsPDF library[11]).



Hint: Search for patterns in your uploaded files. You can create your patterns directly by clicking on the above stave or by using the buttons below.
Patterns must contain min. 2 notes, max. 12 notes.

Figure 2: Interface for entering queries to identify tonal, rhythmic, or melodic patterns in a corpus of MusicXML documents.



Lee Actor (2003) - Prelude to a Tragedy

(ActorPreludeSample.xml)

About the finding:

Part name (Instrument): Clarinets in Bb
Part ID: P5
Voice: 1

Key: C major
Measures: 35 - 38

Figure 3: Virtual score rendering of a document from the results list; the search pattern is highlighted in red color.

MusicXML Analyzer was implemented by means of standard web technologies (HTML, CSS, JavaScript, PHP), in particular by utilizing the following libraries and frameworks: Laravel[12], jQuery[13], D3.js[14], Bootstrap[15], Typed.js[16], Dropzone.js[17].

A short demo video that showcases the main functionality of the tool is available at https://dl.dropboxusercontent.com/u/4194636/MusicXML-Analyzer.mp4

A fully functional online demo[18] of MusicXML Analyzer is available at http://music-xml-analyzer.herokuapp.com/

MusicXML Analyzer can also be downloaded and modified (according to the MIT open source license) from GitHub: https://github.com/freakimkaefig/Music-XML-Analyzer.

Future directions

In its current implementation, MusicXML Analyzer performs an exact match search, i.e. only documents which have the exact same value in their MusicXML markup will be found by the search function. We are planning to implement a more sophisticated melodic similarity algorithm (cf. Grachten et al., 2002; Miura and Shioya, 2003) that allows for the configuration of different similarity thresholds.

At the same time, we are adapting MusicXML Analyzer for a recent project on a large corpus of German folksongs. Besides monophonic melodies, this collection of folksongs also contains machine-readable metadata (region, date, etc.) and lyrics. Accordingly, we are trying to enhance the search features of MusicXML Analyzer in a way it can not only search songs for melodic patterns, but also for metadata parameters and keywords from the lyrics. Such an enhanced MIR system could be used to analyze the following research questions:

- Are there characteristic melodic and linguistic patterns for German folksongs, from a diachronic perspective as well as from a regional perspective?
- Are there melodic-linguistic collocations, i.e. do certain melodic patterns co-occur with certain keywords or phrases?

The Preparation of the Topic Model

Rachel Sagner Buurma
rbuurma1@swarthmore.edu
Swarthmore College, United States of America

Replacing "How something is made, with a view to finding out what it is" with "How something is made, with a view to making it again" – the Essence with the Preparation – is linked to an option that's completely antiscientific: in reality, the starting point of the Fantasy [of the critic's writing of a novel] isn't the Novel (in general, as a genre), but one or two novels out of thousands.

-Roland Barthes, *The Preparation of the Novel,* Session of December 9, 1978, 13.

The Literariness of Topic Modeling

This short paper reports on the progress of my attempt to construct a reading of topic modeling using state-of-the-art literary criticism. I argue that dominant digital humanities understandings of topic models assume some of the characteristics of literature most essential to twentieth-century criticism – counter-factuality, a mediated form that is ultimately separable from aesthetic characteristics, and an efficient, self-enclosed, total form. More specifically, I show that topic models also tend to be read by digital humanists according to the assumptions, protocols, and caveats we accord to the interpretation of realist fiction. While often revealing and productive, many digital humanists' uses of topic modeling are indebted to assumptions about the literariness and fictionality of topic models that we have yet to fully understand. Drawing on work by Stephen Ramsay, Johanna Drucker, Alan Liu, and others that theorizes continuities between the values of literary criticism and computational processes, I suggest that we temporarily set aside the idea that topic modeling reveals the "contents" of a set of novels (or of any other corpus). Instead, drawing on Roland Barthes' late work on *The Preparation of the Novel*, we might rethink topics as preparatory notes written by no one, as an imaginary archive whose contents furnish a productively alienating, too-perfect map of the novel's preparation. In *Preparation*, Barthes moved away from his earlier work's emphasis on totalizing interpretations of literature's meaning to think about models of the text that allow for a more partial and slow view of the process of meaning creation. Topic modeling has the potential for helping us towards a Barthesian reimagination of the novel's reader as the novel's writer, of the search for the fantasy origins of a novel as a method that pulls us away from formal totality and a form-content divide. While this reorientation comes out of literary studies, I also suggest that it might have applications for more instrumental uses of topic modeling outside the realm of the humanities, in which assumptions about topics as equivalent to a document set's "contents" also tend to draw on our conventions for reading realist genres.

Fictionality and the Topic Model

The past few years have seen the rapid popularization of topic modeling among humanist scholars in general, and among scholars of literature in particular. The literature on topic modeling abounds in stern and salutary warnings about the limits and dangers of topic modeling for humanistic study. One can read about the dangers of introducing algorithmic black boxes into literary research, the concern that literary scholars are unprepared to fully (or even partially) interpret the topic models and their related data, and the worry that they fail to understand even the interpretive choices made during corpus preparation. Part of the worry derives from a larger assumption that topic modeling "reveals" the "contents" of novels. We assume that literary critics dipping their toes into topic modeling will shed their traditional interpretive caution in the face of the algorithm's authority, and will misunderstand the un-semantic nature of topics or accept meaningless correlations as meaningful. I want to suggest that all such warnings are relevant only given a very limited understanding of what a topic model is, its imagined relation to the corpus from which it derives, and the goals of the model's interpreter. These warnings do usefully help us think about some of the invisible interpretive choices we make when we choose chunk and clean documents, apply stoplists, select a number of topics to train, and - most importantly, assign semantic labels to unsemantically generated topics. And yet these warnings assume either that topic models aspire to be mimetic maps of the corpuses they model or that technologically unsophisticated interpreters of topic models imagine that this is the case. This is not surprising; the assumption that topic models are a realist genre is pervasive in literature on topic modeling, literary and otherwise. Yet if we relieve ourselves of this constraint and instead substitute a more plausible frame – the topic model's fictionality – we will be able to enjoy a wider range of relations between model and corpus.

In place of assuming that topic models belong to the realm of realism, then, we might pay more attention to the generative uncertainty of topic modeling and to its literal fictionality. Topics are probabilistically-created formations, and the algorithm that generates topic models is based on the enabling – but crucially, counterfactual – "assumption that documents have multiple topics." (Boyd-Graber et al., 2015). By looking at the documents we offer it, the algorithm generates topics that, in given proportions, compose each document. (Or, rather, it generates the probability that a certain percentage of words in every given document were generated by a given particular topic.) Topics, of course, don't actually exist prior to the documents that generate them; they don't actually exist independently in the same way the documents at all. They are, in a certain sense, fictions. Topics are things that might have existed – but didn't! - given the existence of the document set in question. While we can and sometimes do relegate this fact to the realm of methodology, the fictionality of topics is crucial to remember for any literary-critical uses of topic modeling, for it reminds us that these models offer us a view of our document set radically at odds with any other more literal sources of a novel we might use – such as an author's notes towards a novel, or a catalog of the virtual or actual library of books a novelist brings to the writing table, or even the looser sense of social "discourses" that exist prior to novels and which we might imagine in part "composing" a novel. Using a few targeted examples drawn from topic models of corpuses of nineteenth-century novels of varying sizes and comparing them to some examples of nineteenth-century novelists' notebooks, I suggest that reimagining topic models as fictional notes might be not just a theoretical exercise but a practical way of conceptualizing the relation between topic model and corpus.

[3] Benjamin Schmidt warns, for example, that "simplifying topic models for humanists who will not (and should not) study the underlying algorithms creates an enormous potential for groundless — or even misleading — "insights."" Schmidt worries that a pair of assumptions about topic models – that they are "coherent" and "stable" – "let humanists assume that the co-occurrence patterns described by topics are meaningful; topics are useful because they describe things that resemble "concepts," "discourses," or "fields."" Schmidt is worried, that is, that the appearance of semantic meaning we find in "good" topics will seduce humanists into thinking that they have discovered the "contents" of novels – whereas what topic modeling really offers us is exactly a non-semantic machine indexing of a set of texts about which our approaches tend to be based on ground assumptions about semantic meaning. Benjamin Schmidt, "Words Alone: Dismantling Topic Modeling in the Humanities." *The Journal of Digital Humanities* 2:1 (Winter 2013), http://journalofdigitalhumanities.org/2-1/words-alone-by-benjamin-m-schmidt/

[4] One recent paper, for example, describes good topics with the example of "trout fish fly fishing water angler stream rod flies salmon…" explaining that the topic "is specific. There is a clear focus on words related to the sport of trout fishing. It is coherent. All of the words are likely to appear near one another

in a document. Some words (water, fly) are ambiguous and may occur in other contexts, but they are appropriate for this context. It is concrete. We can picture the angler with his rod catching trout in the stream. It is informative. Someone unfamiliar with the topic can work from general words (fishing) to learn about more unfamiliar words (angler). Relationships between entities can be inferred (trout and salmon both live in streams and can be caught in similar ways)." (Boyd-Graber J, Mimno D and Newman D (2014) Care and Feeding of Topic Models: Problems, Diagnostics, and Improvements. In: Airoldi E M, Blei D, Erosheva E A, Fienberg S E (eds.), *The Handbook of Mixed Membership Models and Their Applications*. Boca Raton, FL: CRC Press, Taylor and Francis Group, 2015.)

[5] As Boyd-Graber et alia note, "Topic models are based on a generative model that clearly does not match thway humans write. However topic models are often able to learn meaningful and sensible models." (2014: 15).

Éditions Critiques Électroniques Et Structuration Du Contenu Sur Les Plateformes De Consultation Numériques: Normes Et Pratiques

Introduction et cadre conceptuel

L'édition critique électronique, part active des humanités numériques, est aujourd'hui en pleine expansion, comme en témoigne la multiplication de projets d'envergure dans le domaine[1]. Parallèlement à la création de ces projets, les éditeurs électroniques effectuent également un travail important de définition de ce champ disciplinaire. La réflexion épistémologique, développée par les théoriciens, est également nourrie par les praticiens. Multiforme, le travail de définition d'un champ disciplinaire en cours de structuration et d'évolution est primordial pour asseoir la discipline sur des bases conceptuelles solides. Ainsi, dans chacune des monographies récentes consacrées aux humanités numériques, la question de l'édition critique électronique est traitée et débattue[2].

Pour définir l'édition critique électronique, les chercheurs disposent du terreau historiographique et conceptuel façonné par l'édition critique traditionnelle et la philologie. L'édition critique électronique se situe en effet au lieu de rencontre de la philologie et des techniques informatiques. L'évolution apportée par les nouvelles technologies dans ce domaine est significative. Les humanités numériques, auxquelles se rattache l'édition électronique, impliquent de nouveaux modes de recherche, transdisciplinaires et collaboratifs, dans lesquels les techniques informatiques ont toute leur part (Burdick et al., 2012). Les éditeurs électroniques, justement, considèrent que l'imprimé n'est plus le vecteur de transmission principal du savoir. Selon eux, le web peut contribuer à améliorer la diffusion des connaissances. Ainsi, ces éditeurs tirent parti des outils technologiques afin d'améliorer et d'approfondir l'accès au texte pour le lecteur. (Vanhoutte, 2010).

Normes de structuration des éditions critiques traditionnelles et leurs évolutions numériques

Les éditions critiques traditionnelles, imprimées sur papier et regroupées dans des collections spécialisées[3], répondent à des codes stricts de structuration du contenu. C'est un jeu complexe de normes de lisibilité, élaborées au fil des siècles, qui a donné au texte imprimé son maximum d'efficacité et en a permis une lecture facile et rapide (Vandendorpe, 1999). Ces normes ont été mises en place au fil du temps, en fonction des pratiques de lecture et des règles établies par les éditeurs. Elles sont de divers ordres et portent sur différents aspects du texte : disposition et découpage du texte dans la page, orthographe, ponctuation ou encore syntaxe. L'homogénéité que l'on perçoit dans les éditions critiques est due à l'édiction de règles très précises qui permettent de guider le chercheur dans chacune des étapes de l'établissement du texte. L'apparat critique, cœur du travail du philologue, comporte lui aussi ses codes de structuration particuliers (Duval, 2006).

Lorsque l'on passe au support numérique, ces conventions disparaissent en partie. A l'écran, il s'agit donc de reprendre les normes élaborées pour l'imprimé et de les faire évoluer afin qu'elles s'adaptent aux particularités du format numérique (Souchier, 2012). Les éditeurs qui s'occupent des livres et des artefacts scientifiques numériques, dont font partie les éditions critiques électroniques, doivent donc d'une part reprendre certains codes sémiotiques du livre imprimé pour les adapter au format numérique, et d'autre part inventer de nouveaux codes propres à l'environnement numérique.

Problématique

Il existe un standard dévolu à l'encodage des documents textuels dont font partie les éditions critiques : il s'agit bien entendu du langage XML/TEI. Mais si la structuration des données est régie par les règles de la TEI, la présentation finale de l'information n'a pas fait, pour sa part, jusqu'à ce jour, l'objet d'une quelconque normalisation. Dans notre communication, nous nous attacherons précisément à cette question de structuration et de présentation du contenu sur les plateformes de consultation des éditions électroniques. Ce qui nous intéresse est de savoir quelles sont les règles empiriques de structuration, de disposition et de présentation de l'information qui peuvent être observées dans les éditions électroniques. Comment est-ce que les normes de présentation du texte édité, de l'apparat et des outils de recherche ont évolué de l'imprimé à l'écran ? Nous ferons une étude sémiotique de l'édition critique électronique. Ainsi, nous pourrons voir si l'édition critique électronique actuelle est, ou non, en voie d'inventer de nouveaux codes de structuration de l'information et de lecture du contenu.

Méthodologie et résultats attendus

Pour étudier cette question, nous analysons un corpus d'éditions critiques électroniques sélectionnées par choix raisonné. Nous avons constitué un corpus de douze éditions qui illustrent la diversité des démarches éditoriales observées dans le champ des éditions électroniques : éditions critiques originellement publiées sur papier et transposées en format numérique, éditions critiques publiées simultanément de manière électronique et papier et enfin éditions critiques électroniques natives. Elles ont été développées par divers types d'institutions : universités (Ecole nationale des chartes ou Université de Virginie par exemple), instituts de recherche (à l'image de l'Institut Huygens) ou maisons d'édition (Sd-editions notamment). Enfin, certaines de ces éditions électroniques sont le fait d'initiatives personnelles de chercheurs, comme c'est le cas pour l'édition électronique des œuvres de Petrus Plaoul. Pour mener notre étude, nous nous fondons sur l'observation de ces éditions électroniques ainsi que sur les recherches déjà menées dans ce domaine, incluant les études les plus récentes.

Les éditions critiques électroniques retenues pour notre corpus d'observation sont diverses : elles couvrent les traditions anglo-saxonnes et françaises et portent sur des documents d'archives ou des œuvres littéraires. La variété des types d'éditions critiques que nous avons retenues répond d'abord à un souhait d'examen le plus complet possible des points centraux de l'édition critique. Nous allons donc présenter un état des lieux des éditions critiques électroniques, au travers d'une analyse de la structuration du contenu.

Pour mener notre étude, nous avons élaboré une grille d'observation. Cette dernière est concentrée sur trois pôles : l'apparat critique, le paratexte et les outils de navigation et recherche proposés aux lecteurs. C'est en fonction du positionnement initial de l'éditeur électronique que nous allons comparer les normes de structuration et de présentation de l'information des éditions critiques électroniques. En effet, le positionnement éditorial joue un rôle important dans la fonction assignée à l'édition électronique. Dès lors, des tendances normatives s'observent au sujet de la structuration du contenu dans chacune des catégories d'éditions électroniques (éditions natives ; éditions traditionnelles au départ et publiées ensuite de manière électronique ; éditions simultanément publiées de manière traditionnelle et électronique). Bien entendu, le public de l'édition critique participe aussi, à tout le moins par ses attentes, à l'élaboration des éditions électroniques. Ainsi, la place du public et le rôle qu'il tient sont abordés à chacun des points d'observation (apparat critique, paratexte, outils).

Les observations que nous ferons nous permettront de dégager des tendances et caractéristiques des éditions critiques électroniques afin de comprendre comment ces éditions sont organisées et comment s'y créent des normes de structuration de l'information.

Notes

[1] Un répertoire des éditions critiques électroniques est tenu par Patrick Sahle ; il compte plus de 360 projets qui varient aussi bien par le type de sources éditées que les langues et époques concernées (http://www.digitale-edition.de/).

[2] Citons par exemple *Digital humanities* (Burdick et al., 2012), *Debates in the Digital Humanities* (Gold, Klein, 2012), *Digital humanities in practice* (Warwick et al., 2012), *Defining digital humanities* (Terras et al., 2013) qui consacrent tous des pages ou des chapitres à l'édition critique électronique. En outre, certaines publications récentes sont plus particulièrement dédiées à l'analyse des éditions critiques électroniques elles-

mêmes : *Digital Critical editions* (Apollon et al., 2014) et *Digital Scholarly Editing* (Pierazzo, 2015).

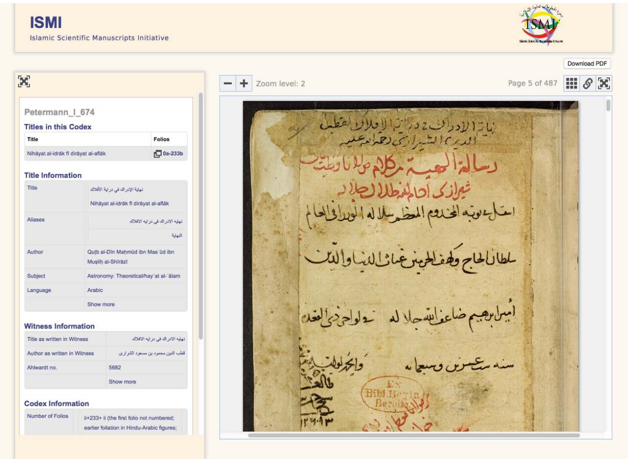
[3] Prenons l'exemple de la maison Honoré Champion, qui propose les trois collections suivantes dédiées aux éditions critiques: *Classiques français du Moyen âge*, *Textes littéraires de la Renaissance*, *Textes de littérature moderne et contemporaine*.

An Islamic Manuscript Database as a Network of Objects

Robert Casties
casties@mpiwg-berlin.mpg.de
MPIWG, Germany

The ISMI project

The Islamic Scientific Manuscripts Initiative (ISMI) is a project by the Max Planck Institute for the History of Science and the Institute of Islamic Studies at McGill University in Montreal to collect and make accessible information on all Islamic manuscripts in the exact sciences (astronomy, mathematics, optics, mathematical geography, music, mechanics, and related disciplines), whether in Arabic, Persian, Turkish, or other languages ranging in time from the 8th to the 19th century. Since 2007 the project has collected information on over 4000 texts existing in 14500 witnesses in 7500 codices, as well as information on over 2000 persons. A preliminary website with a subset of information on 130 codices is already available online (https://ismi.mpiwg-berlin.mpg.de).



Petermann_I_674

Titles in this Codex

Title	Folios
Nihāyat al-idrāk fī dirāyat al-aflāk	0a-233b

Title Information

Title	نهاية الإدراك في دراية الأفلاك Nihāyat al-idrāk fī dirāyat al-aflāk
Aliases	نهايه الادراك فی درايه الافلاك النهاية
Author	Quṭb al-Dīn Maḥmūd ibn Mas'ūd ibn Muṣliḥ al-Shīrāzī
Subject	Astronomy: Theoretical/hay'at al-'ālam
Language	Arabic

Witness Information

Title as written in Witness	نهايه الادراك فی درايه الافلاك
Author as written in Witness	قطب الدين محمود بن مسعود الشرازى
Ahlwardt no.	5682

Codex Information

Number of Folios	ii+233+ ii (the first folio not numbered; earlier foliation in Hindu-Arabic figures;

Figure 1: Online view of codex Peterman I 674 (Staatsbibliothek Berlin)

The project's goal is to create a catalogue database of all relevant manuscripts and record as much information on these manuscripts as available. The collected data contains basic bibliographic information but also paleographic and codicological information, and also information about the content of the texts and information about the uses of the manuscript and its users.

The manuscripts sometimes and notes and colophons providing information about the reading of a text or the use of a text in teaching, about sponsors and the acquisition and ownership of the manuscripts over time. With this information the database not only provides a powerful bibliographical research tool for scholars in the field, but also helps to answer questions pertaining to the historical and social context of knowledge like: Was the author working as an isolated individual or as part of a scientific group? Was this a well-known text? Did it influence subsequent workers in the field? Was it studied at a court or in a school?

A manuscript database

Cataloging old manuscripts is already a task that overwhelms standard bibliographical databases. There is the problem of anonymous authors at the same time as a proliferation of authors with the same or similar names. The integration of information from different sources is made difficult by libraries changing the names of their collections and their numbering systems or libraries themselves being incorporated or centralized into other institutions. Adding to that are the problems of handling of Arabic writing and the multitude of slightly different Arabic romanization systems.

Other requirements also arose in the project early on: for example the need to record and present outdated information. In many cases authorship information has been misattributed widely and for long times so that scholars coming to the database looking for specific information may search under a wrong name or assume the database to be in error unless the common misattribution is also presented with arguments of why the old information is superseded.

Manuscripts as network of objects

The database development started in 2006 with a new data model based on the idea of a network of flexible objects and relations. Objects can have arbitrary attributes which are text strings. The relations between objects are also like objects and also have attributes.

The objects are things like an abstract *TEXT*, a concrete *WITNESS* and a real or imaginary *PERSON* while relations like *is_exemplar_of* connect a text and its witnesses and *was_created_by* connects the texts and a person as its author. The same person can at the same time also be connected to other witnesses as a copyist or as a sponsor.

binding: cardboard with leather spine

Figure 2: Data model showing relations between text, witness, person and codex objects.

The flexible nature of the relations made it easy to introduce new relation types as it became necessary in the research process, for example to record the documented reading of a manuscript or the misattribution of authorship.

This concept of a network of objects with flexible relations, also called an attribute-graph exists in database products like Neo4J today but those were not available in 2006 which led to the development of a custom database called "OpenMind". The database software is Open Source, written in Java, uses a conventional SQL database backend and a Web-based frontend.

Challenges of networked data

The network-like structure of data in the database makes it easy to add new relation types or new attributes to objects while at the same time making it more difficult to create simple forms for entering data for things that are composed of multiple objects in the data model. A form for a manuscript for example not only creates a witness object but also creates relations to a text object, multiple person objects, codex, collection, library and place objects, creating those objects if they do not exist.

Visualising and querying such networks of data objects is also a new challenge where few established tools and concepts exist. Data can be projected into conventional tools like tables and spreadsheets researchers may be familiar with but these do not exploit the full potential of existing relations. Network visualisation tools and methods on the other hand make if often difficult to browse and search for specific items and require a careful selection of semantically relevant relations for the application of standard graph-theoretical measures.

The project currently explores different tools and methods and gathered input from expert scholars in the field in a workshop in February 2016 to be presented at the conference.

Le portail d'édition numérique de sources, http://xml-portal.symogih.org/, que nous présentons aux DH2016 au travers de deux projets d'édition numérique n'est pas un outil de visualisation d'images ou de textes comme pourraient l'être des systèmes de type Omeka ou Drupal. Il s'agit de mettre à disposition de manière dynamique à la fois le texte d'une source mais aussi les données d'une base relationnelle qui constituent son apparat critique. Il faut concevoir ce portail d'édition davantage comme une brique de développement du projet symogih.org.

Le projet symogih.org (Système Modulaire de Gestion de l'Information Historique) a développé un modèle générique de stockage des données historiques permettant leur interopérabilité et leur publication [http://symogih.org/, tous les sites web ont été consultés le 30 octobre 2015]. À partir de ce modèle a été mis en place un système d'information collaboratif pour la recherche en histoire qui est aujourd'hui utilisé par 15 projets de recherche et environ 50 utilisateurs individuels. La plateforme du projet symogih.org offre un outillage numérique accessible et pérenne pour le stockage et la publication de données extraites de l'étude de documents archivistiques et bibliographiques.

Il est possible d'intégrer des données de nature variée qui décrivent l'activité humaine, sociale, économique ou intellectuelle rassemblant, autour d'événements datés et sourcés, des acteurs individuels ou collectifs, des concepts ou des objets géographiques. Le système autorise également l'articulation de ces données avec des textes codés en XML – traités selon les recommandations de la Text Encoding Initiative [https://groupes.renater.fr/wiki/symogih/symogih_manuel/edition_de_textes_en_xml-tei] – ou encore la mise en relation avec des images et leurs métadonnées. La réalisation d'un système d'information géographique (SIG) [http://geo-larhra.org/] joue un rôle essentiel dans ce modèle afin d'associer à ces différents objets leur "empreinte spatiale" et ainsi permettre des analyses spatiales diachroniques.

L'un des derniers développements du projet symogih.org a été la mise en ligne d'un portail de publication des éditions numériques élaborées au sein du LARHRA. Si symogih.org permettait aux chercheurs de mettre à disposition les données structurées issues de leur travail analytique, le portail d'édition rend désormais possible la contextualisation d'une source écrite grâce à ces mêmes données. Les textes encodés en XML/TEI sont stockés sur un serveur eXist-db à partir duquel sont développés différents services (visualisations du texte et des données, géolocalisation, possibilité d'export, moteur de recherche). Le point de jonction entre le texte numérique et la base de données se situe à l'intérieur même des balises TEI où sont intégrés les identifiants du système d'information qui font le lien avec les données structurées. Des fonctionnalités de visualisation peuvent être développées à partir des textes encodés stockés dans une base de données native XML, offrant davantage d'interactivité avec les données et augmentant l'expérience de lecture. De plus, grâce aux technologies web, via les langages XQuery + HTML/Javascript, le portail d'édition numérique permet de collecter des données au-delà du référentiel commun de symogih.org directement à partir du web de données (DBpedia, IdRef, ...).

À ce jour, la partie publique du portail recueille deux projets, l'un d'édition de sources (les *Mémoires* de Léonard Michon), l'autre d'annotation sémantique et de contextualisation de documents concernant l'histoire des savoirs scientifiques à l'époque moderne (Society religion science) [http://xml-portal.symogih.org/web-publications.html]. Un troisième projet d'édition de documents est en cours d'élaboration et verra bientôt le jour : l'édition des Actes des synodes des églises réformées de Bourgogne.

L'édition numérique des *Mémoires* de Léonard Michon fait partie d'une recherche doctorale [Letricot, Rosemonde. *Édition critique numérique des* Mémoires *de Léonard Michon (1715-1746)*. Sous la direction de Hours, Bernard. Université Jean Moulin Lyon 3, LARHRA UMR5190] qui vise à mettre à disposition du public et de la communauté scientifique l'édition critique du Journal historique d'un notable lyonnais relatant la vie des élites bourgeoises de la ville de Lyon de la première moitié du XVIIIe siècle. Le travail d'encodage XML/TEI s'est principalement centré sur l'identification des segments d'information et des entités nommées (personnes, institutions, lieux, etc.) ce qui permettra de recourir à des analyses quantitatives sur les pratiques d'écriture (fréquence, récurrence de noms, etc.) et sur la nature des informations données dans l'ouvrage, que nous pourrons ensuite traduire en parcours de lecture pour le public (parcours thématique, biographique, chronologique, etc.).

Quant aux Actes des synodes des églises réformées, ils représentent une source essentielle pour la connaissance du protestantisme français sous l'Ancien Régime. Ces assemblées réunissent régulièrement des représentants de toutes les églises d'une province pour traiter des affaires qui leur sont communes : questions financières, disciplinaires, doctrinales, etc. Si les sources sur le protestantisme français font l'objet d'une édition chez Droz dans une sous-série de la collection "Travaux d'Humanisme et Renaissance" intitulée "Archives des Églises réformées de France", il n'y avait pas de projet en Humanités numériques sur le sujet [Une édition "papier" des Actes des Synodes Provinciaux des Églises Réformées est en cours chez Droz, le premier volume édité par Didier Boisson a été publié en 2012 et concerne l'Anjou-Touraine-Maine (1594-1683). Le second volume proposera les actes des églises de Bourgogne et sera édité par Yves Krumenacker]. Ce sera bientôt le cas avec l'édition sur le portail XML du projet symogih.org des Actes des synodes des églises réformées de Bourgogne au XVIIe siècle, réalisée sous la direction de Yves Krumenacker de l'Université Jean Moulin Lyon 3.

Ces deux projets d'édition ne se limitent pas à la seule publication de sources mais proposent une édition enrichie par des renseignements récoltés dans des sources complémentaires, saisis dans la base collaborative du projet symogih.org et utilisés non seulement pour préciser l'un ou l'autre renseignement fourni par le texte, selon la démarche d'annotation classique d'une édition papier, mais en proposant également une explication contextuelle dynamique – que permet l'édition numérique – en croisant toute sorte de données et tout en conservant leur traçabilité, par l'enregistrement des sources et de la bibliographie pour chaque information. Il est ainsi possible de reconstituer, par exemple, la généalogie et la carrière d'un pasteur, ou sa bibliographie [L'utilisation d'une base de données collaborative et cumulative permettant de multiplier les sources : journal de pasteur (Bernus, Auguste (1888). Le ministre Antoine de Chandieu d'après son journal autographe inédit 1534-1591. *Bulletin historique et littéraire publié par la Société de l'histoire du protestantisme français*, Tome XXXVII), sources régionales (Papillon, Philibert (1742). *Bibliothèque des auteurs de Bourgogne*. Dijon: Philippe Marteret), *Registres de la Compagnie des pasteurs de Genève*, édités chez Droz].

Les lieux mentionnés dans les écrits et dans la documentation annexe, sont renseignés et géolocalisés dans le gazeteer du projet symogih.org. À partir des données spatiales encodées dans le texte XML, on pourra ainsi réaliser des cartes interactives illustrant différents aspects du codage : villes organisatrices des synodes, lieux d'origine des pasteurs, carte des églises absentes, parcours professionnels des pasteurs. Des fonctions interactives permettront de rebondir de la carte vers les textes ou les informations respectives.

Nous soulignerons lors de la présentation l'apport de la visualisation dynamique des documents pour les deux éditions, chacune avec ces spécificités. En particulier, l'intégration directe des données de la recherche permet une plus grande interactivité : l'apparat critique peut être à tout moment complété au fil des découvertes des chercheurs par la mobilisation simultanée de données provenant d'un silo d'information commun. De plus, les interfaces de visualisation spatiale, ou les graphes mettant en évidence les relations entre les textes et leurs contenus, facilitent l'accès aux documents édités. Les nombreuses possibilités d'enrichissement et d'exploitation des textes amènent les chercheurs en histoire, mais aussi le public, à une découverte sous d'autres angles et avec de nouvelles perspectives du contenu des textes édités.

Nous souhaitons montrer l'apport pour la recherche historique d'un portail d'édition numérique de sources, en insistant sur les bénéfices d'une utilisation croisée de textes encodés en XML/TEI et d'une base de données collaborative. Les projets présentés permettent de retracer le processus de traitement de l'information, de la source à son édition numérique dynamique.

Constructing Evidence in the Photographic Archive: The Experience of Digital Humanists

Alexandra M Chassanoff
achass@email.unc.edu
School of Information and Library Science, University of North Carolina Chapel Hill

Widespread digitization of cultural heritage materials has presented scholars with unprecedented access to primary sources. For digital humanities scholars, who craft arguments from examination of primary sources, increased access to materials has been celebrated as the "democratization of historical research" (Bolick, 2006). Presumably, such changes in archival research environments have influenced how humanist scholars work. Indeed, recent research has confirmed that technological advancements have significantly impacted scholarly practices (Rutner and Schonfeld, 2012; Chassanoff, 2013). Yet *how* humanists evaluate and use digitalsource materials to construct narratives is less well-understood.

In this paper, I report on findings from a one year qualitative study examining digital humanists' scholarly use of one kind of digital source material - digitized archival photographs. Using a case study approach, I examine the practices and processes at play in the construction of historical evidence. This research is guided by the following questions:

- How and why are digital humanists using digitized archival photographs in their research and teaching activities?
- What factors and qualities matter to them in their experiences in the photographic digital archive?

The goal of this study is to provide an in-depth, holistic understanding of a complex interaction space made up of, but not limited to: digital surrogates of archival objects, user perceptions and attitudes, environmental constraints, and historical training and orientation. Empirical research in digital environments tends to focus on single components of the interaction (e.g., user and interface; user and artifact) as they relate to specific aspects of information behavior, or to conceptualize information use as the successful fulfillment of stated information needs. Yet such perspectives do not attend to the impact that ecological factors may have on user interactions with materials. Adopting a phenomenological stance enables a focus on understanding "how persons construct meaning" through examinations of their particular experiences with certain phenomenon (Wilson, 2002). In this study, exploring *how and why* scholars use digital photographs helps to reveal the emergent qualities and attributes that make this experience meaningful for participants.

Semi-structured interviews were conducted with sixteen participants (9 men and 7 women) throughout the spring and summer of 2015. Recruited participants came from a variety of academic departments, including History, English, African-American Studies, American Studies, Classical Studies, and Musicology. Each participant preselected two examples of digitized archival photographs they had used in research and teaching. Two customized web pages, which I termed *Photograph Scenarios*, were created in an attempt to replicate where possible their original experience viewing and encountering the digital photograph. I also collected supplementary materials related to each participant's image use, including conference presentations, class presentations, course syllabus, dissertation chapters, and journal articles. Data were analyzed using open coding and thematic analysis in order to surface salient aspects of the experience related to interpretation and use. To strengthen and verify the analysis, triangulation across data sources was employed.

Figure 1: Photograph Scenario used in interview from Library of Congress collection (http://www.loc.gov/pictures/item/2002707085/)

The findings presented in this paper shed light on both practical concerns and intellectual challenges that surface throughout the experience of constructing historical evidence. Descriptive quotations from interview transcripts alongside examples of image use illustrate the functional ways humanists are using digitized archival photographs in their scholarly activities (e.g., to make historical assertions, to corroborate existing information, etc.). A typology illustrating how scholars use digital photographs is presented below.

Humanist used photograph to...	**Interview excerpt**
Corroborate existing information	"A lot of times we need to look at these historic photos to actually know what it actually looked like and not just our idea of what it looked like"
Make historical assertions	"And I was having trouble finding certain types of ferries that I know existed because of other records. You know, like you would find references to their being a rope ferry, but then you could never find a photo to see exactly what they meant by that."
Reference historical documentation	"Because we were working on just one of the bridges, and as you can see from where they had, it's on the well, the left and the right side, it shows the different bridges that were there."
Elicit reactions from viewer	"But I'd always try to find good touristy photos to show some good 60s and 70s touristy photos or whatever, just to make it livelier"
Present community perceptions at time of creation	"…it's sort of like what did the community, or the boosters of the community, think was important? Because, hey, it's what they were trying to put out for the public…"
Juxtapose against other sources	"Yeah, and that's exactly what I did, is I put it in conversation with other images like it."

Table 1: Typologies of Use

The cases presented demonstrate the extent to which material conditions of *experience* (rather than the tools through which users discovered or accessed resources) can impact interpretive practices and further use.

One salient theme is the factors that motivate participants to use photographs. In one case study, a participant discovered a "vernacular body of images" that led them to collect similar types of visual sources. In another case, a participant selected their project topic after encountering multiple published images depicting what they term "radical masculinity" in the Communist party. They describe their discovery experience: "But then I started noticing there was a lot of- not this image in particular- but there were several other ones that were repeatedly published, of Communists bandaged and showing black eyes and stuff, after confrontations with the police or vigilantes, so that was the first thing I noted."

Other cases illustrate the discrepancies between viewing digital photographs online and encountering them in person. In one case, a participant describes the advantages of obtaining a high quality scan from an archivist rather than accessing and using the "tiny tiny little print" displayed in the online collection. In another case, a participant attributes the discovery of a number of details that became central to their historical argument only after viewing a physical version of the photograph in person:

> So, there are a whole number of things that I never would have seen [if I hadn't also viewed the photograph in person], I think. And a whole range of- you know, the physical image has a whole affect to it that you don't get from a glowing screen.… I can look at the digital image from the [library], and zoom and zoom in to see it, but I never would have seen [this important detail] if I was just looking at a 2 inch by 3 inch digital version.

Both of these examples demonstrate the importance of individual scholars' interpretive experiences as a means for understanding the conditions that enable further use of these primary sources.

Digital humanities scholars undoubtedly face a number of practical and hermeneutic challenges in using source materials from digital archival research environments. As spaces of knowledge production, online archives must support numerous heterogeneous practices in order to remain useful and relevant. At the same time, navigating online archives to find and use sources requires digital humanists to be competent at varying levels, including: interfaces, digitization quality, overall orientation to the archive, and domain-specific heuristics (Yakel and Torres, 2003).

While there has been unquestionable growth in access to digital archival materials, there have been few empirical attempts to understand the factors and qualities that matter to scholars as they interact with digital sources. The case studies presented in this paper will inform design and development efforts in the digital humanities community by focusing on the end-users of these systems and their needs. A holistic, methodological approach which emphasizes scholars' experiences evaluating, interpreting and using materials in scholarly activities allows for an exploration of the mediating factors underlying these practices. Such an orientation enables us to extend our attention beyond simply exploring the material constraints of resource discovery and access, which are often modeled on analog approaches to communication. Instead, this study broadens the emphasis to, in the words of Gregory Bateson, "the difference that makes a difference."

This paper introduces a digital humanities project at the Max Planck Institute for the History of Science (Max-Planck-Institut für Wissenschaftsgeschichte, MPIWG) that aims to unlock the treasure chest of local knowledge written in the genre of Chinese local gazetteers for computer assisted analyses.

In the past two decades, a great amount of historical documents have been digitized and put on the Web to enable easy access for scholars around the globe. In parallel, the amount of searchable full-text versions of historical texts has increased, which opens the possibility of text mining the contents for large scaled analyses. Many works in this direction have been proposed and got recognition, while they are also criticized for drawing conclusions from seemingly imprecise results due to the restriction that their algorithms have no knowledge about the meanings of the different pieces in a text (Jockers, 2013; Google Ngram Viewer; Chen et al., 2007).

An alternative approach is thus to first "teach" computers what each pieces of a text means before asking computers to run automatic analyses. Such "teaching" is done by tagging, or called markup. Many digital humanities projects have been using TEI, a standard for text encoding based on XML, to tag their research materials (TEI; Flanders).

In the Local Gazetteers Project, since the genre organizes knowledge in a very structural way, we are also using tagging to teach computers the meanings of texts in order to turn them into data tables to enable computer assisted analyses including GIS mapping. However, since the amount of texts is huge, we also propose a research data repository for scholars to collaborate in this project and to aggregate their results.

What are the Chinese Local Gazetteers?

The Chinese local gazetteers is a genre of texts that has been produced in China consistently from the 10th century on to even today. Most of them are compiled by local officials as a major means to collect and aggregate historical, social, and geographical knowledge of an administrative region for governing purposes. There are at least 8,000 titles of pre-1949 local gazetteers still extant today. They cover almost every well-populated region in historical China.

Despite being compiled by different officials for different regions, the local gazetteers have developed a pretty consistent structure of "describing" local knowledge. Most gazetteers contain the following chapters: history, geography, local government, infrastructure (buildings, schools, temples, bridges), local products (grains, plants, animals, drugs, commodities), people (local officials and celebrities), and literature. The vast number, the longue durée, the width in geographical coverage, together with the extensive and consistent selection of topics have made the local gazetteers major sources for knowledge about regions for scholars from later periods. To date, several digitization projects on the local gazetteers have been conducted by either commercial vendors or public institutions, and thousands of titles have been made available in searchable full texts for scholarly access.[1]

The Project's Goal

Local gazetteers are well studied, but the vast amount of information contained within also makes scholars struggled to study them analytically. We noticed that the local gazetteers often organize knowledge by listing the items: list of temples, lists of flora and fauna, lists of local officials, etc. (See Figure 1 for an example.) This characteristic makes the local gazetteers a database by nature.

The goal of this project is to transform this genre into a scholarly enhanced database in order to enable new forms of digital historical analyses. By turning texts (of lists of things) into data (tables), it will be much easier to aggregate the rich knowledge written in all the extant local gazetteers to compile a database for historical China on local knowledge across geographical regions and time periods. Research-oriented queries, visualization of query results, and further large scaled analyses will then be more easily realized with such a database.

Our approach

We have identified and developed a set of digital tools to help this process. They are: (1) an **extraction interface** that helps historians to tag and to transform digital texts and their built-in structures into *data tables*; (2) a **research data repository** where historians can *share and publish* their data collected via the extraction interface; (3) a set of **digital analytical, visualization, and analysis tools** that can be applied on the collected data for posing research questions.

福建通志

Figure 1 Two pages from the chapter of "local products" from *Fujian tongzhi* (Qing, 1737). The pages list items according to categories. The bigger fonts represent the names of the items, while the smaller fonts are descriptions of the items. (Image source: http://ctext.org/library.pl?if=en&file=50305&page=80.)

I. An extraction interface for transforming digital texts into data

Due to the well-formatted organization of the local gazetteers, some scholars have tried to write computer programs to parse the digital texts in order to collect data for their own research (Mitchell, 2015; Chang, 2015). However, due to the fact that each of the local gazetteers has slightly different formats, it is difficult to write generic computer programs that can work on all the gazetteers. The China Biographical Database project (CBDB) tackled this problem by building an interactive user interface that allows scholars to describe observable writing patterns of the text in regular expressions (Wikipedia, 2015) – The Smart Regex Tool. The compiled regular expressions can be saved, run against other texts, and modified to fit slightly different writing patterns. CBDB used this interface and efficiently collected 250,000 records on local officials from 290 local gazetteers using only 420 man-hours (Pang et al., 2014).

We inherited this interface from CBDB and further improved it so that scholars can define different tag sets and regular expressions to capture information relevant to topics they are interested in. Figure 2 to Figure 6 are the step-by-step screenshots of how we use this interface to tag a text on local product and to export the result into a table. The resulting table contains not only the names, categories, descriptions, alternative names, and usages of the products, but also the source gazetteer, the chapter name, and page number as well as geographical coordinates for mapping purpose.

II. Compiling a global database from local records: A research data repository

Our extraction interface provides a semi-automatic way of transforming texts into data tables. Nevertheless, compiling a global database through this interface will still take a lot of time. We envision it to be a collaborative work among scholars with different research interests and specialties, and we eagerly need to be a way to give credits to scholars who contribute the data in the academic world. We found that the philosophy behind the open source software Dataverse, developed by Institute for Quantitative Social Sciences at Harvard University with the philosophy of "dedicated to sharing, archiving, and citing research data" (IQSS, 2015), matches our needs and will allow our project to meet the open access policy of the Max Planck Society and the "Berlin declaration".[2]

We are still working on a way to aggregate the produced tables into one database in order to enable joint queries on records drawn from different gazetteers.

III. Computer assisted analyses on large scales

By transforming texts into data tables with predefined shared schema, it enables computers to easily process and analyze the data on large scales with better accuracy. We envision there can be multiple tools connected to our data, and scholars can choose which tools to use based on their research needs.

At the moment we are using the open source software PLATIN GeoBrowser (http://platin.mpiwg-berlin.mpg.de/) to create geospatial visualization for our data with one click away. PLATIN doesn't just display the geospatial distribution of the data on a map but also provides an animated timeline and user-defined pie charts, which we found very helpful for historians for preliminary analysis (Figure 8 and Figure 9).

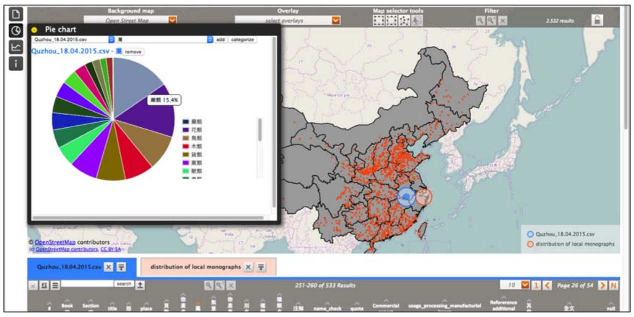

Figure 8 LGMap service (based on PLATIN) with Pie Chart function for analyzing categorical data.

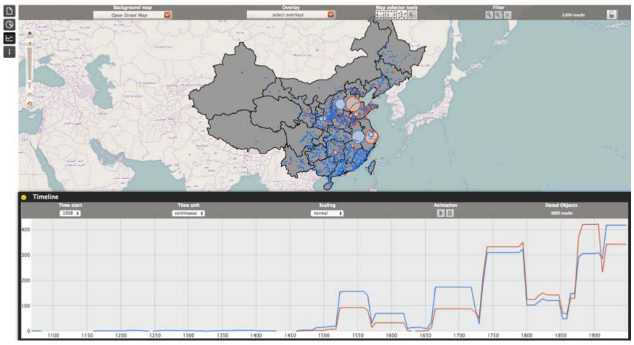

Figure 9 LGMap service with Timeline function showing temporal distribution of two datasets.

Concluding Remarks

This is an ongoing project. As a history of science study, we are collecting data from the chapter of local products in order to understand how local identities were constructed through the compilation of local products. In 2016, MPIWG will invite visiting scholars to use our digital tools to collect and analyze data of other topics from local gazetteers. This will also be a chance to further examine the model we proposed: from data collection from digital texts, aggregation of data in a research data repository, to digital tools for analysis and visualization.

Who's Doing What?: Examining The Relationships Among Subjectivity, Agency, and Syntax In The 19th Century Novel

Jonathan Yu Cheng
jonathan.cheng@huskers.unl.edu
University of Nebraska-Lincoln, United States of America

Gabrielle Kirilloff
gkirilloff@gmail.com
University of Nebraska-Lincoln, United States of America

Introduction

The relationship between action and identity is a significant element of understanding the way that characterization functions within literary works; many memorable characters are in part defined by their actions. This link between character and action raises the question of whether **specific** types of characters, or subjects, are consistently associated with certain types of action. Our project seeks to address this question by looking at the relationship between elements of a subject's identity and the actions associated with that subject. Our research builds off of work begun by the University of Nebraska-Literary Lab that explores the relationship between behavior and gender in the 19th century novel. The research begun by the Lab attempts to situate questions of gender and agency within the context of 19th century notions of propriety; is the Victorian valorization of passive women and active men reflected in novels from the period?

This project adds on to our initial foray into questions of gender; what is at stake is still very much a question of the allocation of agency. This avenue of research revolves around the question of when and why inanimate objects fill the subject position in sentences. This research also queries whether certain types of characters behave differently from others: what do kings do that peasants do not? Our project examines the agency associated with male, female, human, and non-human actors by studying the different types of verbs used in conjunction with different types of subjects. This research explores the question of whether or not certain types of subjects **behave** differently in our corpus, and if so, in what ways and to what effect.

Methodologies

The initial foray into the study of gender and genre performed by the University of Nebraska-Literary Lab relied on POS tagging and used an R programming script to extract the first pronoun that it encountered, along with the first verb that followed this pronoun, and entered each as a relationship into a data frame. The male pronouns "him," "his," "he," and "himself," and the female pronouns "she," "her," "hers," and "herself" were extracted. Thus, in the following sentence, the pronouns "she" would be extracted and grouped with the verb "walked."

> After dinner, she walked outside.

This approach was also our initial model for extracting non-human actors. For example, in the following sentence, we could similarly extract the pronoun "it" and the verb "howled."

> The wind was fierce; it howled into the night.

However, such an approach has several shortcomings. The first of which is that multiple verbs associated with a single subject in a sentence are not extracted. The second, is that this method only captures pronouns. Instances of personification, which often rely on nouns rather than pronouns, are ignored by this model. In order to solve these issues, we turned to the Stanford Dependency Parser, a tool that provides a representation of grammatical relations between words in a sentence. For example, in the sentence "The wind is dancing and howling," the parser would extract two subject verb pairs, "wind, dancing" and "wind, howling." The output looks as follows:

```
det(wind-2,The-1)
nsubj(dancing-4,wind-2)
nsubj(howling-6,wind-2)
aux(dancing-4,is-3)
root(ROOT-0,dancing-4)
cc(dancing-4,and-5)
conj:and(dancing-4, howling-6)
```

Using the parser allowed us to collect subjects that were not pronouns and allowed us to correctly associate multiple verbs with a single subject. It also allowed us to easily collect gender data, since we could simply collect any nsubj pair that contained a gendered pronoun.

While the parser does identify subject and verb pairs, it does not differentiate between human and non-human subjects. To differentiate between these subject types, we created a script that allows us to extract non-human agents and the verbs associated with them by ignoring sentences in which the subject is a gendered pronoun, a proper name, or a title. In performing our research, we realized that human subjects were indicated by either a pronoun (such as he), a proper name (such as Mary), or a title (such as the priest). If a subject did not fall into one of these three categories, the subject was most likely a non-human entity.

Ignoring nsubj groupings in which one of the words is a gendered pronoun was straightforward. In order to block proper names, we ran the Stanford Named Entity Recognizer on the texts in order to create a list of proper names from the corpus. We then ignored nsubj groupings that contained one of these names. Finally, in order to ignore titles, we created a dictionary of titles derived from vocabulary lists for non-native english speakers. These lists contained titles such as "captain," professions, such as "baker," terms signalling family relationships, such as "mother," and general terms for human agents, such as "girl." We then recorded each subject-verb relationship that did not contain one of these three categories into a data frame. However, in a separate script, we also used this list of titles to extract nsubjs that contain any of these titles. Our process allows us to use our program to assess the frequency of recurring syntactical relationships, essentially counting the number of times each verb is associated with male, female, human, and non-human subjects.

Observations

The initial results observed by the Nebraska-Literary Lab in their study on gender indicate that certain verbs were strongly associated with male characters while different verbs were strongly associated with female characters. Continuing this research, Matthew Jockers and Gabrielle Kirilloff confirmed these results in their work, which used the Stanford Dependency Parser in the manner discussed above. Jockers and Kirilloff found that a verb can be used to predict the gender of the pronoun associated with it, with 89% percent accuracy. Given the high degree of accuracy obtained from this analysis, we can conclude that within our corpus of 19th century fiction, authors chose to portray male and female characters differently by associating them with divergent groups of verbs. This result is not surprising, especially given the way in which ideas about proper behavior differed for males and females within 19th century society. However, this result still has several far-reaching implications, one of which is that "actions," or verbs, are in fact an important part of creating and determining character.

One of the shortcomings of the analysis on gendered pronouns and verbs is that it does not take into account other aspects of character identity. A princess and a witch may perform the same actions, but the implications are radically different. Similarly, certain types of characters may be associated with verbs typically associated with the opposite gender; though both are male, clerics and soldiers are no doubt associated with different actions. The data we extracted is a first step toward broadening this work; our extraction of specific subjects (such as wife, soldier, cleric) allow us to more closely look at character identity. In querying our data, our results thus far support the findings on gendered pronouns and verbs. For example, the verb "wept" was found to be strongly associated with female pronouns. In examining specific types of actors, we found that "women," "mothers," and "woman" were the most frequent actors associated with "weep," "weeping," and "weeps" respectively.

Future work

Our initial foray into our corpus has produced a wealth of data; at this stage our next step is to organize and query this data, asking more specific questions about the relationship between subjects and actions. For example, we have hypothesized that instances of objects performing actions occur more often in certain genres, specifically the Gothic. Over the coming months we intend to begin studying whether the actions associated with male, female, human, and non-human subjects are associated with specific genres. This type of analysis is challenging, largely because of the difficulties associated with collecting accurate Genre data. Genres are not rigid categories and many works participate in multiple genres. In addition to exploring the effects of genre, we also intend to more thoroughly examine the types of non-human and human agency we are extracting. Man-made objects, objects found in nature, animals, and supernatural beings are just a few of the types of non-human agency we have observed. We would like to begin exploring and categorizing these differences in an attempt to better understand our data. Because the Stanford Dependency Parser allows us to look closely at syntactic relationships, we also intend to expand our research to encompass the objects of actions, essentially asking, who is doing what **to whom**. This question has important implications for studies of gender and character identity.

Linking Etymological Dictionaries

When studying low-resource languages, historical documents or dialectal variation, researchers often face the problem that lexical resources are sparse, dated, or simply unavailable. At the moment, the problem is addressed by different initiatives to either aggregate language resources[1] in a central repository or to collect metadata about them[2]. The availability of this huge and diverse amount of material, often in different formats, and with a highly specialized focus on selected language varieties, poses the challenge how to access and search this wealth of information. Our project aims to address both aspects:

- **uniform access to lexical resources**. At the moment, most resources are distributed across different providers. Platforms to query or browse this data are available, but they use different representation formalisms and remain isolated from each other. We employ **Linked Data** to develop interoperable representations to access distributed resources in a uniform fashion.
- **search across multilingual resources**. We are not only interested in a specific language, but also, in related varieties: Much of the material we have is sparse, and we can address gaps in our lexical knowledge by consulting background information about form and meaning of possible cognates in other languages.

The project will implement search functionalities as web services and provide a prototypical web interface that allows to query Linked Data versions of open lexical resources. As a first step towards this goal, this paper addresses representation formalisms and data modelling, illustrated for an etymological dictionary of the Turkic language family.

Linked Open Data

Linked (Open) Data defines rules of best practice for publishing data on the web, and since (Chiarcos et al., 2012), these rules have been increasingly applied to language resources, giving rise to the **Linguistic Linked Open Data** (LLOD) cloud (Chiarcos et al., 2013)[3]. A *linguistically relevantresource* constitutes Linguistic Linked (Open) Data if (1) its elements are uniquely identifiably by means of **URIs**, (2) its URIs **resolve via HTTP**, (3) it can be accessed using **web standards** such as RDF and SPARQL, and (4) it includes **links** to other resources. It is Linguistic Linked Open Data (LLOD) if – in addition to these rules –, it is published under an **open** license. For etymological dictionaries, the capability to refer to and to search across distributed data sets (federation, dynamicity, ecosystem) in an interoperable way (representation, interoperability) allows to design novel, integrative approaches on accessing and using etymological databases, but only if common vocabularies and terms already established in the community are being used, re-used and extended. (Moran & Brümmer, 2013) established lemon (McCrae et al., 2011)[4] for representing etymological data. Inspired by the pre-lemon inventory (de Melo, 2014), we introduce lemon extensions for etymological relations, illustrated for the linked data edition of the Starling Turkic etymological dictionary. With further dictionaries for Turkic languages becoming available as a result of our project, these are linked with each other and with language resources from contact languages such as Mongolian, Iranian, Caucasian, Arabic, and Russian.

Fig. 1: XML snippet

The **Tower of Babel (Starling)**[5] is a web portal on historical and comparative linguistics (Starostin, 2010), widely used in academia to publish etymological datasets over the internet. Starling allows exploring its dictionaries by means of faceted browsing using a coarse-grained phylogenetic tree (Fig. 2.a). We illustrate its data structures for the Turkic Etymological Dictionary (Dybo et al., 2012) with an example result for the query **meaning="bird"** (Fig.2.b).

Following the **Proto-Turkic** root, we find a cross-reference to the Altaic dictionary, and the **meaning** (sense) of the proto-form in English and Russian. The following entries pertain to **cognates** in different Turkic languages: They provide complex information including one or multiple **forms**, **co-indexed** with the meaning field, and optionally augmented with additional gloss (e.g., 'moth' for Middle Turkic/Chagatai), bibliography (as a hyperlink, Fig. 3) or additional comments (e.g., < Az. for Halaj). We used an XML export of the Starling data (Fig. 1) to create RDF and (by converting cross-references) Linked Data.

Data Model for the Turkic Etymology

Following LLOD conventions, we employ the Ontolex/Lemon vocabulary (McCrae et al., 2011)[6] as shown in Fig. 4. Originally developed to add linguistic information to existing ontologies, Lemon evolved into a de-facto standard to represent lexical resources as LLOD. Here, we focus on Lemon extensions to represent etymological cognates: Etymological relations involve a relationship on the level of meaning (sense) and on the level of form, and thus require a novel property between one **LexicalEntry** and another. Between etymological cognates, it is not always clear whether one was the source of the other, or a more indirect relation holds. To express a generic etymological link without additional directionality information, we introduce the property **lemonet:cognate**. If source and target are known, a subproperty **lemonet:derivedFrom** is introduced. Similar to **lemonet:cognate**, it is transitive, but it is not symmetric. Distinguishing **lemonet:cognate** and **lemonet:derivedFrom** follows de Melo's apparent directionality differentiation. Here, however, we provide a formal definition as a (minimal) extension of Lemon following (Chiarcos & Sukhareva, 2014) which supports inferring general cognate relations by subsumption and transitive/symmetric closure. In the Starling data, the directionality of etymological links is generally known, so we represent etymological relations with **lemonet:derivedFrom** between lexical entries from different Lemon lexicons. By subsumption inference, transitivity and symmetry of its superproperty, **lemonet:cognate** relations can be inferred automatically between all language-specific forms.

Applications

The **Comparative-Lexicographical Workbench** (Fig. 5) will provide novel search functionalities extending the functionality of existing platforms, form-based search and a gloss-(meaning-) based search, currently applied to the Turkic language family and its contact languages.

- **gloss-(meaning-)based search**. Dictionary lemmas are complemented with a gloss paraphrasing their meaning. Linked Data allows transitive search over sequences of bilingual dictionaries (e.g., Kazakh-Russian-English).
- **form-based search**. Given a lexeme in a particular language, say, Kazakh, and a set of related languages, say, the Turkish languages in general, the system will retrieve phonologically similar lexemes for the respective target languages.

Both search functionalities aim to detect candidate cognates. The data provided by Starling represents a gold standard, but can also be directly integrated into the search process: In Fig. 5, we query for Chalkan **ана** and possible cognates from Turkic (as an inherited word) or Mongolic (as a possible source of loan words). The results are organized according to the taxonomic status of the varieties in *www.multitree.org*. They include a gloss from a Chalkan dictionary (marked by subscript C), but in addition provide form-based matches (subscript +) from the Starling dictionaries (S), e.g., with Turkish **ana** and its etymologically corresponding forms, etc.

Fig. 5: Design study: Form-based search in the Comparative-Lexicographical Workbench

Summary

We described preliminary steps towards the development of a Comparative-Lexicographical Workbench that uses Linked Data formalisms to retrieve cognates as given in etymological dictionaries as well as to automatically identify cognate candidates from different languages (which are similar in form and meaning). In our presentation, both will be illustrated for the Turkic language family, and we will show how both aspects complement each other.

#ww1. The Great War on Twitter

Frédéric Clavert
frederic@clavert.net
Université de Lausanne, Switzerland

Since 2014, some of the countries that were formerly belligerent of the Great War – most particularly France and UK – have organised a series of commemorations of the First World War, known as the 'Centenaire' (France) or the 'Centenary' (UK). We can assume that there is a strong link – that cannot let a historian indifferent – between those commemorations, collective memory and historical studies.

Though studies about collective memory are numerous since the famous works of the French sociologist Maurice Halbwachs (Halbwachs, 1950), few of them are examining how collective memories are being expressed – maybe even transformed – on social networks on-line.

In the case of the Centenary of the First World War, a set of questions can be asked: What is the on-line echo of the commemoration of the centenary of the 1st World War? What is the behaviour of Memorial/Heritage Institutions about the 1st World War on Twitter? How do they transmit information about the Centenary? Is there an influence of the English predominance on Twitter about the Centenary on how non-english-speaking twitter accounts are considering the 1st World War? Are there specific subjects that are discussed on-line? Which 'temporalities' are present in tweets when Twitter users speak about the Great War on-line?

Though we are not yet able to respond to all those questions, we'll use our database of tweets in order to answer them at least partially.

Indeed, since the 1st April 2014, around 1.5 millions of tweets containing a hashtag (keyword) linked to the 1st World War were written by over 350 000 Twitter accounts in several languages (mainly English and French). Twitter is a good field to analyse relationships between history and collective memory, memorial institutions and citizens, historians and a wide non-academic audience. We started to explore this database (which is still expanding): we intend to show how a historian can collect, analyse and interpret those tweets, using Digital Humanities methodologies and software in order to answer questions about collective memory of the First World War online.

Tools and Methodologies

We are using 140dev, a PHP open source script within a LAMP environment to collect tweets through the Twitter streaming API. The tweets are then stored in a MySQL database. Diverse information (tweets and their metadata, hashtags, user information, mentions, retweets) about those tweets can easily be extracted through SQL queries. Those queries can also be used to extract different kind of relations: between tweets, between Twitter users or even between hashtags (*ie* if a Twitter user mentioned or retweeted another twitter user, if two users wrote the same hashtags, etc). Concerning privacy, we respect the Twitter API Terms.

To analyse tweets, we are using mainly two sets of methodologies/software: social network analysis and network visualisations (with Gephi: mention, retweets or hashtags are considered a link); text analysis through the theory of the *mondes lexicaux* (Reinert, 1993) as it is implemented in the IRaMuTeQ software (Ratinaud and Dejean, 2009) . The combination of both tools and methodologies has been described by (Smyrnaios and Ratinaud, 2014). IRaMuTeQ, thanks to time-stamped metadata, can also help us working on temporalities. Indeed, clusters that are defined by this software can be projected in time: we can know, day-by-day, the most used kind of tweets. It helped us, for instance, finding that French fallen soldiers are not described with the same words the 11th of November in comparison to the rest of the year.

The methodologies and tools that remain to be found for this research concern temporalities – even if IRaMuTeQ has helped us answer some question on time. There are several temporalities that are expressed in this corpus: the constant feed of information that is the nature of Twitter; the temporality of each twitter user; the temporality of the Centenary (which is different from one country to the other, and from the Great War temporality); and the temporality of the War itself.

First results

Language

English is overwhelmingly present in this corpus. Around 10% only of the collected tweets are not in English. Among those 10%, French is largely in majority and German almost absent, even though German hashtags are collected. The fact that Twitter is an English-based social network does not explain fully this disequilibrium between English and other languages. The Memorial institutions' communication policies on Twitter are better factors to explain it.

The decentralized communication policy of British memorial institutions (the BBC and all its Twitter accounts or the Imperial War Museum for instance) is obviously more efficient than the French centralized communication policy of the *Mission du centenaire*. French WW1-related museums do not have Twitter accounts or do have one but do not follow twitter implicit rules such as the use of a general hashtag like #ww1 or the French #pgm.

British and French are not commemorating WW1 the same way

The most striking difference between the French corpus and the English one is the fact that both linguistic areas do not commemorate the Great War the same way. There are two major differences between both countries:

- French are mainly remembering the soldiers (*Poilus*). British citizens are remembering soldiers, but also battles.
- The French are focusing on the end of the war, the Armistice, on the 11th November. The British are focusing on the way they entered the war.

English public history and French history amateurs

Thanks to the Network visualisations, this corpus also helps understand how public history is present in Britain, in contrary to France where it just begins to appear. The presence of amateurs of history in the French corpus also shows that French historians are not on twitter, in contrary to amateurs who, next to the *Mission du Centenaire,* are structuring discussions about the First World War on Twitter.

Conclusion

Comparing multilingual corpora

To compare our two main corpora (the French one and the English one) that can be extracted from the database, we had to use the two main pieces of software the same way on both corpora and then to 'humanly' compare the results. We could not find any tools able to compare two corpora that are in different languages.

Distant reading / Close reading

This research project shows that, for historians, it is still important to keep a direct link with each single primary source, as some information can be learned from the interpretation of single tweets. Though methods used in this research are dealing with Franco Moretti's notion of *distant reading* (Moretti, 2007), it proved strategic to be able to go back to every single tweet. The software used, if metadata are kept all along their use, allow this.

Twitter and the rest of the web

Why Twitter? The fact that the Twitter API, though sometimes very unstable, is very convenient to use is one of the criteria of this choice. Is it really pertinent in terms of research? Shouldn't we have broader sources? How to extrapolate the project's results to other on-line social networks? Last but not least, the difficulty to anticipate hashtags to be collected might introduce biases in our research.

Future of this research project

The question of 'temporalities' and their imbrications (the temporality of Twitter / the temporality of users / the temporality of the commemorations / the temporality of the First World War itself) should be the next step of this research. But, as it will require the use of Named Entity Recognition, extending our research to places will be possible as well.

A Method for Record Linkage with Sparse Historical Data

Introduction

Massive digitization of archival material, coupled with automatic document processing techniques and data visualisation tools offers great opportunities for reconstructing and exploring the past. Unprecedented wealth of historical data (e.g. names of persons, places, transaction records) can indeed be gathered through the transcription and annotation of digitized documents and thereby foster large-scale studies of past societies. Yet, the transformation of hand-written documents into well-represented, structured and connected data is not straightforward and requires several processing steps. In this regard, a key issue is entity record linkage, a process aiming at linking different mentions in texts which refer to the same entity. Also known as entity disambiguation, record linkage is essential in that it allows to identify genuine individuals, to aggregate multi-source information about single entities, and to reconstruct networks across documents and document series.

In this paper we present an approach to automatically identify coreferential entity mentions of type *Person* in a data set derived from Venetian apprenticeship contracts from the early modern period (16th-18th c.). Taking advantage of a manually annotated sub-part of the document series, we compute distances between pairs of mentions, combining various similarity measures based on (sparse) context information and person attributes.

Task Definition

Major challenges when dealing with people-related data are homographic person names referring to different persons as well as the existence of name variants referring to the same person. These are well-known issues in the field of Natural Language Processing for which various approaches have been devised, first via mention clustering (Mann and Yarowsky 2003; Artiles et al. 2008), more recently via linking to a knowledge base (Ji and Grishman 2011; Shen et al 2015).

In the context of historical data, dealing with person name ambiguity is all the more difficult since data is inherently sparse and uncertain (resulting in poor mention context) and since knowledge bases such as DBpedia (Lehmann et al 2013) contain very little about past average laypersons (resulting in poor entity context). It is however an essential step prior to any historical data analysis (Bloothooft et al 2015), which we address as part of the *Garzoni* project. This project aims at studying apprenticeship in early modern Venice by extracting information from archival material. Part of this material have been manually annotated, including mention links towards unique entities. Starting from a subset of the current data, we present a method for person record linkage, with the objective to complement its disambiguation coverage and to bootstrap a system to better automate entity disambiguation during annotation, in an active learning fashion.

The *Accordi dei Garzoni*

The *Accordi dei Garzoni* is a document series from the State Archives of Venice which originates from the activity of the *Giustizia Vecchia* magistracy. This judicial authority was in charge of registering apprenticeship contracts in order to protect young people while they were trained and/or providing domestic services (Bellavitis 2006). As a result of this regulation, information for much of apprenticeship arrangements got centralized, today reflected in a dense archival series.

The *Accordi* consists of about 55,000 contracts registered from 1575 until 1772. Each contract features an apprentice, a master and often a guarantor, sometimes two. A sample of 11,000 contracts have been manually annotated and the resulting data is stored in an RDF triple store. For each person mentioned in a contract, annotators created a *person mention* and, importantly, linked it to a *person entity*. They did so either by selecting an already existing entity in the database or by creating a new one. Given the difficulty of this task, only a limited number of entities have been disambiguated; the annotated dataset can therefore be considered as correct but not exhaustive.

The present work considers annotated documents from the period 1586-1600, for which statistics about contracts and entity/mention ratio are shown in Table 1. We use a subset of this dataset (bolded line in the table) as a *golden* set for our experiments.

Count	**whole period**	**1586-1600**
# annotated contracts	11,525	2,687
# mentions	31,952	7,589

# entities	26,641	6,599
# entities with # mention > 1	1793	382
avg mention per entity	1.09	1.08
avg mention per entity with # mention > 1	2.44	2.38

Table 1. Entity-Mention stastistical profile for the whole vs. selected period

Approach

Given a set of mentions, our objective is to estimate the likelihood that two mentions refer to the same entity. We represent each mention by a vector of features and compare them pairwise using various similarity measures. The list of selected features at mention and contract levels are presented in Table 2 and 3 respectively.

Feature	Variable Type
first name	string
surname	string
patronymic	string
gender	categorical
age	integer
profession	categorical
geographical origins	string

Table 2. Mention-level features

Feature	Variable Type
workshop toponym	string
workshop parish	string
workshop sestriere1	string
workshop insi gna	string
contract year	integer
contract duration	string
master profession	categorical

Table 3. Contract-level features

With respect to our dataset and features, several points should be emphasized. First, data sparsity: it is common for a mention to have just a few features. Second, features are not evenly sparse (cf. Figure 1) and do not contribute equally to a possible linkage. Core features such as *name*, *surname*, *patronymic*, *gender* and *profession* must strongly correspond in order to consider a link as reliable. On the other hand, rare features such as *workshop insigna* can be very informative when shared by two mentions and should also be valued by the linkage algorithm. Finally, features are dependent, particularly on the role of the person (e.g. age indicated only for apprentices).

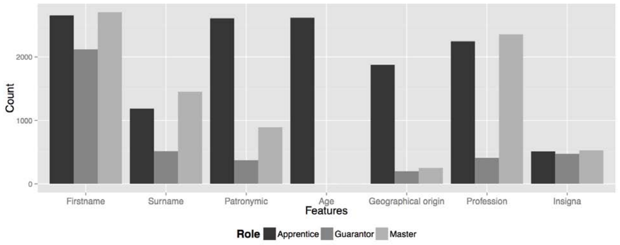

Figure 1. Distribution of features by role

We construct three matrices of size $N \times N$, where N is the number of mentions in the dataset. The first matrix Φ, the *feature matrix*, stores similarity scores of mentions pairwise. Scores are computed using measures over features as follows:

- *year of contract*: the feature-score is measured via distance and diminishing returns. Each year of distance between 1 and 15 and between 15 and 30 decreases an initial score of 1 by 0.01 and 0.025 respectively, with a definitive cut-off after 30. For example, two contracts from 1590 and 1594 have a score of 0.96.
- *age*: similarly as per year, each year of distance of the difference between two ages decreases an initial score.
- *gender* and *profession*: the feature-scores are based on exact matches.
- *name*, *surname*, *patronymic* and *workshop toponym*: the feature-score is based on the Deverau-Levenshtein string metric (Cohen et al, 2003). For example, *Polo* and *Pollo* have a similarity measure of 0.95.
- *geographical origins* and *insigna*: the feature-score is based on a token-based variant of the Jaro-Winkler metric. For example, *Friulano* and *del Friuli* have a similarity measure of 0.82.

The score of each pair is stored in Φ: it is the L2 norm of the resulting feature-score vector.

The second matrix Γ, the *combination matrix*, stores values that indicate whether a pair of mentions shares similar feature combinations or not. To build such matrix, we leverage the *golden* set and identify combinations of features which produced a linkage on a role-by-role basis (e.g. master-master or guarantor-master). Features are considered activated when their feature-score is equal or above 0.84[2] and we filter out combinations occurring once. The score of a mention pair in Γ is 1.0 if the combination of activated features is valid for the given role pair; 0.5 if the role pair does not match but the combination is valid; 0.0 otherwise. This matrix accounts for feature dependencies and the different ways to name a person with respect to his/her role.

The third matrix Δ, the *filtering matrix*, scores mention pairs according to the number of activated core features (1.0 if 3 + features – out of 5 – are activated, 0.0 otherwise[3]).

Given the three matrices, we normalize them and consider the following function to compute the similarity score of a mention pair *p*:

$$S(p) = \delta_p[\lambda\pi_p + (1-\lambda)\gamma_p]$$

where δ_p is a boolean parameter taken from Δ which activates the filter over core features for pair *p*; π_p is the feature score taken from Φ; γ_p is the combination score from Γ; and λ is a parameter giving priority over vector features or combinations of features. $\delta \in \{0, 1\}$ and $0 \leq \lambda, \pi, \gamma \leq 1$. This function allows us to adjust the different parameters: core vs sparse features (δ), feature scores (π) and feature combinations (γ).

Evaluation

We evaluate our approach in terms of coverage and precision. With respect to coverage, we verify our method over 100 thresholds from 0.99 to 0.0. For each threshold, we compare linkage curves as the percentage of links obtained over the total possible against the coverage of the *golden* set. Precision is based on manual annotation of 50 randomly selected linkages.

Both procedures are repeated with λ ∈ {0.1, 0.5, 0.9} and δ activated or not, for a total of 6 configurations. The objective is to understand the individual contributions of the three components to our function.

Results and Discussion

Results for the first and second evaluation procedure are presented in Figure 2 and Table 4 (resp.). Highest precision (0.61 and 0.3 in Table 4) is obtained with a balance between feature combinations and feature scores (λ = 0.5). δ proves very useful for filtering the input space (from 28,7M possible pairs to 44,2K), and lowers the number of false positives, especially for links between apprentices (cf. line 'w-o AA' in Table 4). The combination of the two (filtered input space and equal weights) provides the best results, especially for masters and guarantors. Linkage curves can be explained similarly: low λ entails a step-like curve (three steps at 0.0, 0.5 and 1.0), while high λ creates a Gaussian over the disambiguation space.

	active			δ not active		
	λ = 0.1	λ = 0.5	λ = 0.9	λ = 0.1	λ = 0.5	λ = 0.9
All	0.21	0.3	0.21	0.0	0.26	0.15
without A-A	0.22	0.61	0.22	0.0	0.48	0.67

Table 4. Precision with threshold >= 0.9 (* means not-significant statistics

This confirms that a balanced approach might be the best solution in a setting where data is sparse (high λ), the *golden* set is present but of limited coverage (low λ), and some prior assumptions on the required features can be made (δ). As shown in Figure 3, the graphs with λ = 0.5 and δ = 1.0 collapse more gradually, providing the widest effective linkage space to explore. Eventually, results also suggest to proceed in an active learning fashion, where the system learns iteratively with new data as part of the *golden* set.

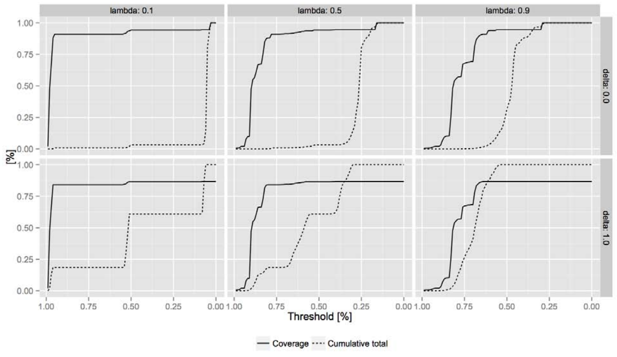

Figure 2. Linkage curves for the 6 parameters settings, over thresholds

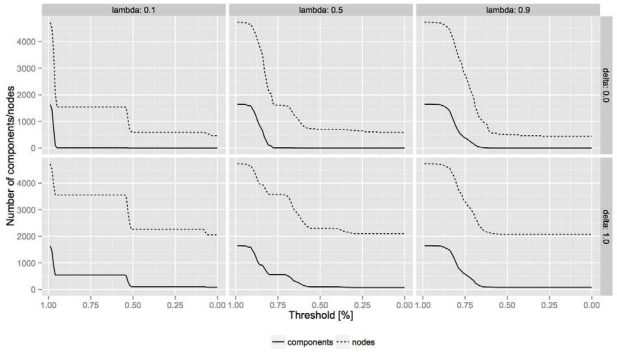

Figure 3. Graph properties for the 6 parameter settings, over thresholds

Finally, in order to further motivate our work, Figure 4 shows the largest components of the deduced social network with and without automatic disambiguation. The linkage method has the nice property of enlarging small components before gradually connecting them.

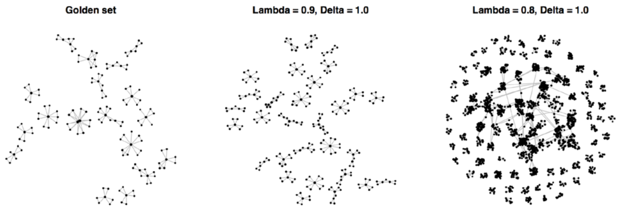

Figure 4. Largest components of social networks from golden set (left-most) and from disambiguated datasets (center and right-most)

Conclusion and Future Work

This paper presented a system to perform record linkage over mentions of persons from sparse historical data. It deals with different constraints such as data sparsity and limited prior knowledge. We plan to apply the system to different datasets and to integrate it into a transcription and annotation interface, in order to use it for live, aided record linkage.

Metacanon.org: Digital Humanities and the Canon

Nathaniel Allen Conroy
nathaniel_conroy@brown.edu
Brown University, United States of America

Can the digital humanities offer an alternative to traditional modes of canon formation? This paper argues that quantitative methods can both enrich our understanding of the way canons are formed and help us create more flexible and interactive alternatives to traditional canons. Over the last year, I've built a tool for generating dynamic literary canons and placed it in public beta at http://www.metacanon.org. Metacanon measures the canonicity of literary works by calculating the number of times they are mentioned in scholarly journals and using an algorithm to assign a uniform score to each work based on this data. While this certainly does not amount to a measure of aesthetic value or "greatness," it does offer a concise snapshot of the body of literary works that are most discussed by scholars. Currently, it only covers twentieth century American fiction, but future versions will be expanded to include other genres, periods, and nationalities. For scholars, this will provide a tool for quickly measuring the relative centrality or obscurity of particular works as well as a tool for measuring how canons change over time. For students and the general public, it will offer a far more inclusive, flexible, and interactive alternative to the fairly predictable greatest books lists that currently act as arbiters of literary value outside of academic circles.

In the wake of Pierre Bourdieu's Distinction (1979), literary studies has developed a nuanced critical apparatus for rethinking the role played by the canon and canonicity in the perpetuation of cultural capital. Our current scholarly common sense insists that far from reflecting aesthetic value, canons actually create this value socially, often thereby reinforcing hegemonic cultural values and hierarchies. And yet, even as we know this, the actual collection of texts that is consistently taught, written about, and by extension canonized remains relatively stable. By examining the frequency with which particular works are mentioned in various scholarly networks, Metacanon creates an accessible representation of this trend and in doing so introduces a greater level of transparency into the dominant allocation of literary values. In doing so, this project is similar in some respects to work being done by Mark Algee-Hewitt and Mark McGurl at the Stanford Literary Lab, although using different means and with different ends in mind. Whereas Algee-Hewitt and McGurl have produced a master list of 350 twentieth century novels by combining several "found lists" supplemented by a survey of scholars working in the field of postcolonial literature, Metacanon uses an approach that takes advantage of a wider array of harvested data drawn from thousands of journal articles. This reflects the very different goals of this project. Rather than producing a necessarily limited corpus suitable for datamining, Metacanon is primarily intended as an exhaustive but flexible representation of the canon. This allows for a much larger interactive list, but I've also found that the Metacanon list is much more diverse in terms of gender (and likely ethnicity) than the McGurl and Algee-Hewitt list, even though they consciously aimed to create a corpus that would be more representative than most standard lists. What this indicates is that although most publicly available "greatest books lists" tend to over-represent white men in their construction of literary value, scholars themselves tend to work on a much more diverse array of literary texts. In other words, there is already a working canon in existence that is much more diverse and representative than the standard lists and surprisingly more so even than Stanford's intentionally varied list; it's just that this working canon isn't generally available in an accessible, objectified form. Metacanon takes the first steps toward producing this more accessible form, even as it integrates flexibility and transparency into its framework.

The current version of Metacanon (0.6) is limited to twentieth century American fiction. As such, however, it is the most comprehensive relational database of American fiction from this period. Of course, there are more extensive listings of American literature available (for example, the Chadwyck-Healey Bibliography of American Literature). However these offer no way to easily distinguish between highly canonical works and more obscure works. In essence this forces readers looking for a definitive list of American fiction to choose between the unwieldiness of comprehensive bibliographies and the partiality of much shorter "greatest books" lists and standard field lists. What makes Metacanon unique is that it harnesses digital technology in order to offer both the expansiveness of a comprehensive bibliography while at the same time measuring the relative centrality or obscurity of each particular work.

This digital framework also allows users to become active participants in the construction of the canon rather than merely passive recipients. For example, one user might choose to see a list of the most canonical novels published between 1970 and 1979, or even more interestingly the most canonical novels of the 70s according only to data from the 80s or 90s. Another user might choose to see a list consisting only of science fiction written by women. A third user might choose to alter the algorithm to calculate canonicity based only on citations in a single journal. Contrary to the widespread fear that digital or quantitative approaches to literature are fundamentally opposed to nuance and flexibility, Metacanon demonstrates that this need not be the case, at least in so far as questions of canon formation are concerned.

While most of what is written above concerns Metacanon's value as a public humanities initiative and as an aid to students, this project has growing implications for literary scholarship more broadly. One of the most fascinating lines of inquiry in the digital humanities today is the use of quantitative textual analysis to trace the connections between literary form and reception over time. For example, scholars like Richard Jean So, Hoyt Long, Ted Underwood, and many others have used digital text mining to demonstrate relationships between particular formal features of literary texts and the social categories that govern their movement through the world, such as attributed aesthetic value and genre. As the precision of Metacanon's measurement of canonicity improves, researchers could use this data along similar lines to ascertain connections between literary form and canonicity over time.

Mining Leitmotif in James Joyce's 'Ulysses'

Ronan Crowley
crowle01@gw.uni-passau.de
Universität Passau, Germany

Gábor Mihály Tóth
gabor.toth@maximilianeum.de
Universität Passau, Germany

James Joyce is one of the most admired, emulated and mythologised masters of twentieth-century prose. His *Ulysses* (1922) is among the cardinal texts of literary modernism produced between the world wars. The text creates its numinous effect through the repetition of short phrases over the course of a quarter of a million words. As early as 1929, critics invoked the musical device of leitmotif to explain this form of literary repetition (Curtius, 1929). Leitmotif describes a signature phrase or cue that accompanies and signals the presence of a character, locale or theme in a work. The device achieved a new importance in the nineteenth century through the opera of Richard Wagner, and it quickly migrated from music to literature in the writings of Édouard Dujardin, Thomas Mann and Marcel Proust. In Joyce's hands, the pervasive use of the device amounts to "a sort of linguistic magic-realism" (O'Callaghan, 2011). But whereas musical leitmotif is conveyed through auditory recall – listeners recognise a brief musical phrase as an instance of leitmotif – written language cannot always offer this immediacy. The problem is a singular one: how do readers and how do computational tools recognise and unify the discrete instances of leitmotif that are distributed across a text?

Methodology

The proposed paper will report on a series of experiments that combine methods of corpus and computational linguistics with close reading to gauge a fuller extent of the repetition in the novel and to assess its worth as leitmotif. From the perspective of text analysis, leitmotif is the purposeful repetition of textual fragments (or n-grams) in a text or over a collection of textual documents. Our computer assisted retrieval of leitmotifs is based on the following set of assumptions: First, for a sequence of words to be a leitmotif, it must capture a (human) reader's attention through distinctive word choice or unusual collocation. This distinctiveness ensures a reader can recall earlier occurrences. Second, a given sequence of words functions as a leitmotif only if it occurs in a limited number of chapters or episodes of *Ulysses*. The sequence must occur in more than one episode but not in all eighteen. Key to distinguishing a given sequence is a limitation in the number of its occurences. Finally, previous scholarship has observed that Joyce not only repeated leitmotifs verbatim but also paraphrased, transposed, abbreviated or otherwise altered their individual elements (see Büchler et al., 2014 in this context). A computational approach needs to take stock of this state of affairs.

Work to Date

At the current stage of our research, we focus on bigrams. By treating each episode of the novel as a single document, we have constructed a document collection to measure the inverse document frequency (idf) of bigrams in the collection. The use of idf metrics enables us to retrieve those bigrams occur in a given number of episodes. Initially we set a threshold of occurrence at two, three and four episodes; in the light of the results produced we are continually revising this threshold. As a second step, the uniqueness or distinctiveness of bigrams was investigated by measuring the probability of their occurrence in a contemporary corpus of English texts put together from documents in Project Gutenberg and Archive.org. This helped to filter out very common constructions that enjoy a high idf. Named entities were also eliminated from the list of bigrams. We have also examined bigrams for "fuzziness" – gauging whether the constituent elements reoccur but with words inserted between them or in a reversed or otherwise transposed order. We have produced a list of around two hundred bigrams that are candidates for consideration as leitmotifs. Finally, a striking feature of Joyce's style in *Ulysses* is the frequent use of compound coinages. Not only did he insert such neologisms into the text, but he also split them, reusing the constituent units of compounds in close proximity. This stylistic device also contributes to the pervasive sense of repetition in *Ulysses*, functioning as an alternative to and special case of leitmotif. To identify this type of repetition, we have retrieved and split all compound coinages in the novel, and examined whether their constituents reoccur within a given word distance.

Challenges

The main obstacle to identification is the "protean nature" of leitmotif itself (Bribitzer-Stull, 2015). Whereas a highly distinctive phrase like Joyce's "Agenbite of inwit," which occurs in *Ulysses* seven times (Joyce, 1922), can readily be identified as a leitmotif, the associative potential inherent in even very short units of language means it is not always clear how one is to distinguish leitmotif from mere linguistic flukes or from instances of more general intertextuality (Kristeva, 1967). Examples of the latter include lexical priming (Hoey, 2005) and natural language collocation – for example, if an author writes "he opened the," a reader of English would reasonably expect the next word to be "door." At the moment, our list of candidate leitmotifs is checked by close reading bigrams within the context of the sentences in which they occur in the novel. Those bigrams that are accepted or judged as valid instances of leitmotif are added to a purpose-built database.

Outcomes

In addition to extending the inventory of leitmotifs identified in *Ulysses* (see, for example, Schutte, 1982), the experiments and the subsequent analysis have another key goal. They are meant to test the hypothesis that leitmotif not only offers a way to flag the presence of a character, locale or theme in the novel, but also creates a series of "primitive hyperlinks" or "analogue hyperlinks" (Cope and Phillips, 2006) threaded throughout *Ulysses*. Critics have often invoked hypertext to explain the myriad connections established within Joyce's work (e.g. James, 1999), but our research will lead to an online hypertext edition of *Ulysses* that allows the reader to explore the non-linear reading paths created by leitmotif.

WordPress as a Framework for Automated Data Capture, Filtering and Structuring Processes. The New Order of the Authors

The Exhibitium Project, awarded by the BBVA Foundation, is a data-driven project developed by an international consortium of research groups. One of its main objectives is to build a prototype that will serve as a base to produce a platform for the recording and exploitation of data about art-exhibitions available on the Internet. Therefore, our proposal aims to expose the methods, procedures and decision-making processes that have governed the technological implementation of this prototype, especially with regard to the reuse of WordPress (WP) as a development framework.

According to the project's purpose, it was necessary to create a device that, to the extent possible, could capture in automated way information on art exhibitions from any Internet source. Consequently, the inquiry into the possibilities of web mining strategies emerged as a priority from the early stages. Taking into account the high expressiveness and flexibility of linguistic structures usually used in the description of art exhibitions, our project opted for a mixed platform which combines the potential modeling system based on textual indicators, the heuristic means that characterize some methods -such as the Bayesian classification- and the human supervision provided by a well trained team of editors.

1. General overview. WordPress as a framework of the Expofinder system

As Baumgartner et al. (2009: 1) established, the web data extraction task is usually divided into five different functions: (1) the web interaction, which mainly comprises the navigation through predetermined web pages containing the information sought; (2) the extraction of the searched data by means of a software that identifies, extracts and transforms them into a structured format; (3) the setting of a specific calendar that enable to perform automatically the extraction tasks in regular sequence; (4) the processing of the captured data, which includes filtering, transformation -if applicable-, refining and integration; and (5) the delivery of the resulting structured data to a variety of data analysis-based systems.

Assuming this distribution as the most convenient for our purposes, we decided to include them in the Exhibitium's architecture grouped into two large blocks.

A. A block consisting of an automated capture system of information robust enough to ensure the reliability of the collected data.

B. A second block made up by the set of elements necessary to store the data, including functions for filtering, cleaning, management, structuring and description. This block also incorporates a system to export the collected data to those platforms that will process and analyze them during the second phase of the project.

Block A was called Beagle, and block B became known as ExpoFinder. Both blocks work in a coordinated manner, so that what is extracted by Beagle is put at the disposal of ExpoFinder. The two blocks are part of an unified system configured by a cyclic algorithm: Beagle captures, ExpoFinder analyzes and approves the captured information, the team of editors validates or discards what ExpoFinder has previously approved, and Beagle recaptures again (see figure 1).

Regarding the software, after preliminary versions based on own developments, it was decided that the most interesting option between the free software and open source solutions currently available (as the openness philosophy is a sine qua non requirement of this project) would be to use WP as framework of the system. The main benefits that the use of WP as framework offers for our project can be synthesized in the following items: a database with a flexible and very solid organizational structure; a layer of a core application with numerous hooks which allow to maximize its functionality; and a high easy management system to carry out tasks on the two sides (server and client), assuming both administrator and user roles. Thus, for the implementation of the Beagle-ExpoFinder system we took advantages of the predefined data base, the available APIs and the set of data visualization templates to build solutions using an application that is already fully functional.

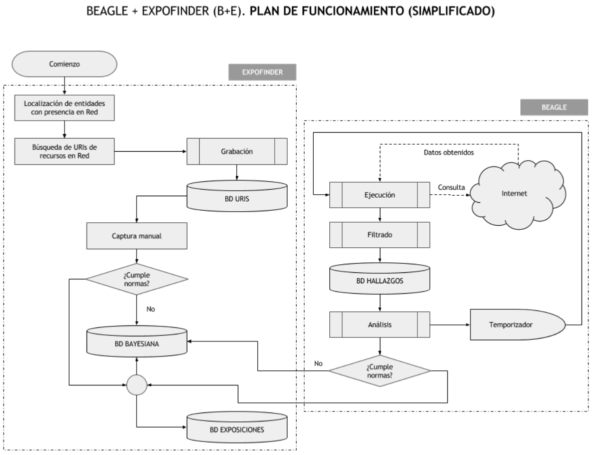

Figure1. Beagle + ExpoFinder. Operating plan (simplified)

We used WP without adaptations, that is, as it can be downloaded from the Internet. All the functionality of our application lies, then, on the code itself that constitutes WP, so it is not supported on variant versions (forks) of the original program. Hence, any improvement provided by the computing community will be directly usable by our project without further adaptations. As part of the requirements of the development of the Beagle-ExpoFinder system (B + E), from the beginning it was considered that the programming work did not constitute a «tailored suit» for the Exhibitium project. On the contrary, we expect that this work can be useful in other projects with a small number of modifications or by using configuration files or other similar systems. For that reason, our choice was to implement B + E by means of a «WP theme», solution that easily allows us to readapt the software to different purposes.

2. Beagle and Expofinder development and technical features

Beagle captures – as it has been said- by automated means web data concerning temporary art exhibitions from any source of information, and includes a filtering mechanism. The automated capture process uses the tools of WP API, particularly WPCron. Likewise, the frequency of the process is configured according with the options offered by ExpoFinder to the system administrator. Beagle employs two statistical complementary functions to «predict» the degree of the adequacy of the captured information to the ExpoFinder preconditions: 1. One of this is based on the intersection of a set of «positive» and «negative» keywords with a proportional weight assigned to each one, which is also based on the shortest path algorithm of Bellman-Ford; 2. The other is defined by its heuristic nature; it employs a naive Bayesian classifier to guide the «human» editor during the task of discriminating whether or not an information captured by Beagle is valid. The latter is able to improve their efficiency through continuous learning processes (each discarding or acceptance made by the «human» editor refines the system «perceptiveness» (see figures 2 and 3).

Notes

[1] Generation of knowledge about temporary art exhibitions for a multivalent reuse was the topic of the proposal presented to the 2014 competition organized by the BBVA Foundation for projects in the field of Digital Humanities, resulting selected from over 250 submissions. The project website is available at: http://exhibitium.com. The Exhibitium Project began in January 2015 and will end in December 2016, so currently we are completing the first phase.

[2] They are: iArtHis_Lab (http://www.iarthislab.es) and Khaos (http://khaos.uma.es) at the University of Málaga; Techne, ingeniería del conocimiento y del producto (http://www.ugr.es/~tep028/quienes_somos_es.php) at the University of Granada; and CulturePlex at the University of Western Ontario (http://www.cultureplex.ca).

[3] Specifically, the ultimate Exhibition's purpose is to extract unprecedented and strategic knowledge about temporary art exhibitions through the use of a variety of data mining techniques.

[4] Although, in reality, according to the Tom McFarlin's statement in his popular page «tuts +» (http://tutsplus.com/), it is more a foundation that a framework. And maybe he is right: a framework consists of a set of conventions as well as libraries and tools that allow us to easily start working on an application. In short, it provides the means by which an application can be built from scratch, from the database schema to the front end. However, a foundation allows to «extend» an existing application. WP has its own well-defined internal mechanisms, and the foundation simply expands its operation or takes advantage of it for their own benefit.

[5] The advantages that a robust mechanism as such provided by WP offers for the maintenance of a security system (essential in any development accessible through Internet), or the substantial savings in time and resources involved in a CRUD structure records management -which is both sufficiently malleable to suit any need and rigid enough to follow canonical deployment patterns (such as the «nonce» safeguards in the capture forms), are weighty arguments when opting for the use of one framework or another.

[6] Even though this document is not largest enough to expose in detail the list of selected preconditions of significant terms used by Beagle in order to filter the captured information, we want to emphasize that this is a «weighted» relationship of lexemes in which each root term is assigned a total «weight» in the set (1 to 3). When the entire process is complete, the absolute amount of the sum corresponding to the found terms is weighted with the relative values (relating to the length of the text where they have been detected) to assign a positive or negative evaluation to the whole information.

[7] The Bellman-Ford algorithm (or Bellman-Ford-Moore) calculates the shortest paths from a single source vertex to all other vertices in a weighted digraph. It is slower than Dijkstra's algorithm for the same problem, but more versatile, since it is suitable to deal with graphs using negative numbers for edge weights. ExpoFinder takes advantage of it in its weighting mechanism, useful for us because we work with lists of lexemes for words used as «positive» or «negative» markers.

[8] In machine learning terminology, the «naive Bayesian» constitutes a family of simple probabilistic classifiers based on the application of Bayes' theorem about the hypothesis of independence between variables. Widely studied since the 1950s, it began to be used since the beginning of the next decade as a taxonomy method capable of self-optimization in the recovery community text. We use the frequency of occurrence of a given lexeme as a trigger, so that ExpoFinder can contribute to the semi-automated selection of relevant information from the experience gained. It is not a pure discriminative mechanism, but an auxiliary tool that has proven to be useful for application operators.

The Project Zeri Photo Archive: Towards a Model for Defining Authoritative Authorship Attributions

Introduction

The global project of data conversion of the notable Italian 'Zeri Photo Archive' into a Linked and Open Dataset[1] primarily regarded the analysis of the **description model of the available records**, so as to define a collection of suitable ontologies to describe such a complex domain.

Indeed, the uniqueness of the Zeri collection[2], which includes about 290,000 photographs of works of art and monuments, lies in the rich documentation of the described artefacts, mostly related to provenance, attributions, restoration events and their connections to the collection of 46,000 books and 37,000 auction catalogues (Mambelli, 2014).

The full project entails, together with the ontological modeling, the production of the RDF dataset, the creation of proper links to the LOD cloud, and the definition of the user interface for browsing the dataset.

F Entry Ontology

The first activity of the project had been the **formalization of the** Scheda F ('Fotografia') (Mibact, 1999) , – the metadata standard of the Italian Istituto Centrale per il Catalogo e la Documentazione (ICCD) – by mapping the schema onto CIDOC-CRM model (Crofts et al., 2011). In the conversion we initially considered the specific flavor of the Scheda F used by the Zeri Foundation, i.e. its subset of 113 fields (based on the experimental 1.04 version of the ICCD standard) and an handful of custom extensions to it. A deep analysis of the schema of the Scheda F showed that it is organized in semantically independent sections (called "paragrafi", or *paragraphs*), each one belonging to a specific FRBR concept (Work, Manifestation, Item); this allows the mapping to proceed by logical sections affecting only a limited number of entities and relating these entities to the data documented by the fields of the schema.

Before accomplishing the mapping, we proceeded with the creation of a **new ontology called FEO** (*F Entry Ontology*[3]). Since our final goal was to make available Scheda F data in a triple store, the target language we chose was OWL 2 DL. The current version of FEO introduces the classes and properties that characterize three specific concepts: the photograph, the work of art that is the subject of the photograph, and the Scheda F itself describing the photograph and its subject.

So, through the use of well-known ontologies – i.e. CIDOC-CRM, but also PROV-O (Lebo et al., 2013), and FaBiO (Peroni and Shotton, 2012), as part of the SPAR Ontologies[4] (Peroni, 2014) – plus the FEO ontology developed *ad hoc*, most of the content expressed as descriptive entries in the Scheda F have been already formally represented (Gonano et al., 2014).

OA Entry Ontology

In this presentation we propose an extension of our work on the Zeri Photo Archive by introducing a **new ontology** for representing works of art and their related information, namely, the OA Entry Ontology[5]. In particular, this ontology is based on the *Scheda OA* ('Opera d'Arte') – another ICCD metadata standard[6] – and proposes a mapping between the content standard and, again, the CIDOC-CRM, in order to create shareable descriptions of metadata[7]. In addition, other kinds of information that are not easily representable through the aforementioned standards, such as certain peculiar relations between works of art, are modelled by means of new classes and properties created in the OA Entry Ontology. This last allows to describe, in particular, the work of art and the related items, by focusing on some classes (e.g. copy, derivation, fake, drawing, model, replica, sinopia) and by using properties as necessary connection typization (e.g. conceived or former).

HICO and authorship attribution

Moreover, in this paper we further investigate a way for providing a clear and shareable representation of questionable information, i.e., the **authorship attribution of works of art**. In the Zeri Photo Archive there are particular authorship attribution created by either the Zeri Foundation cataloguers and/or by Federico Zeri (collector of photographs) himself, and such attributions (that could be accepted or discarded at certain point) are accompanied with the criteria that corroborate the cataloguers' choice.

In order to provide a precise characterisation of all these aspects, we discuss the adoption of **HiCO**, Historical Context Ontology (Daquino and Tomasi, 2015) as a way for enabling a definition of authoritative attributions based on Zeri cataloguers' own criteria. HiCO[8] is an OWL 2 DL ontology we created for describing contents of data (e.g., an authorship attribution), in particular cultural heritage data, and data creation itself (e.g., RDF statements representing above mentioned authorship attribution) as part of an interpretative process. Cultural heritage object is a wide concept: it includes any sort of representation of culture heritage embodied in a tangible form like artifacts (books, documents, and, as in this case, works of art), but also any concept, assertion and interpretation somehow bounded to cultural objects.

With the hico:InterpretationAct class it's possible to **describe the interpretation act as a process**:

- the conceptualization of the interpretation and its classification, for enabling further relations among different kind of interpretations;
- the embodiment of the interpretation as RDF statements, for representing information extracted from the content of the object of interest.

Two fundamental object properties complete the process: the hico:hasInterpretationType property and the hico:hasInterpretationCriterion property. The former states an arbitrary classification of the interpretation, which can be simply defined as philological, historical, semiotic, linguistic etc. The latter is a briefly explanation of the criterion used to state information extracted from a source, e.g. a literally transcription, a hypothesis, or the adoption of the literature about a specific argument.

A crucial aspect of the project is the **correct formalization of statements** so as to allow the ontologically-consistent coexistence of data created by different actors that express contradictory statements about the same subject (e.g., authorship attribution data of a work of art), in order to guarantee the data integration with Pharos (Reist et al., 2015) project partners, of which the Zeri Foundation is a member. By the use of SWRL rules applied to relations between sources, criteria and context information used by an agent to explain his interpretation, **we could formally infer when an interpretation can be considered authoritative**.

An example of authoritative assertion

We could give an **example**. We state aside the interpretation (i.e. the assertion "An artist X is author of a specific work of art Y in a specific time Z") which sort of interpretation we are dealing with (i.e. authorship attribution), and which criteria have been used by the cataloguer to assert such proposition. A provenance statement ensures both author of assertion (i.e. interpretation) and author of data conversion are fully described, ensuring that no contradictory statements will affect data validity.

When necessary conditions for stating authorship are fulfilled, an attribution may be inferred as authoritative. In the example (Fig. 1), we have an attribution which respects minimal requirements for being considered an **authoritative assertion**:

- it has been stated by a well-known author (i.e. the cataloguer of Zeri Foundation);
- it considers as criterium an authoritative source (i.e. the photo depicting the work of art);
- it agrees with another interpretation, i.e. Federico Zeri classification.

This obviously doesn't entail that the attribution is surely correct, but it can be a useful tool for historians when searching for different attributions and related criteria adopted in interpretative process.

Conclusions

To conclude, as said before it will be the natural completion of the Zeri Project the RDF triple store set up, the creation of links to other datasets, and the definition of the user interface for browsing the linked open dataset. All these activities are now object of our research group industry and the final publication of the project is expected for the middle of 2016. Data had already been transformed in a RDF/XML dataset, according to above mentioned ontologies. Next steps of the project involve thus data publication, ensuring access to them through a SPARQL endpoint. When published, data will be enriched with further RDF links to major datasets and authority files online (e.g. VIAF for people and works, Getty thesauri, GeoNames for places[9]). This ensures our data will really be part of the LOD Cloud, avoiding creation of another data silo. So enriched data will then be exploited in a new smart application, which will enable users to search data about both photos and works of art. Through this modelization data and new relations will be easier discovered, enhancing user experience.

Materiality and Metadata of Digitised Photographs: A Theoretical Inquiry

Vinayak Das Gupta
vinayak.dasgupta@gmail.com
Maynooth University, Ireland

This paper suggests a separation between the content, the carrier, and the presentational forms of the digitised photograph (as opposed to a born-digital image) and presents the draft for a metadata schema that is able to record the circulation of the object. The arguments presented in this paper are adapted from the research conducted for a recently-submitted doctoral thesis.[1]

Scholarly study of the photographic image, specifically with the 'material turn' in anthropology and cultural studies,[2] has attempted to inspect the photograph as a physical object (Batchen, 1997, Edwards, 2002, Edwards and Hart, 2004). This process of inspection expresses the complexity of the social existence of objects and allows the investigation of the photograph as a material object whose understanding is augmented by its form. Photographs have specific modes of circulation, production, and consumption, and their inspection has potential beyond the critiques of representation alone.[3] The inherent bias of the indexical qualities of the image over its material properties may overlook the social and cultural contexts within which the photograph is born and used. While current digitisation techniques have found accurate methods of copying the content image, the description of its materiality remains a challenge. If the physicality of the photograph is central to its understanding, this paper inspects the possibilities of providing the digital referent with the material information. It presents an examination of both the materiality of the photographic image (and its transformation into a digital object), and the means through which the presentational forms of the original may be inscribed in the digital referent.

The digitised photograph is a material object: to observe this materiality, a separation between the content and the carrier of the object is required. The photographic image is printed on paper, and this paper is the carrier of the content image. Similarly, the content of the book is carried in the physical form of the book — the paper, glue, and ink that hold it together. In the physical object (as opposed to its digital counterpart) the content and the carrier are closely inter-linked to the point where their separation is difficult. However, the carrier may change at different moments of time, which may provide the object with different contexts: consider an image that was first printed on photographic paper, then printed in a newspaper, and then, perhaps, in a book. The different material existences of the image provide contexts that locate it within different points in history. The digital object is, similarly, carried by electronic circuits. That the digital object has materiality, then, is undeniable. The problem, perhaps, in identifying this materiality lies in the degrees of separation between the circuits and the perception of the object. To view an electronic image, a screen — an enabler — is required. The experience of the object then is governed by an intermediary system. The dislocation between the carrier of the object and the experience of the object is perhaps the source of a material fallacy.[4] If it is acceptable to think of this separation between the content and the carrier, it is possible to argue that the digital object is merely one iteration of a different carrier. The digitised image, then, is the original image, in a new material form.

The photograph has multiple lives; it exists within sociocultural contexts, and to understand it, the content image must be seen in conjunction with its material form. Since the inception of photography, photographic images have been used in a variety of contexts, and have been presented in a multitude of ways; the carrier often determines the use the content image is put to. Whether preserved in photoalbums (arranged thematically or sequentially), sold as postcards for the curious, or published as documentary evidence the presentational form of the photograph weighs heavy on the readings of the image. Presentational forms, in particular, guide the way in which photographs were used after their inception, and also the way they were understood. It is, here, important to distinguish between the carrier and the presentational form: the carrier is always material, while the presentational form is ideological. The materiality guides the technical production of the image, and bears the imprint of time on it. The presentational form reveals the social, political, cultural, and religious contexts within which the photograph is *used*.[5]

This paper proposes to include the material specifics of the physical photograph at the level of the metadata of the digitised image. Metadata schemata for visual resources, such as CDWA and VRA Core, articulate the description of objects by distinguishing between Work and Image.[6] This separation attempts to describe the complex relationship between the original and the surrogate. In a similar vein, this paper suggests a separation between the content, the carrier, and the presentational form of the photograph in its descriptive schema. For photographic images, it is more important to record its material transformations than separate the original from the copy.[7] While the content image remains the same, different material specifics of the photograph change as the object adopts new carriers and new presentational forms. The proposed schema is able to record multiple carriers and presentational forms for the same photographic object. This would, potentially, help to examine the circulation of the photographic object — a key concern of scholarly research in the field. This schema also presents the possibility of being extended to a linked data format that multiple curators can add to in order to articulate information about the same object. The paper presents a blueprint for the proposed schema — the structural and the functional aspects of its design.

Notes

[1] Thesis titled 'From Evidence to Essence: Curating Thematic Collections with Photographs from the British Raj' submitted in partial fulfilment of the requirements for the degree of Ph.D to Trinity College Dublin on 30th September 2015.

[2] Material cultural analysis, from an anthropological position, questions the assumed superiority of language over other forms of expression (Miller, 1987).

[3] John Tagg (1988) discusses the manner in which the currency and the value of material objects arise in certain distinct and historically specific social practices.

[4] Joanna Sassoon (2004) presents an engaging examination of the materiality of digital photographs. However, the central rationale in her paper takes premise on the assumption that digital objects have no material existence.

[5] A similar concern may be seen in the area of textual editing with concerns about the primacy of the document over the text. For further reading see, for instance, Hans Walter Gabler's 'The Primacy of the Document in Editing' (2007).

[6] VRA Core 4, in fact, is built around three record types — Work, Image, and Collection.

[7] Walter Benjamin in his seminal essay 'The Work of Art in the Age of Mechanical Reproduction' contends that for photographs, asking for the mechanically produced, original print is non-sensical.

Notes from the Transcription Desk: Modes of engagement between the community and the resource of the Letters of 1916

Vinayak Das Gupta

The *Letters of 1916* is Ireland's first public humanities project. It collects, digitises, transcribes, encodes, and makes available through its electronic platform epistolary documents written between 1st November 1915 and 31st October 1916. The year 1916 was one of transition for Ireland: between its involvement in the Great War and the rise of militant nationalism, the country was divided by sentiment, separated by ideals. 2016 sees the centennial commemoration of the Easter Rising[1] across Ireland. A more complex interpretation of the events that transpired in Easter week 1916 has entered national consciousness and with it the interest in the smaller and more personal accounts of those caught up in the ensuing violence. The rhetoric of the letter presents personal perspectives and individual memory traces; the collected letters provide an insight into those fragmentary stories that, inspected together, constitute a collective consciousness. Letters are shared experiences that connect people across geographical spaces.[2] The unique personal perspective of the epistolary form challenges the perceptions of established history, questioning the role of memory and the acts of commemoration that this era suggests.

Since Jeff Howe's coining of the term 'crowdsourcing' in 2006 (Howe 2006), a number of pioneering projects have provided legitimacy and validity to the process.[3] The *Letters of 1916* considers crowdsourcing in the widest possible sense of the term; the processes of collection, transcription, and curation are done through public engagement. The focus of this paper rests on the volunteer community associated with the project[4] and provides an inspection of the levels of its engagement, a study of its interests and motivations, and how future projects can adapt this investigation into community interaction. Sharon Leon, discussing her observations while working on the *Papers of the War Department 1784-1800*, identifies and categorises these motivations into six fields: (a) an interest in history, (b) a sense of civic duty, (c) a specific point of scholarly research, (d) engagement based on genealogical and family research questions, (e) educational assignments, and (f) curiosity about how the transcription tool and process works (Leon 2014). This paper extends these assumptions, inspecting specifically the affect of the epistolary form on the transcriber. The topical nature of this project raises questions beyond the ones that Leon raises.

The investigation in this paper traces the manner in which the community engages with the content, a hundred years since they were written, not merely as historical documents but as individual memory traces that express personal sentiments. The centenary creates a renewed vigour in the study of these documents and the paper questions if the engagement with these letters produce a more nuanced understanding of this conflicted time. As Leon points out, one of the driving forces of community transcription lies in an active interest in scholarly research. This paper attempts to understand this very engagement in the *Letters of 1916* project; some of the letters in the resource, particularly those received from personal collections, have been unavailable to the public until this point. Does the possibility of discovering these little stories and personal narratives that are weaved within the politics of the time, create an interest that emphasises the novelty of discovery? As the transcriber actively engages and researches these documents, do her motivations lie in the possibility of unearthing new knowledge?

A data-driven examination of transcriber-activity, as evidenced in the project, suggests that individual members of the community create self-fashioned roles. The transcriber who reads and re-authors these letters, the encoder who attributes TEI[5] markup to the transcribed text, and the researcher who provides contextual information for the letter are all employed in the production of these electronic documents but their engagement is at different levels. This paper attempts to understand this division of roles based on the modes of engagement that are apparent. Re-authoring of these letters raises another question: as Barthes suggests, the relationship between the reader and the writer is complex and deeply problematic (1977). Does the re-authoring of these letters create a deeper investment in the narrative? This investment is reiterated when we consider the private emails exchanged between members of the *Letters of 1916* volunteer network and the project staff where concerns are raised over the urgency, validity, and authority of the initial transcription; the accuracy and the model of the transcription becomes a point of contention between the members of the community.

This paper considers the proposed questions in three stages and at three levels to gain a clearer understanding of the role of the transcriber within the *Letters of 1916* project. In the first instance, a statistical inspection of the metadata for the transcribed letters provides an examination of the volume and the rate of transcription over the course of the project. The engagement of the individual transcriber with specific themes[6] within the collection is revealed in the process; this mode of investigation aids in viewing the community, not as a homogenous cluster, but as individuals with specific interests and different points of engagement. The visualizations generated from these analyses illustrate the interests of the community at a macro level. In the second instance, the *Letters of 1916* volunteer network is approached with a focused survey. This ongoing survey presents the second phase of coordinated feedback that this project records. The questionnaire is designed to cover a range of topics that both reinforce the results of the statistical analysis and ask questions that lie outside the scope of data-driven inquiry. The focused design of the questionnaire is informed by the preliminary phase and attempts to tease out the motivations that lie at the heart of crowd-sourced projects such as the *Letters of 1916*. In the third and final instance, the most-prolific transcribers[7] in the project are approached for interviews regarding their role in the process of transcription. These interviews are detailed and provide a closer study of the desires of the community. The methods utilised in this paper move from a macro to a micro level, from the data to the individual, in order to derive a concrete and axiomatic base to study the modes of engagement that the *Letters of 1916* project and, perhaps, all crowdsourced projects have.

The success of a crowdsourced project lies in creating effective engagement between the community and the resource. This paper provides an investigation of the motivations and the desires of individuals that drive these forms of public history projects forward. The topical nature of this research, combined with the affect of epistolary documents, creates a unique opportunity for this study, a model for future projects to further develop their volunteer community, and the critical foundations on which future study of community transcriptions may be based.

Notes

[1] The Easter Rising was an armed insurrection launched by a minority of Irish nationalists against the British Empire in 1916. The Rising was contained to Dublin and suppressed following a week of fighting. It is seen as the genesis of the later Irish War of Independence. For further reading see, for instance, Max Caulfield's *The Easter Rebellion* (1998).

[2] Janet Gurkin Altman, contemplatig about the form of the letter, contends that while letters connect two geographical points they also serve as a bridge between the sender and the receiver. The epistolary author can either choose to emphasisne either the bridge or the distance (1982).

[3] Since Howe's definition of the term there have been several pioneering project based on crowdsourcing. For instance, see *Transcribing Bentham*, *Papers of the War Department 1874-1800* and *What's on the Menu*?

[4] As of October 2015 there are 1159 registered users on the *Letters of 1916* site. These users transcribe, on average, 192,409 characters a month.

[5] The Text Encoding Initiative (TEI) is a consortium which develops and maintains a standard for the representation of texts in their electronic forms. For further information see http://www.tei-c.org/index.xml

[6] Letters can belong to one or multiple themes including *The Easter Rising*, *World War I*, *Family Life*, *Love Letters*, *Official Documents*, *Politics*, the *Irish Question* and more.

[7] Each month the *Letters of 1916* Project generates a list of "top" transcribers. This list is determined by the number of characters a specific individual has transcribed in that time frame.

Introduction: automatisation dans l'audiovisuel

Les besoins de rationalisation des coûts et des moyens de production en Europe et dans le monde amènent les services de médias audiovisuels à avoir de plus en plus recours à de l'automatisation au cours de leurs phases de production comme de post-production. La notion d'automatisation fait en elle-même débat dans la mesure où elle est très mal définie : la plupart des dictionnaires indiquent un laconique « Fait d'automatiser ». Il serait plus juste de la qualifier de « stratégie qui vise, par l'emploi de méthodes et de moyens normalisés et optimisés de technologies, à la réduction de l'intervention de l'Homme dans la réalisation d'une opération ou d'une série d'opérations ». Une tâche automatisée relève ainsi de l'ajout de systèmes informatique, robotique,... dans le but de se substituer à l'Homme – réaliser le montage d'un produit audiovisuel par un algorithme, ou remplacer 3 cadreurs par un seul qui pilote 3 caméras à distance est une tâche automatisée. En ce sens, l'automatisation est actuellement portée par les constructeurs de matériel audiovisuel professionnel à travers des systèmes plus ou moins complexes. La conception de ces outils d'automatisation du « workflow » demeur e partielle et aucun système global unifié n'est actuellement proposé. De ce fait, les chaines de télévision associent équipements traditionnels et automates. Le workflow désigne, dans le jargon de l'audiovisuel, l'intégralité de la chaîne de production de l'idée au produit final archivé au sens de (Leleu-Merviel, 1997).

La production d'images et de sons s'est toujours accompagnée d'instruments plus ou moins élaborés (il est difficile de réaliser un film sans caméra). Cependant, le contrôle de cet outil, la prise de décision quant à son utilisation, change d'entité avec l'automatisation. Le matériel est le même, mais son utilisation est gérée, commandée par un automate. Selon (Arendt, 1958), l'action d'un agent humain est imprévisible, car elle est inextricable d'un réseau de relations humaines. Sans pour autant lui enlever son appellation d'artefact, il est nécessaire de s'interroger sur la nature d'un produit qui n'émerge plus uniquement des processus sociotechniques, mais sur des règles d'inférences d'une unité de calcul informatique. Aussi se pose la question de l'impact de cette diminution de l'intervention humaine dans la production audiovisuelle sur sa réception par le spectateur. Un produit audiovisuel est un artefact à but communicationnel, créé par des humains pour des humains. En effet, les choix des acteurs – au sens de (Latour, 2005) – de la création d'une l'œuvre audiovisuelle ont un impact (variable mais bien présent) sur ce dernier. Si le type de produit (fiction, publicité, émission de divertissement, journal télévisé,...) va influencer les modalités de réception de ce produit – ce que (Jauss, 1978) appelle l'Horizon d'attente – les paramètres de conception et de réalisation du produit doivent eux aussi rentrer en compte. Il est probable que l'automatisation des systèmes de production audiovisuelle, entraînant un formatage plus fort du produit à créer, impacte le sens construit par le spectateur. Toutefois demeure la question de l'importance de chaque maillon de la chaîne de production : quelle est la signifiance apportée par l'humain vis-à-vis d'un automate dans la production de l'œuvre ?

Méthodologie: analyse des processus sociotechniques et étude statistiques

L'analyse des processus sociotechniques en régie de production et des acteurs du programme sur le plateau, comparée aux nouvelles méthodes de travail d'un « workflow » automatisé, permet de relever des différences dans la conception du produit. Ces différences, dans l'esprit des travaux de (Latour, 2005) seront soulignées par les agents contribuant à la création du produit eux-mêmes. Ainsi, la méthode permet de déceler des finesses qu'une simple comparaison des tâches à effectuer ne permet pas. Par la suite la mise en parallèle avec un test d'impact de plusieurs versions d'un même événement télévisuel (traditionnelle et automatisée) sur le public permet au chercheur de faire le lien entre modification d'un réseau d'acteurs de la chaîne de produit et sens construit par le spectateur.

Dans le cadre de cette étude, une captation multi-caméra et à plusieurs systèmes de captation a été mise en place. Le sujet filmé relevait de parenthèses musicales lors d'une remise de diplômes à l'Université de Valenciennes. Trois systèmes ont été utilisés en parallèle :

- Un système "témoin", mobilisant une régie professionnelle d'une vingtaine de personnes, étudiants de master audiovisuel de l'Université de Valenciennes ;
- Un système "semi-automatisé", utilisant une régie miniaturisée pour une personne (réalisateur professionnel) ainsi que des caméras robotisées pilotées à distance par un second opérateur ;
- Un système "mono", consistant en une caméra filmant le sujet en plan large fixe.

Par la suite, les encadrants de l'équipe “standard” et les intervenants de l'équipe “semi-automatisée” ont été interrogés sur la préparation et le déroulement de la captation dans leurs régies respectives. Ces résultats ont été croisés avec une étude statistique de l'utilisation des différentes caméras et des réalisations sur les séquences filmées, reconstitués à partir de l’enregistrement des réalisations ainsi que de chaque caméra individuellement.

	Témoin	Semi-automatisé
Nombre de caméras	7	3
Minimum de plans par caméras	1	3
Maximum de plans par caméras	22	6
Ecart type	7.06	1.53
Moyenne	8.71	4.33

Illustration 1: Éléments statistiques issus de l'analyse des réalisations

Les premiers résultats ont souligné une préparation plus forte de la réalisation et un formatage des angles de caméras pour la régie semi-automatisée par rapport à la régie standard. Du fait que les cadres soient mémorisés par le système de contrôle des caméras robotisées, ces derniers sont peu appelés à évoluer au fil du temps, simplifiant les échanges entre réalisateur et opérateur des caméras. À l’inverse, les valeurs de plans du système témoin sont plus fluctuantes. Malgré cette différence, les valeurs employées par les deux systèmes sont globalement identiques quant au découpage de l’espace pour le réalisateur.

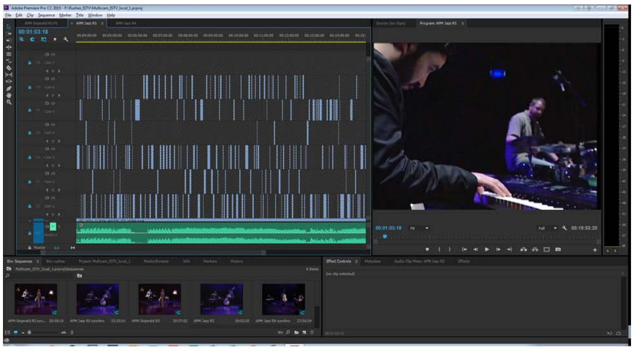

Illustration 2: Capture d'écran de la reconstitution des réalisations sur un logiciel de montage

Suites prévues: tests d'impact et nouvelles captations

Dans la continuité, un test d'impact des séquences filmées sur le public sera effectué selon une adaptation de la méthode Média-Repères (Labour, 2011), qui a pour objectif de diagnostiquer l'impact d'un extrait vidéo sur le public par l'identification des construits de sens chez la personne. La méthode permettra de distinguer des registres de sens construit chez le spectateur afin de discriminer les apports de chaque système de captation en fonction de leur impact sur le public. En particulier, une partie du protocole se fondra sur l'analyse des émotions du spectateur lors du visionnage via le procédé SYM (Yvart et al., 2016). Les résultats issus de cette expérimentation prochaine seront présentés lors du congrès.

Des améliorations sont prévues pour la prochaine étude des systèmes de captations, où la récolte de traces se verra renforcée afin de d'améliorer la qualité de la réminiscence des acteurs ainsi que de d'identifier des nouveaux paramètres quant à l'impact de l'automatisation chez le spectateur. De plus, il sera possible de tester les différents systèmes de captation successivement (ce qui évite les contraintes de placements des multi captations) et pourra se faire sur les mêmes équipements, mais utilisés soit par des humains, soit pilotés par des machines.

Background

The background for this paper is work in progress in E-ARK: an EC FP7 pilot B project[1] having as its main objective the creation of an open source, digital archiving system with attendant standards and tools to be deployed in seven pilot instances. Hence practical application is at the heart of the project, which is led by archivists, researchers, SMEs, digital preservation / archiving membership organizations and government home offices, who together seek to fill the current digital archiving lacuna. E-ARK is a wide-ranging project: we are taking and integrating existing best practices into a digital archiving system, so that it is suitable not only for national archives and government agencies, but also for regional, local, business and research archives of many shapes and sizes. A legal study taking account of varying national legal directives delineates how the archiving system can be deployed against a pan-European backdrop.

At the heart of the system is the OAIS standard (OAIS), with data arriving at an archive via Submission Information Packages (SIPs), which are then stored in the archive as Archival Information Packages (AIPs) and subsequently retrieved upon access as Dissemination Information Packages (DIPs). E-ARK is also addressing an eclectic range of sources: both structured and unstructured data, atomic and complex, including records from Electronic Records Management Systems (ERMSs); databases; geodata; and computer files.

The project stakeholders are similarly also drawn from a wide pool of varied users, and include public administrations, public agencies, public services, citizens, researchers and business. Re-use of information is a key project objective, and we are employing the latest Big Data tools / techniques / architecture such as Hadoop and Lily to present users with innovative access methods, such as the data mining showcase using geodata. We are also building on techniques used in creating an Oracle data warehouse of US 1880 census data (Healey and Delve, 2007).

Although E-ARK is being spearheaded by national archives, it is a key objective to be relevant and useful to a broad church, and to that end the paper should be of interest to many in the Digital Humanities community, not just archives, so we will be including use cases tailored to this end.

Scope of the Paper

E-ARK has conducted a GAP analysis that identifies user requirements for access services, which are described in project report D5.1 (Thirifays et al., 2014). The study investigates the current landscape of archival solutions regarding currently-available access components and identifies gaps and requirements from the perspective of national archives and third party users, as well as content providers. This report has identified a major gap in the identification process, where users browse and search collections to identify material of potential interest. It states that a lack of comprehensive metadata that is available and indexed in finding aids, compromises their performance and efficiency, which directly impacts the user experience and the user's access to the archival holdings in their entirety.

To fill this gap, work on the E-ARK Faceted Query Interface and Application Programming Interface (API) aims to establish a scalable search infrastructure for archived content. It is important to note that here we are not working with the whole content ecosystem of an archive, but instead concentrating only on indexing and searching of the born-digital E-ARK Information Packages (IPs). The goal is not to replace existing systems but to augment these components (like available catalogues) with a "content repository" that can be searched based on a full text index. This content repository concentrates on search and access based on the content (ie. data/files) contained within an AIP rather than selected metadata elements. The reference implementation employs scalable (cluster) technology, as scalability issues must be taken into account when operating a detailed content-based search facility. A major task in the context of the reference implementation is the development of a faceted query interface for searching archived content that can be utilized directly by end-users or integrated with other software components like archival catalogues.

Work on *Query and Indexing* concerns the configuration and generation of a repository index that holds detailed information on the archives' digital holdings. For developing a reference implementation, it is important to provide a solution that is flexible and configurable with respect to a range of requirements. The exact configuration of the faceted search interface will be driven by requirements of the access components (like DIP creation)[2] as well as individual institutional requirements and content specific aspects. As a consequence, the reference implementation developed within E-ARK must provide a configurable query interface that should be accessible via a service API. This API can be used through a web interface and/or an access component for searching the repository based on a full text index.

The reference implementation integrates this query API with a repository implementation, which in turn provides access to an application layer via its access API. The application layer implemented in E-ARK develops end user components for search, access, and display of archived records. Figure 1 provides a conceptual overview of the architecture and workflow supported by the reference implementation.

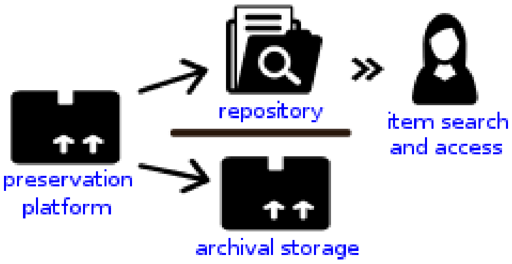

Figure 1:[3] IPs are received and processed by an ingest system like the ESSArch Preservation Platform[4]. As part of the ingest workflow, the information packages are written to an archival storage medium. In addition[5], these packages are also ingested into a content repository that provides basic data management capabilities and search. The created repository records are indexed and can be queried by an end-user application through a service interface. At the repository level, random access is provided on an item/file based level.

The goal of the E-ARK Faceted Query Interface and API is the establishment of a reference service that enables application components to search through the entire archived data and to link the applications with the data management layer[6] (provided through the content repository). The reference implementation will concentrate on data management functionality that supports search, access, and data mining (like providing a CRUD API and support for versioning). The implementation of a fully-fledged archival data management system, however, is out of focus for the reference implementation.

The search functionality is provided by an indexing infrastructure which generates a full-text index for data being ingested into the data management component (ie. the content repository). The goal is to enable end users to efficiently search archival records based on different aspects (or facets) extracted from the archived data and metadata. The search index includes enclosed archival descriptions (metadata) but most crucially the archived data itself (e.g. based on extracted text portions) and generated technical metadata (like file format information).

The employed indexing techniques are not intended to provide a finding aid based on archival metadata, as for example provided by archival cataloguing systems. The intention of the E-ARK Faceted Query Interface and API is to provide a complementary service that takes advantage of information retrieval techniques like full text indexing, faceted search, and ranking to improve the search through archived data. The indexing workflow is however configurable and able to extract specific information from the archival metadata. This flexibility can for example be utilized to develop specific search facets and/or to handle information related to data confidentiality.

The Faceted Query Interface and API are being developed as part of the E-ARK reference implementation which builds upon a scalable technology stack. The intention is to provide an archiving and search solution that works for different payloads. The reference implementation can therefore be scaled from a single host out to a cluster deployment that is capable of maintaining large volumes of data, e.g. in the magnitude of hundreds of terabytes of archived data organized in hundreds of millions of repository records. The indexing infrastructure is however intended to be deployed next to established archiving systems in order to extend the functionality of the available finding aids. The intention is not to replace the existing systems but rather to extend these infrastructures.

The final paper proposes to add further details of deploying the above scenario with use cases making use of geographic data integrated with the peripleo tool from the Pelagios project[7]. We will describe the implementation of a complete archival workflow that includes conversion procedures necessary to support text-based search as well as geographic information retrieval and spatial browsing. We will also show how Big Data techniques such as denormalisation and dimensional modelling used in creating the AIPs can facilitate the discovery methods we outline.

Introducción

Europeana, como biblioteca digital europea, se considera como el medio de referencia para compartir el extenso patrimonio europeo de distintas categorías y del que son depositarias instituciones de diversa índole, ya sean públicas o privadas. Desde la puesta en marcha de esta biblioteca han estado presentes instituciones relevante y entre ellas bibliotecas como la *British Library*.

Para las bibliotecas también es importante su integración en Europeana ya que las dota de una visibilidad imposible de imaginar en los ámbitos más restringidos en los que se encuentran localizadas las bibliotecas y les permite compartir su extenso patrimonio.

El proceso de adaptación de la información, tradicionalmente estructurada en bases de datos relacionales, al modelo de datos abiertos de Europeana (*Europeana Data Model*, EDM) es excesivamente complejo, difícil de automatizar y requiere de la intervención de expertos. La complejidad estriba fundamentalmente en la brecha semántica que existe entre la forma en la que las bibliotecas almacenan y estructuran su información, en general, y la forma de representación que requiere *Europeana*. Este modelo de datos es una especificación conceptual basada en etiquetas semánticas que se integran en los datos de forma que datos y metadatos forman un todo.

Las mayoría de las bibliotecas cuentan en la actualidad con una base de datos relacional, un modelo de datos de representación en el que ya se muestran detalles que trascienden los conceptos del mundo modelado, especificando características más relacionadas con la implementación de conceptos y relaciones.

Es necesario, pues, extraer la semántica conceptual del modelo relacional y trasladarla al modelo que Europeana define y exige para poder integrar en ella la biblioteca y dar visibilidad a su patrimonio.

SAMEBibl, automatización del proceso de migración a Europeana

SAMEBibl , nace con el objetivo de cubrir el proceso completo de migración de una biblioteca para su integración en la Europeana. Este proceso, que se muestra en Figura 1, parte del modelo origen de representación de la información y lo transforma en el modelo destino.

La semántica de los dos modelos, origen y destino, es cualitativamente distinta y por tanto, el proceso requiere que se conciban modelos conceptuales intermedios que evolucionan progresivamente hasta obtener el modelo necesario para la integración de los datos en Europeana.

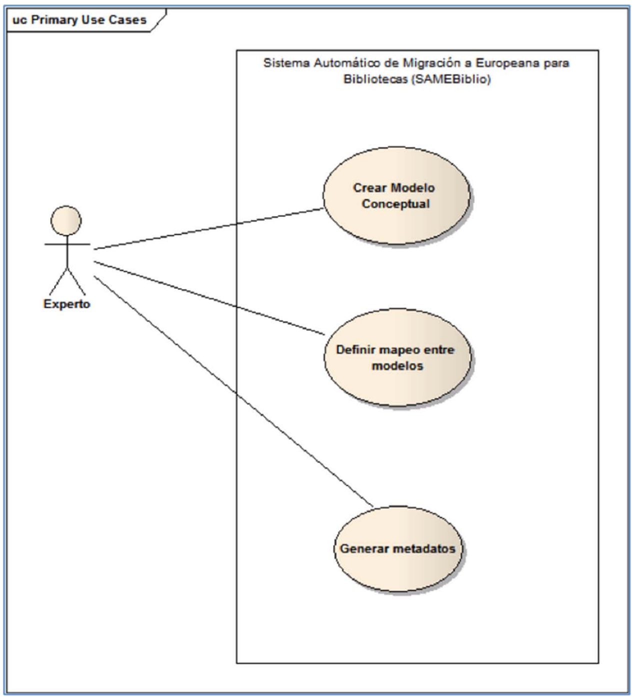
Figura 2. Pantalla interfaz Samebibl

SAMEBibl automatiza casi todo el proceso de migración, aunque se requiere la intervención del experto de la biblioteca con el objeto de establecer las correspondencias mas convenientes entre los componentes del modelo original y el modelo de *Europeana*, permitiendo asimismo la elección de la información que se considera más oportuno migrar. La interacción del experto con el sistema se realizará de forma amigable, presentando la información que se quiere migrar de forma independiente a su representación interna en el modelo que se ha definido, es decir, no es necesario que cuente con conocimientos técnicos en lo que a repositorios y datos abiertos se refiere.

La aplicación desarrollada consta de tres componentes principales:

- Un traductor dirigido por la sintaxis que extrae la semántica del modelo relacional a partir de las estructuras sintácticas que se identifican en el esquema de la base de datos, y que dan lugar a un modelo conceptual intermedio.
- Un módulo que permite establecer las correspondencias, es decir, definir el "mapeado", entre cada uno de los conceptos y relaciones del modelo conceptual extraído por el traductor y el modelo de Europeana. Para ello se requiere la intervención del experto de la biblioteca.
- Un traductor que, a partir de la información obtenida de los registros de la base de datos, la información facilitada en el mapeado por el experto y los elementos del modelo conceptual, genera los metadatos basados en *EDM* en un formato XML/RDF necesario para poblar el repositorio que será recolectado por *Europeana*.



uc Primary Use Cases
Sistema Automático de Migración a Europeana para Bibliotecas (SAMEBiblio)
Experto
Crear Modelo Conceptual
Definir mapeo entre modelos
Generar metadatos

Figura 3. Casos de uso Samebibl

El proceso de migración no sólo presenta complejidad interna. La cantidad de información manejada y transformada puede ser de tamaño considerable y por tanto, requerir de tiempo para su realización. Además, la información puede ser cambiante o se puede añadir información nueva. Es importante, por tanto que SAMEBibl dote de persistencia a la información que se ha generado de la persistencia necesaria para permitir su modificación y actualización. Debido a esto, la información relativa a los modelos y sus correspondencias, es almacenada para permitir tanto su actualización y mejora, con la revisión o incorporación de nuevas reglas de mapeado tras la incorporación de nuevos elementos semánticos.

Esta característica facilita el mantenimiento automático del repositorio que incorporará los cambios surgidos en el entorno operacional de la base de datos relacional.

SAMEBibl , por tanto, es una herramienta que cubre una necesidad detectada en muchas bibliotecas,. Esta necesidad es mayor en aquellas bibliotecas que no tienen recursos suficientes como para contar con expertos técnicos que realicen el proceso de transformación del modelo de su base de datos relacional a *Europeana*., y esta es la situación en la que se encuentran la mayoría de las bibliotecas europeas que son de menor envergadura pero que son depositarias de un gran patrimonio. Sus tres características más relevantes son:

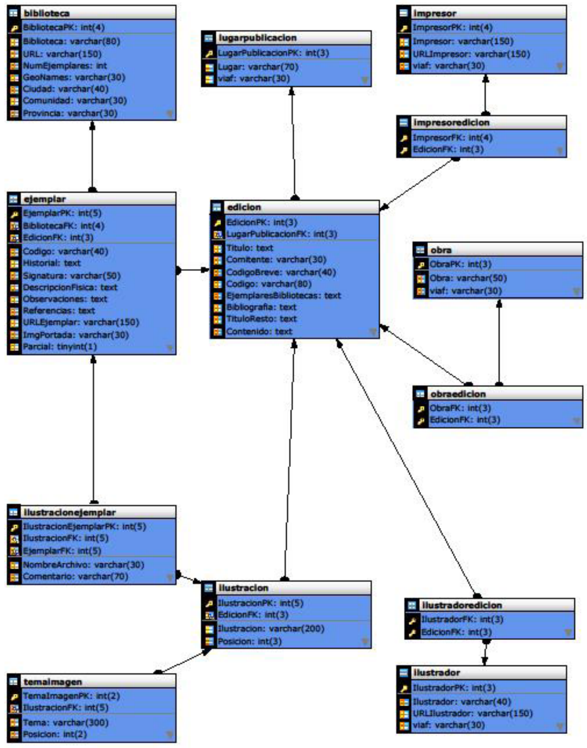
- la automatización completa de las funciones de extracción de la semántica conceptual y generación de metadatos. Estas dos funciones abarcan los elementos técnicamente más complejos del proceso de migración. Su total automatización aísla al usuario de esta complejidad.
- la simplicidad y naturalidad en la operación de la funcionalidad de mapeado, al contar con una interfaz sencilla que permite al usuario de la biblioteca establecer las correspondencias semánticas entre los modelos de acuerdo a sus criterios de forma intuitiva y amigable.
- la flexibilidad del modelo adoptado en la representación del conocimiento relativo a los modelos y sus correspondencias. Esto permite proporcionar ante una herramienta de propósito general que puede ser empleada por cualquier biblioteca basada en un modelo relacional. Asimismo hará muy sencilla la adaptación de la herramienta en el futuro para soportar la migración a nuevos modelos de metadatos semánticos distintos de *EDM*.

Aplicación de *SAMEBibl* a la Biblioteca Digotal Ovidiana

SAMEBIbl ya ha sido aplicada en la *Biblioteca Digital Ovidiana (desde ahora BDO)* (*www.oviduspictus.es*) dedicada a la obra ilustrada de Ovidio y que alberga los datos y las imágenes de todos los ejemplares de las ediciones impresas entre los siglos XV al XIX que se encuentran en las bibliotecas españolas. Es un proyecto que se esta llevando a cabo en varias fases.

Con el objeto de poder compartir la información de la BDO en Europeana, se ha utilizado SAMEBibl para llevar a cabo la migración .

El modelo lógico relacional de la base de datos de BDO que se muestra en Figura 3 es un modelo complejo ya que refleja la rica semántica y estructuración de la información almacenada en la misma



Tras el proceso de migración se obtienen los objetos semánticos correspondientes a los diferentes conceptos identificados a partir de la semántica extraída del modelo lógico relacional como se muestra en la Figura 5.

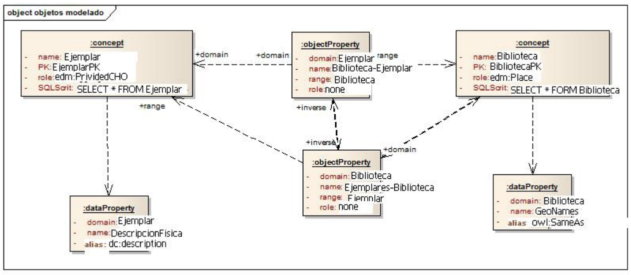


Figura 5. Objetos generados para los conceptos Ejemplar y Biblioteca

A partir del modelo de objetos generado se generan los metadatos y el archivo RDF/XML que permite la integración de la información en el repositorio., tal y como se muestra en Código 1

Conclusiones

- El proceso de migración de una biblioteca digital basada en un modelo de datos relacional a Europeana entraña una gran dificultad. Esto es debido en gran parte a la gran brecha existente entre ambos modelos, el primero de naturaleza más lógica y orientada a la representación de los datos y el segundo conceptual. Esta se constata, entre otras cosas, por el reducido número de bibliotecas que se han integrado en Europeana.
- Faltan herramientas para las bibliotecas puesto que las existentes no cubren todo el proceso, son difíciles de emplear y, o bien no son específicas para Europeana , o son muy costosas.
- El software SAMEBibl desarrollado, integra y automatiza, en la medida de lo posible, todos los procesos de la metodología. Esta herramienta lleva a cabo un proceso de traducción sintáctica y semántica del modelo origen con el establecimiento de las relaciones y reglas de transformación que da lugar a un archivo en un formato interpretable por un repositorio.
- La metodología y la herramienta cumplen con los objetivos planteados como demuestra su validación mediante un caso real, la Biblioteca Digital Ovidiana (http://www.ovidiuspictus.es).

"Parcours numérique", Canada

Cinq constats, déjà soulignés par plusieurs chercheurs (dont Steven Harnad et Jean Claude Guédon, par exemple) nous semblent démontrer l'urgence de développer des politiques institutionnelles pour promouvoir l'accès libre:

1. Cinq multinationales (Wiley, Elsevier, Springer, Taylor and Francis, Sage) gèrent la quasi-totalité de la presse scientifique. Elles prennent depuis des années en otage les contenus produits par les chercheurs;
2. Les contenus publiés sont payés par l'Université (qui paye la recherche des chercheurs);
3. Les bibliothèques sont obligées de payer une deuxième fois ces mêmes contenus;
4. Cela réduit fortement la circulation des contenus scientifiques au seul profit d'entreprises qui ne jouent aucun rôle dans leur production et qui ne contribuent nullement à leur visibilité;
5. Ce système est maintenu en place par le dispositif des évaluations académiques – pour des raisons de CV, le chercheur publie sur des revues "accréditées" quand il pourrait, sans frais ou presque, publier en accès libre.

Pour sortir de ce mécanisme pervers il faut d'abord essayer de faire résistance au modèle imposé par ces multinationales, d'où l'importance des efforts de remettre en question ces politiques d'abonnement, comme l'a fait la Bibliothèque de l'Université de Montréal qui s'est désabonnée de l'offre panier de Wiley en janvier 2014. Mais il faut aussi proposer de nouveaux modèles.

Depuis longtemps, plusieurs initiatives essaient d'aller dans ce sens en faisant la promotion de l'accès libre, entre autres bien évidemment, pour le domaine francophone, érudit.org et revues.org (OpenEdition) tout comme des revues qui remettent en question les problèmes de modèle économique au nom de cette cause. Avec les Presses de l'Université de Montréal nous avons créé une collection en accès libre, "Parcours numériques", au printemps 2014, avec déjà cinq ouvrages parus.

La collection est basée sur l'idée qu'il doit y avoir une complémentarité entre l'édition papier et l'édition numérique, car ces deux formes de publication présupposent des idées différentes de lecture et deux approches différentes à la réception des contenus.

Le livre papier – et on entend ici également le numérique homothétique (epub ou pdf) qui reproduit à l'identique le livre papier sur un support numérique – permet une lecture linéaire. Une thèse peut y être présentée et argumentée de façon complexe. Le lecteur sera capable de suivre de manière linéaire le développement de l'argumentation, de faire un cheminement avec l'auteur en se laissant accompagner d'un bout à l'autre du discours. C'est pour cela que nous avons fait le choix de publier des livres assez courts (120/200 pages) : c'est la longueur adéquate pour présenter une thèse et la démontrer à l'aide d'une argumentation unique et cohérente. Sur un livre papier, on peut passer plusieurs heures pour suivre l'auteur dans tout son raisonnement. Mais il faut que le discours soit linéaire : tout ce qui entraîne une sortie par rapport au chemin principal doit être évacué. L'appareil critique, les références, les parenthèses, les exemples, les images, les statistiques, les détails… tous ces éléments viennent casser la linéarité de la lecture.

L'édition numérique augmentée, en revanche, présuppose une lecture non linéaire, qui procède par approfondissement. On commence par lire un premier texte sur un sujet, on souhaite en approfondir un aspect, puis on glisse sur un contenu qui se trouve ailleurs et qui nous permet d'en savoir plus sur ce qui au départ ne semblait qu'un détail. On navigue, on flâne, le parcours emprunté n'existe pas avant la navigation, il n'a pas été prévu par un auteur ou un éditeur. Ces derniers ont suggéré des pistes, ouvert des portes… puis la navigation est laissée aux lecteurs, à leurs envies, à leur créativité. Dans ce sens, il n'est pas vrai, comme le voudrait Nicholas Carr, que le numérique détruit notre capacité d'attention : il s'agit d'une attention différente, disséminée, qui permet l'approfondissement mais empêche de suivre un discours plus long et unitaire.

La collection "Parcours numériques" offre donc ces deux possibilités de lecture. L'édition en ligne augmentée offre le texte en intégralité, en libre accès, ainsi que toute une série de contenus additionnels qui seront autant de portes prêtes à être ouvertes pour nous emmener ailleurs, vers des approfondissements, des sujets connexes, d'autres formes de contenus, d'autres plateformes, d'autres parcours, qui n'ont pas été nécessairement prévus par l'auteur ou par l'éditeur du livre. C'est également pour cette raison que l'édition en ligne augmentée est gratuite : elle permet d'avoir accès à un univers connecté au livre, un univers qui n'a été créé ni par l'auteur, ni par l'éditeur. Si par la suite le lecteur souhaite se plonger pleinement et complètement dans la thèse de l'auteur afin d'en connaître et d'en comprendre les moindres aspects, il aura probablement davantage envie de le lire de façon linéaire et donc de l'acheter en papier, en epub ou en pdf.

De cette manière, on permet une circulation libre des contenus, un cercle vertueux où est mis en avant le travail de l'auteur grâce aux liens qui sont créés vers d'autres contenus, produits par d'autres. On met simultanément en place un réseau de connaissances et un dialogue. Mais on permet aussi, grâce au papier et à son double numérique homothétique, au discours linéaire de l'auteur d'exister, clair, identifié, reconnaissable. Deux lectures qui ne sont pas en compétition donc, mais qui se complètent.

Notre présentation révèlera les données sur les ventes au cours des deux premières années, les résultats du modèle économique choisi, ainsi que des données sur la plateforme en ligne.

Introduction

The study of an individuals' personality traits is a new line of research that emerged only recently, primarily through the investigation of dialogue systems and weblogs (Gill et al., 2012; Konstantopoulos, 2010; Mairesse and Walker, 2006; Mairesse and Walker, 2007). This paper proposes a novel application for personality classification by leveraging on cognitive computing research and by exploiting the poetic production of theatrical plays. More specifically, this research is circumscribed to the analysis of Shakespeare's tragedies, which offer a rich spectrum of characters for a detailed and in-depth study. This research does not aim at introducing the innovative technological aspects of personality classification in cognitive computing but rather at employing such technology in the study of English literature, and analyse some implications that arise from the results.

Before presenting the core of this research, we outline the psychological theory of the "Big Five," its implementation as well as its extension in IBM Watson. Successively, in Section 2, we introduce the data used, the method applied and the results obtained in our analysis. In Section 3, we discuss some useful applications and extensions for literature scholars. Finally, we conclude by presenting some considerations for future research.

IBM Watson and the Big Five personality insight

Cognitive computing originated in the early 60s, however, it has been improved dramatically in recent years, achieving significant success through the launch of IBM Watson in 2010. IBM Watson simulates human cognitive systems by implementing advanced natural language processing, information retrieval, knowledge representation, automated reasoning, and machine learning technologies to the field of open domain question answering (Ferrucci et al., 2010; Ferrucci, 2012). Among human cognitive activities, one of the most employed is the capability to understand and forecast other people's personalities. As described in the Big Five theory (Norman, 1963) formulated by scholars in psychology, each individual presents a different aptitude in identifying characteristic patterns of thinking, feeling and behaving in others. The Big Five theory is the main theory on which IBM Watson has been built; it distinguishes between five broad dimensions underlying an individual's personality, namely openness, conscientiousness, extroversion, agreeableness, and neuroticism.

- Openness mirrors the level of scholarly interest, imagination and an inclination for oddities.
- Conscientiousness is the propensity to be reliable, to show self-control and act obediently.
- Extroversion comprises vitality, positive feelings, confidence, amiability and the propensity to look for incitement in the organization of others.
- Agreeableness is the inclination to be merciful and agreeable as opposed to suspicious and adversarial towards others.
- Neuroticism is the propensity to encounter obnoxious feelings, for example, outrage, uneasiness, wretchedness, and powerlessness.

Next to the Big Five personalities, IBM Watson takes into account the concept of "Needs," which are described by the literature as universal needs shared by all human beings (Ford, 2005; Kotler and Armstrong, 2010). Along with Big Five and Needs, IBM Watson takes into account the psychological concepts of Values which are defined as "desirable, trans-situational goals, varying in importance, that serve as guiding principles in people's lives" (Schwartz, 2006). As mentioned on the IBM Watson website[1] "Schwartz summarizes five features that are common to all values: (1) values are beliefs; (2) values are a motivational construct; (3) values transcend specific actions and situations; (4) values guide the selection or evaluation of actions, policies, people, and events; and (5) values vary by relative importance and can be ranked accordingly."

Method and Results

Our objective consists in comparing the personality of the main characters of three Shakespeare's tragedies in a positive versus negative sentimental context. To establish these contexts we use the work of Nalisnik et al. (Nalisnick and Baird, 2013) on sentiment analysis to divide the characters of the play into two groups. The first group is composed of those characters towards which the main character expresses mainly positive sentiments; the second group comprises those characters towards which the main character expresses mainly negative sentiments. In practice, we extracted each instance of continuous speech from the plays[2]. The groups divisions take in account the sentiment valence and the minima of sings that the IBM Personality Insights needs to produce significant results and then assumed that each speech act by one speaker was directed towards the character that spoke immediately before him. We used this assumption to replicate Nalisnik's data but, as he pointed out in his paper, "This assumption does not always hold; it is not uncommon to find a scene in which two characters are expressing feelings about someone offstage.". We retrieved the sentiment valences for each main character[3], reported in the following tables:

Hamlet's Sentiment		**Othello's Sentiment**		**Macbeth's Sentiment**	
Valence Sum		**Valence Sum**		**Valence Sum**	
Guildenstern	31	Iago	71	Murderer 1	22
Polonius	25	Cassio	38	Banquo	16
Gertrude	24	Brabantio	27	Duncan	8
Horatio	12	Duke of Venice	24	Angus:	7
Ghost	8	Montano	7	Macduff	5
Marcellus	7	Desdemona	-1	Which 3	5
Osric	7	Lodovico	-4	Which 1	1
Bernardo	2	Emilia	-10	Young Siward	-4
Laertes	-10			Lennox	-11
Phelia	-5			Seyton	-20
Rosencrantz	-12			Lady Macbeth	-39
Claudius	-27				

Table 1: Tables representing the sentiment valence sum, and the used groups for each main character. Positive scores stand for a character's positive attitude towards others and negative scores stand for a negative attitude

	Positive	**Negative**
Hamlet	6655	3455
Othello	3424	2407
Macbeth	1293	1852

Table 2: Word counts per characters of positive and negative sentimental context

By assembling all continuous speech sequences directed to the characters in the different groups, we created two text groups: the first group contains all lines of the main character towards the others when expressing positive sentiments, the second group includes those speech sequences characterized by a negative sentimental connotation. We performed this task for three main characters, more specifically Hamlet, Othello and Macbeth. In Table 2, the positive and negative word counts for these text assemblies are plotted.

Finally, we used IBM's personality insight service to create personality profiles for each of the main characters based on the positive and negative texts. Figures 1, 2 and 3 represent the distribution of needs and values with respect to the positive or negative sentimental valence. Points on line represent independence with respect to the latter. For needs and values falling below this line, the distribution is characteristic for the expression of negative sentiments. We also created personality graphs with respect to the groups. Although they are calculated as percent of a given facet (as indicated by the x axis), the facets vary between low and high values. Thus, the bars in the graph begin at 50% and can either be low (to the left) or high. A score of 50% signifies that the facet is balanced.

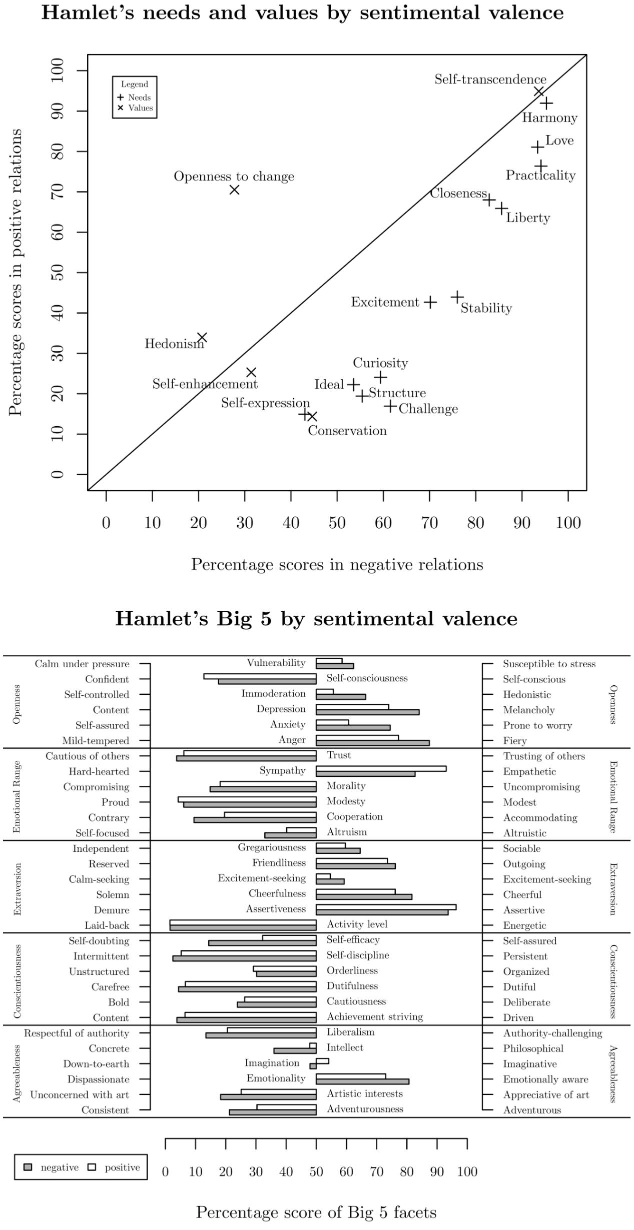

Figure 1: Hamlet's scores for Needs, Values and the Big Five categories

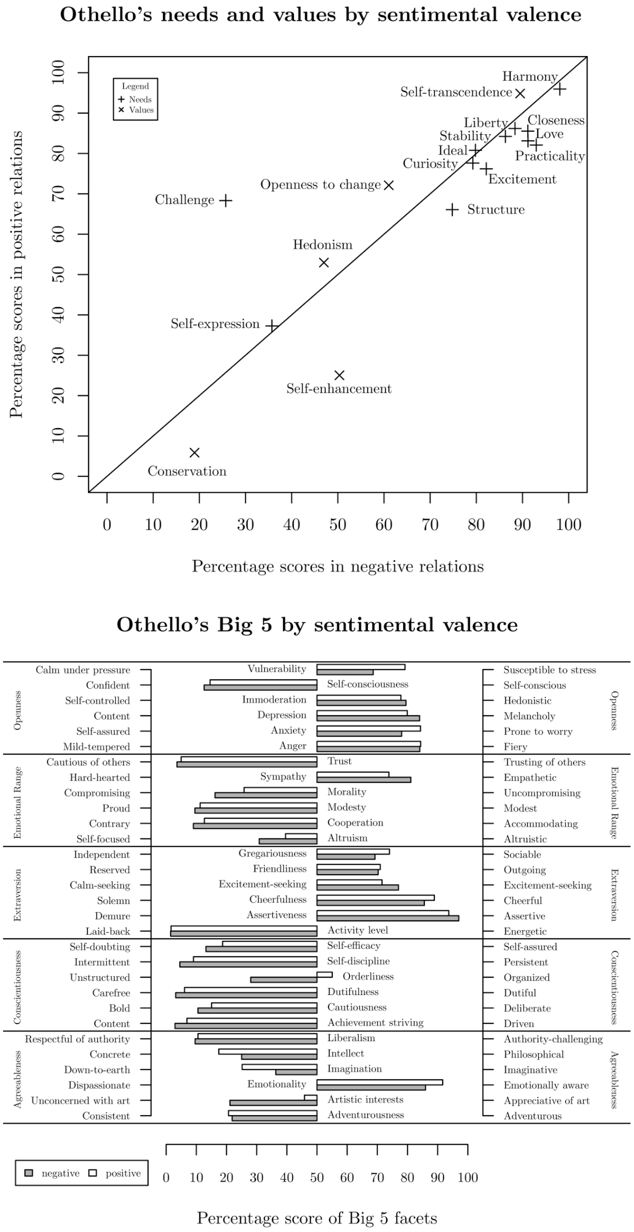

Figure 2: Othello's scores for Needs, Values and the Big Five categories

Some Insights and Discussion

A quantitative approach to character clearly generates a comparatively large amount of linguistic data. The question is, how are we to use this data? What can such an approach offer Shakespeare studies and the humanities more broadly? How does the data we have generated contribute to the critical conversation in a sub-field like character criticism (Hazlitt, 1845; Bradley, 1992; Desmet, 1992; Yachnin and Slights, 2009) which has such a long and distinguished history. There are two answers to this question. First, our analysis shows in a more concrete and detailed way than ever before, the close relationship between character and language, something easy to forget in the context of a representational practice like theatre which is so dependent on non-linguistic features, such as gesture, costume, and stage properties. Playgoers, however, do not just see character; they also hear it. And in the modern humanities classroom, they read it. Accordingly, words play a significant role is crafting what we would now call the "personalities" of Shakespeare's stage. Our approach offers a new means of isolating and analyzing these verbal features of character. The second way in which our work contributes to Shakespeare studies has to do with something our data does not tell us. To understand what we mean by this, consider for a moment why it is that the words associated with some characters generate a personality profile that anyone familiar with the plays knows does not quite fit? Why, for example, does Hamlet have a verbal data set that makes him seem much more serious and honor-driven than he actually is It is because the technology we are using is not capable of accounting for context and therefore cannot detect things like irony and wordplay, two things that are extremely important components of the way language articulates character and personality. While this may be viewed as a methodological weakness from the perspective of information technology, it is a great strength from the perspective of the humanities. For it is precisely at those moments that the data fails to deliver coherent results that we are forced to ask compelling questions about language and art: why do words that seem to mean one thing have the opposite effect on stage? What is the relationship between the literal and implied meanings of words in the constitution of dramatic character? In the end, this facet of our contribution to Shakespeare studies illustrates something important not just about our project specifically, but also about the digital humanities generally: the value of applying computational technology to literary texts lies not in the promise of "better data" or irrefutable "facts," but rather in the way such technology returns us again and again to the fundamental humanist questions that help us understand how literature and art work[4].

Future Research

In this paper we introduced novel techniques based on cognitive computing to get an understanding of characters in Shakespeare's plays. This research explores newway of computer-assisted methods for the investigation of literature. Nonetheless, some technical issues need to be overcome in order to improve the quality of this new methodology. First, an improved methodology to outline the sentiment polarity needs to be developed. Second, the low representativity of IBM's personality model needs to be enhanced in order to catch literary phenomena in sources such as Twitter, Wikipedia, and other such corpora. Thus, recreating a personality insight service based on a literary work corpus would surly enhance the results of our method.

Introduction

Data visualisation has become one of the most relevant DH topics, due to the advent of Big Data in Humanities research practices, and to the need to make complex statistical analyses accessible to users without a technical background. Although several visualisation libraries, such as d3.js, are now freely available online and are relatively easy to use, it is still a challenging task to provide simple and effective interface design, avoiding both over-complex and over-simplified solutions. When the data to be displayed have undergone complex processing, for instance automated text analysis, it is of paramount importance to preserve all the information conveyed by such analyses, while making it understandable to the users.

In this work, we present a collaboration between communication design and natural language processing (NLP) researchers, devising effective strategies to display different aspects of the semantic content of texts. The outcome of the collaboration is the ORATIO platform, specifically developed to *compare* different points of view automatically extracted from text. The most challenging tasks, indeed, concerned the visualisation and the exploration of differences and overlaps detected through automated text processing.

Use case

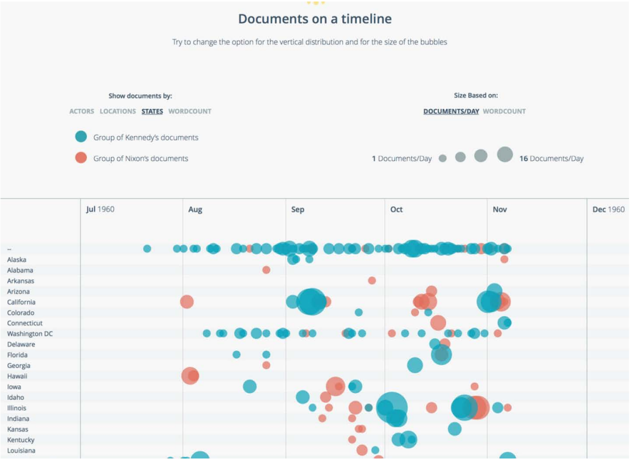
Our use case concerns the comparison between Nixon's and Kennedy's speeches uttered during the U.S. presidential campaign in 1960. The corpus consists of 282 documents by Nixon (830,000 tokens) and 598 documents by Kennedy (815,000 tokens)[1]. The overall goal of the project was to track the difference in language and content between the two opponents, and make it available through a platform which makes use of a "generous interface": first providing all the information to the user, and then enabling him to handle the visual model through a number of options and filters (Whitelaw, 2012). Infact, in our setting, researchers are supposed to reshape and reduce the visualizations in order to prove theories or discover new interesting aspects related to the processed text. The proposed navigation pattern complies with the paradigm "Overview first, zoom and filter, details on demand" (Heer and Shneiderman, 2012).

Other existing approaches do not start from an overview, but from an empty window, where the user can build up a personal view, while investigating the relationships inside the data. We rely on such approaches in order to design the last visual model of the platform (Fig. 6), while the others take from the first one, starting from an overview.

ORATIO Description

To cope with corpora richness, a multiple view approach has been adopted (Mauri, Pini, Ciminieri and Ciuccarelli, 2013): rather than providing a single view, with all the information, five different perspectives have been identified, each exploring a different piece of information in a comparative way. The first view is the *Summary*, whose goal is to provide the user with a general overview of the two corpora, including geographical, temporal and size information. Each corpus is associated with an imagine and a color (blue for Kennedy, red for Nixon), which remain consistent across all the platform views. Under *Summary*, users can see how speeches are distributed on a map (according to the place where the talk was given, included in the metadata), on a timeline (based on day of the speech in the metadata), and what linguistic features characterise each corpus (i.e. number of speeches, average words in a document and total number of words). For instance, in Figure 1 a compact representation of three corpus dimensions is given: the x-axis represents the timeline, the y-axis includes the list of cities where the speeches were given, and the dimension of the bubbles corresponds to the number of speeches uttered in a certain place at a certain time point.

The visualisation shows, for instance, that Nixon pledged to visit all the 50 States, while Kennedy did not held any speech in some States that were less critical to the victory of the elections (e.g. Hawaii or Vermont). Another interesting aspect of the electoral campaign emerging from this view is that, despite having visited less States, Kennedy was more active than Nixon: he stopped in a higher number of cities (239 cities overall, against the 172 cities visited by Nixon), and had about twice as many speeches, press releases, statements and remarks as his opponent (about 550 for Kennedy and 260 for Nixon). This is highlighted by the prominence of blue over red bubbles.



Documents on a timeline

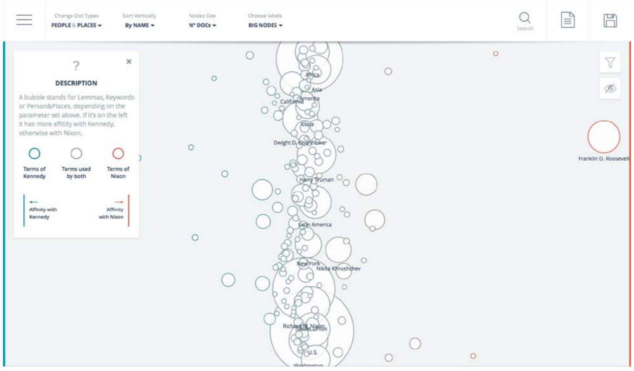
Try to change the option for the vertical distribution and for the size of the bubbles

Show documents by: ACTORS LOCATIONS STATES WORDCOUNT

Size Based on: DOCUMENTS/DAY WORDCOUNT

Fig.1: Summary view of the two speech corpora

The second view, called *Affinity*, targets the need to understand the relevance of topics in the political debate and the presence of important differences between the two candidates. In this view, specific word classes such as verbs, keywords or persons' names are displayed as circles, whose size is proportional to the number of occurrences in text. The more the terms occur in both corpora, the more they are displayed towards the center of the window. If they occur prevalently (or only) in Kennedy's or Nixon's speeches, they are displayed towards the left or the right side of the window, respectively (Fig. 2).



Change Dot Types: PEOPLE & PLACES

Sort Vertically: By NAME

Nodes Size: N° DOCs

Choose labels: BIG NODES

DESCRIPTION

A bubble stands for Lemmas, Keywords or Person&Places, depending on the parameter set above. If it's on the left it has more affitity with Kennedy, otherwise with Nixon.

Fig. 2: *Affinity* view showing the most relevant personal entities discovered in the corpora.

The third view, displaying *People*, gives a network-based representation of the people automatically recognized in the corpora by a Named Entity Recogniser (Finkel et al., 2005). If two or more people are mentioned within the same sentence, they are linked in a spatialized graph. As with the other views, users are then able to filter out elements from the visualization, in order to discover new patterns (Fig. 3a). In our specific use case, filters and other selection strategies are really useful, since the complete network is very large and difficult to read at a glance (Fig. 3b).

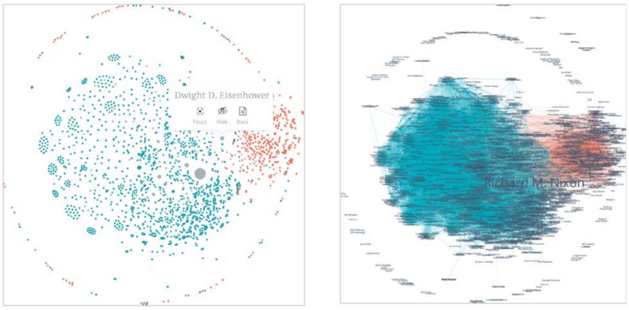


Fig. 3a: *People* view after filtering Fig. 3b: The default network in *People* view

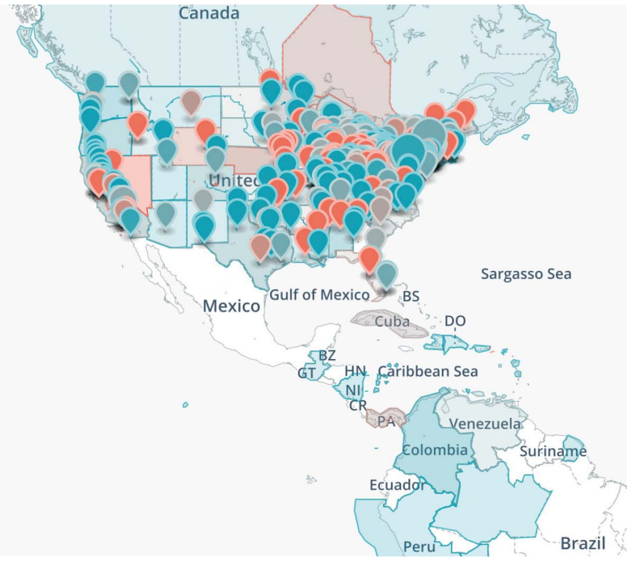

Fig. 4: *Places* view with visited places (marked with cursor) and mentioned places (colored)

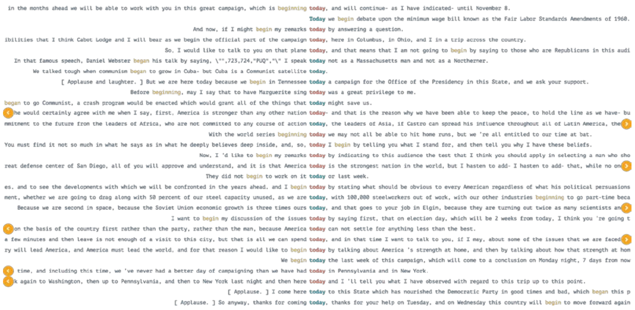
The *Places* view provides a comprehensive visualisation of the geographical information contained in the two corpora. It displays the metadata about the place where the speeches were uttered together with the GPEs mentioned in the speeches, automatically extracted with the same Named Entity Recogniser used for *Persons*. These two pieces of information are usually displayed separately, since the most widely used visualisation strategies based on heatmaps would not allow to distinguish them. However, we devised a solution where both can appear on the same map, while being easily distinguishable: the locations where a speech was uttered are marked with a cursor, while the mentioned places are highlighted on the map as colored areas. The comparison shows that Kennedy devoted more attention to specific areas outside US, while Nixon was more concerned with domestic policy. For instance, Kennedy mentioned several times places in Latin America, since one of the key themes of his campaign was the "Good Neighbor" policy, a topic not covered by Nixon.

The last view, named *Concordances*, is inspired by linguistic research and recalls the family of concordancer tools (see for instance Kehoe and Renouf, 2002). In contrast with the previous models, this functionality takes a different approach, since there is no overview and the user is supposed to create a representation in order to answer questions and prove hypotheses. Specifically, a user can look for a particular keyword or concept and see all the sentences where it appears, typographically aligned to ease readability. In a second step, other important terms close by the given concept can be displayed as well (Fig. 5).



```
 in the months ahead we will be able to work with you in this great campaign, which is beginning today, and will continue- as I have indicated- until November 8.
                                                                                                  Today we begin debate upon the minimum wage bill known as the Fair Labor Standards Amendments of 1960.
                                                                  And now, if I might begin my remarks today by answering a question.

                                                           [ Applause. ] So anyway, thanks for coming today, thanks for your help on Tuesday, and on Wednesday this country will begin to move forward again
```

Fig 5: the *Concordances* view, displaying the use of "today", compared with the presence of the term "begin".

Conclusions

We presented the ORATIO platform, specifically developed to compare the content of two different corpora in the political domain. The work is the outcome of a collaboration between researchers in Communication Design and Natural Language Processing applied to Digital Humanities. Although NLP allows to process and extract information from large corpora with minimal efforts, it has drawbacks, which are then inherited by the presented platform. For instance, persons' nodes (Fig. 3) need to be disambiguated in order to merge nodes representing co-referring mentions (e.g. "J. F. Kennedy" and "Jack Kennedy"). Also geo-political entities (Fig. 4) require disambiguation and geo-referencing. This was performed completely automatically, but errors are possible, and this kind of visualisation makes it even more straightforward to spot them.

In order to address these issues, possible solutions could be to *1)* give users the possibility to inspect the content of the documents containing displayed information (from *distant* to *close* reading), and then *2)* give them the possibility to manually correct the displayed information (e.g. drag and drop some elements in the space, delete nodes, etc.). The development of new interfaces enabling such human intervention would be very important and represents the future direction of our research.

Arduino Circuits and Javanese Puppets: 'Re-materializing' Digital Archives through Tangible Interfaces

Miguel Escobar Varela
m.escobar@nus.edu.sg
National University of Singapore, Singapore

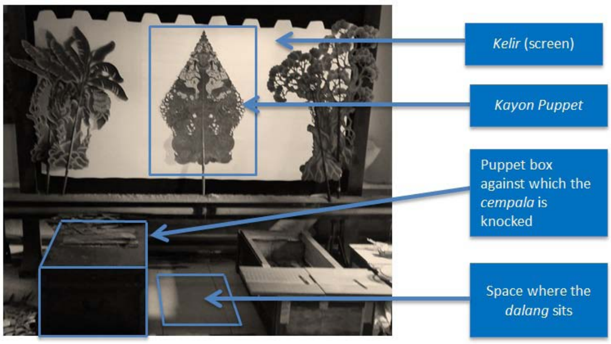
The creation and analysis of digital collections is a key aspect of the digital humanities. Deciding what to archive, how to organize the documents, and how to present them to the public are never easy questions. But in the case of theatre and performance archives, these questions are especially complex since theatre performances are necessarily transient and they depend on the embodied co-presence of actors and spectators. In order to document the embodied and ephemeral nature of theatre performances, digital archives often try to include a wide array of documents (video recordings, photographs, motion capture data, 3d models of theatrical spaces and technical scripts). The makers of digital theatre archives are at pains to contextualize their materials and account for aspects that cannot be easily documented and transmitted. Can interaction design help communicate these aspects? Is it possible to imagine and construct interfaces that can communicate cultural context, transcending the limitations of a computer screen, mouse and keyboard?

To investigate these questions within the context of an Indonesian performance archive, I developed a Tangible User Interface (TUI) using open source hardware (Arduino microcontrollers and an array of sensors) and culturally-coded objects that are important for the performances in the archive. This interface was developed as an interactive artwork for educational museums and as a thought experiment on how tangible, culturally-specific interfaces can constitute instances of academic research outputs in the digital humanities.

The archive in question is the Contemporary Wayang Archive (CWA, http://cwa-web.org), a collection of digital recordings and metadata pertaining to Javanese wayang kulit (shadow puppetry), which I have been developing with my collaborators at the National University of Singapore since 2012. Wayang kulit is the oldest theatre form of Indonesia and one of the most important theatre traditions of Southeast Asia. It consists of a form of puppetry where a dalang (narrator-puppeteer) singlehandedly moves all the puppets, speaks all the character parts, jokes with the audience and directs the musicians. He is at the same time a puppeteer, a storyteller, an orchestra conductor and a stand-up comedian. In order to communicate with the audience and the orchestra, he uses different objects in order to control the progression of the story. For this project, I wired different sensors into these objects in order to develop a TUI that recreates the spatial setup of a conventional wayang performance and three key material components of this setup:

- A kerlir or screen where videos from the CWA are projected.
- The kayon. This puppet is shaped like a leaf and it has different narrative functions. In between scenes, the dalang rotates it around its axis and places it on a banana log at a specific angle (either 45^0, 90^0 or 135^0) to indicate the progression of the story. This visual cue is important for audience members that don't watch the entire show. A conventional performance lasts eight hours and the audience members often come and go, drifting in and out of attention. Depending on the specific angle of the kayon, knowing audience members can estimate the specific moment in the development of the performance (which is divided into three main acts). For my interface, I used an Inertial Measurement Unit (IMU) and a wireless sensor in order to detect rotation (angular velocity) in the puppet. By rotating an actual puppet, users of this interactive artwork can navigate to a different digital video in the collection.
- The cempala. By hitting this wooden mallet against the puppet chest, the dalang cues the musicians to start and stop the musical accompaniment. For the interactive artwork, I wired the cempala to a Piezoelectric sensor to measure vibration. When the users of the artwork knock the cempala against a box that mimics the puppet chest, they can start and stop the videos and additional contextual information appears on the projection screen.

- The usage of these objects is not exactly the same in this interactive artwork display as it is in an actual wayang performance. But it can invite users to think about the importance of materiality and embodiment for this particular theatre tradition. In such a way, this interactive artwork can be considered a piece of digital scholarship, a research output of the DH research into wayang kulit that complements the forthcoming online version of the archive and other publications that might arise from this research project (see, for example www.wayangkontemporer.com).



Kelir (screen)

Space where the *dalang* sits

Figure 1. Conventional wayang kulit setup

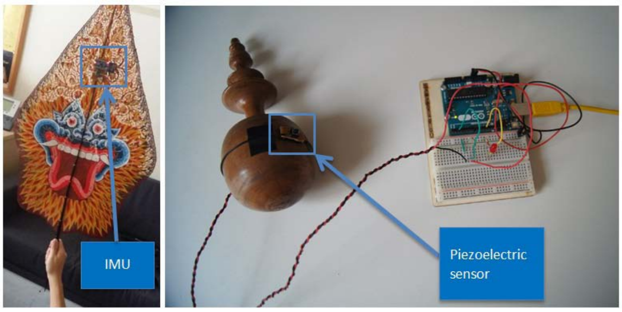

Figure 2. IMU sensor attached to the kayon (left) and piezoelectric sensor attached to the cempala (right)

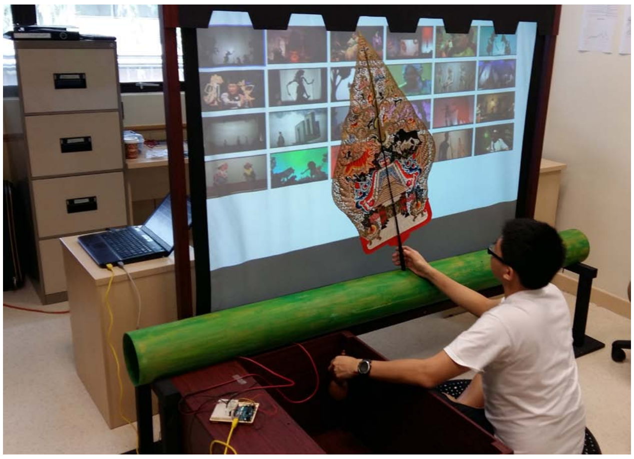

Figure 3. A user interacting with the TUI

- Although this artwork has a very specific origin and function, I hope it will resonate with scholars working in other areas of the digital humanities who are engaged in building and theorizing new artefacts for the communication of academic research. The objective of this short paper is to frame the creation of this artwork within the larger context of the digital humanities, exemplifying modes of scholarship that can emerge at the intersection of cultural knowledge, open hardware and digital technologies.

Topical Diversification Over Time In The Royal Society Corpus

Peter Fankhauser
fankhauser@ids-mannheim.de
IDS-Mannheim, Germany

Jörg Knappen
j.knappen@mx.uni-saarland.de
Universität des Saarlandes, Germany

Elke Teich
e.teich@mx.uni-saarland.de
Universität des Saarlandes, Germany

Science gradually developed into an established sociocultural domain starting from the mid-17th century onwards. In this process it became increasingly specialized and diversified. Here, we investigate a particular aspect of specialization on the basis of probabilistic topic models. As a corpus we use the Royal Society Corpus (Khamis et al. 2015), which covers the period from 1665 to 1869 and contains 9015 documents[1].

We follow the overall approach of applying topic models to diachronic corpora (Blei and Lafferty 2006, Hall et al. 2008, Griffiths and Steyvers 2004, McFarland et al. 2013, Newman and Block 2006, Yang et al. 2011) to map documents to topics. Probabilistic topic models (Steyvers and Griffiths 2007) have become a popular means to summarize and analyze the content of text corpora. The principle idea is to model the generation of documents with a randomized two-stage process: For every word w_i in a document d select a topic z_k from the document-topic distribution $P(z_k \mid d)$ and then select the word from the topic-word distribution $P(w_i \mid z_k)$. Consequently, the document-word distribution is factored as follows:

$$P(w_i \vee d) = \sum P(w_i \mid z_k)\ P(z_k \mid d).$$

This factorization effectively reduces the dimensionality of the model for documents, improving their interpretability: Whereas $P(w_i \mid d)$ requires one dimension for each distinct word (10s of thousands) per document, $P(z_k \mid d)$ only requires one dimension for each topic (typically in the range of 20-100). Topics are thus not given explicitly for each document, but constitute *latent* variables: A variety of approaches exist to estimate the document-topic and topic-word distributions from the *observable* document-word distributions. We use Gibbs-Sampling as implemented in Mallet (McCallum 2002).

For the preliminary analysis in this paper, we process documents as is, without segmenting them further into pages, only excluding stop words but not performing lemmatization or normalization in order to stay reasonably close to the original source. We experimented with the number of topics ranging between 20 and 30, reporting here results on 24 topics. Cursory analysis of multiple runs with different seeds (Steyvers and Griffiths 2007) shows that the resulting topics are rather stable.

Table 1 displays the top words for the topics with manually assigned labels and their overall percentage of occurrence. We can roughly distinguish four groups of topics; three non-thematic groups and one thematic. The first group comprises topics arising from documents in *Latin* and *French*, some of which are also translated into English. The second group *Formulae* and *Tables* relates to highly formalized modes of information presentation. The third group of topics is also clearly non-thematic but relates to general scientific processes: *Observation* and *Experiment* both contain rather general verbs and adjectives in addition to nouns. *Events* contains words describing remarkable events. *Headmatter* includes formulaic expressions typically occurring at the beginning and end of documents that are letters. All topics in this group are relatively frequent. Finally, the topics in the fourth group (*Geography* through *Chemistry*), consisting mainly of nouns, indeed have a fairly clear thematic interpretation.

Table 1: Top words and percentages for topics

To investigate topical trends in the corpus we follow the approach in (Hall et al. 2008), by averaging the document-topic distributions for each year *y*:

$$P(w_i \mid y) = 1/n \sum P(z_k \mid d_j)$$

with *n* the number of documents in a year. *Figure 1* shows a selection of five topics with the most pronounced change over time. Interestingly, some of the major changes occur for non-thematic topics: The topic *Observation* declines sharply from over 30% to less than 1%. The topics *Experiment* and *Formulae* on the other hand increase starting around 1750. This indicates a substantial paradigm shift over time. Indeed, as Gleick (2010) vividly describes, the early stages of the Royal Society were largely devoted to observing and reporting about natural phenomena. The non-thematic topic *Latin* reaches its peak in the early 18th century, and the thematic topics *Cells* and *Chemistry* show a clear increase with the beginning of the 19th century.

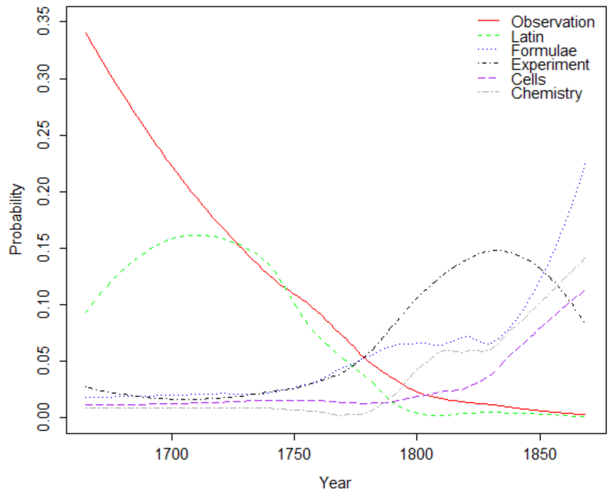

Figure 1: Major topical trends for selected topics

To gain a better understanding about the correlation of topics, we cluster them hierarchically on the basis of the Jensen-Shannon divergence between the topic-document distributions:

$$P(d \vee z) = P(z \mid d) \,/ \sum P(z \mid d_j)$$

Topics that typically co-occur in documents have similar topic-document distributions, and thus will be placed close in the tree.

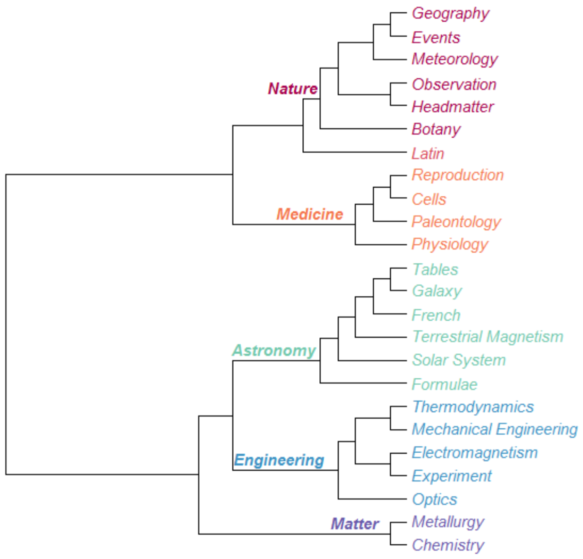

Figure 2: Hierarchical clustering of topics by their topic-document distribution

The resulting tree in *Figure 2* indeed identifies meaningful subgroups. Cutting the tree into six groups - *Nature, Latin, Medicine, Astronomy, Engineering, Matter* - allows us to investigate the overall topic distribution over time (*Figure 3* with *Latin* left out):

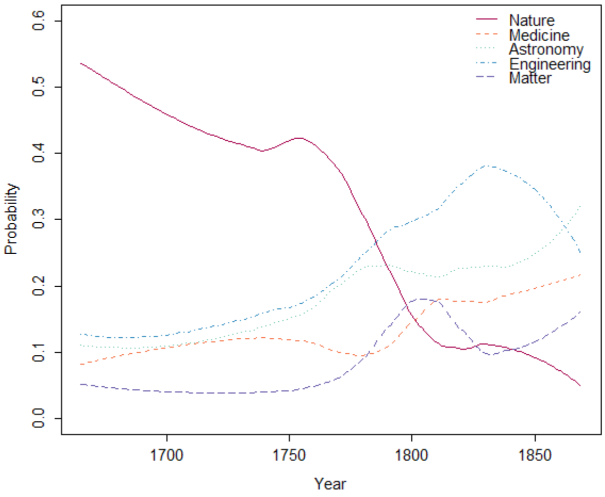

Figure 3: Distribution of topic groups over time

The topic group *Nature* comprising reports of all kinds of natural phenomena (Gleick 2010) clearly decreases over time, which is partially to be attributed to the strong decrease of the topic *Observation* in this group. The topic groups *Medicine* and *Astronomy* increase over time, whereas the topic groups *Engineering* and *Matter* also generally increase but with some intermediate peaks. Similar to the overall trends at the level of individual topics (*Figure 1*), the biggest overall change occurs in the 2nd half of the 18th century.

Looking at the individual trends together, *Figure 3* clearly indicates topical diversification: Until around 1770, the dominance of the topic group *Nature* leads to a highly skewed distribution of topic groups, whereas after 1770 topic groups are distributed much more evenly. The amount of skew can be characterized by the Shannon-Entropy:

$$P(d_y) = -\sum P(z_k \mid y) \log_2 P(z_k \mid y)$$

of the year-topic distributions $P(z_k \mid y)$ (Hall et al. 2010), with highly skewed distributions having low entropy. Indeed as can be seen in *Figure 4 (left)*, the entropy (*ent*) increases fairly consistently during the 18th century and levels out during the 19th century, reflecting a general increase of topical diversity over time.

It is interesting to compare this with the mean entropy of the *individual* document-topic distributions (*ment*):

$$H_{\text{mean}}(P_y) = 1/n \sum H(P_d)$$

with n the number of documents d_j in year y. This measure decreases over time, i.e., while the overall topical diversity increases, the individual documents become more specific in terms of their topic distributions.

The difference between the entropy of year-topic distributions and mean entropy of individual document-topic distributions,

$$JS\,(P_y) = H(P_y) - H_{\text{mean}}(P_y)$$

is the Jensen-Shannon divergence, which is usually applied to two distributions, generalized to the n topic distributions of all documents published in year y. The two opposing trends of these quantities lead to a constantly increasing Jensen-Shannon divergence, with a particularly sharp increase between 1750 and 1800. *Figure 4 (right)* depicts similar trends based on the 24 individual topic distributions. At this level, the year-topic entropy (*ent*) shows less of a clear trend, but mean entropy (*ment*) also clearly decreases, and consequently the Jensen-Shannon divergence clearly increases. Thus, at both levels of abstraction we can observe a clear diversification of the topics assigned to the individual documents. This strongly indicates a growing separation of individual scientific disciplines over time.

As an alternative perspective on topical entropy *Table 2* gives examples of authors with more than 20 papers. The first three authors have the lowest entropy. The dominating topics for Cayley and Owen clearly characterize their main theme of work. Conversely, Rev. John Swinton's top topic *Headmatter* (62%) does not really reflect the overall theme of his publications (Orientalism), but rather their style as letters to members of the Royal Society – the dominant form of publication in this period. The second three authors have the highest entropy, their three top topics together amount for less than 50% of their overall topic distribution. However, they do characterize the main line of work of the authors in question fairly well.

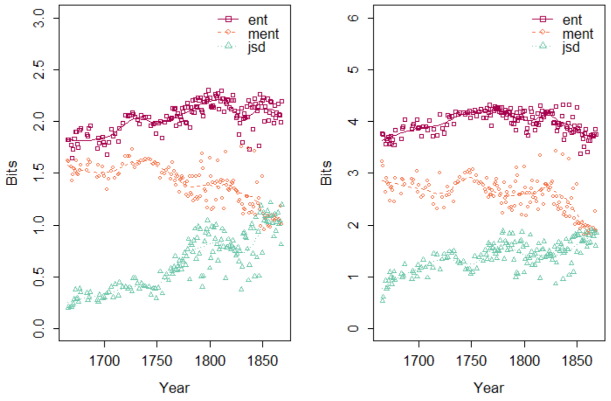

Figure 4: Entropy (ent), mean Entropy (ment), and Jensen-Shannon Divergence for topic groups (left) and individual topics (right)

Author	Papers	Ent	Ment	Jsd	Years	Top Topics
Arthur Cayley	30	1.26	1.12	0.14	1850-1866	Formulae
Richard Owen	26	1.83	1.58	0.25	1843-1869	Paleontology
John Swinton	35	2.50	2.05	0.45	1753-1774	Headmatter
John Davy	58	4.05	3.33	0.72	1800-1856	Experiment, Chemistry, Physiology
William Watson	39	4.03	3.09	0.95	1739-1778	Events, Observation, Botany
Edmond Halley	65	3.93	2.75	1.18	1683-1731	Solar System, Observation, Latin

Table 2: Authors with minimum entropy (top) and maximum entropy (bottom)

In this paper we have analyzed the progression of topics in a corpus of the Royal Society of London. Our main result is the observation that the overall mixture of topics becomes more diverse over time, while the topics of individual documents become more specialized. These two opposing trends lead to a topical fragmentation of scientific discourse, which can be quantified by means of the generalized Jensen-Shannon divergence between the topic distributions of individual documents per time period. We are currently working on consolidating our analysis, experimenting with documents segmented into pages, focusing the analysis on different text types, and more carefully evaluating the resulting topic models (McFarland et al. 2013).

Of course, topic models only provide one, rather broad perspective on diversification of domain specific language. We plan to apply our approach also to other levels of linguistic analysis, such as terminology or grammar.

Writing Composition in the Close Reading Cycle: Developing The Annotation Studio Idea Space

Kurt Fendt

Massachusetts Institute of Technology, United States of America

Building on the success of Annotation Studio—MIT's collaborative, open source annotation tool—a new application called the Idea Space expands the functionality of the platform to cover the point in the cycle of close reading where annotation turns to writing composition. This new interface allows students to arrange annotations into an outline, which, when exported to a word processor, retains citations of the original text along with full metadata and links to their annotations. This paper discusses the basis for the Idea Space in assessment of student annotation and in conceptions of digitally aided student scholarship. It also describes the development of the Idea Space as a modular application, complementary to Annotation Studio but easily adaptable to other environments, and presents a working prototype of the Idea Space.

The Annotation Studio online application has been used successfully over the past three years as a tool to support student textual annotation and collaborative reading, and its user base has expanded exponentially over the past two years in educational institutions around the world. In addition to facilitating textual annotation and reading-group formation, Annotation Studio has the potential to provide a writing space in which student annotations may be organized and used as the basis for the development of arguments by the individual or by collaborating groups. We are working, in effect, to develop a pedagogy and a tool that will support a seamless integration of the processes of close reading, annotation and writing. The aim of this new tool, the Idea Space, is to help students learn to collect sources, analyze content, form arguments, properly cite sources and confidently manage the writing process.

Recent assessment has shown that deep engagement with texts through forms of close reading and annotation can have a significant impact on students' ability to become better academic writers. A few studies have pointed specifically to the role of collaborative annotation in strengthening and expanding students' annotation practices, their engagement with textual analysis, and their ability to incorporate and analyze sources in their written work. Yet, collaborative annotation, supported by an online social annotation tool, such as HyperStudio's Annotation Studio, is a relatively new pedagogy, and initial adoption of Annotation Studio has focused on its efficacy as a tool to improve students' critical reading. Preliminary experimentation has suggested that the tool can help students visualize verbal patterns in texts; deepen their in-class discussions; anchor their claims with more detailed textual evidence; dig deeper into contextual and cultural meaning; and provide more thoughtful peer review of each other's texts in progress. Other parts of the writing process, such as organizing evidence, analysis, and claims into coherent argument structures, lie just outside the scope of the current implementation of Annotation Studio.

The Annotation Studio team have therefore prototyped a new "Idea Space" extension of Annotation Studio, in which each student's annotations are displayed and organized around key terms. In this space, the student's or group's annotations (including images and other media) may be sorted, arranged and structured to form arguments and provide the basis for developing supporting materials that compose the substance of academic writing. The Idea Space will help students organize citations, comments, and preliminary text to create an outline of an essay which in turn can be fed back into the annotation tool for further revision and for review by writing instructors. The Idea Space will provide both a workshop space for the development of writing and a window into the writing process itself, from which an instructor will be able to engage with the student.

While the Idea Space presents a novel interface, its scholarly and pedagogical basis is as grounded in ancient practices as annotation itself. When Juliet Fleming takes on the question of how we can usefully define "what reading is," she proposes the metaphor of "cutting." Fleming's suggestion—that reading has always been a process of pulling material from a text and adapting it to the reader's purposes—resonates with the way in which many students currently use Annotation Studio: first flagging evidence in the text through the collaborative annotation process, then later drawing on these same pieces of evidence to compose written arguments. Just as digital interfaces help realize an ideal environment for annotation, they also offer myriad ways in which to support and enrich this process of cutting. The ease of sorting, filtering, duplicating and rearranging material in digital settings affords a fast and intuitive way to turn from annotative reading to composition. The capacity of these virtual materials to retain links to one another, keeping track of where and when annotations or edits have been made, can not only relieve reader-authors of some of the work of managing citations, but also give scholars a greatly augmented record of their own process. This record can, persist throughout the scholarly cycle when works exported from the Idea Space are themselves uploaded into Annotation Studio.

While the Idea Space is conceived as adding to Annotation Studio's support for student work, its modular design and implementation enable it to work in combination with other tools and sources of data. The application's first data module retrieves annotations from the Annotation Studio database, whose format conforms to open annotation standards, meaning that the interface could easily extend other annotation environments. A simple design for adding new data modules gives instructors the ability to tailor the application for use with their own combinations of tools and archives. Far more than a visual organizer for annotations, the Idea Space is a tool through which users can combine, juxtapose and adapt any scholarly material in the composition of compelling and richly contextualized writing.

1. Introduction

This study discusses the methodology used in *The Digital model of Andalusia's Late Gothic Heritage* project to develop new models of heritage interpretation through the application of GIS and Graph visualization to provide new perspectives of Andalusia's heritage by considering social, political, economic and cultural evolutions. Given the special period context considered, late 15th and early 16th centuries, the project used a variety of sources to relate heterogeneous historical data on different subjects in order to create a historical spatial database and to respond questions such as: How was the construction process in Andalusia between 1433 and 1560? What period and region had more constructive activity? How did the opening of the Andalusia´s eastern border modify the dynamism of the territory? What features are more common in each time period? What professionals have worked together on a building or quarry? Is this reflected in the architectural language produced?

Andalucía's territory is the consequence of a huge numbers of different cultures that passed through it - from Roman and Islamic to Christian. During the 15th century, Spain had profound transformations, both political and cultural. The Christian reconquest led to the centralization of the cultural production in major cities generating important flow of new knowledge. Also, the consolidation of the Iberian Peninsula´s borders and the growth of contacts with Europe, and in a near future with America as well, helped to improve the cultural expansion and exchanges between the political leaders, intellectuals, scientists and technicians (García C., 2011).

These transformations are documented by a large number of sources that usually focus only on one particular aspect. In this sense, some sources are about professionals that worked at the quarries, others are about building construction and labor contracts, or about journeys and meetings that the workers had had. On one hand, we are dealing with the data from researchers that studied the biography of a particular professional or studies that have been dedicated to the constructive evolution of a city or a building. On the other hand, we are analyzing historical cartography sources that show different territorial changes and stages over time (kingdoms, dioceses, borders, etc).

Thereby, our goal is to build a spatial-temporal database capable of linking information that at first glance may seem unrelated. Visualizing and relating these attributes through an information system on cultural heritage has steered our work in two directions: the creation of systems built around the entities, and the implementation of analyses to observe and interpret their relationships.

In this study we demonstrate how all different historical information could be organized and structured in two types of digital models - GIS and graphs - that will are applied to our case study and allow us to generate a more comprehensive and flexible understanding of the phenomenon of the late Gothic period as a complex system through a combined knowledge of space, time and actors.

Working with these two tools has provided new perspectives at the Late Gothic heritage, creating new groups and subgroups of entities, and new relationships that could be easily translated to other case studies. We also created different categories - for each technology - designing two models of organizational structure. On the one hand, we use GIS with a spatial approach, the space is the product and simultaneously the producer of a series of relationships (Lefebvre, 2000) whose analysis can be performed using the alphanumeric attributes of each spatial entity or its topology. On the other hand, using graphs we have an abstract approach to visualizing a network of professionals and works over the Late Gothic period. The creation of the two models is because each of these tools requires a specific way of organizing data. While GIS works with a system with fixed relational databases that support SQL "join" operations, using it as the main query language and organizes spatial data in layers and attributes, Graph model uses the NoSQL system (Not Only SQL) and organizes data in nodes and edges (Robinson et al., 2013).

2. GIS model

The process of creating the GIS model will be developed in eight dynamic and interrelated phases: database design schema (figure 1); collection, processing and data selection; data entry and analysis in ArcGIS software; production model views; assessment of the problem; data interconnection; generating queries and reports; system development documentation and dissemination of the model (Ferreira Lopes and Pinto Puerto, 2015). The longest stage of the process is the creation of spatial entities - data entry - around 75% of the time and effort undertaken in the research will be used to collect, treat and create the data so that they can later be analyzed. The big difficulty lies in its accuracy. For certain entities, the maps and information of the 15th and 16th centuries does not allow us to reach an urban scale precision which forced us to work with a territorial scale. That is the case, for example, of the kingdoms, buildings, quarries or paths layers (figure 2).

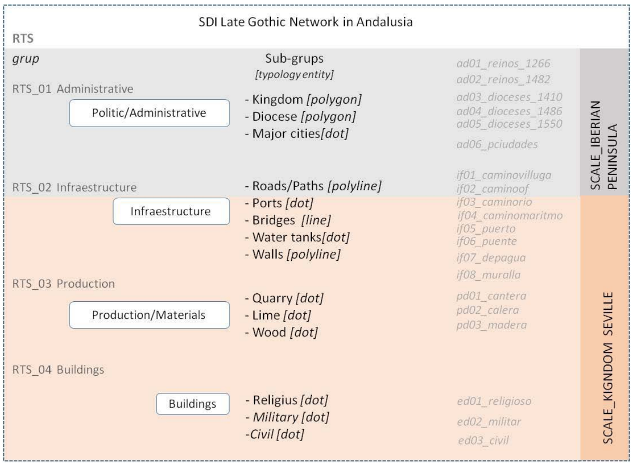

Figure 1: Andalucía's Late Gothic Heritage database schema

Also, some gaps are constantly present in the attributes; in many cases we have incomplete information, which somewhat limited our analysis of certain data. That is the case, for example, of some *"date"* attributes. However, working with GIS allows us to take these gaps temporarily - once it offers an easy way to edit and add new data, which is one of the main advantages that the tool offers. Our SDI are created in the ISO 19100 series standards, Open Geospatial Consortium standards and the recommendations of the guidelines of INSPIRE and LISIGE in order to be extended, edited and viewed by other researchers.

3. Graph Model

The construction process of the Graph Model has been developing in three phases: 1) data collection, 2) scheme creation and 3) queries and analysis. This paper will deal with the proposal and outline gathering held in conjunction with the Culture Plex Lab at the University of Western Ontario in Canada.

Our "starting point" was the Cathedral of Seville. Knowing that the construction of the Cathedral was one of the events most responsible for the flow of knowledge at that time and knowing that a lot of professionals had worked or had some kind of work relation with it, this strategy was more realistic and reachable, initially (figure 03).

To create the Graph model we are using the software Sylva DB (de la Rosa et al., 2013) developed by the CulturePlex Lab, which has allowed us to create a scalable and flexible way to organize, structure, manage, visualize and analyze our mass of data. With all the data in *SylvaDB*, we can see the links between different professionals and works, as well as between quarries and workers, parts of building and professionals, quarries and buildings. This tool has redirected the process in a way that otherwise would have been too taxing in terms of time and computation - we were now not required to create innumerable tables and charts to collect all the information.

After having a clear starting point and already with a certain amount of professionals collected - about 300 workers - the next step was the creation of a schema through which we discern graphic patterns. At this moment, in the Graph model we have 1.000 relationships and 850 nodes (figures 04, 05 and table 1).

4. Conclusions

Different research methods based on new technologies applied to understanding the same phenomenon provide a greater depth of the problem. In this sense, the use of multiple methods has allowed us to achieve three important aspects: to promote different perspectives on the subject allowing a wider view about the object of study; include a large variety of variables in the study; provide multiple analyses of the same concept, which increases the validity of the research that remains open and upgradeable. Therefore, what we seek is to provide new methods but also new approaches that do not override other traditional systems, but enrich the discussion on the past and its relationship with the inheritance.

Funding

Choosing Words for Stylometric Authorship Attribution: Evaluating Most Distinguishing Words (MDWs) vs. Most Frequent Words (MFWs)

Introduction

The results of stylometric authorship attribution studies are strongly influenced by four choices:

1. **Candidate Authors** – The choice of candidate authors should be based on the historical context of the texts to be attributed.

2. **Representative Texts** – Representative texts should be chosen that are similar in genre, topic and time frame as the texts to be attributed (Argamon et al, 2003; Stamatatos, 2009).

3. **Analytical Method** – Many analytical methods are available. Burrows' Delta is often considered to be the 'gold standard' to compare other methods (Burrows, 2002).

4. **Distinguishing Features** – One list of features to distinguish among candidate authors can provide greater distinguishing power than another list of features. This paper is about identifying the most distinguishing list.

Grammatical function words are used by all authors, but authors do not use function words in the same way or with the same frequencies. Therefore, different usage frequencies for function words are useful in characterizing an author's writing style. Although the specific function words that are distinguishing among authors vary from study to study, their effectiveness as features to set apart an author's writing style is well established (Mosteller and Wallace, 2007; Holmes, 1998).

Discriminant analysis is a statistical technique to classify objects into known categories based on a set of features about those objects. The technique was developed by Sir Ronald Fisher, a botanist. He illustrated the technique by classifying iris flowers into three species using four features – the length and width of sepals and petals (Fisher, 1936).

The approach is to compute linear combinations of the features that best separate the categories from each other. The most distinguishing combination of features is called the first linear discriminant function (LD1). Additional combinations (LD2, LD3 and so on) are computed that are orthogonal to each other to maximize the separation among categories. After computing the discriminant functions using a training set of data for objects with known classification, the discriminant functions can be used to classify objects of unknown classification into the categories to which they most likely belong.

The discriminant analysis concept is illustrated in figure 1 for a two-category problem and two dimensions. Each ellipse in the graph encircles the items within a category. LD1 shows the direction of greatest separation between the two categories. Discriminant analysis can be extended to classification problems with any number of categories and dimensions.

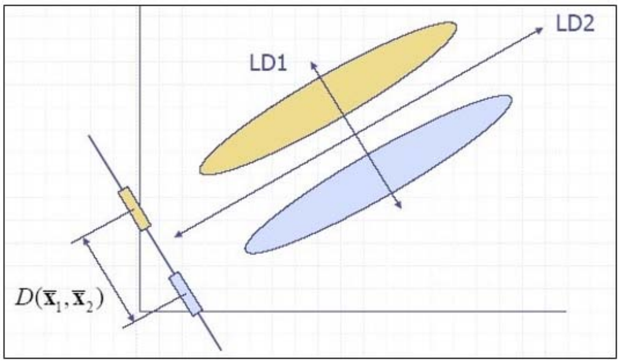

Figure 1. Graphical illustration of discriminant analysis for two categories with two discriminant functions

Discriminant analysis can be used in authorship attribution since the problem is similar to that of classifying plants into species based on their physical features. In attribution, the process is to use a set of texts of known authorship to determine the discriminant functions using non-contextual words as the features, and then classify texts of unknown authorship into the set of authors using the discriminant functions.

A variation of discriminant analysis called stepwise discriminant analysis (SDA) first determines a subset of the most distinguishing features from a comprehensive list of features and then formulates the discriminant functions (Goldstein and Dillon, 1977). The most distinguishing features are the best predictors for classifying objects into the proper categories.

In our stylometric work we have observed the utility of SDA to choose the words to use as distinguishing features in authorship attribution studies. This observation agrees with work done by other researchers (Smith and Aldridge, 2011). From a comprehensive list of non-contextual words, SDA identifies the most discriminating word first and subsequent words in descending order of discriminating ability. It stops when none of the remaining words add to the discriminating ability of the set of words. Thus, we end up with a subset of words that are the best predictors of authorship.

Another approach often used to select distinguishing features for authorship attribution is to use a list of the most frequent words listed in descending order of frequency in a set of representative texts of the candidate authors' works. Consequently, we considered this research question:

For a given set of authors and representative texts, and using Burrows' Delta as the analytical method, will the most distinguishing words (MDWs) identified by SDA give more distinguishing power in the analysis than using the most frequent words (MFWs) approach?

The corresponding null and alternative hypotheses are:

H_0: Using non-contextual MDWs selected by SDA is not more distinguishing among candidate authors than using a set of MFWs.

H_a: Using non-contextual MDWs selected by SDA is more distinguishing among candidate authors than using a set of MFWs.

Method

To answer our research question, the metric we used for a set of words' distinguishing power was the difference in Burrows' Deltas for the two authors with the smallest Deltas to that text. If the null hypothesis is true, the differences between Deltas should be about the same whether using MDWs or using MFWs. If using MDWs produces larger Delta differences than using MFWs, that evidence would support the alternative hypothesis.

We used the difference in Deltas between the nearest authors because it is an indication of statistical power. Analogous to the power of a microscope, statistical power is a statistical technique's ability to distinguish between things that are close together. The greater the distance between Deltas, the greater the power of the technique used to calculate the Deltas.

To conduct the study we used *The Federalist Papers*, commonly used for testing the usefulness of authorship attribution methods. *The Federalist Papers* are well suited to the problem as there were a total of 85 published papers written by Alexander Hamilton, James Madison and John Jay. Fifty-one were known to have been written by Hamilton, fourteen by Madison, five by Jay, and three written jointly by Hamilton and Madison. Twelve had disputed authorship, but have subsequently been studied extensively and are commonly attributed to Madison.

Because the attribution of the disputed papers is relatively non-controversial, *The Federalist Papers* provide a useful basis for comparing attribution methods. Since our research objective was not to answer the attribution question, but rather to compare methods of answering the question, using *The Federalist Paper* removed the question of correct attribution for a more direct comparison of the distinguishing ability of SDA-selected MDWs compared to MFWs.

Using only the 70 papers of known authorship as the representative texts, we applied SDA and selected the MDWs from a large list of non-contextual words, and then calculated Burrows' Delta distances for each paper to each of the three candidate authors. We compared these results to the results of using sets of MFWs ranging from 50 to 500 words in increments of 50 words.

Results

The SDA procedure select 29 words as the most distinguishing words for *The Federalist Papers*. Those 29 MDWs produced 100% correct classification of the 70 representative texts and provided greater distinguishing power than MFWs for the 12 disputed texts. As shown in figure 2, for *The Federalist Papers*, MDWs have from 1.5 to 4 times the discriminating power of MFWs.

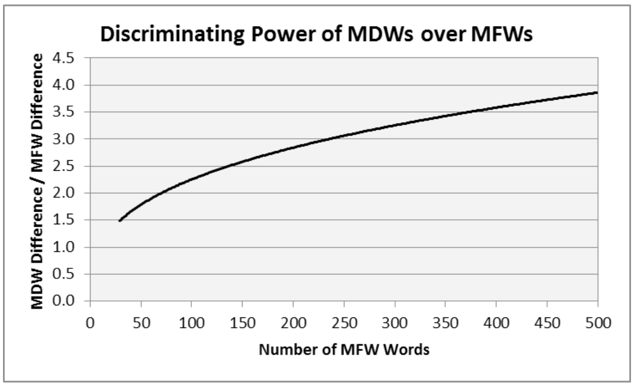

Figure 2. Comparison of the discriminating power of MDWs vs. MWFs

To understand why this occurs, examine table 1 and notice where each of the 29 MDWs appears on the MFW list.

Feature Words	MDW Rank	MFW Rank	Feature Words	MDW Rank	MFW Rank	Feature Words	MDW Rank	MFW Rank
and	1	4	the	11	1	from	21	23
upon	2	53	matter	12	364	for	22	18
whilst	3	1231	notwithstanding	13	983	any	23	41
by	4	13	also	14	241	thereby	24	3585
it	5	9	before	15	406	even	25	122
which	6	11	against	16	69	no	26	47
just	7	278	lest	17	6598	him	27	236
particularly	8	715	into	18	72	nay	28	1677
on	9	28	there	19	48	one	29	45
a	10	6	out	20	213			

Table 1. Comparative ranking of MDWs and MWFs for *The Federalist Papers*

Words in a list of MDWs often are not included in typical MFW lists. For example, note that the word, *whilst*, is the third most discriminating word selected by SDA and yet it is not even in the top 1000 MFWs. Even though Mosteller and Wallace identified *whilst* as a key indicator of authorship for the disputed papers, MFW lists of less than 1231 words would miss this highly distinguishing word. Notice further that 12 of the 29 MDWs are not even in the top 200 MFWs. So using MFWs will miss many highly distinguishing words.

Discussion

Thus, we reject the null hypothesis and assert that MDWs provide more distinguishing power between the Deltas for the two closest authors to the texts to be attributed as compared to MFWs. Our results show that MDWs can provide greater sensitivity than MFWs in discovering stylistic word-choice differences among candidate authors. The finding that it only takes 29 words selected by SDA to correctly classify all of the disputed Federalist Papers is a striking example of the power of using SDA-selected MDWs, since over 350 MFW words – more than ten times as many words – were required to achieve the same results.

Although some research has shown that variations of Delta may perform better than Burrows' original formulation (Evert et al., 2015; Hoover, 2004), we have found that using modifications of Delta does not improve the performance of MFWs relative to MDWs.

Conclusion

We conclude greater discriminating power can be achieved with a small set of MDWs chosen by SDA than with even large sets of MFWs. Using SDA-selected MDWs a researcher is more likely to make correct attributions and may be able to do it with fewer representative texts and for smaller texts. As a result, a researcher will have a greater likelihood of discovering new insights about the possible authorship of unattributed or disputed texts.

File Formats for Archiving: Stability and Persistence Issues

Peter R. Fornaro

Introduction

A well chosen file format is an important aspect in the process of archiving digital information. A typical example are image files for archival purposes. Unfortunately it can be shown, that even a well-defined file format like TIFF can have partially proprietary, vendor-based features. Today it is inevitable to digitize analogue photographs or images because the originals are endangered by unstoppable physical decay. Because of the continuous process of scanning, digital images are an important part of our cultural heritage already and they account for a constitutive part of our contemporary multimedia output in social, scientific and economic ambits (Kuny et. al., 1998). Unfortunately any digital object must be migrated in periodic cycles, because of technological changes. Hardware migration is only one of the steps needed to ensure that a digital file can be rendered in future. The file format definition is of the same importance. If such a definition becomes obsolete, the existing file must be converted into another one that is not in danger to be outdated (Heath et. al., 2011). Therefore it is necessary to judge and optimize all relevant factors that define the sustainability of a file format definition. Even more important is the persistence of a file format if a storage solution with very long cycles of migration is used, as presented in the Monolith-Project (Fornaro et. al., 2014) or the Rosetta-Project. In those cases a lifecycle of several decades can be expected.

We discuss in this document the long-term stability of existing image file formats and derive possible new approaches. We will show in detail what weaknesses exist, that endanger the future rendering of the content. In addition an image file format definition for archival needs is proposed, based on the already existing widespread standard TIFF. The proposed approach follows the concept of the Portable Document Format (Oettler et. al.,2013), PDF and its archival derivative PDF/A. The recommended specification is called TI/A, *Tagged Image for Archives*.

Problem

If digital file formats are not well chosen, the content won't be accessible in future because it can no longer be decoded as a consequence of one or multiple technological issues (Rothenberg, 1995). A "file format" basically defines the logical structure and meaning of the bits within the bit stream and thus it is essential for correct interpretation and proper rendering of the coded data. Unfortunately a file format or parts of its logical structure and definition can become obsolete, like hardware does. As a result the information renders useless, even-though the bit stream is still properly readable. To prevent such obsolescence the file format must be migration. In most cases this is more complex than creating a simple duplicate of a bit stream; the file has to be restructured. In addition every migration can reduce image quality or introduce artefacts. Therefore it is necessary to use a file format for long-term preservation of digital data that is stable, simple, well-documented and reliable. Unfortunately most image file formats do not fulfill the needed requirements. Even open standards like the Tagged Image File Format (TIFF) can have partially vendor specific, proprietary content that decreases long-term stability. TIFF is one of the most widespread formats used to represent high quality image data in archives. TIFF is a well known, established, flexible, adaptable file format for handling images and data within a single file, by including various header tags. TIFF offers some features that are rarely used and not supported by most applications. The TIF format is quite complex and parts of the original definition have become obsolete, while new, not formally standardized additions have been made. As a consequence it would be easily possible to create a TIFF file that is fully conformant to the TIFF Revision 6.0 specifications but would be virtually useless because no existing software is be able to open and render it, migration is the needed.

Migration is an expensive task. Therefor numerous approaches for archival storage solutions exist that do not or only rarely need to be migrated. Most of those solutions make use of a very stable carrier and a simple interface to access data. Monolith is such an example for an "eternal" storage. Monolith (Gubler et. al., 2006) is based on chromogenic optical film, that has a life expectancy of up to 500 years. The data is stored on Monolith as 2D-barcode, enriched with human readable metadata. For such a solution the data format is of very high importance because any format obsolescence reduces migration cycles drastically.

Approach

Since a digital archive has the goal that the file can be rendered in a indefinite but possibly far future, a simplistic approach is necessary. Therefor a TIFF suitable for long term archiving should require only a minimal set of features (tags) that are necessary to allow a correct future rendering of the data and the essential descriptive metadata. We therefore propose a subset of the full functionality of TIFF that is fully compatible with the de-facto TIFF standard itself but marks some tags as **mandatory**, some as **optional** and some as **forbidden** in order to guarantee the correct rendering in the future. In addition to the core functionalities, it is crucial to define a minimal set of metadata for archival applications, following standards like Dublin Core or METS (Loeffler et. al., 2007). In analogy to PDF/A format we propose to call this specification *TI/A* or *Tagged Image for Archives*.

In cooperation with the University of Girona in Spain and EASY INNOVA, a technology and innovation centre of Girona, we have started the process of specifying TI/A in co-operation with multiple memory institutions of Switzerland and Europe.

Of course the concept of using a subset of the functionality of TIFF can be applied to any other format common for archiving digital image data like JPEG2000/A (Buckley, 2013) or even video or motion picture like DCP/A (Fornaro et. al., 2014: Goethels, 2009).

Results

It can be shown that a smart chosen file format is very important for successful archiving [9]. With the help of numerous institutions and experts we have drafted a recommendation, based on the existing TIFF standard (http://ti-a.org). The exchange of needs, requirements, dos and don’ts will lead us to a final draft specification of an ideal archival file format for high quality image data that is well supported by an international network of experts. Following the original standard definition of TIFF allows us to define a format that is fully compatible with existing decoders. This approach makes it not necessary to have “out on the market” software modified or enhanced by any means.

Based on that preliminary work we will try to have the document standardized by the International Standard Organisation, ISO. Such a precise definition of the functionalities and their implementation in a Tagged Image File for Archives will help to increase the sustainability of the original image format drastically.

Approaches to Thematic Classification for Latin Epic

Christopher W. Forstall

Background and Motivation

It has long been understood that Greek and Roman epic poems partake of a shared repertory of stock themes and typical scenes: the catalogue of heroes, the warrior arming for battle, the tempest, etc. These themes originally evolved under circumstances peculiar to oral-formulaic composition in archaic Greece, where they served the exigencies of real-time composition in performance by organizing poetic material into mnemonic chunks, each with a predictable internal structure (Rubin, 1995; Minchin, 2001). For later, literate Greeks, and still later for the Romans, who continued to develop the epic tradition, the use of these themes was no longer an aide to memory, but a complex intertextual gesture that formed one of the defining features of the genre (De Jong, 2014; Nünlist, 2009).

The study of elemental, thematic building-blocks in epic and related genres has a long history, through the twentieth century and even earlier, including work by Claude Levi-Strauss, Milman Parry, and Vladimir Propp. While catalogues and typologies of epic themes exist (*e.g.*, Edwards, 1992), at the same time significant disagreement remains over their definition and delineation. Here we take first steps towards automated detection of theme in epic, defining features that target scene-sized samples of text under in bag-of-words model, and applying both unsupervised and supervised classification methods.

Our research is on intertextuality in Latin epics of the Flavian period, and in particular the ways in which an intertextual relationship at the thematic level can support or undermine specific verbal allusions at the sentence or phrase level. The ability to automatically detect text reuse in Latin epic at the scale of individual verse lines is provided by tools such as Tesserae (http://tesserae.caset.buffalo.edu), Musisque Deoque's co-occurrence search (http://www.mqdq.it/mqdq/cooccorrenze.jsp), and eTRAP's forthcoming TRACER framework (http://etrap.gcdh.de), so that it is now conceivable to generate an exhaustive list of all such correspondences between any two texts. Yet the same efforts have shown that simple text-reuse search alone cannot capture all of the allusions noted by professional commentaries, and that sensitivity to scene-level thematic parallelism would improve both recall and precision over a model based on single verse lines or sentences (Coffee et al., 2012).

Tesserae has in fact produced a prototype thematic search using topic modelling to create scene-level features (Scheirer et al., forthcoming). At the same time, work by the Memorata Poetis project affiliated with Musisque Deoque is carrying out systematic manual tagging of themes in Latin vernacular poetry (Ciotti et al., 2015). Both approaches—the supervised and the unsupervised identification of themes—show promise, although neither has been fully integrated into its respective parent project's verse-level, text-reuse search tool. In the ongoing work presented here, we attempt to combine elements of each approach, comparing unsupervised, bag-of-words classifiers at the scene-level with manual tagging for specific, selected themes. Our ultimate goal is to combine similarity scores for thematic parallelism with existing phrase-level search tools' scores for text reuse in order to improve their accuracy.

Method

We consider a corpus including the three more or less complete epics of the Flavian period—Valerius Flaccus' *Argonautica*, Statius' *Thebaid*, and Silius Italicus' *Punica*—as well as three earlier poems to which our works of interest respond—Lucan's *Civil War*, Ovid's *Metamorphoses*, and Vergil's *Aeneid*. These works are initially subdivided into samples of 50 consecutive verse lines. After lemmatization, tf-idf weighted feature vectors are calculated for each sample, dropping terms common to 50% or more of the samples, and the resulting feature set is reduced using principal components analysis to the most significant 500 components.

The samples still show a strong tendency to cluster by author despite the removal of very frequent words. Since our goal is to examine parallel variation across authors, we attempt to remove a characteristic 'authorship signal' from each author's *œuvre* before classification. A mean vector representing the author is thus subtracted from every one of his samples.

In the unsupervised approach, we then perform k-means clustering on the corpus as a whole. Because we do not have any *a priori* set of themes to look for, we test multiple values of *k* in an attempt to identify the most stable number of clusters. For each possible value of *k*, we perform multiple repetitions and compare pairwise agreement among the resulting classifications using the adjusted Rand index. We also attempt to identify the most stable passages through comparison of error across repeated classifications using different offsets for our 50-line sampling window. For those passages most consistently classified across repetitions, we return to the text to investigate, through close reading, whether the passages indeed demonstrate meaningful similarity.

In the supervised approach, on the other hand, we begin by identifying scenes of interest using a set of *a priori* thematic categories—for example, battle scenes and storms at sea. We then attempt to train a classifier that can distinguish these types. Earlier work on this project has shown that certain thematic contexts can be separated at a coarse scale (e.g, love versus war, generally) using principal components analysis alone; however here we will attempt to achieve finer precision using support vector machines, a popular approach in stylometric tasks and one that has previously been applied to intertextuality in Latin in particular (Forstall et al., 2011).

Results

This work is ongoing, and one of our goals in presenting at DH 2016 is to elicit feedback that will help to shape the design of future experiments. At the same time, early results suggest that the supervised and unsupervised approaches may indeed meet in the middle. For example, many of the most stable passages in the unsupervised classification belong to a 'nautical' theme which includes as a subset the storm theme identified by human tagging. Across 100 different classifications of the six epics, using differently-offset sampling windows, the passages with the lowest rate of disagreement included characteristic descriptions of tempests in *Aeneid* 1 and *Argonautica* 1 (Figs. 1–2). The same class, and a high degree of stability, also marked nautical chase sequences in *Aeneid* 5 and *Argonautica* 8 as well as the recounting of the Argonauts' story in *Thebaid* 5.

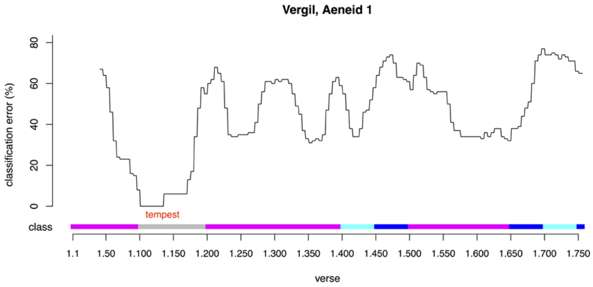

Figure 1. Vergil's *Aeneid*, book 1, after k-means classification with 8 classes. The line shows disagreement between repeated re-classifications. Shaded bands at bottom show classes in one randomly-selected trial.

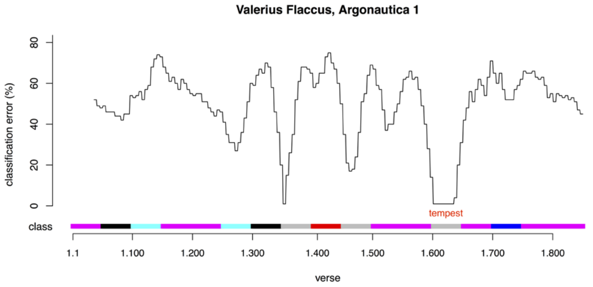

Figure 2. Valerius Flaccus, *Argonautica*, book 1, after k-means classification with 8 classes. Line shows disagreement among repeated re-classifications; shaded bands show the same classes as in Fig. 1.

Implications

The concrete goal of this project is to provide a thematic feature set for automated intertext-detection, compatible with the phrase-based results of existing tools, so that, for example, otherwise slight verbal correspondences can be promoted where they occur within thematically parallel passages and thus are likely more interesting to readers. More generally, we would like to understand how stock themes function in epic intertextuality, and whether they can indeed be sufficiently modeled using a bag-of-words approach. To the degree that they can, we can say that thematic features are in fact made of words and exist on a continuum with the word-level bigrams matched by Tesserae, for example, instead of representing 'deeper', semiotic structures distinct from the word forms that appear on the 'surface' of the text (as in, e.g., Levi-Strauss, 1955)

Toccata : Text-Oriented Computational Classifier Applicable To Authorship

Richard Sandes Forsyth
forsyth_rich@hotmail.com
independent, United Kingdom

Introduction

Many text-classification techniques have been proposed and used for authorship attribution (Holmes, 1994; Grieve, 2007; Juola, 2008; Koppel et al., 2011), genre categorization

(Biber, 1988; Argamon et al., 2003), stylochronometry (Forsyth, 1999) and other tasks within computational stylistics. However, until quite recently, it has been extremely difficult to assess novel and existing techniques on comparable benchmark problems within a common framework using statistically robust methods.

Toccata is a resource for computational stylometry which aims to address that lack, freely available at http://www.richardsandesforsyth.net/software.html under the GNU public licence.

The main program is a test harness in which a variety of text-classification algorithms can be evaluated on unproblematic cases and, if required, applied to disputed cases. The package supplies four pre-existing classification methods as modules (including Delta (Burrows, 2002), widely regarded as a standard in this area) as well as five sample corpora (including the famous *Federalist Papers*) so that users who don't wish to write Python code can use it simply as an off-the-shelf classifier and those who do can familiarize themselves with the system before implementing their own algorithms.

Noteworthy features of the system include:

1. sample corpora provided for familiarization;
2. test phase using random subsampling to give robust error-rate estimation;
3. ability to plug in new techniques or to employ existing standards;
4. option of post-hoc phase applying trained model(s) to unseen holdout data;
5. empirically grounded computation of post-hoc confidence weights to deal with 'open' problems where the unseen cases may not belong to any of the training-set categories;
6. accompanying export file readable by R or similar statistical packages for optional further processing.

Sketch of the System's Operation

Toccata performs three main functions, in sequence:

(a) testmode: leave-n-out random resampling test of the classifier on the training corpus to provide statistics by which the classifier can be evaluated;

(b) holdout: application of the classifier to an unseen holdout sample of texts, if given;

(c) posthoc: re-application to the holdout sample of texts (if given) using the results from phase (a) to estimate empirical probabilities.

Steps (b) and (c) are optional.

Sample corpora

Toccata is a document-oriented system. Thus a training corpus consists of a number of text files, in UTF8 encoding, without markup such as HTML tags. Each file is treated as an individual document, belonging to a particular category. Example corpora are supplied to enable users to start using the system, prior to collecting or reformatting their own corpora.

ajps: ninety poems by 2 eminent 19th-century Hungarian poets, Arany József and Petőfi Sándor. Arany was godfather to Petőfi's child, so we might expect their writing styles to be relatively similar.

cics: Latin texts relevant to the authorship of the *Consolatio* which Cicero wrote in 45 BC. This was thought to have been lost until in 1583 AD when Sigonio claimed to have rediscovered it. Background information can be found in Forsyth et al. (1999).

feds: writings by Alexander Hamilton and James Madison, as well as some contemporaries of theirs. This corpus is related to another notable authorship dispute, concerning the *Federalist Papers*, which were published in New York in 1788. See Holmes and Forsyth (1995).

mags: 144 texts from 2 different learned journals, namely *Literary and Linguistic Computing* and *Machine Learning*. Each text is an excerpt consisting of the Abstract plus initial paragraph of an article in one of those journals, written during the period 1987-1995.

sonnets: 196 English sonnets, 14 each by 14 different authors, with an additional holdout sample of 24 texts, half of which are by authors absent from the main sample.

Validation by Random Subsampling

A major objective of the system is to assess the effectiveness of text-classification methods by a form of cross validation. For this purpose the training corpus of undisputed texts is repeatedly divided into two portions, one used to form a classification model and the other used to test the accuracy of this model. After this cycle a number of quality statistics are computed and printed, along with a confusion matrix. This helps to establish a relatively honest estimate of the likely future error rate of the classifier. After subsampling, the program will construct a model on the full training set. This may then be applied to a genuine holdout sample, if provided.

Classifier Modules

A classifier module is expected to develop trained models of each text category and deliver matching scores of a text to each model, with more positive scores indicating stronger matching. The category with the highest match-score relative to the average of all scores for the text, is the assigned class. Four library modules are supplied "off the shelf".

Module **docalib_deltoid.py** is an implementation of Burrows's delta (Burrows, 2002) which has become a standard technique in authorship attribution studies. Module **docalib_keytoks.py** works by first finding the 1024 most common word tokens in the corpus, then keeping from these the most distinctive. For classification, relative word frequencies in the text being classified are correlated with relative frequencies in each class. Module **docalib_maws.py** is a version of what Mosteller and Wallace in their classic work (1964/1984) on the *Federalist Papers* call their "robust Bayesian analysis", as implemented by Forsyth (1995). Module **docalib_topvocs.py** implements another classifier inspired by the approach of Burrows (1992), which uses the most frequent tokens in the training corpus as features.

The Holdout and Posthoc Phases

The subsampling test phase (above) is primarily concerned with assessing the quality of a classification method. The holdout and posthoc phases are when that method is applied in earnest.

If a holdout sample is given, the model developed on the training set is applied to that sample. The holdout texts may belong to categories that were not present in the training set, so each decision is categorized as correct (+), incorrect (-) or undetermined (?) and the success rate statistics computed accordingly.

This is illustrated in Table 1, below, from an application of the MAWS (Mosteller and Wallace) method to a collection of sonnets. Here the training set consists of 196 short English poems -- 14 sonnets by 14 different authors. This is a challenging problem firstly because the median length of each text in the training corpus is 116 words, secondly because 14 is a relatively large number of candidates.

Table 1 shows the ranking produced on a holdout sample of 24 texts, absent from the training set. Note that 12 of these 24 items are 'distractors', i.e. texts by authors not present in the training set. The program assigns these a question mark (?) in assessing its own decision.

The listing ranks the program's decisions from most to least credible. The upper third include 6 correct assignments, 1 clear mistake and a distractor. The middle third contains 1 correct classification, 3 mistakes and 4 distractors. The last third contains no correct answers, 1 mistake and 7 distractors. (Incidentally, the distractor poem by the Earl of Oxford, ranked twentieth, is more congruent with Wordsworth than any other author, including Shakespeare, and not confidently assigned to any of the training categories.)

This output addresses the very real problem of documents from outside the known training categories. The listing is ordered by a quantity labelled 'credit'. This is the geometric mean of the last two numbers in each line, labelled 'confidence' and 'congruity'. Confidence is derived from the preceding subsampling phase. It is computed from the differential matching score of the text under consideration as W / (W+L), where W is the number of correct answers which received a lower differential score during the subsampling phase and L is the number of wrong answers with a higher score. Congruity is simply the proportion of matching scores of the chosen category that were lower, in the subsampling phase, than the score for the case in question. It is an empirically based index of compatibility between the assigned category of the text and the training examples of that category.

In all kinds of classification, the problem of never-before-seen categories can loom large. (See, for instance, Eder, 2013.) Like most trainable classifiers, Toccata always picks the most likely category from those it has encountered in training, but the most likely may not be very likely. The confidence and congruity scores give useful information in this regard. For example, if we only consider the classifications which obtain a score of at least 0.5 on both confidence and congruity, we find 6 correct decisions, 1 incorrect and 1 distractor. Treating the distractor (assigning a sonnet by Dylan Thomas to Edna Millay) as incorrect still represents a 75% success rate in an "open" authorship problem on texts only slightly more than a hundred word tokens in length, where the training sample for each known category consists of approximately 1600 words, with a chance expectation of 7% success. In other words, three crucial parameters -- training corpus size, text length and number of categories -- are all well "outside the envelope" of most previously reported authorship studies.

Introduction

In her plenary address at the 2014 Digital Humanities conference, Bethany Nowviskie urged the field to consider how “broken world thinking,” an approach equal parts ethical, ontological, and methodological, might enrich digital humanities practice (2015, n.p.). Nowviskie borrows the phrase from information theorist Steven Jackson, who argues for a reparative rather than productivist approach to the study of media and technology, and more specifically, for an increased emphasis on the “moments of breakdown” that allow us to “see and engage our technologies in new and sometimes surprising ways” (2013, 230). In this paper, we take up this shared call and extend it, elaborating an approach to broken-world thinking that is simultaneously informed by examples of historical fabrication in the digital humanities (e.g. Elliott et al. 2012, Sayers 2015) and theories of breakdown and repair from the field of design (e.g. Jackson, 2013; Gabrys, 2011). We take the time-series charts of William Playfair, the eighteenth-century data visualization pioneer, and recreate them using D3.js, a data visualization library commonly employed in digital humanities work (Bostock, 2011). In doing so, we gain valuable purchase on the historical concepts that contributed to the creation of Playfair's charts, many of which-- such as data-- still hold sway today. But by remaining equally attentive to the "moments of breakdown" between the original artifact and our contemporary recreations, we are also able to open new perspectives on the "affordances" of our own visualization tools (Murray, 2011). Our digital "fossils," as we term them, following the work of Jennifer Gabrys, suggest a generative new point of intersection between the fields of digital humanities and design (2011).

Project overview

William Playfair is widely considered the "inventor" of modern data visualization (Tufte, 32). The graphical forms that he first developed, including the bar chart and the pie chart, remain among the building blocks of visualization today (Wilkinson, 2005), and the charts he created are still employed as examples of the crystallizing power of data visualization (Klein, forthcoming). And yet, the techniques he employed, such as copperplate engraving, have long been supplanted by newer technologies. This project seeks to understand how Playfair's techniques affected the images he created, and how our techniques, in turn, affect the images and interactions we create today.

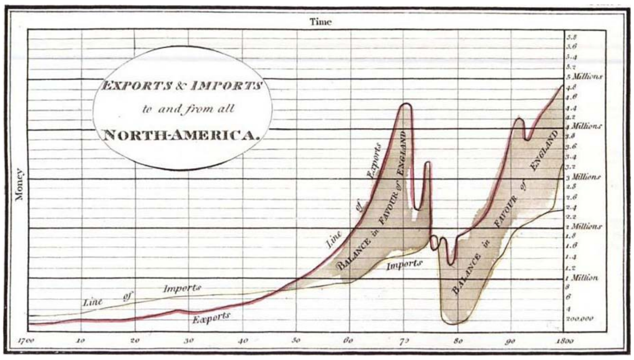

Figure 1: William Playfair, "Exports and Imports to and from all North-America," from *The Commercial and Political Atlas*, 3rd ed. London, 1801

To recreate Playfair's chart, we selected D3, the javascript visualization library employed in contexts ranging from data journalism to scientific research to the digital humanities (e.g. Meeks n.d., Schmidt n.d). In comparison to off-the-shelf software such as Microsoft Excel or Tableau, D3 provides additional control over the structure and style of the data, an advantage when attempting to achieve fidelity to an original image. In addition, D3 is open source; this allowed us to consider additional aspects of the library's design. Finally, D3 was developed in an academic context; its own design choices therefore support a conceptual as well as technical analysis.

We took two approaches to recreating Playfair's chart: the first by adhering to the original as closely as possible, including the use of the original data; and the second by adapting Playfair's design for use with contemporary trade data, taking advantage of D3's emphasis on data transformation. (We employed the US Census Bureau's data on foreign trade). In the sections that follow, we describe these approaches in more detail, with particular attention to "moments of breakdown" and the new perspectives that they granted.

First approach: remediating playfair's original chart as a digital fossil

Jennifer Gabrys, a design theorist who, like Jackson, views instances of breakdown and failure in a generative light, suggests that we view cast-off objects as "fossil forms" rather than waste (2011, 7). These digital fossils provide "evidence of more complex and contingent material events," as well as "traces of the economic, cultural, and political contexts in which they circulate." By recreating Playfair's chart in D3, we also remediate its "fossil form," granting us access to the various contexts in which the chart circulates, both historical and contemporary.

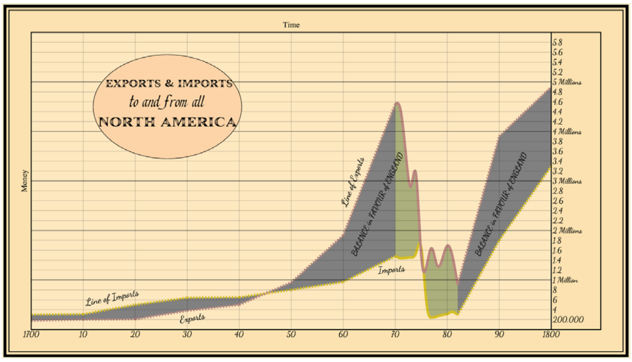

Figure 2: True-to-form recreation of William Playfair's original chart. The gray area emphasizes the uncertainty of the data, while the green area matches the original. Implementation and image by C. Foster

Our interest in creating our digital fossil was to induce the moments of breakdown that might alert us to the contextual differences between past and present; the nature and status of statistical data was one such difference. When consulting the third edition of Playfair's *Statistical Atlas* as a reference, we found no actual data accompanying his charts. D3 assumes that the developer will begin with data, so without it, we could not begin. To compensate, we turned to a data table from a previous edition, but it contained data for only a portion of the date range, from 1770 to 1782. We began by recreating that section of time, but to create the entire chart, we estimated the additional data points. The resultant chart resembled the original, but was premised upon two different data sources, with different degrees of accuracy.

This instance of breakdown and repair illustrates how D3 assumes that a dataset will be presented in a certain format, and that the data will be well-defined, clean, and accurate. The context of D3 is revealed as representative of a culture fixated on data-driven solutions. Rather than present our numbers, actual and interpreted, as the same, we used a technique developed by Kevin Schaul (2013) to create dashed lines for the interpreted numbers. The code he developed, what some might view as a "hack," might be understood as a "repair" of a breakdown within D3, one that enables the visual presentation of defined and undefined data together. By contrast, Playfair's original chart shows us that precise data were not a necessary component of its initial success. Playfair drew his charts' data lines freehand. In fact, there is little evidence that Playfair plotted any actual data points before engraving the lines (Klein, forthcoming).

Second approach: creating an interactive chart in the style of playfair

Our second recreation, an interactive version of Playfair's chart supplemented by modern trade data, revealed additional contexts and biases encoded in D3's design. D3 was designed to facilitate the creation of interactive visualizations (Bostock, 2011). Its built-in functions worked smoothly once we traded out the original dataset for a more consistently formatted, if substantially larger, contemporary one.

It was when we attempted to recreate Playfair's customized labels that we encountered a significant moment of breakdown. All Playfair did to create his labels was to pick an appropriate spot and engrave them. While less extensible than any computational method, Playfair's technique allowed for more flexibility in the visualization's layout. Since we were dynamically generating the charts, we weren't able to use the human eye. Instead, we had to determine a set of rules for where to place text, and then encode them in D3. To ensure legibility, we had to verify three things: 1) that the label was not placed on a part of the chart where the import and export lines were too close; 2) that the label did not intersect with a line; and 3) that the text was placed along a part of the graph that had a consistent slope. As it turned out, determining the points of intersection was a non-trivial task. Even though the ability to illustrate the intersections between lines-- or more generally, the relations among different slices of a particular dataset-- would seem to be a basic requirement of any visualization platform, D3 was constrained by the affordances of its underlying technologies. Playfair thought hard about how to facilitate a "comparative perspective" through the design of his charts, but employing contemporary tools that are constrained for various reasons can affect the range of knowledge that is produced (1801, x).

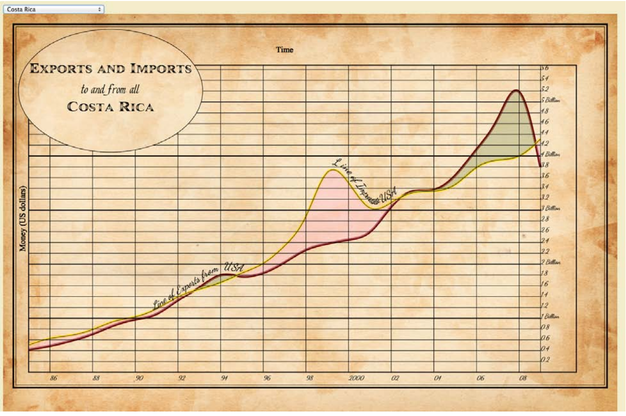

Figure 3: Interactive version of Playfair's time-series charts. The user selects the country to display through a drop-down menu. Implementation and image by E. Pramer

Conclusions

This project illustrates some of the insights that emerge from broken-world thinking as applied to digital humanities tools. Through the process of recreating Playfair's charts, we introduced moments of breakdown and prompted our repairs. We became alerted to the changed relation between data and image, and to how the hidden affordances of both software and platform affect the forms of knowledge that D3 can produce. Copperplate engraving allowed greater flexibility and less reliance on the dataset. By contrast, D3 imposes limits on design and is heavily reliant on a clean dataset. This project shows how an uninterrogated reliance on popular tools can limit the creative expression of humanistic data. We have since extended this study by recreating the visualizations Elizabeth Peabody (1804-1894). Her visualization techniques are far more difficult to recreate using standard tools, underscoring how historical fabrication allows us not only to better understand the past, but also to illuminate the present.

Anonymity and Online Discussion: A New Framework for Analysis

Rolf Fredheim
ref38@cam.ac.uk
CRASSH, University of Cambridge, United Kingdom

Alfred Moore
am2214@cam.ac.uk
CRASSH, University of Cambridge, United Kingdom

We present a way of disaggregating the concept of anonymity and linking it to particular democratic goods. We demonstrate its value in the particular context of studying online commenting by contrasting three distinctive commenting regimes used by the Huffington Post (HuffPo) in the period January 2013 - March 2015. But we think this may have wider relevance for scholars looking at online communication, as modes of identity disclosure are an unavoidable yet consequential design feature of online communication platforms. In this paper we disaggregate three aspects of anonymity: traceability, which we argue relates to inclusion; durability, which influences deliberative quality through varying levels of communicative accountability; and connectedness, which ties users to real-world relations.

Decisions about online architectures have a crucial influence on the quality of communication, but are often adopted by default or with regard to other factors. In the realm of online commenting, we observe a trend of commenting platforms being outsourced to the Facebook commenting API. These changes are often framed and justified in terms of a shift from an anonymous but easily abused environment, to one in which users operate under real-name identities. When we think in terms of a choice between anonymous and real-name architectures, it seems that there is a simple trade off between the goods and dangers associated with anonymity, such as trolling on the one hand and the freedom to express one's views without fear of recrimination on the other, and the goods and dangers of real-name communication, which ties users more closely to discursive norms of civility but which also risks reproducing offline power relations.

We propose to analyse the concept of anonymity in three dimensions. We argue that cross-platform connectedness is associated with increasingly personalised communication as well as less communicative engagement between individual users; durability (continuity) of identity is associated with greater levels of civility, reduced trolling, and higher quality of deliberation (more reason-giving, etc); traceability is associated with exit - that is, people worried about traceability leads people to make a binary decision, to opt out, and the increasingly pervasive traceability promotes exit. Thinking of anonymity in these terms helps resolve some apparent trade-offs: it may be possible to capture the benefits of communicative accountability without the drawbacks of either the abusive space of easy anonymity or of the exposure to offline power relationships associated with real-name spaces.

Disaggregating anonymity

Anonymity exists on one end of a spectrum of degrees of disclosure of identity. In the context of commenting, anonymity means contributions to a discussion are not visibly linked to any particular commenter. Pseudonyms - names chosen by commenters - allow users to keep their real identity private if they wish, yet allows them to maintain a persistent alternate identity in the context of the forum in question. You might have an identity as a commenter on the *Guardian* that you keep separate from your professional networks and from your social networks. Real name comments, obviously enough, appear under your real name, not a pseudonym.

While this is a useful starting point, many scholars analysing the different degrees of disclosure on online platforms have sought more fine-grained distinctions

(Marx, 1999; Ruesch and Märker, 2012). We favour splitting online anonymity into three dimensions: traceability, durability, and connectedness.

Traceability refers to the extent to which your contributions can be traced to your real identity. Traceability is distinct from disclosure of identity to fellow commenters. You can make comments under a pseudonym and yet it may be possible (with some effort) for advertisers or the National Security Agency (NSA) to trace your real identity. Nissenbaum, for instance, argues that anonymity online, in the sense of 'conducting one's affairs, communicating, or engaging in transactions anonymously in the electronic sphere... without one's name being known', is undermined by technologies that have made it possible to track and / or piece together ('infer identity from non-identifying signs and information') the real identities of citizens online even when they are withholding their names or using pseudonyms (Nissenbaum, 1999). Because traceability is strictly distinct from the question of anonymity or pseudonymity *with respect to other commenters*, it does not help us grasp the relation between disclosure of identity and discussion quality.

Durability refers to the ease or difficulty with which online identities can be acquired and changed. Where new pseudonyms are easy to create, online identities are disposable; if you acquire a reputation for abusive or untrustworthy behaviour you can just create a new pseudonym and start again. As Resnick and Friedman put it, cheap pseudonyms create 'opportunities to misbehave without paying reputational consequences' (Resnick and Friedman, 2001). Users are more likely to stick with a particular name, exposing them to the reputational consequences of their behaviour. The durability dimension is particularly important for the possibility of holding commenters accountable for claims they make, enabling challenges in terms of consistency, and exposing uncivil or abusive commenters to sanctions.

The third dimension has to do with **connectedness** or bridging across different platforms and contexts. The most visible example of cross-platform connectedness is sites enabling users to login or register through a third party - typically Google or Facebook - rather than filling in a site-specific form. Connectedness also involves reputation, but is a global rather than local reputation. The durability or stickiness of an online identity is a necessary condition for building a local reputation, but it need not be connected to the wider reputation, a cross-referenced, cross-platform (including real life) reputation, of the sort you would want if you were renting out your apartment to someone you didn't know (as in Airbnb).

The Experiment

The two changes introduced by HuffPo provided us with a natural experiment. We collected more than 50 million comments on more than 50,000 articles featured on the HuffPo front page in the period January 2013 - March 2015.

The first of these phases allowed anonymous commenting. At this time, the platform experienced aggressive 'trolling' and the use of multiple accounts. In December 2013 HuffPo moved to regulate its forum by requiring users to authenticate their accounts through Facebook. On the face of it, little changed in this pseudonymous environment: user names and avatars remained, but behind the scenes Facebook's database helped weed out fake accounts. Users did not have to create a new online identity, give up their old pseudonyms, or change the appearance of their HuffPo commenter profile. We read this first change as primarily about durability of identity.

In June 2014 HuffPo changed to commenting through Facebook, meaning that HuffPo user profiles were *replaced* by Facebook profiles in a 'real name' environment. In this phase, comments appear below the line of the news article under the user's real name, as well as - depending on a user's privacy settings - appearing simultaneously on their Facebook page. This may have the effect that users comment on the HuffPo but speak to an audience located on Facebook. We read interpret this change as a move to more integrated and connected online identities.

While we found more durable online identities were associated with greater civility but less participation in online commenting, we also observed a shift in the sorts of issues on which users most frequently comment. This might be normatively encouraging: the relative rise in articles tagged Gay Voices, we speculate, may be a result of the inhibition of hostile and offensive commenters. Here greater civility seems to promote more participation and inclusive discussion. However, we also note a more general shift away from conflictual and politicized topics and towards 'safer' topics of celebrity, lifestyle and consumer issues. Turning to the second commenting change, we found that the Facebook phase exhibited markedly less argumentative engagement relative to the 'pseudonymous' phase, as evidenced both by an overall reduction in the proportion of replies, and by measures of deliberative quality (Fredheim et al., 2015a, 2015b). This finding points in the same direction as a recent Pew survey that found people were less likely to discuss a controversial issue on social media than in face to face conversation (Hampton et al., 2014).

With these findings in mind, we argue that the pseudonymous phase harnessed the beneficial effects of increased durability, without introducing the costs of connectedness. More broadly, we can link these dimensions of identification to particular democratic goods. The dimension of traceability seems to be associated with inclusion and exclusion, as users make a binary choice to stay on the platform. The dimension of durability or continuity of identity is associated with deliberative quality in so far as (theoretically) it exposes users to communicative accountability and (empirically) is associated with a higher density of reason-giving in commenting. The dimension of connectedness ties users to real-world relations. This favours civility, but it also promotes what Schudson calls 'sociable' conversation rather than more adversarial 'democratic' conversation (Schudson, 1997). We argue that durable and disconnected identities are more conducive to productive, issue-based debate between heterogeneous users. This bears on discussions of polarization. It also bears on the drive towards integration of social media and news discussion.

Indigenous digital humanities. Participatory geo-referenced-mapping and visualization for digital data management platforms in digital anthropology

Urte Undine Froemming
u.froemming@fu-berlin.de
Freie Universitaet Berlin, Germany

In this short paper presentation a participatory ethnographic GIS-mapping approach and an example for a digital platform for the visualization and digitalization of local environmental knowledge will be introduced. The term "Indigenous" is used to refer to those who "have a historical continuity with pre-invasion and pre-colonial societies that developed on their territories and consider themselves distinct from other sectors of the societies now prevailing in those territories" (UNESCO, 2004). Based on examples and research results of the research project ANIK *Alpine risks in times of climate change*, funded (2012-2015) by the German Ministry of Education and Research (BMBF), this paper will question how local environmental knowledge (Pottier, 2003) and local perceptions and handling strategies of climate-related risks may be gathered through participatory GIS mapping (PGIS), (Reichel, Frömming 2015, 2014). Based on applied visual anthropological methods, PGIS is a relatively new cartographical digital approach which includes local perceptions and strategies of action gathered during interviews and participant observation. This approach fosters active participation of local people (Wood, 2012), not only during the research process in the field, but also during the presentation process of the research data as digital spaces of memory.

Preface

The declining birth rate and resulting increase in the proportion of the elderly are serious issues for contemporary Japan. The National Institute of Population and Social Security Research reported that the 2010 Japanese population of about 128,057,000 is expected to decline to about 86,737,000 in 2060 with depopulation accelerating most acutely in local regions (The National Institute of Population and Social Security Research, 2014). Currently, in 7,878 villages in Japan, over half of the population is over the age of 65. From this figure, it is predicted that 2,500 villages will vanish in the next 10 to 30 years (Ministry of Land, Infrastructure, Transport and Tourism, 2014; Masuda, 2014). Given this situation, the preservation of local knowledge is essential and standardized digital archiving methods are required.

Figure 3: Application Schema for Local Knowledge (ver.2015-10-11)

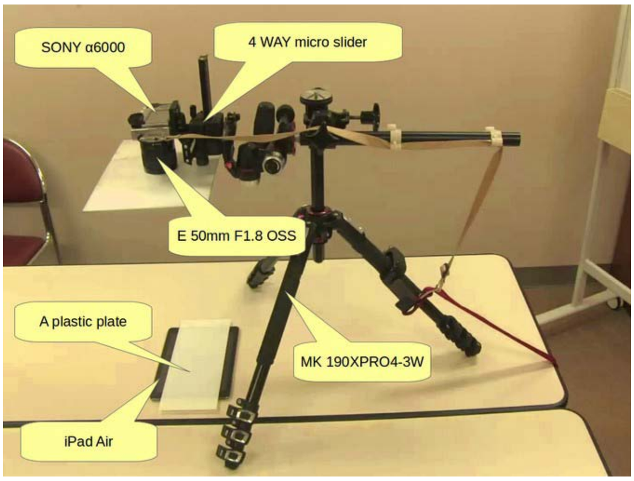

Figure 4: Digital Archiving of photographic dry plates

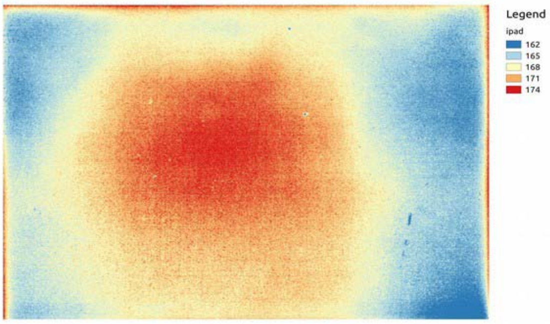

Figure 5: Brightness distribution of iPad Air

In contrast to national treasures, digital archiving for local cultural properties is limited in various respects. Digitizing devices should be versatile because the kind of materials buried is unknown at the onset of the survey. Budgets are therefore limited because most people in possession of such items do not have sufficient financial background. Therefore, the methods for archiving local items and knowledge should be as low-cost as possible. In addition to these problems, a standardized digital archiving workflow and information management rules are required to perform distributed autonomous digital archiving activities. Formulating digital archiving rules that are both open and standardized is also essential in terms of the Long Term Preservation issue (Lorie, R.A., 2001).

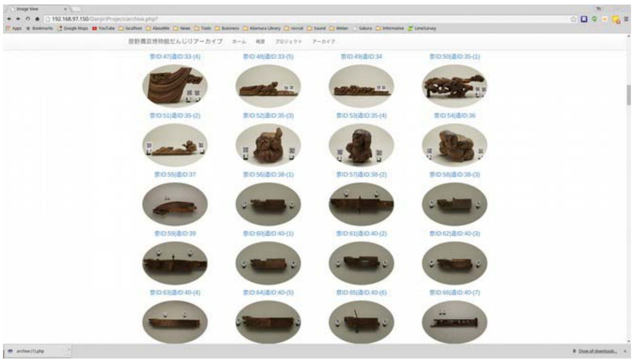

Figure 6: The resulting digital archive system

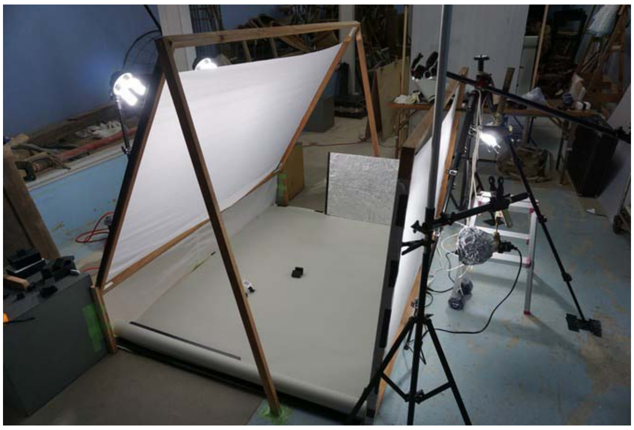

Figure 7: Handmade photo studio for Danjiri elements

Responding to these issues, this paper will propose a low-cost digitizing workflow using an Mirror-less Interchangeable Lens Camera (MILC) and the information standard for local memories and knowledge with the concept of a Work-Oriented Approach (WOA) (Fujimoto 2011). The proposed methods have already been used in two different types of experimental projects and the results will also be summarized in this paper.

The digital archiving workflow

The digital camera is excellent in terms of saving space, versatility, speed of digitizing and later correction, and is therefore the ideal device for basic digital archiving. In particular, the Mirror-less Interchangeable Lens Camera (MILC) has a rich choice of lenses, and is lighter and therefore preferable to than the general Digital Single Lens Reflex camera (DSLR).

Figure 1 shows the workflow of constructing a digital archive using the MILC. In this figure, the workflows are denoted with UML activity diagrams, with automated activities in red, and yellow designating those activities conducted manually. Each automated activity is described by BASH scripts to ensure the clarity of specific procedures, and some call python scripts utilizing open source libraries. In practice, Graphical User Interfaces (GUI) should be provided for ordinal users.

This activity diagram is separated into two lanes, with the left lane showing the digital archiving workflow and the right lane representing the post-production and publishing workflow. In the digital archiving workflow, taking photographs, writing investigative reports, and transferring acquired images to the work station are manually conducted, whereas other activities are done automatically.

To perform these automatic activities, a working directory should be defined as shown in Figure 2. The raw images acquired are automatically copied to the "*raw*" directory and JPEG format images are initially copied to "*main*", and then the raw images are developed and saved in the "*developed*" directory. Thumbnails are saved in "*thumbs*". Finally, unused images are moved to "*sub*" directories. By defining the directory structure, all projects are generalized, and creating an automatic workflow becomes much easier.

The application schema

Promoting such shared and mutual use is essential and will help preserve local memories and knowledge for future generations. To do so, it is important to conform to conventional international standards (Fujimoto, 2009). The ISO 191XX series is a versatile information standard for database construction. This international standard is based on the idea of object-oriented GIS, and it defines a meta-model of geographic features and spatio-time objects. The ISO 191XX series is generally adopted for public geographic information suchas census or infrastructure data. However, it has many other possible applications. Additionally, this standard provides encoding rules by XML, and metadata, geometric information, raster format datasets and tabular form attributes can be denoted as XML elements. Therefore, this standard is also effective in terms of Long Term Preservation issues.

The Figure 3 is the application schema proposed in this paper, which enables the storage of unknown tangible as well as intangible cultural properties in compliance with the standard. This application schema is based on the proposed working flow, and weighs heavily in extendibility. The fundamental classes including the *Consolidation* class, *Material* class, *Surface* class and *DenotedSubject* class are *Abstract* classes, which are actually implemented in specific ways. The grey-colored classes are examples applicable to photographic dry plates and " *Danjiri*" elements. The attributes for these classes are minimum essential attributes, and attributes relevant to each specific item can be defined using the Attribute class. This class specializes three classes: ThematicAttribute, SpatialAttribute and

TemporalAttribute classes. Any kind of attribute can be defined using this classification.

Case studies

The proposed standardized workflow and the database schema have been used in two case studies. One is the digital archiving project of dry photographic plates taken between the *Meiji* period and mid-*Showa* period, while the other is a "*Danjiri*", a traditional large wooden cart used for traditional Japanese festivals, which was completely destroyed by a flood.

In the first case a tablet device, iPad Air, was used as a substitution for a light box, and SONY A6000 was used as a digitizing device (Figure 4 and Figure 5) (Fujimoto, 2015). By using a set of these ordinary devices with three workers, more than three hundred old dry plates were duplicated in about 13 hours in total. In this project, all of the operations were composed almost entirely of open-source software, and performed in batches. Although this project was successfully completed, some improvements were later found for making linkages between the acquired images and investigative reports and application schema.

In the latter study, the digital archiving workflow and the application schema, originally designed for photographic dry plates, were modified for versatility, to make them applicable to the Danjiri elements. In this project, more than three hundred fragments of Danjiri elements were archived in one week by four workers with one day required for setting up the photographic studio, four days for taking photos, and two days for developing the digital archive system (Figure 6). In contrast to the former project, the digital archiving subjects were three-dimensional and lighting instruments were required. To achieve better results within a limited budget, a lighting studio was built using wooden blocks and domestic fluorescent lamps, which were procured on the site (Figure 7).

Conclusions

In digital archiving projects focusing on important cultural properties, intended objects are well known and professional and/or specialized equipment are used to achieve with the best possible results. However, to construct digital archives of locally-kept cultural properties, versatile and inexpensive methods are required. Additionally, a standardized workflow and database schema covering various kinds of materials should be considered.

In this paper, using the concept of WOA, a reasonable MILC is used as a digitizing device, and a standardized workflow enabling automation and database schema compliant with ISO 191XX are proposed. Because the proposed workflow, information schema and libraries utilize the existing international standard and open-source technologies, outcomes including metadata and source codes can be opened. This method is therefore effective in terms of the Long Term Preservation issues. These standardized methods have been tried in two different types of experimental case studies. Although both projects were successfully completed, some continual refinement is necessary to perform a fully automated workflow, especially post-production.

Finally, the methods proposed in this paper can be also applicable in disaster restoration. It is important to preserve memorial items of ordinary people such as family photo albums in order to incite the energy vital for the restoration process. Unfortunately, in fact, after the Great East Japan Earthquake in 2011, a large number of mementoes and keepsakes of the local people were discarded. In such cases low-cost, swift and standardized digital archiving methods are essential.

Playing with French Drama: from Old Research Questions to New Research Tools

Ioana Galleron
ioana.galleron@univ-ubs.fr
LIDILEM, U. Grenoble Alpes, France

While early English drama has been subject to several DH investigations, because "a quite explicit and rigid system of metadata is part of the genre itself" (Mueller, 2014: par27), French theatre of the 17th and 18th century remains largely underexplored, in spite of demonstrations and case studies presented by authors with large international audiences (Moretti, 2005). This paper presents some results of a project inspired by the explorations of the English corpora, but dedicated to the computer aided identification and analysis of theatrical topoi in the French domain.

Topoi can be defined as "recurrent configurations of thematic or formal elements" (adapted from Weill and Rodriguez, SATOR, 1996) and they are highly significant for the French plays, which are largely based on a common stock of characters, scenes and themes, and in which novelty often consists in reuse with a shift of former materials. Considering the vast amount of plays produced over the period going from, roughly, 1630 to 1790 (some 12000 plays, even if the text of many of them is lost), the use of computational tools to track the presence of various topoi over the time appears appropriate. Computer aid can help answer in a (more) rigorous way questions concerning the aesthetics of the French theatre of the period, too often reduced to "classicism", and historical interrogations about moments and reasons when certain meaning units are more in use or relatively abandoned.

While the results of this endeavour are at a very early phase, for reasons to be detailed in the presentation, the very attempt to clarify some of these literary questions shows that the use of the computer is not neutral and modifies the problems to be solved. After a more detailed presentation of the activities undertaken to date, this paper will reflect upon the way in which the methods and tools used to approach the texts modify the initial research questions.

Dramacode: an expanding community for French drama

Identifying topoi using a computer asks in the first place for the existence of digitised texts in a more elaborate format than the pdfs or plain texts offered by Gallica (see http://gallica.bnf.fr). Various initiatives have been taken in this domain in France, either by scholars supported by HEIs and research institutes (see "Molière project" http://obvil.paris-sorbonne.fr/corpus/moliere/moliere) or by individuals with computer skills and a special interest in literature from the 17th and 18th century (see http://www.theatre-classique.fr). Unfortunately, this diversity of initiatives resulted in a great variety of encoding practices, more or less TEI compliant. To reduce this diversity and move towards common standards, an organisation has been created on GitHub. Under the name of "Dramacode", it hosts some 882 plays written or staged between 1630 and 1810 (roughly, 7,3% of the dramatic production of the period), to be progressively re-tagged and enriched with further mark-up. "Dramacode" allows also to publish the contents with a harmonised style-sheet, and to share work on experiments of visualisation of data extracted from the plays.

Finding theatrical topoi through linguistic analysis and literary mark-up

Within this corpus, the plays of Louis de Boissy (1694-1754) have been selected for a pilot study, destined to build strategies for gathering sufficient clues, through various queries, about the existence of a topos in an unknown (i. e., not previously read) play, digitised and encoded in another project.

Louis de Boissy was a French play writer who enjoyed a certain success in the 18th century mainly because of two of his plays, *Le Français à Londres* and *L'Homme du jour*. Beyond these achievements, what renders his work interesting is precisely its mediocrity. Boissy's works are a perfect example of the reuse of topoi, sometimes to follow the fashion, sometimes in an attempt to distinguish himself by revitalising conventional themes and dialogues. He has also the particularity of having worked for the three main theatrical spaces of the period, namely the Comédie-Française, Théâtre Italien and Théâtres de la Foire. Therefore, his texts become a privileged observatory of French comedy in the first half of the 18th century.

Two approaches of topoï identification are developed. The first one consists in developing an ontology for characters and scenes description. Roles and description of roles from the existing plays have been extracted, cleaned, and analysed using an excel spread-sheet. Ten categories appear necessary for describing characters from classical French scenes; five of them were known and formalised since Aristotle, or, at least, since the rediscovery of Aristotle by French authors and thinkers of Renaissance, then 17th century: nationality ("climat" in Marmontel's words, see entry "Moeurs" in Eléments de littérature, 1787), age, sex, occupation ("état") and temperament. Five others were deemed of interest, as allowing potential automatic analysis aimed to spot changes in aesthetic principles: the ontological category (human/ nonhuman/ semihuman), the dramatic or actantial role, the social status ("king", "prince", "marquis", "Dom"…: it seemed useful to distinguish these from information about “état”), the family position, and the collective nature of some characters.

In parallel, types of scenes and other significant recurrences are manually identified and marked-up as “recognition”, “fight”, “complot”, etc. Relevant lines or phrases (labelled with xml:ids) are regrouped as <span>s in the <back> section of <text>; if each span receives, for the moment, a literal description, this will progressively feed into another library and will be later referred to using @ana.

The second approach is based on a linguistic analysis of the speeches, using AntConc to generate concordances and to identify key-words. The initial objective was to spot key-words or linguistic idiosyncrasies of the character of “petit-maître”, whose identification was the primary goal of this research. Indeed, “petit-maître” are not always labelled as such, and therefore their presence in French drama has been underestimated and incorrectly related to a specific period in time (mainly, “decadence comedy” after 1680). If, in time, a complete mark-up of the characters according to the above-mentioned categories (i. e., <temper>) will help identifying as “petits-maîtres” those who are not called as such by roleDesc or other characters in the play, speech identification is for the moment the only option for answering the research question.

New research vistas

When observing the trajectory of this study, the digital approach can be said as having significantly modified the initial perspective and research questions. The TEI tagging of characters and scenes revealed the need to refine methods and categories developed by the narratology and the theatrical analysis in 1970 and 1980, preparing the grounds for more accurate description of character building.

In the meantime, the effort to describe a stylistic specificity of the “petits-maîtres” revealed to be rooted in a larger, two folded research question, concerning the potential differences in speech between characters of the same author. Digital humanities have been, to date, more interested in global stylistic analysis on one side, and in authorship studies, on the other side, while this research project intends to apply the methods of the second approach to fictional speakers. While such an endeavour can be justified by the pretences of French dramatists of the classical centuries to act as kind of “sociolinguists”, the question is as well that of the methods to automatize the analysis of specific speeches when conducted on a large scale (more than 9300 distinct characters presents in the above-mentioned set of plays), and of the explanations to be found for the observed recurrences. Indeed, during the pilot study executed on Boissy plays, it appeared that his characters group, by their speech, less in male and female speakers, but rather in two unexpected classes, one formed by those who tend to speak more about themselves (characters saying “je”), the second by those who address themselves to the the others (characters saying “vous”). The importance of “I” and “You” has already been spotted in theatrical studies (see Craig, 2004), but not the observed repartition, which needs, however, to be checked against the larger corpus, a very time consuming operation for the moment.

It is to be expected that further observation of concordancers and n-grams extracted from very large collections of digitised plays will put into light such other unexpected recurrences, triggering a new understanding about what is a classical play, and contributing to the on-going debate about the nature of the theatre.

Big Data and the Study of Allusion: an Exploration of Tesserae's Multitext Capability

James O'Brien Gawley
jamesgaw@buffalo.edu
University at Buffalo, United States of America

A. Caitlin Diddams
acstaab@buffalo.edu
University at Buffalo, United States of America

This paper aims to explore the methodology and the potential of the “multi-text tool,” an advanced feature of the Tesserae Project. This tool is capable of identifying potentially interesting textual parallels between works, and collating all instances of these and similar phrases throughout the entire corpus of canonical Latin or Greek. As such it expands the researcher's ability to identify meaningful intertexts among Tesserae results, and makes it possible to quantify the literary influences which act upon a given work.

Tesserae is an online tool that aims to automatically identify allusions and more general forms of intertext between ancient authors. The program can identify specific intertexts between two works, as in previous research which has brought to light new parallels between Lucan's *Bellum Civile* and Vergil's *Aeneid*. A standard Tesserae search identifies a possible intertext when the same words (regardless of inflection) appear within the same phrase in two different texts. This 'bigram' measurement of similarity has been demonstrated to capture roughly 67% of intertexts previously noted in scholarship. The multitext function begins with a standard two-text Tesserae comparison; all bigrams shared between the two texts are then compared to a corpus of additional works selected by the user.

Although the first aim of most Tesserae users is to discover previously unnoted allusions, not all bigram similarities discovered by a Tesserae search are allusions. The program's scoring algorithm attempts to sort the meaningful intertexts sought by the researcher from undesired, coincidental overlap by considering the rarity of the shared words and their proximity to one another. This method has shown to be at least partially effective, yet it does not fully predict the assesment of the expert researcher. Because Tesserae results can number in the tens of thousands, further means of identifying desirable intertexts is necessary, particularly when the number of results is expanded by new search features such as semantic matching, introduced in October 2015. Tesserae's multitext search can be used to trace the history of a phrase throughout the corpus, and thereby eliminate oft-repeated bigrams. This method assumes that phrases appearing in many previous works are less likely to represent allusions.

In addition to identifying new allusions between two works, intertextual scholars often wish to measure the rate of connection between them. The level of active engagement between authors suggests the literary influence of a given work, and we propose a way to quanitfy this engagement. Using the multitext tool, the researcher can eliminate all widely-occuring textual parallels between potentially connected works and retain only unique results, then consider the rate of unique intertextuality against a baseline figure. Unlike the micro-level analysis of individual textual parallels, this macro-level analysis allows the reader to examine the intertextuality between works as a whole.

Our preliminary research shows that specific textual parallels with a large number of multitext results tend to indicate the use of generalized language rather than a meaningful communication between works. For example, Augustine's language in *De Doctrina Christiana* bears measureable resemblance to the language of Quintilian, Cicero, and Tacitus. Yet scholars have long argued that Augustine's primary influence was Cicero. Our multitexts results show Augustine's engagement with Cicero include a large percentage of "unique" intertexts, seldom picked up by other authors. His connections to other authors were mostly composed of "general" intertexts, which appear to consist of standard language used by almost all Latin writers engaged in the discussion of rhetoric. The same method has been previously used to examine Claudian's differential level of interaction with the various authors of Latin epic. The examples of Claudian and Augustine demonstrate the efficacy of unique intertextual connections as a measurement of relative literary engagement.

Although the elimination of oft-repeated language is effective for eliminating meaningless intertexts when considering works at the macro-scale, the scholar in pursuit of specific, meaningful intertexts should not eliminate these parallels. Sometimes a phrase with a large number of multi-texts results is actually more significant than one with fewer multi-text results. Certain phrases are quoted and alluded to so often that they become "viral." These instances do tend to apply in cases where a Tesserae match is ranked particularly high, but it ultimately remains the responsibility of the reader to sort meaningful intertexts from coincidental ones.

The multi-text tool expands the potential big-data research in the field of Classics, allowing for quantitative stylistic analysis at a rate of speed and a level of specificity previously impossible. It is an essential addition to the basic matching of the Tesserae Project, and we hope to see it become an element of digital humanities programs in various academic curricula. From specific analyses of sets of texts to more comprehensive explorations of style, the multi-text tool should be a fundamental resource in the study of allusion in Latin literature. In addition to demonstrating the efficacy of this tool, in this paper we explain how to use the results generated by a multi-text search to build an empirical measurement of authorial engagement, beginning with how to run the module on a personal computer and concluding with how to meaningfully analyze its results and tailor its parameters for individual projects.

Biblissima - Following Medieval Manuscripts and Incunabula through their Existence via a Semantic Web Application

Stefanie Gehrke
stefanie.gehrke@biblissima-condorcet.fr
Equipex Biblissima, France

Biblissima—*Bibliotheca bibliothecarum novissima*—is a Digital Humanities project that brings together libraries and research institutions, whose goal is to provide a single access point to over 40 databases regarding medieval and Renaissance manuscripts and early printed books by the end of 2016.

The project began late in 2012 with nine founding partners: the Department of Manuscripts at the BnF (Bibliothèque nationale de France), the Campus Condorcet, the CESR (Centre d'Etudes Supérieures de la Renaissance), the CIHAM (Histoire, Archéologie, Littératures des mondes chrétiens et musulmans médiévaux), the Centre Jean-Mabillon at the ENC (École nationale des chartes), the CRAHAM (Centre de Recherches Archéologiques et Historiques Anciennes et Médiévales. Centre Michel de Boüard), the IRHT (Institut de recherche et d'histoire des textes), the Digital Document Centre at the MRSH de Caen (Maison de la Recherche en Sciences Humaines), and the SAPRAT-EPHE (Savoirs et pratiques du Moyen Âge au XIXe siècle, Ecole pratique des hautes études).

Funded by the French National Research Agency (ANR: Agence Nationale de la Recherche), Biblissima is concerned with the history of collections and the transmission of texts. In this respect, the project stands somewhat in line with the works of Antoon Sanders, who published his *Bibliotheca Belgica Manuscripta* in 1641-44, and Bernard de Montfaucon and his *Bibliotheca bibliothecarum manuscriptorum nova*, published in 1739, both of which are major inventories compiling lists of manuscripts held in many different libraries in Europe.

In order to create an *Online library of historical collections of France for the 21st century*, our chosen solution was to develop a semantic web application. We released a prototype (http://demos.biblissima-condorcet.fr/prototype) in summer 2015 that provides unified access to a subset of two major iconographic databases: Initiale (http://initiale.irht.cnrs.fr/accueil/index.php) and Mandragore (http://mandragore.bnf.fr/html/accueil.html). An export of the metadata pertaining to the illuminations that depict geographical locations was used as a starting point for the development of our application. People (author or illuminator), institutions (libraries), work titles and places were aligned with the BnF authority records and, whenever possible, also linked to external vocabularies (GeoNames, VIAF, Pleiades, Getty thesauri).

The next step involved generating dynamic web pages that describe a person, a work, an expression, a manuscript, a part of a manuscript or an illumination, and which include links to the corresponding descriptions in the source databases. This original data is enriched with longitude and latitude coordinates for geographical names that were acquired by aligning them with the equivalent GeoNames concepts. It is now possible, for example, to show on two different maps the places depicted in illuminations with the images of the corresponding folios, and the illuminations from manuscripts held in a particular institution.

In addition, a viewer embedded in the page (we currently favour Mirador: https://iiif.github.io/mirador) shows the digitised manuscript or folio when available. The information needed to display these images is structured according to the Shared Canvas data model (http://iiif.io/model/shared-canvas), which is the foundation of IIIF (International Image Interoperability Framework: http://iiif.io). This information is passed to the viewer in form of JSON-LD manifests, which are generated from metadata and image files supplied by the partner institutions. The viewer itself is client-based and features a deep-zoom capability for the loaded images, the possibility to display associated metadata, and also the superposition of different layers, such as an image and the corresponding textual transcription.

The data model behind the application is based on CIDOC-CRM (http://www.cidoc-crm.org) and FRBRoo (http://www.cidoc-crm.org/frbr_inro.html) and our data is already available in RDF format. Beyond taking into account the different levels of work, manifestation and item (using the classes F4 Manifestation Singleton for manuscripts as well as F3 Manifestation Product Type and F5 Item for early printed books), we intend to group manuscripts and early printed books as productions of certain expressions (class F2 Expression). Illuminations are understood as features (class E26 Physical Feature) placed on a folio or page, and provenance marks will be modelled in the same way. Based on the lessons learned through developing our own ontology, we will be able to give feedback about the data.bnf.fr, FRBRoo and SharedCanvas ontologies, as well as other theoretical foundations.

We are currently working on extending this prototype, which was developed using the semantic web application framework CubicWeb (https://www.cubicweb.org/). In addition to manuscripts, we will be including early printed books, with a strong emphasis on book provenance, by integrating data from the following four sources: Esprit des Livres (database on auction and other sales catalogues, ENC), Bibale (database on historical book collections, IRHT), Europeana Regia (database on three important historical collections of the Middle Ages and Renaissance), as well as CR2I (Catalogues Régionaux des Incunables Informatisés, CESR) and CRIICO (CR2I Centre-Ouest, CESR). Resolved challenges include the creation of ARKs (Archival Resource Keys) for each manuscript (BnF and IRHT) and codicological unit (BnF). At a later stage, digital editions of inventories of manuscripts in TEI XML will be integrated as well.

This short paper will present the latest version of the semantic web application for Biblissima's data cluster.

DH Poetry Modelling: a Quest for Philological and Technical Standardization

Introduction

Standardization has become an increasingly important process in relation to academic research, as it provides a better way for exchanging information. Humanities and cultural studies have followed, however, a heterogeneous path in which creativity and tradition play an essential role. Comparative studies in literature, and especially poetry, are a clear example of this eclectic situation. There is not a uniform academic approach to analyze, classify or study the different poetic manifestations. Things get even worse when comparing poetry schools from different languages and periods. The result of this uncoordinated evolution is a bunch of varied terminologies that means to explain analogous metrical phenomena through the different poetic systems whose correspondences have been hardly studied (González-Blanco and Sélaf, 2014).

The existing digital poetic repertoires and databases are a good example of this situation, as they constitute a rich kaleidoscope of multilingual virtual poetry, constituted by lyrical collections in French (*Nouveau Naetebus*), Italian (*BedT*), Hungarian (*RPHA*), Medieval Latin (*Corpus Rhythmorum Musicum, Annalecta Hymnica Digitalia, Pedecerto*), Gallego-portuguese (*Oxford Cantigas de Santa María, MedDB2*), Castilian (*ReMetCa*), Dutch (*Dutch Song Database*), Occitan (*BedT, Poèsie Neotroubadouresque, The last song of the Troubadours*), Catalan (*Repertori d'obres en vers*), Skaldic (*Skaldic Project*), or German repertoires (*Lyrik des Minnesänger*), among others.

Interoperability among these different poetic corpora would be desirable, as having a common search engine to extract information from all of these databases at the same time would have a deep impact for comparative studies in literature, linguistics and other humanities disciplines. We are, however, far from this reality as interoperability is not possible due to a lack of standardization both in technological and philological fields.

Philological standardization

During the Middle Ages and the Renaissance, the powerful influence of Latin made scholars inherit the terminology of Classical poetry treatises and apply it to Romance languages, regardless of their different linguistic traits and verse structures. When vernacular theories started to arise, each literary school set up its own terminology and classification system. This multiplicity led to complex situations, such as the creation of conceptual genres that only exist in some traditions.

Spanish conceptualization models are a good example to illustrate this situation: the classical system of Bello (1955), first published in 1835, divided all the structures into binary and ternary feet (imitating the classical Latin terminology):

Binary		**Ternary**	
Trochaic:	óo	Iambic:	oó
Dactylic:	óoo	Amphibrachic:	oóo
		Anapestic:	ooó

Later, the musical analysis system applied by Navarro Tomás (1956) was followed as a valid system through many years, using concepts like *anacrusis*. In the last years, there have been many different approaches to explain the Spanish panorama, as it is shown by the semantic comparative model designed by the Czech Oldrich Bělič.

The international context is richer, especially in English, with two prominent schools: 1) A traditional approach based on stress and classical feet; and 2) A generative approach based on the terminology and concepts shown through text grids that take into account word boundaries, with a strong impact on poetic theories (Gerber, 2013: 147).

The models described are just an example of the idiosyncrasy that can be observed in each literary tradition. Although the current ICT infrastructures are prepared to harvest different types of collections and models, it is necessary at a first stage to standardize metadata and map vocabularies and terminology at the philological level in order to build a consistent able to be shared between the different traditions.

Technological standardization

The lack of unified criteria is translated into many different uncoordinated technologies when research data are transformed to build digital projects and do not even follow a standard, in most cases. The multiplicity of technologies used includes SQL databases, TEI and XML markup languages, semantic web technology standards (RDF, OWL, SKOS), natural language processing systems (NLP) and visualization tools.

Relational databases have been deeply used by the first digital poetic repertoires combining an ER (Entity-Relationship) model, together with the data model based on records for the logical implementation (Elmasri and Navathe, 2011, 27-ss). The problem of representing ER composition model is that the result shown is data centered, but it is not enough to mark textual items that need to be analyzed from a metrical point of view.

There are other projects based on XML solutions, as TEI has a specific module for poetry analysis, "Verse", with a rich set of tags to describe metrical schemas, rhymes, accentual structure and syllabic varieties. However, this model is not widely used by the different projects, and the lack of philological unified criteria makes it difficult to translate literary schemas into XML tags, making researchers create new tags or express nuances with customized attributes for each project.

The key for interoperability both in philological and technological fields is a common reference system, for which semantic web technologies are a powerful solution. Building a linked data model by adding a semantic layer of metadata to the existing databases does not alter their internal structure. This solution requires, however, to assume unified criteria on the philological model that serves as a reference.

Although semantic web technologies have had success in archives libraries and museums (group known as LODLAM http://lodlam.net/), its application to poetic corpora is very different, as there are only a couple of studies dealing with some of the above mentioned aspects (Bootz and Szoniecky, 2008 and Zöllner-Weber, 2009), but there is not a standard conceptual model of ontology referred to metrics and poetry. The closest works related to this topic are probably the conceptual model of CIDOC, the controlled vocabularies of English Broadside Ballad Project http://ebba.english.ucsb.edu/ and the linked data relations offered by the Library of Congress (http://id.loc.gov/), which do not offer enough information on metrics vocabulary. There are also interesting computational approaches which use automated linguistic analysis or text mining, based on the morphological and phonetic structure of each language. Results have been impressive, as one of the greatest advantages is the speed of the analysis of big amounts of text (Gervás, 2000). Nevertheless, the integration of these technologies with the previous models described is not easy, and solutions are often customized for the variation of natural language used, most times standard English.

Our approach

What we propose in this paper is not a new method for analyzing poetry, but an abstract model based on a working methodology supported by a double standardization system, both at philological and technological levels. In relation to this aspect, it must be highlighted that it needs to be carried out by an interdisciplinary and coordinated team, which requires a careful design of data architecture in different levels. Our proposal aims to set up a procedure to combine philological criteria to map vocabularies and concepts which might have common means and properties in the different traditions and to insert them into an abstract framework in which each of these elements can fit as individuals of an ontology which gathers the main poetics concepts shared by most traditions. We have worked on some first approaches in this sense, building our first ontology prototype, based on our ReMetCa Spanish project: www.purl.org/net/remetca (González-Blanco, and Del Rio, et al., 2014), populated with a controlled vocabulary in SKOS, that can be found in http://vocabularios.caicyt.gov.ar/pmc/. These preliminary results, which served as prototype and a basis to build the current model, have been applied to different poetry projects, such as the edition of *Cancionero de Baena*: http://sade.textgrid.de/exist/apps/SADE/Dialogo_Medieval/index.html or the description of poetic collections in http://www.poetriae.linhd.es/, but they need to be expanded and improved to analyze other poetic systems.

This paper has been developed thanks to the research projects funded by MINECO and led by Elena González-Blanco: Acción Europa Investiga EUIN2013-50630: Repertorio Digital de Poesía Europea (DIREPO) and FFI2014-57961-R. Laboratorio de Innovación en Humanidades Digitales: Edición Digital, Datos Enlazados y Entorno Virtual de Investigación para el trabajo en humanidades, and the Starting Grant ERC-2015-STG-679528 POSTDATA.

Translating Electronic Literature. Multicultural, Multilingual and Cross-Platform Encounters

Monika Górska-Olesińska
ikagorska@gmail.com
University of Opole, Poland

Mariusz Pisarski
mariusz.pisarski@techsty.art.pl
University of Warsaw, Poland

Sea and Spar Between by Stephanie Strickland and Nick Montfort is a poetry generator that repurposes, combines and re-mixes words and phrases from Emily Dickinson's poems with those taken from Herman Melville's *Moby Dick* into an (almost) endless sea of stanzas (the program produces about 225 trillion stanzas arranged on a toroidal surface). In his keynote speech to the U.S. Library of Congress, Stuart Moulthrop defined *Sea and Spar Between* as both "an immensely long-form computational poem" and "a remarkably compact poem generator." Transferring such a complex e-literary work into a different language and cultural context raises vital questions regarding the very nature of translation and adaptation in the digital age.

The first Polish version of the program, presented by us in 2013 at Electronic Literature Organization Conference in Paris and published online in 2014 in Techsty (both as a program and as a glossed code with Montfort's and Strickland's comments), greatly multiplied the distributive authorship of the work as a whole, revealing new culturally and linguistically determined aspects of code, grammar and style, and adding a complex layer of interdependencies.

See and Spar Between poses a translational challenge which in some languages might seem impossible to accomplish. Polish, our target language, imposed some serious constraints: one-syllable words became disyllabic or multisyllabic; kennings taken from Melville's work required a different morphological, lexical and grammatical arrangement; and most of the generative rhetoric of the original (like anaphors) had to take into consideration the grammatical gender of Polish words. As a result, the javascript code, instructions that accompany the javascript file, and arrays of words that the poetry generator draws from, needed to be expanded and rewritten. Moreover, at several crucial points of this rule-driven work, the nature of Polish language forced us to modify the code.

In 2015, we started work on porting the *Sea and Spar Between* generator from its javascript+html5 web browser context into XBOX 360 Kinect motion-sensing environment, where the input is controlled by user gestures. This adaptation, which will be available both in English and Polish will be semantically oriented. We aim to use Kinect affordances to program various haptic gestures recognized by the sensor in a way that ensures coherence between interactive gestures and the content of the poem, between the user's haptic activity and their cognitive processes. Moving from one platform to another, from the Web to Kinect, will involve translating mouse and keyboard gestures (point-and-click, numerical input) into a gesture vocabulary of sensor technology. As an adaptation, our work aims at incorporating the dominant themes of Strickland and Montfort's work into user movements during the multidimensional navigation of the work. If the generated stanzas are compared to fish in the ocean, the screen to an infinite canvas and the reader's navigation to a sea voyage, then Kinect port transforms these very metaphors from subject of "translation" into a finite set of gestures that are in sync with the work's semantics and the authorial intentions behind the generator. For this reason alone, the port to Kinect cannot be a translation of a more radical type, in which Dickinson and Melville are replaced with any other poets from any other language.

Once again, the question arises of what we translate/adapt/port when we translate a digital work of art for digitally enhanced venues and for an audience of "digital natives."

In the course of translation of *Sea and Spar Between* and its adaptation for different platforms, the process of negotiation between the source language and the target language involves the factors unseen in traditional translation. Strickland and Montfort read Dickinson and Melville and parse their readings into a computer program, which as a translation, or port, from Python to javascript, is already a derivative. This collision of cultures, languages and tools is amplified when transposed into a different language. The transposition involves the original authors of *Sea and Spar Between*, the original translators of Dickinson and Melville into Polish, and us, turning the process into a multilayered translational challenge, something we propose to call a distributed translation. The forthcoming port to Kinect makes these issues even more challenging and exciting.

The problems at hand

In the context of the current onslaught cultural artefacts in the Middle East face from the iconoclasts of the Islamic State, from the institutional neglect of states and elites, and from poverty and war, digital preservation efforts promise some relief as well as potential counter narratives. They might also be the only resolve for future education and rebuilding efforts once the wars in Syria, Iraq or Yemen come to an end; and while the digitisation of Archaelogical artefacts has recently received some attention from well-funded international and national organisations, particularly vulnerable collections of texts in libraries, archives, and private homes are destroyed without the world having known about their existence in the first place.[1]

Early Arabic periodicals, such as Butrus al-Bustānī's *al-Jinān* (Beirut, 1876–86), Yaʿqūb Ṣarrūf, Fāris Nimr, and Shāhīn Makāriyūs' *al-Muqtaṭaf* (Beirut and Cairo, 1876–1952), Muḥammad Kurd ʿAlī's *al-Muqtabas* (Cairo and Damascus, 1906–18/19) or Rashīd Riḍā's *al-Manār* (Cairo, 1898–1941) are at the core of the Arabic renaissance (*al-nahḍa*), Arab nationalism, and the Islamic reform movement. These better known and—at the time—widely popular journals do not face the ultimate danger of their last copy being destroyed. Yet, copies are distributed throughout libraries and institutions worldwide. This makes it almost impossible to trace discourses across journals and with the demolition and closure of libraries in the Middle East, they are increasingly accessible to the affluent Western researcher only.[2]

Digitisation seemingly offers an "easy" remedy to the problem of access and some large-scale scanning projects, such as Hathitrust,[3] the British Library's "Endangered Archives Programme" (EAP), MenaDoc or Institut du Monde Arabe produced digital facsimiles of numerous Arabic periodicals. But due to the state of Arabic OCR and the particular difficulties of low-quality fonts, inks, and paper employed at the turn of the twentieth century, these texts can only reliably be digitised by human transcription (c.f. Märgner and El Abed, 2012).[4] Funds for transcribing the tens to hundreds of thousands of pages of an average mundane periodical are simply not available, despite of their cultural significance and unlike for valuable manuscripts and high-brow literature. Consequently, we still have not a single digital scholarly edition of any of these journals.

On the other hand, gray online-libraries of Arabic literature, namely *al-Maktaba al-Shāmila*, *Mishkāt*, *Ṣayd al-Fawāʾid* or *al-Waraq*, provide access to a vast body of, mostly classical, Arabic texts including transcriptions of unknown provenance, editorial principals, and quality for some of the mentioned periodicals. In addition, these gray "editions" lack information linking the digital representation to material originals, namely bibliographic meta-data and page breaks, which makes them almost impossible to employ for scholarly research.

Our proposed solution

With the GitHub-hosted TEI edition of *Majallat al-Muqtabas*[5] we want to show that through re-purposing well-established open software and by bridging the gap between immensely popular, but non-academic (and, at least under US copyright laws, occasionally illegal) online libraries of volunteers and academic scanning efforts as well as editorial expertise, one can produce scholarly editions that offer solutions for most of the above-mentioned problems—including the absence of expensive infrastructure: We use digital texts from *shamela.ws*, transform them into TEI XML, add light structural mark-up for articles, sections, authors, and bibliographic metadata, and link each page to facsimiles provided through EAP and HathiTrust; the latter step, in the process of which we also make first corrections to the transcription, though trivial, is the most labour-intensive, given that page breaks are commonly ignored by *shamela*.ws's anonymous transcribers. The digital edition (TEI, markdown, and a web-display) is then hosted as a GitHub repository with a CC BY-SA 4.0 licence for reading, contribution, and re-use.[6]

We argue that by linking facsimiles to the digital text, every reader can validate the quality of the transcription against the original we can remove the greatest limitation of crowd-sourced or gray transcriptions and the main source of disciplinary contempt among historians and scholars of the Middle East. Improvements of the transcription and mark-up can be crowd-sourced with clear attribution of authorship and version control using .git and GitHub's core functionality. Such an approach as proposed by Christian Wittern (2013) has recently seen a number of concurrent practical implementations such as project GITenberg led by Seth Woodworth, Jonathan Reeve's Git-lit, and others.

In addition to the TEI XML files we provide structured bibliographic metadata for every article in *al-Muqtabas* (currently as BibTeX). The TEI edition will be referencable down to the word level for scholarly citations, annotation layers, as well as web-applications through a documented and persistent URI scheme.

In order to contribute to the improvement of Arabic OCR algorithms, we will provide corrected transcriptions of the facsimile pages as ground truth to interested research projects starting with transkribus.eu.

To ease access for human readers (the main projected audience of our edition) and the correction process, we also provide a basic web-display that adheres to the principles of GO::DH's Minimal Computing Working group. This web-display is implemented through an adaptation of the TEI Boilerplate XSLT stylesheets to the needs of Arabic texts and the parallel display of facsimiles and the transcription. Based solely on XSLT 1 and CSS, it runs in most internet browsers and can be downloaded, distributed and run locally without any internet connection—an absolute necessity for societies outside the global North.

إلا أن اليد العاملة فيه اختلاف سياسة الدول في الأخذ بالعلوم النافعة وإنهاض
رجالها، ونشر التعليم المفيد والتهذيب وتوسيد الأمور إلى حكمائها وإبطالها، فقد
تختلف السابقة عن اللاحقة في هذا المضمار، وتخلف أمة غيرها فتقودها بعاداتها
وتأخذها بنظامها فتستلب منها الأفهام والأفكار، ويرجع هذا إلى فناء طريقة تائدة في

Figure 1: The web-display of *Digital Muqtabas* based on TEI Boilerplate.

Finally, by sharing all our code, we hope to facilitate similar projects and digital editions of further periodicals. For this purpose, we successfully tested adapting the code to ʿAbd al-Qādir al-Iskandarānī's monthly journal *al-Ḥaqāʾiq* (1910–12, Damascus)[7] in February 2016.

Conclusion

The paper will discuss the challenges cultural artefacts, and particularly texts, face in the Middle East. We will propose a solution to some of these problems based on the principles of openness, simplicity, and adherence to scholarly and technical standards. Applying these principles, our edition of *Majallat al-Muqtabas* improves already existing digital artefacts and makes them accessible for reading and re-use to the scholarly community as well as the general public. Finally, we will discuss the particular challenges and experiences of this still very young project (since October 2015).

Notes

[1] For a good example of crowd-sourced conservation efforts targetted at the Armenian communities of the Ottoman Empire see the Houshamadyan project, which was established by Elke Hartmann and Vahé Tachjian in Berlin in 2010 and launched an "Open Digital Archive" in 2015. Other digitisation projects worth mentioning are the Yemen Manuscript Digitisation Project (University of Oregon, Princeton University, Freie Universität Berlin) and the recent "Million Image Database Project" of the Digital Archaeology Institute (UNESCO, University of Oxford, government of the UAE) that aims at delivering 5000 3D cameras to the MENA region in spring 2016.

[2] In many instances libraries hold incomplete collections and only single copies. This, for instance, has caused even scholars working on individual journals to miss the fact that the very journal they were concerned with appeared in at least two different editions (e.g. (Glaß, 2004) see (Grallert, 2013; Grallert, 2014)).

[3] It must be noted that the US-based HathiTrust does not provide public or open access to its collections even to material deemed in the public domain under extremely strict US copyright laws to users outside the USA. Citing the absence of editors able to read many of the languages written in non-Latin scripts, HathiTrust tends to be extra cautious with the material of interest to us and restricts access by default to US-IPs. These restrictions can be lifted on a case-by-case basis, which requires at least an English email conversation and prevents access to the collection for many of the communities who produced these cultural artefacts; see https://www.hathitrust.org/access_use for the access policies.

[4] For the abominable state of Arabic OCR even for well-funded corporations and projects, try searching inside Arabic works on Google Books or HathiTrust.

Archives Distant Reading: Mapping the Activity of the League of Nations' Intellectual Cooperation

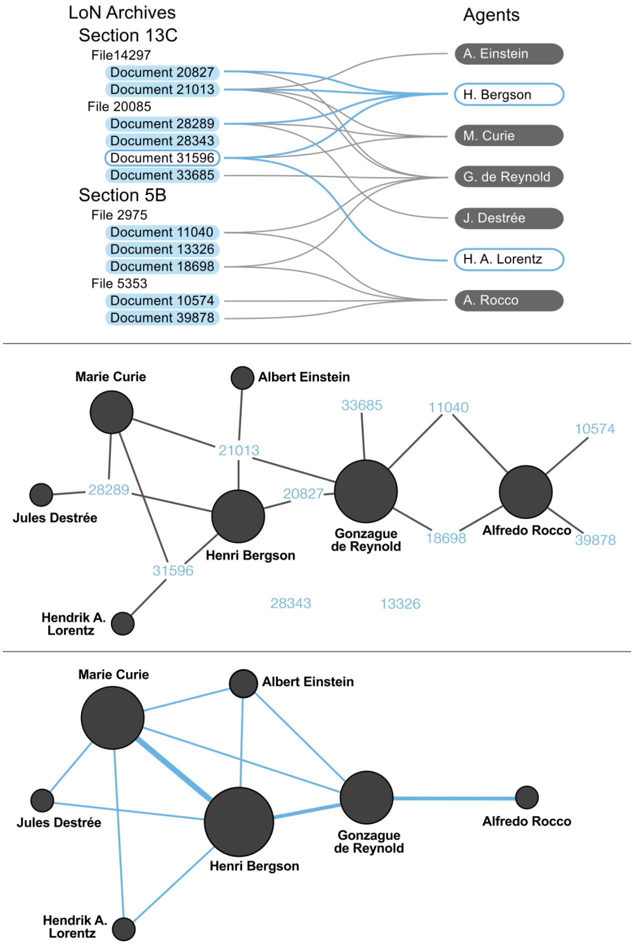
Martin Grandjean
martin.grandjean@unil.ch
University of Lausanne, Switzerland

Introduction

Founded in 1922 by the League of Nations upon observation that the pacification of Europe may benefit from a better collaboration between scientific elites, the *International Committee on Intellectual Cooperation* (ICIC) is responsible for coordinating the restructuration of knowledge circulation. Bringing together leading researchers at the height of their career, such as Albert Einstein, Marie Curie and George Hale, chaired by Henri Bergson, the Committee weaves a complex network between transnational scientific institutions and societies, congresses and individuals (Pernet, 2014).

This paper proposes an analysis of the work and functioning of the organization between 1919 and 1927 by setting up a database containing metadata of thousands of documents contained by the ICIC funds (United Nations Archives, Geneva). Visualized as a network of 3.200 people (tens of thousands of relationships), this work provides a new understanding of the internal organization of the Intellectual Cooperation, as well as completely new insights about its relations with the rest of the scientific and diplomatic world. In particular, we will show the necessity to compare the “micro” structure of relationships as mapped by the archive with the “macro” formal structure of the institution. Do the thousands of documents, in a *distant reading* approach (Moretti, 2013), confirm the internal organization of the League of Nations or do they show individuals/communities that bypass the official hierarchy?

As an opening to an epistemological debate, this research questions the relationship between the researcher, the database and its sources: are the metadata of an archive corpus usable information, regardless of their unique qualitative content? More technically, it also addresses the issue of data visualization and modeling in the historical sciences.



Figures 1-3. From a relational database to a network. The relational database links documents with their agents (Fig. 1), a relation that is then mapped as a 2-mode network (Fig. 2). By projecting the documents on the agents, the 1-mode network of co-occurrencies is fully exploitable (Fig. 3).

Sources

Initially launched in 1922 as a consultative commission, the ICIC quickly mobilized the major part of the *International Bureaux* section secretariat (upon its stabilization a few years later as a permanent commission), resulting in the production of very vast archives. In the period covered by our study, 1919-1927, which can be qualified as the start-up years of the dynamics of intellectual cooperation in Europe and the World, the funds contain 27.000 documents, mostly internal and external correspondence, about the main missions of the commission: university relations, bibliography coordination, educational matters and various enquiries.

Methodology

We are particularly interested in individuals who are personally concerned by the documents. Firstly, we indexed all the documents by creating a relational database (fig.1) of all "agents" (senders and receivers). In order to analyze the co-occurrences of agents in the same document, the database, displayed as a 2-mode network (fig.2), is projected onto a 1-mode network (fig.3). Each of the 3.200 agents are connected to its co-occurring by an edge whose weight reflects the intensity of the relationship.

Data analysis and visualization

This paper presents the final result of years of manual indexing (intermediary results have already been presented as case-studies in Grandjean, 2015 and Grandjean, 2014). The complete graph (fig.4) displays 38.600 co-occurrences between 3.200 agents of the complete set of documents from 1919 to 1927. The size and color of the nodes are proportional to the number of appearances of the individuals in the index. The size and color of the edges are proportional to the number of co-occurrences of the two people they bind.

Beyond an apparently low visual intelligibility, due to the amount of information and the dataset complexity, such a graph already makes the measurement of its mathematical properties possible (centrality measures, as detailed by Koschützki et al., 2005 or Newman, 2010). Developed as an interactive online visualization, it provides a global view and a more instinctive navigation in the archive directory.

This type of graph is necessary in order to observe what happens at the margins of the institution (and thus also to understand the geography of the object: what is central and what is peripheral). However, as so often in network analysis, the core is so dense that we can not distinguish the edges and therefore makes a more advanced visual analysis impossible.

Here comes the challenge of readability: how to show that elements are not only connected horizontally to other elements by maintaining a macro-structure that does not always correspond to the natural organization of the agents?

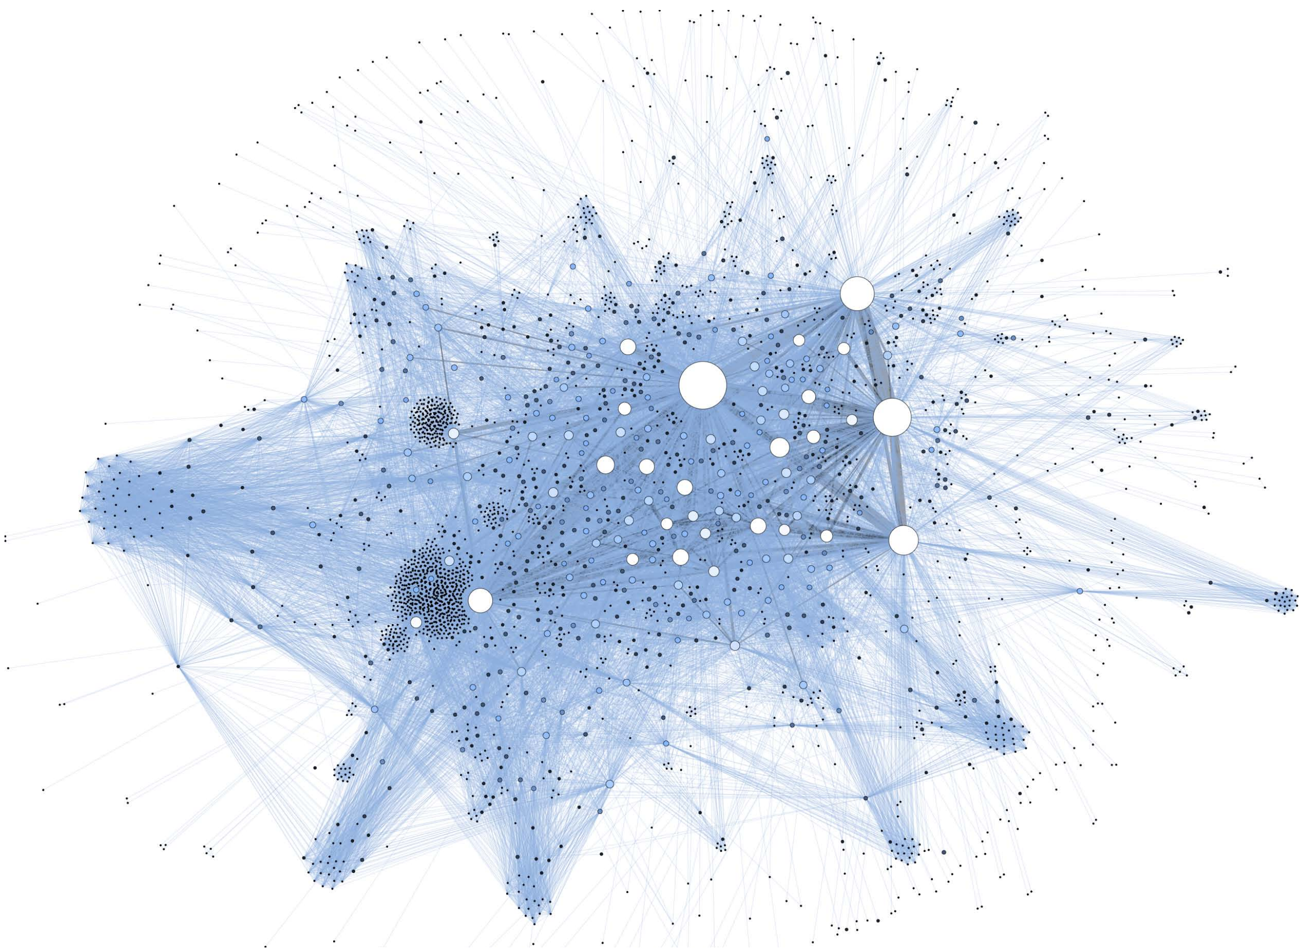


Figure 4. The network of the Intellectual Cooperation. 38.6K co-occurrences of 3.200 agents of the documents in the League of Nations' Intellectual Cooperation archives (1919-1927, 27K documents).

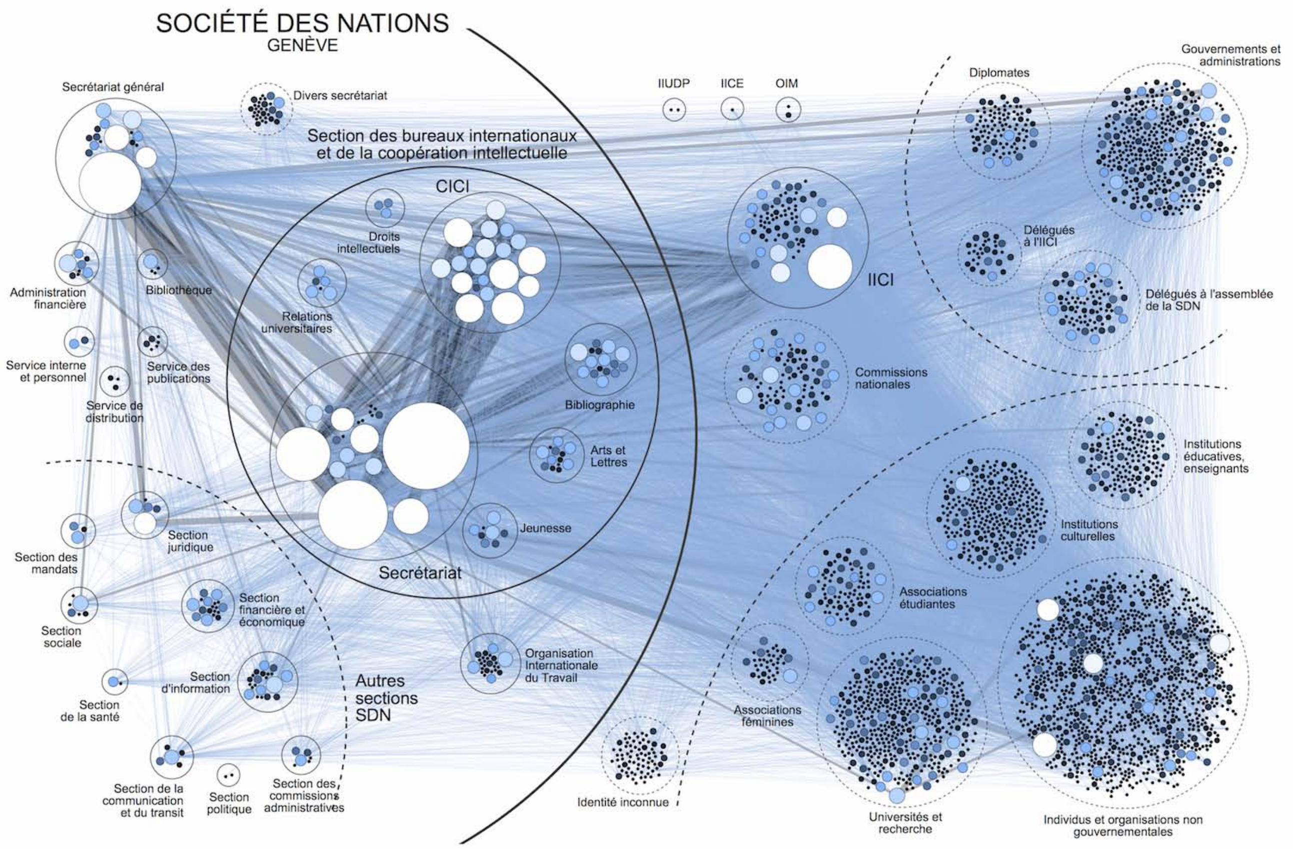

Figure 5. Untangling the network. Same network as Fig.4 but mapped according to the institutional structure of the League of Nations, introducing a 3rd dimension.

As many opportunities to play with scale exist (Brailly and Lazega, 2012), we chose to flatten the institutional organization on the relational structure (fig.5). Hence our research question: do the scientists, diplomats and senior officials - who constitute the network of intellectual cooperation - structure their relationships in coherence with the organization of their institution? Or, are they the ones that determine the links that their institutions maintain together? Forced distribution of nodes under an administrative "geography" make it easier to read the edges between groups. We also note that this is a way to provide a spatial distribution that does not vary over time, and thus allows the study of several successive moments of the network, without losing the mental map. This system is also suitable for superimposing prosopographical information.

Perspectives

It is often at the periphery of the network that the most interesting personal trajectories may be found. As such, this display allows us to discover and highlight the thematic affinities of some of the privileged interlocutors of the ICIC: government delegates, heads of international scientific organizations or partners seeking asylum under the authority of the League of Nations.

The consistency of many internal networks can be evaluated: is the plenary commission a clique (cluster where each and every node is connected to all the others)? Are the expert sub-committees coherent communities? And are these communities created by a well defined group of documents or by a heterogeneous collection of correspondences on various themes?

Pushing further the distant reading, we will also see that the macro-analysis of the institutional level reveals structures that were not clear at the individual level, showing the need for a constant back-and-forth between the scales. This will also be an opportunity to recall that network analysis is a modeling process that does not relieve the researcher of the consultation of the archival documents themselves. From a quantitative approach, we return to the qualitative: the structural organization of a network is definitely a "qualitative, morphological" information (Moretti, 1999; 68) derived from the quantitative compilation of individual relationships.

Introduction

The HathiTrust Research Center (HTRC) aims to facilitate large-scale computational text analysis of the contents of the HathiTrust Digital Library (HTDL) through data services and analytical tools. We conducted a study of current and potential users of the HTRC to investigate how scholars integrate text analysis into their research. Our study aims to inform the development of HTRC services and also to generate deeper insights into scholarly research practices with large-scale digitized text corpora.

Background

Studies on the use of digital content by humanities scholars, ranging from humanities cyberinfrastructure (ACLS, 2006) and patterns in scholarly practices (Brockman et al., 2001; Palmer and Neumann, 2002; Green and Courtney, 2015), to discipline-specific studies

(Zorich, 2012; Babeu, 2011; Rutner and Schonfeld, 2011), reveal that scholars acquire and analyze digital content in multi-faceted ways. Several investigations particularly examine scholarly uses of digital tools (Frischer et al., 2006; Toms and O'Brien, 2008; Gibbs and Owens, 2012). Computational text analysis dates from the beginnings of humanities computing (Hindley, 2013), and the resources of the ARTFL Project (Argamon et al., 2009; Horton et al., 2009), MONK (Unsworth, 2011), Wordseer (Muralidharan and Hearst, 2013), Voyant and TaPOR (Rockwell et al., 2010), and Lexos (LeBlanc et al., 2013), among others, inform the current work of the HTRC to provide a secure computational and data environment for researchers to conduct analyses of content from the HathiTrust Digital Library.

Our study builds on an earlier user needs assessment conducted for the HTRC and its Mellon Foundation-funded Workset Creation for Scholarly Analysis project. That earlier study analyzed interviews and focus groups in order to identify capabilities needed in large text corpora to facilitate scholarly research use (Fenlon et al., 2014). These desired capabilities included the ability to create and manipulate collections as reusable datasets and research products, the ability to work at different units of analysis, and access to highly enriched metadata (Green et al., 2014; Fenlon et al., 2014).

Our present study especially builds upon that previous investigation by examining the text analysis research practices of current and potential users of the HTRC.

Research Design

Goals

Our study's primary goals are:

- To analyze current scholarly research practices with textual corpora to identify user requirements for HTRC services;
- to develop illustrative use cases of text analysis research for shaping training curricula; and
- to obtain information for guiding the development of HTRC research services in the University of Illinois Library's Scholarly Commons and similar digital scholarship centers.

While the findings of this study specifically will inform the development of services to meet the needs of HTRC users, it also contributes broader insights into how to develop similar digital resources and research services for computational text analysis.

Methods

We conducted fifteen semi-structured interviews with students, faculty, researchers, administrators, and librarians who pursue work that includes text analysis, or have familiarity with text analysis methods. Some participants were recruited at professional conferences for digital humanities and libraries, while others were active in HTRC user group forums. Several of the interviewees had previously interacted with the HTRC, and most had experience with the HTDL. The participants were from various disciplines — including English, Anthropology, History, and Computer Science —and ranged from newcomers to digital humanities to long-time researchers.

We performed an initial analysis of the interview data through open coding and will continue detailed qualitative analysis using ATLAS.ti. Data was independently coded by the authors to ensure inter-coder reliability. While we are still actively analyzing interview data, we identified several preliminary themes discussed here. These themes include strategies for obtaining and managing data, research workflows and results, collaborations, and teaching.

Analysis and Discussion

Data Acquisition and Management

Several respondents characterized text analysis research as being time-intensive in spite of the speed of computational tools. One interviewee noted, 'It's funny, often people think, "Oh we have it digitized, now it's useful." Scholars realize that you have a lot more work to do after that. And that can often slow projects down terribly.'

The interviewees indicated that gathering, managing, and manipulating text data comprised a considerable portion of their work. An interviewee explained, 'I think the biggest challenge is data, getting good data to work with. I think people underestimate the problems and difficulties in doing that.'

Interviewees also expressed a desire for improved ways to identify and extract the content they needed, especially when navigating large-scale collections to find the volumes, pages, or passages relevant to a research project. As one interviewee remarked, 'Even if you had somehow structured your texts, I would be saying, "What was left out? How do I bring it back in?"'

Research Workflows and Results

Several interviewees described the potential of text analysis to challenge previously held understandings of text, as differences between human and computational readings emerged. One respondent noted, 'There are many cases in which the computer is at least as good—if not better—a reader than humans are. That's very difficult for people to accept... sometimes the computer gets it right and it bears looking at that difference. So we kind of want to get that new ground truth on this kind of work.'

Many researchers highlighted the importance of interpretive work in understanding how the tools interact with the text, and characterized the interactions as dynamic. One respondent observed, 'I yearn for workflows where the scholar could actually set their own tokenization rules.... It would be a way that we could create less language-specific [rules] or control the language specificity of the algorithm. I think that is the real need.' Several respondents highlighted the importance of tools that flexibly fit into various stages of the research process, and also are accessible to users of different skill levels. Interviewees also suggested enhancements specific to the HTRC, which included expanded visualization capabilities, improved generation of statistics about text corpora, and better ability to handle languages other than English.

Research Collaborations

Interviewees repeatedly cited collaboration and research support, both virtual and in-person, as important. Many interviewees worked with digital humanities initiatives, and reported that their local resources ranged from limited technical support to well-resourced research centers. For some interviewees, online support communities— such as Digital Humanities Questions and Answers or Stack Overflow — also were significant.

Interdisciplinary collaborations between departments and across institutions emerged as the most prominent kind of partnership, but interviewees also noted the challenges that such collaborations pose. As one interviewee explained, 'Collaborations between institutions: much more difficult. There's money, there's institutional blockages, and then anything over half a dozen people, it gets complicated very quickly. And so the people dynamics get very complicated.' Some respondents noted that these collaborations affected their research practices and acquisition of research resources.

Interviewees reported that their collaborations with libraries ranged from non-existent to critical partnerships. Many saw the library as a key space because 'the library is actually the one functioning interdisciplinary space on a university campus.' Collaborations with the HTRC and digital repositories for working with data also were important to respondents.

Teaching and Training

Interviewees mentioned their active efforts and intentions to incorporate computational text analysis into their teaching. Some remarked on institutional constraints that make it difficult to incorporate computational tools into curricula. As one respondent explained: 'I once imagined teaching a class in which students learn to script and actually run analyses against data, but I was told, basically, that that class isn't a humanities class anymore—that belongs in computer science.'

Some stated that the courses that they currently teach may not require or allow for the incorporation of computational analysis. Yet others noted that there is only a limited amount of technical or scientific skills that a humanities student could realistically master within a short period of time, with one interviewee noting that 'you can only get people to learn so much about the math; as much as they can learn, they should — at the same time, it's hard.'

Although the demand from students for learning about computational text analysis was, overall, reported to be increasing, some interviewees noted that they are constrained by not only limited resources, but also uncertainty as to how to carry out such activities. One interviewee reported prevailing sentiments that the digital humanities 'doesn't even fit anywhere,' leading to the question of whether 'there should be a whole separate department that's digital humanities,' or to offer training within existing curricula.

Conclusion

The immediate aims of this study are to generate an updated framework of user requirements that will guide the development of the HTRC's educational programming and research support services and also to inform forthcoming Mellon Foundation-funded development of the HTRC Data Capsule. But our preliminary findings also provide insights into scholars' needs as they increasingly incorporate text analysis in research and teaching. These findings also reveal how digital scholarship centers, information professionals, and providers of digitized content can best support scholarship as digital humanities resources evolve.

New Maps for the Lettered City: a Data Visualization Exploration of 19th Century Salons in Mexico

Silvia Eunice Gutiérrez De la Torre
silviaegt@gmail.com
Würzburg Universität, Germany

Visualizations have a central role in the Digital Humanities. The second most popular author-chosen topic word of DH2015 was visualization (cf. Figure 1 from Weingart, 2015). Yet, when one revisits all accepted abstracts at DH2015 with the keyword "vis(z)ualization", one may notice that not many of these texts indicate which libraries were used for interactivity (only some mention D3), and even fewer had direct links to their websites for testing (many were prototypes).

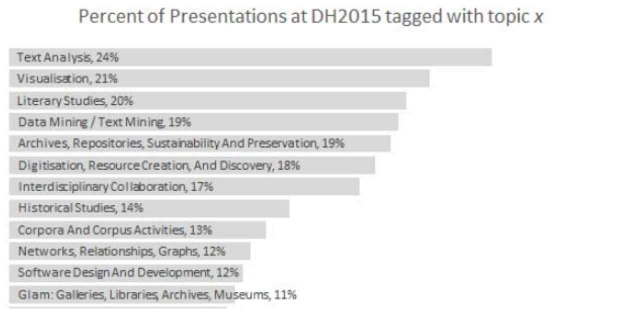

Figure 1. Fragment from graphic with the topical coverage of DH2015 (Weingart, 2015)

One of the more common visualizations are those of relational data. In Katrien Verbert's more thorough survey of interactive visuals in DH2014's presentations, relations-visualizations represent 50% of all prototypes (that is 29 out of 58). The most popular way to represent relationships are uni- or bi-directional graphs (23 out of 29) and only one of them used a matrix to display connections (see figure 2 from Verbert, 2015). To crack open the discussion on the pros and cons of this visualization technique, I will show how I answered some questions of cultural history, more specifically of Latin American Literary History, with a tailored interactive matrix (to this the visualizations visit: http://www.sgutierrez.seewes.de/).

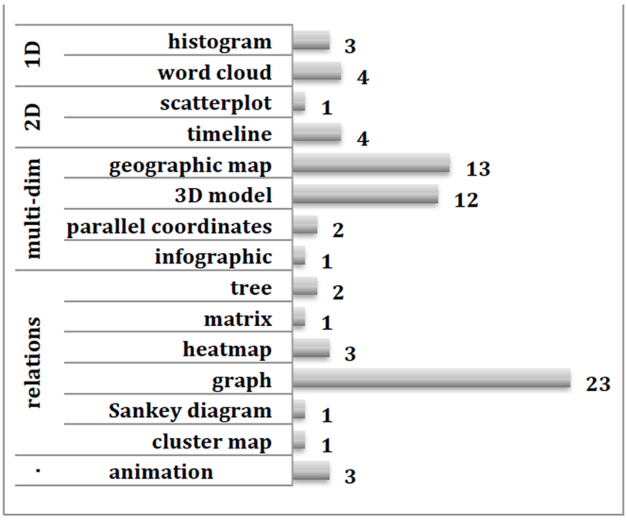

Figure 2. Visualization techniques used by work presented at DH14 (Verbert, 2015)

Theoretical Framework

The history of associations is a goldmine for the intellectual queries of scholars interested in literary and intellectual history. In Latin America, for instance, the appearance of Angel Rama's posthumous book *The lettered city* (1984), lead to a series of studies concerned with the constitution of enlightened groups, especially in new nation-states. As the capital city of one of the most powerful ex-Spanish Colonies, the lettered network in Mexico City makes an interesting case study. However, despite the valuable monographic studies on this subject (most notably Perales Ojeda, 2000 and Sánchez, 1951), which register around 200 active literary societies during the 19th century, no overview on the subject has been possible and not all questions have been resolved. How diverse or homogeneous were these groups? Who were their most recurrent actors? Were certain generations more likely to be part of groups from a certain literary movement? I will propose a way of using visual and interactive displays of literary societies' membership data to answer these three questions.

Before me, others have sought to gain new insights by exploring the possibilities of data modeling to understand modern sociability. The *Berliner Klassik Gesseligkeit Datenbank* (The Societies Database of the Berlin Classical Period, 2013) aimed to understand the cultural bloom of the early 19th century and Stanford's *Salons Project* (2012) was designed to get an understanding of the social composition of the French Enlightenment network. However, to date, there are no online dynamic visualizations of either of these projects.

Methodology

a) data collection

The network's information was obtained by scrapping each associations' entry in the Encyclopedia of Mexican Literature (ELEM). Since ELEM is the most complete source of biographical data for 19th century Mexican writers, it is very unlikely that information about these writers can be found elsewhere; thus, I only considered members with an entry in this source. This procedure leaves out many characters, but it is at least representative of the known characters of the lettered city. It contains information of 51 associations (founded between 1808 and 1894) and of 195 members born between 1781 and 1870.

b) data model

The database derived from these two nodes (members and associations) was modelled to answer my research questions, but its metadata is designed to be reusable: members were assigned standard identifiers using Jeff Chiu's VIAF reconciliation service for OpenRefine (Chiu, 2015), and neutral aspects about these nodes—such as birth and death dates or founding and closing dates—were included. In addition to these neutral aspects, I added two categories that scholars have used to cluster literary characters and societies, namely, generations and literary movements.

Figure 3. Network visualization where nodes are 19th century Mexican societies and edges represent the number of common members between them

c) visualization

My first attempt was to follow the most common visualization for networks in the digital humanities, the Gephi-spaguetti (see figure 3). I did everything I could to enhance readability. I set the societies-nodes' size according to the number of connections they had with other associations and the thickness of the edges to vary depending on how many common members two groups had. Even more, in order to get a chronologically-ordered layout I used Spekkink's useful plugin, the Event Graph Layout (Spekkink, 2014). From this display, I was able to confirm kinship-relationships between societies. That is, that although persistence was never their *forte*, when one looks at the number of members that went from an extinct society to the next new one, one gets the impression that despite the ephemeral nature of these groups, there was still a type of continuity among them. Yet, even when I created an interactive graph with Sigma.js it was very hard to read the quantitative differences between my nodes' connections. On the one side, I was interested in creating a visual display that allowed interactivity, providing end-users with both additional information for each data-point and the possibility to select specific ranges of the network. On the other, I wanted to control the order of my data and the quantities' color-coding for readability. The solution was provided by a Python-library, Bokeh.

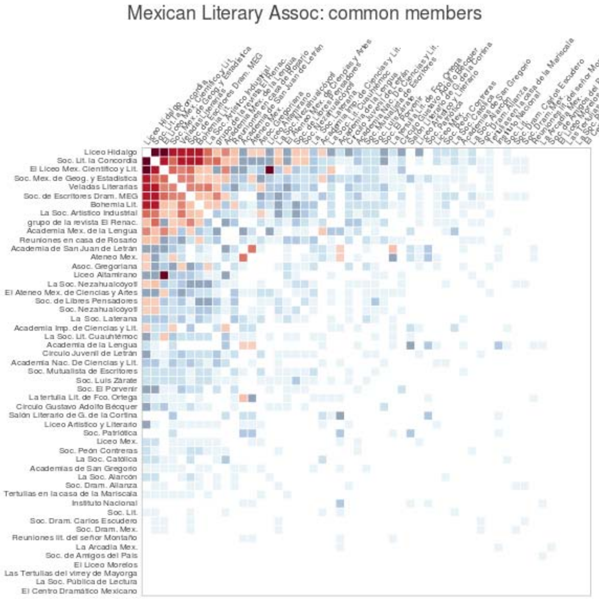

Figure 4. Co-occurrence matrix of literary societies ordered by the sum of common members with other associations

Results

The first visual I created was a co-occurrence matrix where each literary association was compared against all others. This display allowed me to understand how many members each pair of associations had in common. In order to enhance the identification of meaningful co-occurrences, I followed the principles of sequential color schemes –where low data values are represented by light colors and high values by dark ones (Wyssen, 2014) – and I assigned different colors and alphas according to the quantities' distribution of my data: associations' pairs above or equal to five common members were coded in red, and below five, in blue (see Figure 4). Additionally, I set different and consecutive alpha values to each glyph according to their exact value (intersections of less density had lower alphas). This display was helpful to address the question on the diversity or homogeneity of literary societies: with this tailored visual I was able to identify the homogenous hub of ten literary associations around the *Liceo Hidalgo* that had a considerable amount of common members, suggesting that although they had different approaches they were nonetheless constituted by recurring members (cf. Figure 5).

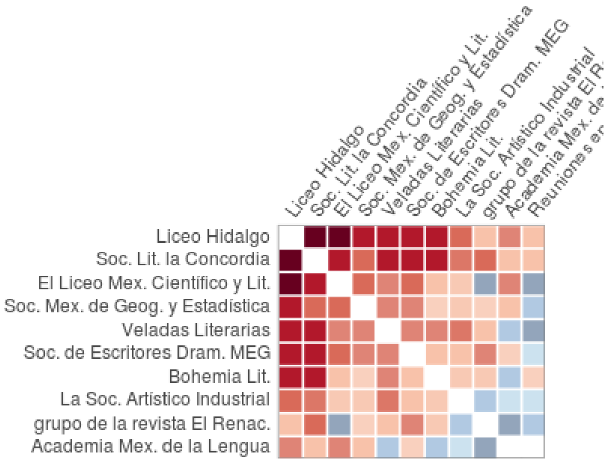

Figure 5. Selection of societies with the highest common-members' density

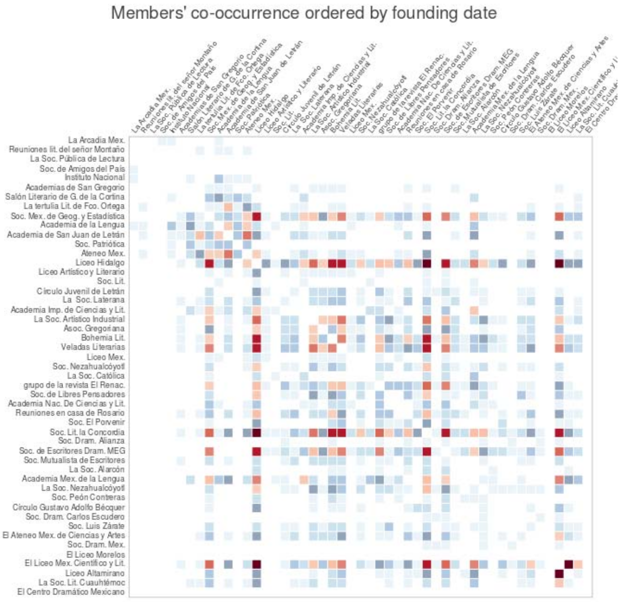

Figure 6. Associations' co-occurrence matrix by founding date

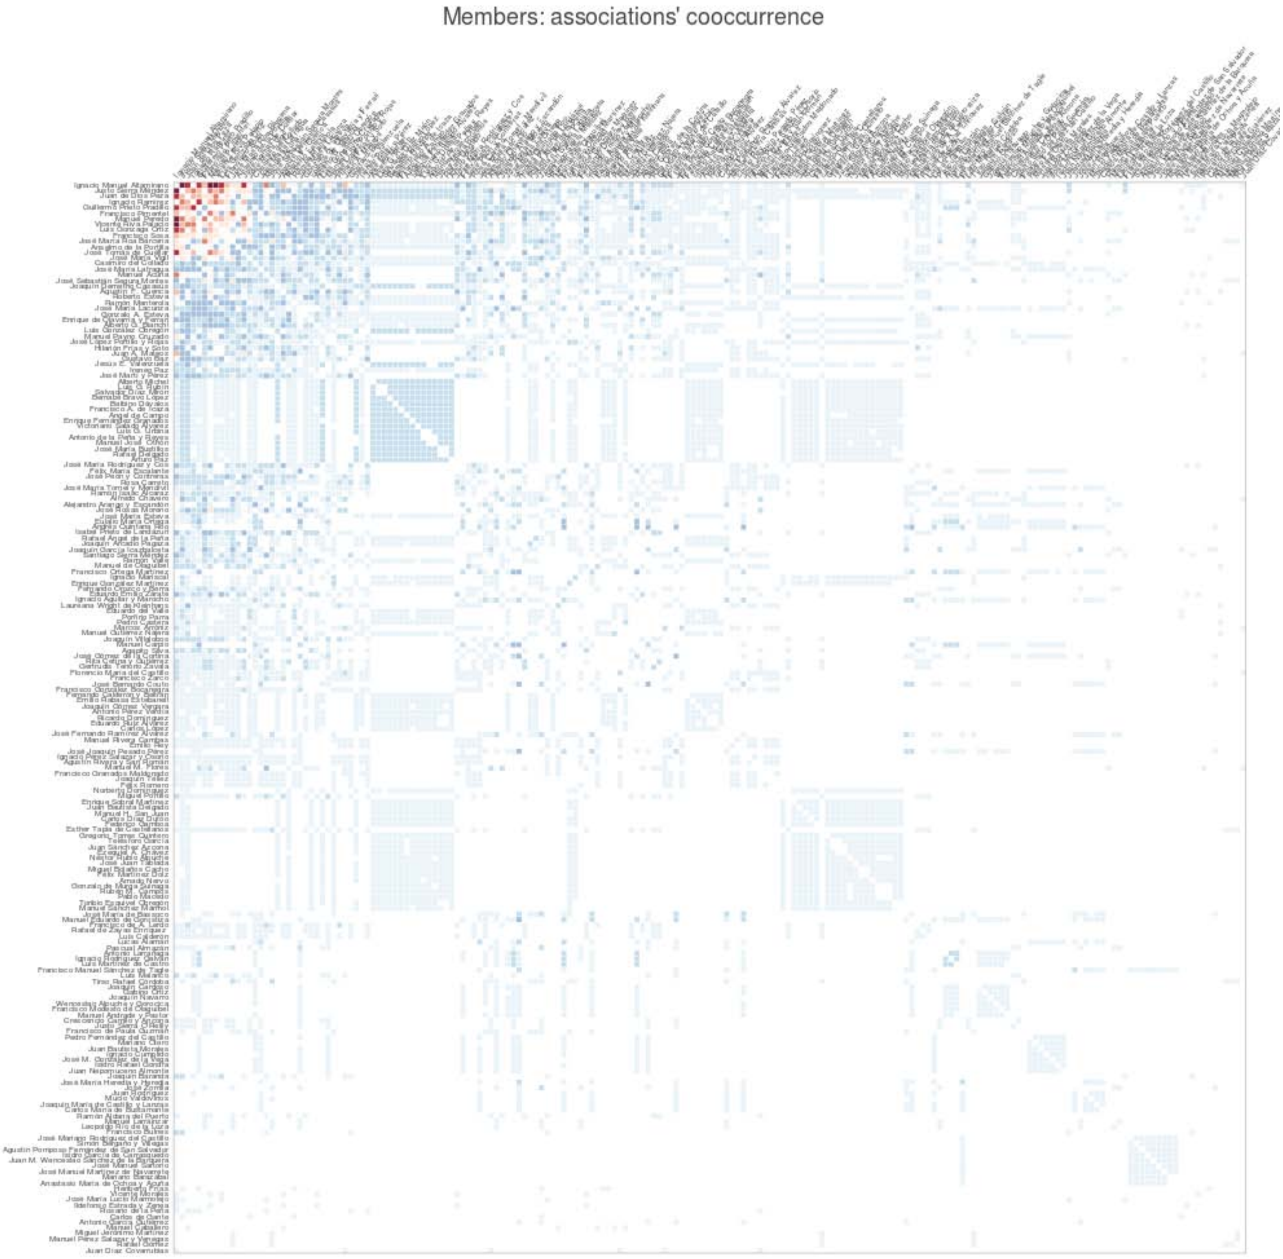

Figure 9. Members' co-occurrence matrix ordered by maximum summed values.

Moreover, when I changed the order of the matrix (by founding date, see Figure 6) I was able to understand these connections in its temporal dimensions. For instance, when zooming on the glyphs for the *Liceo Hidalgo* (see Figure 7) one can easily identify the previous societies with which this association had enough common members to consider them as predecessors, or which other later groups could be considered as successors for the same reasons.

Finally, in another color coding of the glyphs (by the literary movement that was in vogue when these societies were established) I could identify which societies of the same period had more common members (see Figure 8).

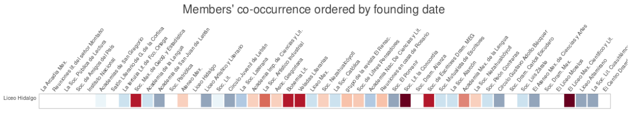

Figure 7. Liceo Hidalgos' co-occurrences, a box-selection of the associations' matrix by founding date

Conversely, I created another matrix –this time comparing members— which was useful to understand which characters co-occurred more often in the same associations and thus address the second question, namely, which were the most recurrent actors in the network (see Figure 9). The result: thirteen characters formed the core of actors who were most involved (see Figure 10). This information, however, could have been obtained with a simple bar-chart. The difference in perspective that this matrix offers is that it allows the user to see that these characters were not only in many but also similar associations (which can be retrieved by hovering the glyphs), and, additionally, it makes evident how proportionally small this core is when compared to the whole matrix.

Finally, to address the second question –namely, the correlation between generations and literary movements–, I created a matrix where associations were ordered by founding date on the y-Axe, and members by birth date on the x-Axe, and where the colors were coded according to their correspondent literary movement (see Figure 11). The dark colors of the glyphs represent the literary movement of a given society (all the blue ones are from the neoclassic movement, for instance), and the light colors in the background represent the members' generations (for example, in light orange -in a vertical division- are all the members of the *Renacimiento* generation). Arranging them like this enabled me to take snapshots of different societies and observe the generations' patterns of membership-adscription. For instance, I could note that although the group formed around the *Renacimiento* magazine was heavily constituted by its homonym generation (see Figure 12), almost half of its members were born in the timeframe of the previous generation (coded with a light yellow background).

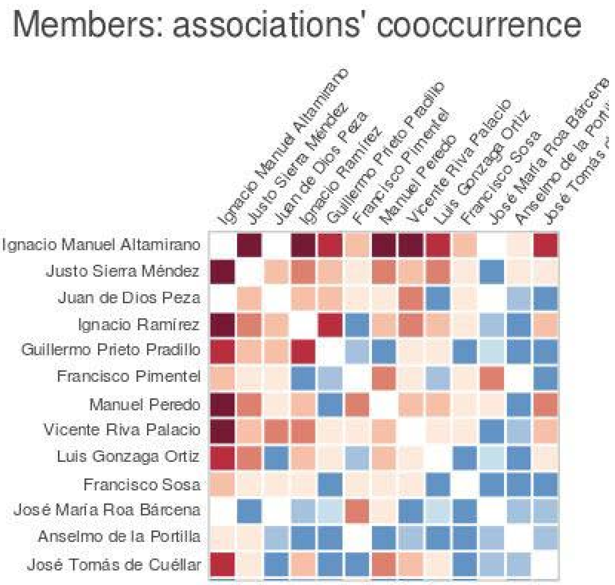

Figure 10. Members' co-occurrence snapshot done with the selection tool of Bokeh's visuals.

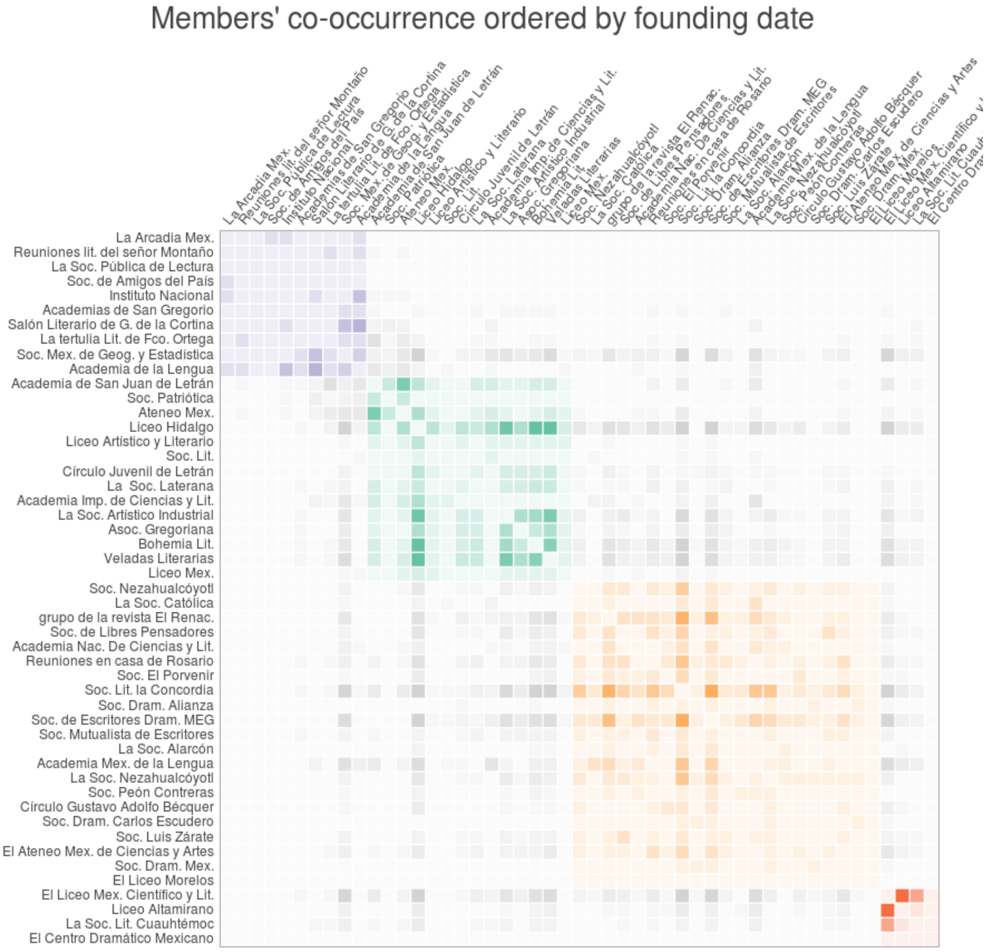

Figure 8. Societies' co-occurrence matrix with literary movements' color-coding.

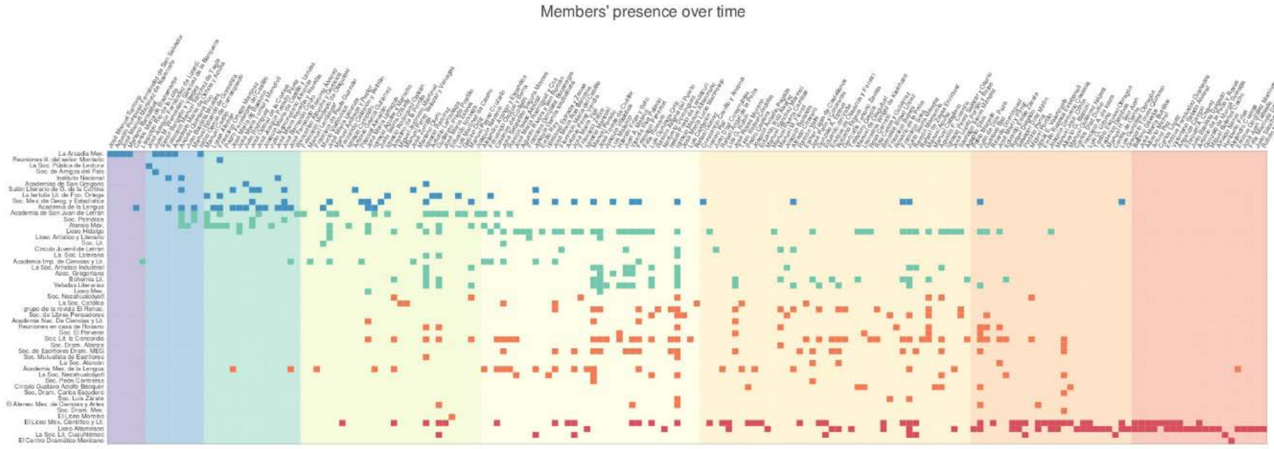

Figure 11. Generations versus literary movements: a co-occurrence matrix

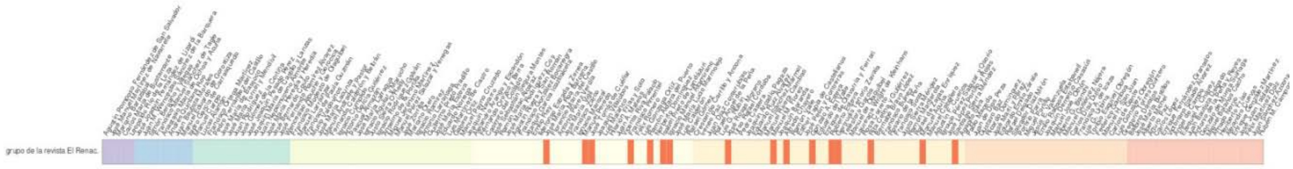

Figure 12. Active members in *Grupo de la Revista el Renacimiento*

Conclusions

In this paper I have shown how customized visualization of modeled data can enable new readings and lead to new understandings of how societies were formed in a key period of national history. Among other things, matrices help us "see" connections between previous categories of literary history (like generations and literary movements), between societies, but also between members, thus supporting new narratives of the lettered city were the alleged homogeneity of this "elite" group can be seen in a nuanced perspective that integrates complexity without sacrificing abstraction.

Project Dialogism: Toward a Computational History of Vocal Diversity in English-Language Literature

Adam Hammond

University of Melbourne, Australia

Abstract

Over the past several years, we have worked to develop a human-interpretable computational method for quantifying "style" in literary texts. In projects focused on modernist texts, we have demonstrated the usefulness of this approach for studying dialogism (or multi-voicedness) in literature. Now we propose to extend our method to the "big data" scale by using a tool we have created, GutenTag (http://www.projectgutentag.org/). Our research promises insights into the historical evolution of dialogism in English-language fiction.

Aims and Approach

Dialogism — the literary practice of allowing characters to speak in their own distinctive manners, without altering their speech to suit the particular linguistic practices and prejudices of the author — has been recognized as an ethically and politically significant aspect of fiction since the early twentieth century. Russian critic Mikhail Bakhtin, who coined the term "dialogism," has been particularly influential in arguing that the dialogic novel could support pluralistic modes of thought that model democratic social systems. Yet despite the widely recognized importance of dialogism as an analytic category in literary studies, it is one that has proven difficult to study computationally, particularly at the "big data" scale. While style has proven a tractable aspect for computational literary study, and while excellent work has been produced on distinguishing character voices within literary texts using style-based methods (Burrows, 1987; McKenna and Antonia, 1996; Rybicki, 2006), existing approaches present two significant drawbacks. First, their reliance on Burrow's PCA-based methodology means that while this work often produces reliable and insightful results, its computational outputs are generally not human-interpretable; they may be able to show *that* an author distinguishes characters based on linguistic style, but not to tell us *how* they are differentiated. Further, these methods tend not to be suitable to expansion to the "big data" level, since they require significant manual annotation of character speech in the texts under investigation. Our method — a human-interpretable quantitative method for analyzing literary style — and our tool — which performs automatic structural tagging of plain text — make such research possible, and thus open the way for the first large-scale investigation of dialogism in literary fiction.

Background

Since 2011, we have been laying the foundations for a computational history of dialogism in English-language fiction. The first step was developing and refining our six-dimensional approach to quantifying literary style. Our method is based on six discrete aspects of style: objectivity (words that project a sense of disinterested authority); abstractness (words denoting concepts that cannot be described in purely physical terms); literariness; colloquialness; concreteness (words referring to events, objects, or properties in the physical word); and subjectivity (words that are strongly personal or reflect a personal opinion). To build our stylistic lexicons, we produce a relatively small set of words carefully selected for their stylistic diversity, which human annotators evaluate in terms of the six stylistic aspects listed above. Next, we use an automatic procedure to collect information on how these words are employed in all English texts in the 2010 image of *Project Gutenberg* (Brooke et. al., 2016). Using this information, we are able to derive stylistic information for any word in our target text, and to build stylistic profiles for any character or speaking voice within a text.

We have demonstrated the usefulness of our six-style approach to literary problems in two projects. One project focused on free indirect discourse (FID) in Woolf's *To the Lighthouse* and Joyce's "The Dead" (Brooke et. al., 2016). Our intention was to employ our method to test the long-held hypothesis that FID represents a stylistic middle ground between the neutral style of an objective narrator and the more extreme styles of personalized characters as rendered in direct discourse. Our method confirmed this assumption and, because it produces human-interpretable results, shed some new light on Woolf's text in particular, finding that while Woolf's upper-class characters exhibit a conventional power dynamic (they are more authoritative, more literary, more concrete, less objective, and less colloquial than characters of other classes) her female characters reverse these conventional dynamics: they are more objective, more abstract, less colloquial, and less subjective. The other project undertook a quantitative investigation of the problem of voice in T. S. Eliot's *The Waste Land* (Brooke et. al., 2015b). While it is generally agreed that *The Waste Land* is composed of many speaking voices, these voices are not explicitly identified, nor are their points of transition provided. Our work explored methods of automatically segmenting and clustering voices in the text; we used the human-interpretable results of our six-style approach to evaluate the performance of various approaches and arrive at a blended human/machine interpretation.

The other key foundation for our work is GutenTag, an open-source software tool released in October 2015 (Brooke et al., 2015a). Two aspects of GutenTag are particularly relevant to the present project. First, it allows users to quickly create large, customized literary corpora. Working from the 2010 image of Project Gutenberg (PG), metadata provided by PG and derived automatically from other sources, and our automatic decision-tree genre classifier, one can, for example, easily assemble a large corpus of nineteenth-century novels in English. Second, it uses our sophisticated rule-based method to automatically generate reliable, genre-specific structural tags in standard TEI XML. Crucially, our tagging system is able to distinguish character speech from narration and identify individual characters in novels; and to separate character speech from stage directions and setting descriptions in plays, associating each speech with a character in the dramatis personae.

Developing a Metric for Dialogism

With the major pieces in place to conduct our research into the history of dialogism, our main task is to develop a reliable quantitative metric for the dialogism of a given literary text. We will proceed by calculating stylistic profiles for each character using methods already established in previous work. We will include a minimum word cutoff to exclude characters for which the stylistic profile is likely to be too noisy due to lack of data. Next, assuming multiple characters, for each style we will treat each character as a datapoint and calculate a weighted variance, where weights are applied based on the relative proportion of speech by each character, to produce a number that indicates overall stylistic variation across characters for that stylistic dimension in the given text. We can average across styles to produce a single metric.

We will experiment with calculating dialogism based on stylistic variance between (a) individual characters, (b) groupings of characters (based on gender, social background, age, etc.), and (c) social networks. This will allow us to track (a) texts in which the speech of individual characters is highly varied, (b) texts in which, for example, male characters speak in a highly distinct manner from female characters, and (c) texts in which members of distant branches of a derived social network speak in their own differentiated styles. To carry out this analysis, certain modifications will be necessary to the GutenTag system; namely, methods to detect social networks in texts and to automatically identify character groupings (a method for identifying character gender is already in place; methods for identifying other groups will be more difficult, but we will explore them).

Research Questions

With these technical foundations in place, we will be ready to present our answers to some of the following questions. Our aim is not to cover all of them, but to offer detailed investigations of those that yield the most interesting results.

- Which texts in PG are the most stylistically diverse, according to our quantitative definition? Are they texts by authors traditionally celebrated as dialogic (Austen, Woolf, Joyce, translations of Dostoevsky) or are they non-canonical texts? If the latter, do these texts register qualitatively as "dialogic" to a human reader? What does a close reading of these texts reveal about the viability of our automatic method?
- How does stylistic diversity map onto historical time? Do periods of political turmoil (wars, revolutions, natural disasters, strikes, etc.) correspond to changes in the average stylistic diversity of fiction? What can we learn about the social role of fiction by studying this relationship?
- How is stylistic diversity distributed geographically? Which regions produce the most stylistically varied writing?
- How is stylistic diversity distributed among genres? Does our method support or refute Bakhtin's claim that the novel is the most dialogic of the genres, and poetry the least dialogic? Can dialogism be meaningfully compared across genres?
- Are authors of different ages, classes, and genders more or less likely to produce dialogic fiction?

How does the stylistic diversity of fiction track against that of non-fiction? Does non-fiction become more or less dialogic over time, and does it follow a similar curve to that of fiction? Do changes in the dialogism of fiction anticipate changes in non-fiction, or are the two unrelated?

Measuring the Dynamics of Lexico-Semantic Change Since the German Romantic Period

Introduction

The dynamics of language change over time are most evident in the lexicon component of natural languages. In particular, the gradual semantic changes words may undergo have a strong effect on the comprehension of historical texts by modern readers. Yet, efforts to automatically detect and trace this lexical evolution are scarce. Our study follows the work of Kim et al. (2014) who detected lexico-semantic changes in English texts over the 20th century via a series of neural network language models. Our models were trained on the German part of the *Google Books Ngram*[1] corpus (Michel, et al., 2011; Lin et al., 2012), which covers over 657k German books. Such models have the particular advantage that they can be queried for the semantic similarity of arbitrary words. We tested this query option by sampling nouns from *Des Knaben Wunderhorn* (Arnim and Brentano, 1806-1808), a collection of German folk poems and songs from the German Romantic period. The choice of this volume is merely motivated by our interest in the literary period it belongs to. We detected interesting semantic changes between 1798 (often taken as the starting point for the German Romantic period) and 2009 (last year in the Google corpus).

Methods

Using the specific contexts in which words appear in order to determine the (distributional) meaning of words is an old idea from linguistic structuralism (Firth, 1957). For a long time, this appealing approach could not have been seriously investigated due to the lack of suitably large corpora and adequate computational power to deal with distributional patterns of words on a larger scale. Thus, only few studies on automatically detecting semantic change have been conducted up until now, with a clear focus on the high-volume data provided by Google Books. This collection is widely popular due to its immediate availability and enormous coverage despite well-known problems stemming from both the quality of optical character recognition (OCR) and the sampling strategies used to compile it (Pechenick et al., 2015).[2]

Early approaches towards modeling lexico-semantic change patterns used frequency and bi-gram co-occurrence data (Gulordava and Baroni, 2011), as well as (context-based) classifiers (Mihalcea and Nastase, 2012). Riedl et al. (2014) built distributional thesauri to cluster similar word senses. All of these approaches detected lexico-semantic changes between multiple pre-determined periods. In contrast, neural network language models can be used to detect changes between arbitrary points in time, thus offering a longitudinal perspective (Kim et al., 2014; Kulkarni et al., 2015). In our experiments, we use a skip-gram model, a simplified neural network that is trained to predict plausible contexts for a given word, thereby generating (computationally less expensive) low-dimensional vector space representations of a lexicon (Mikolov et al., 2013). Despite their simplicity, neural network language models are a state-of-the-art approach, with details concerning ideal implementation solutions and training scenarios still being under dispute (Baroni et al., 2014; Schnabel et al., 2015).

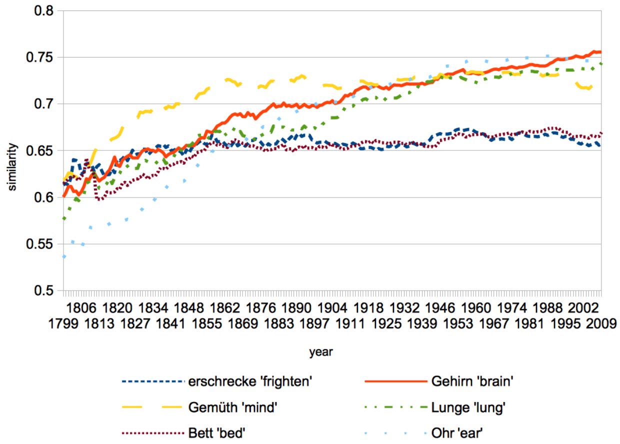
Experiment

We trained our models on 5-grams spanning the years 1748 to 2009, using a uniform sampling size of 1M 5-grams per year; the first 50 years were used for initialization only. Test words for high-lighting semantic change patterns were selected from *Des Knaben Wunderhorn* by identifying the ten most frequent nouns, i.e. *Gott* [‘god’], *Herr* [‘lord, mister’], *Liebe* [‘love’], *Tag* [‘day’], *Frau* [‘woman, miss’], *Mutter* [‘mother’], *Herz* [‘heart’], *Wein* [‘wine’], *Nacht* [‘night’] and *Mann* [‘man’]. For each of these ten nouns we selected the three words most similar to them (according to the cosine of their respective vector representations) during 1799 and 1808 and between 2000 and 2009, tracking how the similarity of these words developed between 1798 and 2009. The programs used for our experiments and resulting data are publically available via GitHub.[3]

Results

The cosine similarity between the 1798 and the 2009 vector representation of the ten test words is rather high, ranging from 0.72 for *Mann* to 0.84 for *Wein*, thus showing only minor semantic changes. Manual interpretation of their most similar words revealed an interesting change for *Herz* (see Fig. 1) that is nowadays more similar to other anatomical terms (such as *Gehirn* [‘brain’], *Lunge* [‘lung’], or *Ohr* [‘ear’]) and less likely to be used metaphorically (such as indicated by *erschrecke* [‘frighten’], or *Gemüth* [archaic for ‘mind’]). As this change predates Google Books’ tendency to overrepresent scientific texts (at least for English, cf. Pechenick et al., 2015) this finding can be assumed to be an example of true lexico-semantic change. The example also demonstrates a need for a metric incorporating frequency information and normalization of input, since *Gemüth* is an archaic form for *Gemüt* nonconformant with modern German spelling conventions, although it is rated as currently similar to *Herz*.

Fig. 1 Lexical semantics of *Herz* [‘heart’] as expressed by its similarity with six other words; similarity-axis not depicting whole range of possible values (0–1)



Conclusion

This research note has gathered preliminary evidence for the feasibility of corpus-driven studies into German diachronic semantics. We advocate a computational, neural network-based approach where the evolution of lexico-semantic changes is traced by similarities of distributional patterns in the context of words over time.

Looking backwards for semantic changes is, however, constrained by the quality and quantity of linguistic data available. While the primary corpus we use for determining semantic evolution patterns, the Google Books Ngram corpus, is remarkably large, it suffers from a idiosyncratic sampling policy, as well as OCR shortcomings and even more advanced issues, such as the absent normalization of historic orthographic variants. Other historic corpora dealing with the latter quality issues (such as the *Deutsches Textarchiv*) are plagued by their comparatively minuscule size.

Future research in Digital Humanities, besides dealing with these issues, will exploit the similarity data in order to make proper use of them under a humanities' perspective and, thus, hopefully determine the added value of such computational results. This can be achieved by incorporating complementary types of data (e.g. historical, economic ones) to render additional evidences to change patterns. Since this is a huge and complex task, we plan to make our similarity data publically available on a website, together with an easy-to-use interface, as a humanities tool for comparative, diachronic lexico-semantic studies, with several user-adjustable parameters (e.g. different grain sizes of time intervals, alternative ranking metrics, *etc.*). From a methodological perspective, we plan to focus our research on protocols for training models covering long timespans, a metric to measure the quality of historic language models (probably including the need for a manual evaluation) and a way to include frequency information–a word which is no longer used cannot be said to be unchanged in its semantics. Such a system would ideally be tested by an in-depth study of the semantics of carefully selected words, including a comparison with prior, hermeneutically guided work in the humanities as a rich, yet completely informal background theory.

Notes

[1] An *n*-gram is a sequence of *n* words plus information on their frequency/probability of occurrence for a given corpus. The available version of the corpus does not consist of running text, but of *n*-grams instead.

[2] The *Deutsches Textarchiv* (DTA) can be considered as a counter example, at least, as far as the quality of OCR is concerned. Yet, DTA suffers from tremendous size limitations in comparison with the (German portion of the) Google corpus, since this corpus for historic German texts contains only about 2.4k texts (http://www.deutschestextarchiv.de/list).

Academic Pillow-Talk and Two Immersive Explorations of Linguistic Space

Rachel Marion Hendery
r.hendery@uws.edu.au
Western Sydney University, Australia

As Virtual Reality emerges as an accessible technology, researchers have begun to experiment with its potential for data visualisation. In this paper I will use two particular VR visualisations of linguistic data as a springboard for discussing the affordances of different immersive technologies for research.[1]

The first visualisation is a geographically-anchored walkthrough of data held in the PARADISEC linguistic archive (Thieberger and Barwick, 2012). A user moves across a representation of a geographic region and sees markers on the landscape representing the metadata of the relevant PARADISEC materials for that location: number of speakers, amount and diversity of material held. Audio and text appear when the user gazes at a marker. Looking up, the user can also see the historical relationships between the languages as a network. Such a visualisation could be adapted to represent the holdings of other kinds of archives, so the discussion in this paper has implications for digital humanities more generally.

The second visualisation is a more abstract three-dimensional cloud of coloured points laid out on three axes. The user is located initially in the midst of this cloud, and can move through it in any direction. The colours, sizes and shapes of the points, as well as their location on the x, y, and z axes, can be mapped to variables of any kind of data, and therefore this too has implications beyond linguistic research. For my purposes, they represent linguistic features derived from the *World Atlas of Language Structures* (WALS) (Dryer and Haspelmath, 2013). To demonstrate one use case, different measures of linguistic complexity can be graphed on the x, y, and z axes (e.g. WALS features 1A+2A, 22A, 49A, etc). Colouring the points according to the geographical location of the languages, with shape determined by genetic affiliation makes it easy to explore clusters of types of complexity.

Both of these visualisations can be viewed in a pseudo-3D environment using WebGL in a desktop browser. For a more immersive experience, however, they can also be viewed inside a virtual reality headset such as the Google Cardboard or Oculus Rift. Alternatively, the visualisations can be displayed on the inside of a fulldome such as those used in a planetarium. Through a recent successful LIEF grant, Western Sydney University and a number of partners have been able to construct an ultra-high resolution experimental fulldome ('DomeLab' http://www.niea.unsw.edu.au/research/projects/domelab).

Display via virtual reality headset is the most straightforward sort of immersion. The viewer is embodied amidst the data, and simple movements from everyday life (e.g. looking around) translate directly into the virtual space. Display of the visualisation in a browser is at the other extreme of (non)immersion. However, many users are familiar with the translation of three-dimensional space onto a flat screen from modern computer games, so it can still give a sense of movement, rotation, and interactivity.

A hybrid of these two experiences, perhaps less familiar, is the dome. The user lies on the floor inside the dome, and the visualisation is displayed on the concave walls of the dome above. Because the user is surrounded by the screen, the experience is far more immersive than the display of a visualisation in a computer browser. Metaphors of movement and space have to be adapted for such a display, however, as most of the display surface is above the user.

This paper will discuss the reasons why we might want to explore linguistic data visually, and what we gain or lose by doing so in the various environments described above. Lev Manovich notes that information visualisation is the representation of datasets in such a way as to reveal structure (Manovich, 2010). Linguists are obsessed with structure. Since at least Pāṇini (4th century BC, see Vasu, 1891), linguists have conceived individual languages as highly structured; since the Neogrammarians if not before, 'language' as an abstraction that changes and exists outside of its speakers has also been considered a highly structured object of study; sociolinguists are interested in the structure of speech communities and speaker networks; psycholinguists and neurolinguists in the linguistic structures of the mind and the brain. Linguistics is therefore a field that is primed to search for and find structure in its data, and is constantly searching for new ways to do so.

Manovich also describes data visualisation as a matter of reduction and spatialisation, often involving a remapping of the non-visual to the visual. For linguists, reducing linguistic data to features and remapping it to the visual (audio to text, for example) are business as usual. What I would like to discuss in this paper is the spatialisation of the data, and the embodiment of the researcher(s) within that data space.

A very active branch of linguistics involved in data visualisation is linguistic typology. Typology concerns itself with how languages are distributed within the possibility space of all conceivable languages: i.e. "what's where and why" (Bickel, 2007). Because linguistic data has an inherent geographical dimension, the predominant linguistic visualisation typologists use is a map. I have followed this lead for my PARADISEC visualisation. However, Manovich also points out that both designers and their audience tend to treat spatial dimensions as primary (Manovich, 2010:8). Therefore it makes sense also to experiment with mapping these to other, perhaps more significant features of the linguistic data. This is the impetus behind my data graph visualisation. By translating the WALS data to a more abstract 3D graph, different relationships, clusters and structures become apparent. In the full paper I demonstrate examples of this.

Data visualisations can have a variety of purposes (see e.g. Dransch, 2000; Purchase et al., 2008). They can be a way to explore data to generate ideas or observations that then inspire future research. They can be an attempt at scientific modelling, instantiating more fully formed pre-existing ideas. Or they can be a way of communicating information to others. An early study of user experience in 2D, 3D and immersive data visualisation (Modjeska, 2000) showed that users generally find 2D representations of the data more efficient, but enjoyment and motivation increases with the degree of immersiveness. This suggests that VR visualisations might be best suited for the playful exploration of data described above than for serious scientific modelling. They may also be well suited for communication of ideas when it is not essential that the audience grasp complex details.

These are therefore the motivations behind the two linguistic data visualisations I describe. With the PARADISEC map visualisation it is not essential that a user come away with perfect recall of what exactly the archive holds, but rather with a sense of its richness, and increased motivation for using the archive in the future. The data graph visualisation is aimed at researchers who want to explore language data creatively in order to generate new ideas.

Finally, I discuss how the affordances of the VR headset versus the Dome depend on one's beliefs about the locus of knowledge production. In the 'lone wolf' researcher model, an individual generates ideas in a relative vacuum, or at least, the important connections for the researcher are among and with the data itself, not with other people. For this model, a VR headset is ideal. In the world of the headset, the researcher is alone with the data: the mundane is quite literally blacked out. The dome, on the other hand, is designed to be experienced communally. The floor is covered with large pillows, and people lie head-to-head or side-by-side. Curtains delimit the boundaries, but this threhold is permeable: people come and go. It is natural to discuss the visualisations above with those who lie beside you in the half-dark. In this way, research conversations become a kind of academic pillow-talk, naturally imbued with the playfulness, intimacy, and gentleness of such. In the VR headset, you become part of the data; in the dome you become part of a community.

Tracing the Genesis of Pessoa's Envisioned Work: a Digital Edition of his Editorial Projects and Publications

Ulrike Henny
ulrike.henny@uni-wuerzburg.de
Universität Würzburg, Germany

Pedro Sepúlveda
psepulveda@fcsh.unl.pt
Universidade Nova de Lisboa, Portugal

Introduction

A digital edition of Fernando Pessoa, considered one of the most significant Modernist poets and writers, is being established through a collaboration between scholars from the Institute of Literature and Tradition (IELT) of the New University of Lisbon and the Cologne Center for eHumanities (CCeH) of the University of Cologne. The edition focuses on the contrast between the potential character of Pessoa's numerous lists of editorial projects and his few actual publications in lifetime.

Though the digital platform is primarily designed to support the research aims of the project, the procedures can be reused by others (encoding, scripts). From a theoretical standpoint, the question of „work genesis" (on a macro and micro level) is relevant to a wider audience. In the case of Pessoa, the publication of the editorial lists and plans together with the published works in lifetime contributes to the discussion on the genesis and status of each stage of a work.

State of Research and Aims

It has been much debated by literary scholars whether Fernando Pessoa's work should be characterized as fragmentary or unitary (see Coelho, 1949; Gusmão, 2003; Martins, 2003; Sepúlveda, 2013). Due to the low number of publications in lifetime, the existence of a vast literary archive and the use of many fictional authors, named "heteronyms" by the author, the coherence of his work has been questioned. The present edition, in contrast, is based on the assumption that Fernando Pessoa constantly worked on the organization of his work, as witnessed by the many editorial lists, notes and plans which are part of his estate (Cunha, 1987; Sepúlveda, 2013).

These papers are the subject of the digital edition at hand, together with the 60 publications of poems that Pessoa realized in journals and literary magazines. That way, the genesis and evolution of his work as planned by himself can be studied and the published texts be examined in the light of the editorial projects preceding, accompanying and following them during the author's life. A significant part of the documents witnessing the editorial activity of the author have not been published before. For those which have been published, past editions in bookform define themselves by following either the first or the last version of a text, or by choosing from the existent variants from a hermeneutical standpoint (Duarte, 1988; Galhoz, 1993; Martins, 2011; Castro, 2013).

As the textual variants and hesitations are critical to understand shifts in the conception of the work, e. g. when work titles are assigned to heteronyms or the composition of a planned publication is changed, the digital edition aims at offering several coexistent forms of transcription. To facilitate the understanding of the texts and the work they trace, editorial comments are to be added to the documents.

In terms of editorial methodology, the digital edition targets at exploring the possibilities to combine different editorial procedures from a documentary, a diplomatic, a genetic and an enriched edition, overcoming previous oppositions between different editorial approaches to the poet's work. Relations between the editorial projects and the published texts are formalized via the encoding of "work references". By extending the concept of work to include projections which the author makes on a macro level, i.e. outlining his works in terms of titles, authorship, structure and publication organs, the present edition contributes to the debate about the status of the work and its place in the digital edition (Robinson, 2013; Sahle, 2013).

Methods and Results

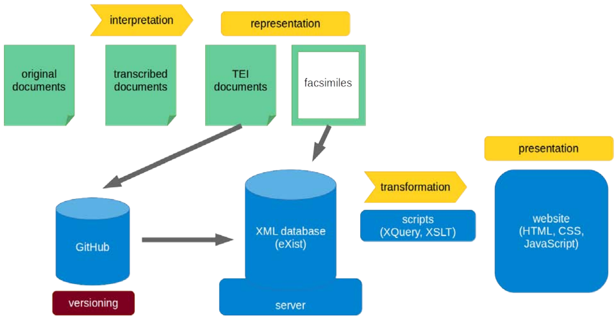

Figure 1: Technical setup and workflow

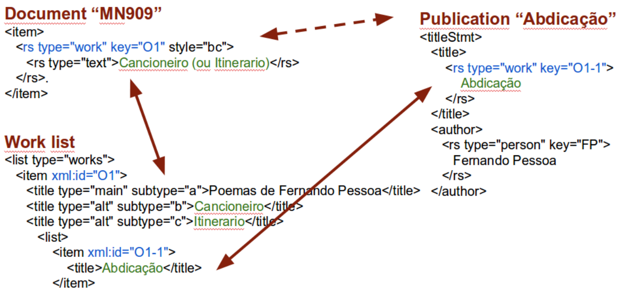
The realization of the digital edition relies primarily on procedures and technologies coming from the X universe. Transcriptions of the documents and metadata are encoded according to the standard of the Text Encoding Initiative (TEI-P5). The TEI documents are stored in an XML database (eXist) hosted on a web server together with the digital facsimiles. While the work on the documents is going on, a GitHub repository reachable at < https://github.com/cceh/pessoa> is used to hold successive versions of both the TEI documents and the application which is developed. Scripts written in XQuery and XSLT control the transformation of the documents' underlying representation into the presentation layer. Some of the components shipped with eXist are used: Bootstrap, JQuery and eXist's Templating Framework plus a SIMILE timeline and the OpenSeadragon image viewer.

The TEI encoding is controlled with a RelaxNG schema based on an ODD file. The recorded metadata include bibliographic details, the date or period of the document's genesis or publication and a genre classification (editorial notes, editorial lists, editorial plans, poetry).

Among the encoded textual phenomena are additions, deletions, substitutions, omissions, variants and notes. First and last variants are especially marked to allow for the establishment of a first and last version of the text. Moreover, the following types of entities are labeled: persons, journals, texts and works. Special attention is paid to the four principal authorial figures of Pessoa: Alberto Caeiro, Álvaro de Campos, Fernando Pessoa and Ricardo Reis. Besides registering their mere occurrence, the role they have is determined (they can be mentioned as author, editor, translator or topic of a work). Occurring persons, journals and works are managed in a central knowledge base which serves as the basis for their identification in the documents and the creation of comprehensive indexes. The following figure illustrates how the relationship between an editorial list and a publication is established via the reference to works:



Document "MN909"

```
<item>
  <rs type="work" key="O1" style="bc">
    <rs type="text">Cancioneiro (ou Itinerario)</rs>
  </rs>.
</item>
```

Work list

```
<list type="works">
  <item xml:id="O1">
    <title type="main" subtype="a">Poemas de Fernando Pessoa</title>
    <title type="alt" subtype="b">Cancioneiro</title>
    <title type="alt" subtype="c">Itinerario</title>
      <list>
        <item xml:id="O1-1">
          <title>Abdicação</title>
        </item>
```

Publication "Abdicação"

```
<titleStmt>
  <title>
    <rs type="work" key="O1-1">
      Abdicação
    </rs>
  </title>
  <author>
    <rs type="person" key="FP">
      Fernando Pessoa
    </rs>
  </author>
```

Figure 2: Example of the encoding of work references in TEI

The document MN909 is an editorial list. One item of the list is a mention of the work "Cancioneiro" or "Itinerario". In the central work list, those titles are assigned to the poems of Fernando Pessoa. One of the poems is "Abdicação" which in turn is represented by a publication carrying that title. Thus, the relationship between the editorial list and the publication is made explicit through the encoding and can be exploited e.g. in the edition's presentation.

Work on the digital edition has been going on since October 2014. It is planned to launch the edition within 2016. Until then, more documents will be uploaded and work on the presentation will be finalized. Results so far can be viewed at < http://projects.cceh.uni-koeln.de/pessoa>.

The presentation is multilingual (Portuguese and English). Access to the material is facilitated by different browsing options: by author, documents, publications, works, genre, and chronology. A simple and an advanced search enable the user to make specific and custom requests. As a first analytic approach to the question of the evolution of Pessoa's work during lifetime, an interactive timeline visualising the chronology of editorial projects and publications has been created.

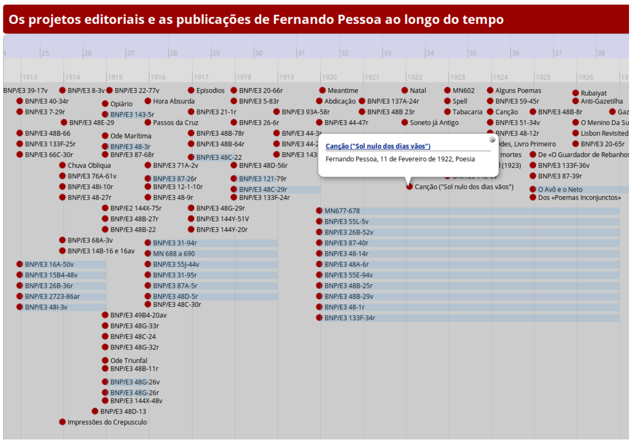


Figure 3: Timeline of Pessoa's editorial projects and publications <http://projects.cceh.uni-koeln.de/pessoa/pt/timeline.html>

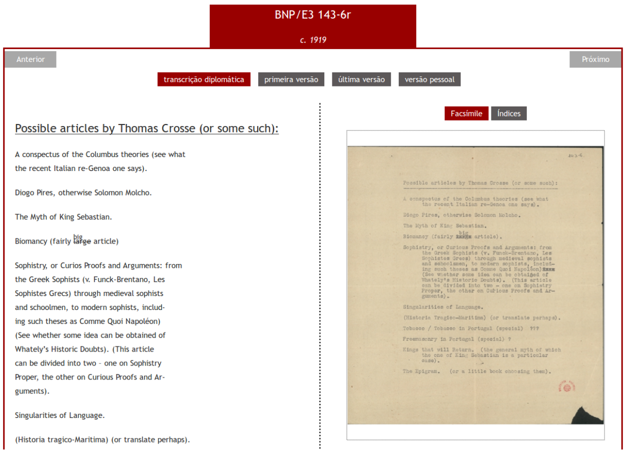
The publications and documents are presented in a synoptic view, juxtaposing the transcription on the left and the facsimile on the right side. The presentation of the documents containing the editorial lists, notes and plans is enhanced by offering the possibility to switch between the diplomatic transcription, the critically established text in the first and last version and a so-called "customized version" where the user can combine transcription features (e. g. if original line breaks should be maintained or omitted). Additionally, the synoptic view can be changed to transcription-index mode, where occurring persons, texts and journals are shown alongside the transcription of the document and links to the central indexes are established. The following figures illustrate the above mentioned features:



Possible articles by Thomas Crosse (or some such):

A conspectus of the Columbus theories (see what the recent Italian re-Genoa one says).

Diogo Pires, otherwise Solomon Molcho.

The Myth of King Sebastian.

Biomancy (fairly ~~large~~ big article)

Sophistry, or Curios Proofs and Arguments: from the Greek Sophists (v. Funck-Brentano, Les Sophistes Grecs) through medieval sophists and schoolmen, to modern sophists, including such theses as Comme Quoi Napoléon) (See whether some idea can be obtained of Whately's Historic Doubts). (This article can be divided into two - one on Sophistry Proper, the other on Curious Proofs and Arguments).

Singularities of Language.

(Historia tragico-Maritima) (or translate perhaps).

Figure 4: Synopsis of editorial list and facsimile <http://projects.cceh.uni-koeln.de/pessoa/BNP_E3_143-6r#facsimile>

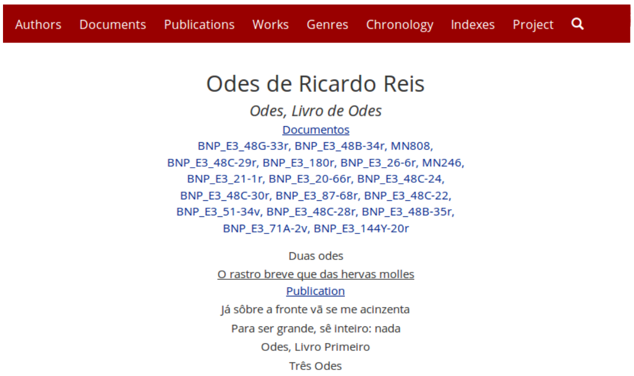
Figure 5: Synopsis of editorial list and index references <http://projects.cceh.uni-koeln.de/pessoa/BNP_E3_143-6r#index>

For each of the four principal authorial figures, the relationships between "works", "publications" and "documents" are presented on an individual page (see figure 6). In the example, the works of Ricardo Reis are listed starting with attested alternative titles of the whole work ("Odes de Ricardo Reis", "Odes", "Livro de Odes"), followed by the titles of individual works. Links to the documents show where the works are mentioned in the editorial projects and links to publications indicate where a work has been published by Pessoa.



Odes de Ricardo Reis

Odes, Livro de Odes

Conclusion

The digital edition of Fernando Pessoa shows that the author was continuously concerned with the organisation of his work and that he persistently planned its publication, even publishing little in lifetime. This supports the hypothesis that his work does have a certain unity, revealing a consistent development and not a fragmentary purpose, as suggested by a large number of critics.

In the edition, this understanding is underpinned by the encoding of micro-genetic textual phenomena in a basic way to elucidate shifts in the conception of work titles, authorship and publication plans in single documents. Developments of the editorial projects on the macro level are traced by encoding mentioned entities in the documents and thereby establishing links between documents, publications and abstract works.

Different editorial procedures are combined to explore the potential of a digital edition which proves fruitful to bring the understanding and editorial presentation of Pessoa's work further than existing print editions, as well as contributing to clarify a major critical topic concerning the author's envisioned unity of his work.

KARREK: Building and Annotating a Kafka/Reference Corpus

J. Berenike Herrmann
bherrma1@gwdg.de
Göttingen University Germany, Germany

Gerhard Lauer
gerhard.lauer@phil.uni-goettingen.de
Göttingen University Germany, Germany

The proposed paper reports on philological and computational aspects of building and annotating a literary corpus. As part of the ongoing corpus-stylistic project Q-LIMO (Quantitative Analysis of Literary Modernity), the KARREK (Kafka/Referenzkorpus), a corpus that centers on German narrative Literature, is designed to enable comparative quantitative-stylistic analyses of Franz Kafka's prose. The corpus includes literary as well as non-literary texts and is tagged for part-of-speech (POS) and enriched by selected types of meta-data (e.g., author, title, date of publication, and [narrative] genre). The number of digital German literary text collections has been growing, and there are several repositories, such as the TextGrid Repository, the German Text Archive (DTA), as well as Gutenberg-DE and individual digital collections (e.g., the Central Catalogue of Digitized Prints [zvdd]). However, so far, no digital resource has been specifically tailored to the needs of quantitative Kafka-research. We offer such a resource, KARREK, which covers the entirety of Kafka's writings (including literary and non-literary ones) as well as a meaningful selection of Newer German Literature, putting a focus on Modernism (ca. 1880 – 1930). What is more, it caters to consistent and high-quality linguistic annotation, text-markup, and metadata. The corpus is hence a unique resource; it will be made publicly available.

Building and annotating the KARREK poses unique challenges typical for textual analysis in Digital Humanities: The first main task is a philological one, selecting the texts that allow meaningful and hypothesis-driven analyses of Franz Kafka's writings. Philological standards of corpus construction are especially high in terms of editorial detail and consideration of cultural, societal and philosophical contexts (cf., Engel and Auerochs, 2010) as well as linguistic ones (cf. Blahak, 2015). KARREK is hence balanced for factors such as canonicity, popularity, (narrative) genre, and linguistic variety. It strives for clarity in terms of literary edition. A special feature of the corpus is its representation of Kafka's reading habits: we assume that a writer's texts may reflect a dimension of 'constructive reading' ('produktive Rezeption', cf. Grimm, 1977), resulting in stylistic similarity with particular authors. For corpus compilation, we thus systematically review the available sources to determine which literary and non-literary works may be candidates for having influenced his writings (e.g., Blank 2001; Born 1990; Born et al., 1983), with ensuing data analysis to explore Kafka's position within a global network of texts and authors.

Our aim to form a reference corpus (with some degree of 'representativeness' for Newer German Literature, Prague Literature, Modern Literature, etc.) requires transforming a substantial amount of 'big literary data' into a consistent corpus. The philological questions transform into computational tasks where retro-digitization (and OCR) is concerned, as well as preprocessing of the data, with consistent metadata (available literature on metadata (e.g., Alemuh and Brett, 2015; Lazinger, 2001), as well as a uniform textual format, including parameters of textual markup (TEI-5). The entire corpus is going to be published in a flexible stand-off format (TCF) which allows further annotation.

For our means, the second main task is the reliable and accurate linguistic annotation for POS (with the STTS tag-set for German). Word class is a reliable indicator of register and genre variation (e.g., Biber and Conrad, 2009), with a high degree of accurate automatic annotation. Although there are high-quality POS-taggers available for German (e.g., Unigram, HMM, and Perceptron Taggers), most were trained on late 20th-Century news texts. To ensure accurate tagging of historically prior and literary texts, for training our taggers, we use as a first resource the POS-tagged corpus of the German Text Archive (DTA) which comprises historical and literary data. In addition, a round of manual error management (on a sample of ca. 40,000 words), as well as training of a CRF-tagger (MarMot) are administered to heighten reported accuracy of POS-tagging for our corpus. We are currently establishing a workflow comprising an eXist-database with an annotation interface, as well as a procedure for evaluation of tagger output for different sections of the corpus. Next to the compilation of the corpus, our project will thus offer more insight into POS-tagging of historical German narrative literary texts.

In DH, tackling representativeness in literary corpus building is an important research task, with theoretical background offered by corpus linguists and computational linguists (e.g., Biber, 1994; Evert, 2006; Lee, 2001). Although methods of 'big data' computing (cf. Anderson, 2008; Manovich, 2015) are extremely promising for digital literary studies, we suggest that in our field creating balanced and representative corpora is a vital question. Since there are only few best practice examples (for German, e.g. the DTA), and representativeness is a recurring issue that by no means may be considered 'once-and-for-all'-solved, the way in which our particular study tackles the issue may be of interest for many similar studies. In the prospective talk, we will thus address 'representativeness', reporting on the decisions made on text selection (author, titles, genre, canon/popularity, 'constructive reading').

We will also provide a description of the linguistic (POS) annotation, including details on our machine-learning procedure and the user interface. Also, the workflow will be presented, elucidating ways of applying it to analogous studies/projects. The talk will give a description of the online publication details. In all, our research shows that building and enriching a particular literary corpus is by far no trivial task, but requires a sound theoretical modeling of the phenomenon constructed and an interdisciplinary method that does justice to philological as well as to computational criteria of high-quality corpus research.

Invisible Cities In Literature And History: Interfaces To Scalable Readings Of Textual And Visual Representations Of The Imaginary

Charles van den Heuvel
charles.van.den.heuvel@huygens.knaw.nl
Huygens Institute for the History of the Netherlands, Netherlands,

Florentina Armaselu
florentinaa@zoomimagine.com
Centre virtuel de la connaissance sur l' Europe (CVCE), Luxemburg

Introduction

At the DH2014 conference it was explained how the *ZoomImagine* software (Z-editor) allows zooming on units of text and contextual information (z-lexias) in order to explore layers of meaning that support critical readings of literature (Armaselu 2014). Changing perspective or analytical viewpoints by using different types of “magnifying glass” is also possible (Figure 1).

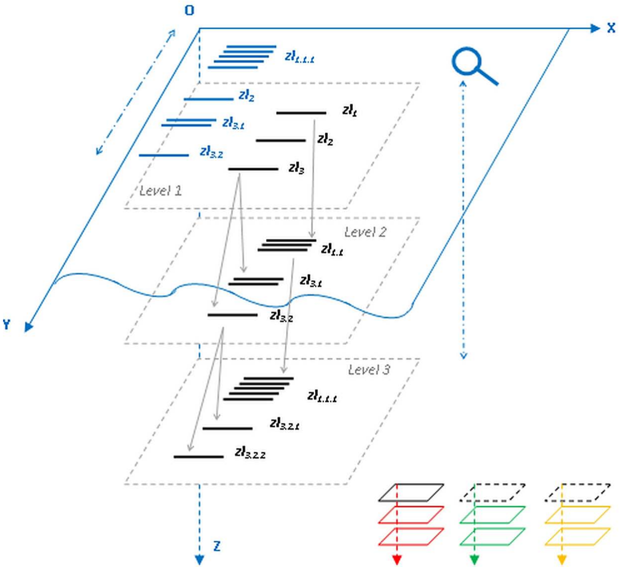

Figure 1. Z-text layout. Levels of z-lexias (center). Changing perspective (bottom right)

In this study the results of two experiments will be discussed in which the Z-editor was used to explore crossovers between text and image and history and literature in descriptions of imaginary cities and imaginary depictions of existing cities. The first case concerns readings of the *Invisible Cities* (1972) in which Italo Calvino (1923-1985) described Marco Polo’s accounts of visits to cities to Kubla Kahn, Emperor of the Tartars. The second one discusses designs for and historical depictions of the citadel of the city

1 Invisible Cities by Italo Calvino Calvino, Italo, Invisible Cities, Vintage Books, London, 1997

1

1 [...]

1

1 CONTINUOUS CITIES * 1

1

1 THE CITY OF Leonia refashions itself every day: every morning the people wake between fresh sheets, wash with just-unwrapped cakes of soap, wear brand-new clothing, take from the latest model refrigerator still unopened tins, listening to the last-minute jingles from the most up-to-date radio.Calvino, 1997:102

1 [...] It is not so much by the things that each day are manufactured, sold, bought that you can measure Leonia's opulence, but rather by the things that each day are thrown out to make room for the new. So you begin to wonder if Leonia's true passion is really, as they say, the enjoyment of new and different things, and not, instead, the joy of expelling, discarding, cleansing itself of a recurrent impurity. [...]Calvino, 1997:102

1 [...] Besides, the more Leonia's talent for making new materials excels, the more the rubbish improves in quality, resists time, the elements, fermentations, combustions. [...]Calvino, 1997:102-103

1 [...] As the city is renewed each day, it preserves all of itself in its only definitive form: yesterday's sweepings piled up on the sweepings of the day before yesterday and of all its days and years and decades. [...]Calvino, 1997:103

1 [...] A cataclysm will flatten the sordid mountain range, canceling every trace of the metropolis always dressed in new clothes. In the nearby cities they are all ready, waiting with bulldozers to flatten the terrain, to push into the new territory, expand, and drive the new street cleaners still farther out.Calvino, 1997:103

2 On the sidewalks, encased in spotless plastic bags, the remains of yesterday's Leonia await the garbage truck. Not only squeezed rubes of toothpaste, blown-out light bulbes, newspapers, containers, wrappings, but also boilers, encyclopedias, pianos, porcelain dinner services. It is not so much by the things that each day are manufactured, sold, bought that you can measure Leonia's opulence, but rather by the things that each day are thrown out to make room for the new. So you begin to wonder if Leonia's true passion is really, as they say, the enjoyment of new and different things, and not, instead, the joy of expelling, discarding, cleansing itself of a recurrent impurity. The fact is that street cleaners are welcomed like angels, and their task of removing the residue of yesterday's existence is surrounded by a respectful silence, like a ritual that inspires devotion, perhaps only because once things have been cast off nobody wants to have to think about them further.Calvino, 1997:102

Figure 2. *Invisible Cities* Z-text. Level 1 (left), 2 (right). Calvino's text unfolding along different lines of "stratification", the "new-old" divide and the "textual-visual" metamorphosis (the visual "becoming" of the text). The first level (left) contains fragments (z-lexias) conveying the meaning of "new" (through words like "new", "renew"). By zooming-in (right), further elements from deeper levels can be surfaced, i.e. fragments entailing the idea of accumulation of "old" (including words such as "yesterday", "past", "residue", "remains", "garbage", "refuse") or visual representations not belonging to the original text but imagined by various artists.

of Groningen in the Netherlands in an atlas of the Flemish engineer Pierre Lepoivre (1546-1626). We will demonstrate that the Z-text model is both suitable for analyzing critical readings and artistic impressions of the Invisible Cities as for assessing different levels of historical evidence of visualizations, such as maps, drawings and designs of existing cities. Furthermore, it allows for navigating in an associative way through imaginary cities of which features might have inspired both Calvino's literary writings as Lepoivre's designs. Contemporary artists still inspired by Calvino seem to delve into a collective visual memory of "cities", in a way Renaissance engineers linked their designs to representations of ideal cities and new fortress towns, from Campanella's City of the Sun to Zamość in Poland. The Z-text model might stimulate to explore digital past and future identities of imaginary and real cities. We will conclude with a discussion of the potential of the Z-editor interface for general debates within the digital humanities.

The Invisible Cities of Italo Calvino

The publication of *Le Città Invisibili* in 1972 by Italo Calvino was directly followed by comments by literary critics and by visualizations of artists inspired by the poetical descriptions of the imaginary cities in the imageless book. The division into 11 themes associated with the city that return each 5 times in the book -City and Memory, City and Desire, City and Signs, Thin Cities, Trading Cities, Cities and Eyes, Cities and Names, Cities and the Dead, Cities and the Sky, Continuous Cities and Hidden Cities- has resulted into various interpretations of these imaginary urban spaces, such as "rhizomatic space" Kerstin Pilz (2003) and "city of strata" Sambit Panigrahi (2014). The zooming functionalities of the editor and Z-text model make it possible for instance to analyze Calvino's description of the continuous city of Leonia that each days breaches through its boundaries of deposited waste at its circumference with these contemporary interpretations (Figure 2).

Another "rhizomatic" expansion imagined via the model - along with the "contextualization" line - enables other readings of Calvino's work, both by critics and himself. Calvino in some occasions looks through the lens of the writer and in other moments through the eyes of the reader or editor and states "that the author's view no longer counts" (Baldi, 2015; Calvino, 2015: 41-42). Calvino sometimes puts the Invisible Cities directly into context by referring to works that similarly are inspired by Marco Polo's travels, such as the poem *Kubla Kahn* (1798) of Samuel Taylor Coleridge or *The Message from the Emperor* (1919) by Franz Kafka. In other occasions references are indirect, for example when Calvino notes that the atlas of Kubla Kahn contains images of "lands visited in thought, but not yet discovered or founded: New Atlantis, Utopia, the City of the Sun [..]" (Calvino, 1997: 147). On a more detailed level the possibility of sideways movements becomes important when Calvino reacts to all those critics who underlined the importance of the closing sentence by claiming that the Invisible Cities is "a many facetted book" with "various possible 'conclusions'" (Calvino, 1983: 41). By combining the zooming functionality with the representation of contextual information a Z-text becomes a multidimensional space of analysis (Figure 3).

Such an interface may be useful for the analysis of the Invisible Cities when Calvino observes: "And yet, all these pages put together did not make a book: for a book (I think) is something which has a beginning and an end [..] It is a space which the reader must enter, wander round, maybe lose his way in, and eventually find an exit, or perhaps even several exits, [..]" (Calvino, 1983: 38). If we enter our concentric city of Leonia again, new associative perspectives pop up. We recognize Calvino's reference to Kafka's story of the Emperor's messenger wanting to report about the death of Kubla Kahn by trying - breaking through the walls surrounding the palace, "the center of the world, piled high with its own refuse." (Kafka, 2012: 28) However, another of Calvino's references, the one to Campanella's concentric walled City of the Sun allows to link the form of Leonia with images of built and not built fortified cities that are related to our second experiment dealing with levels of historical evidence of designs of citadels in the atlas of Lepoivre (compare Figure 5). This comparison is of interest since Calvino once considered a theme "Cities and Form", but decided to merge it with those of other cities (Calvino, 1983: 38).

Imaginary Depictions of An Existing City: Groningen (Netherlands)

Renaissance ideal-fortress cities were ideally radial-concentric cities with a polygonal perimeter with angular bastions. Therefore circumscribing and inscribing circles played an essential role in designing fortified cities and citadels. The design of fortifications was not just functional. Fortification atlases were cultural artifacts amongst other books on architecture such as the Renaissance Vitruvius editions that often contained visual interpretations of the city described in the lost original manuscript. In this context also the four drawings based on the designs of the Italian engineer Bartolomeo Campi of the city and citadel of Groningen in the Atlas of Lepoivre of ca. 1624 must be seen (Heuvel, 1994: 1998) (Figure 4).

The Z-text model and the digital humanities

The Z-text model meets a wide array of new reading and analysis practices discussed in relation to the digital humanities. While the zooming function supports bridging distant and close reading by scalable reading (Mueller, 2012) the combination with contextualization on the various planes to read text and image from various perspectives coincides with notions of deep reading

The drawings 1 and 2 seem to be direct copies of the non-executed design for the hexagonal variant. However, drawing 1 the detail of the bastion is closer to the historical situation since for the pentagonal citadel a similar design for the bastion must have been executed (the only difference would have been the angle of the point of the bastion which in a hexagonal variant is more acute) The design for the bastion corresponds with archeological evidence of excavations in Groningen and with drawings of the bastions of the citadel of Antwerp that were executed according to his designs.

context to assess levels of historical evidence of these four drawings. These levels can only be expressed in terms of "more" or "less" in relation to each other. There is a correlation between the level of detail of the represented (parts of) the citadel and the level of historical evidence. The more we zoom in on a part of the building, the more we get closer to historical evidence that is provided by contextual information.

The case

There is a direct correlation in this example between the degree of detail (zoomed in) and the degree of historical evidence. Drawings 1-4 of Pierre Lepoivre are related to the design of Bartolomeo Campi.

Renaissance ideal - fortress cities were ideally radial - concentric cities with a polygonal perimeter with angular bastions. Therefore circumscribing and inscribing circles played an essential role in designing fortified cities and citadels. The design of fortifications was not just functional. Training in the Military Arts belonged to the education of noblemen, who often collected drawings of fortifications. Fortification atlases were cultural artifacts amongst other books on architecture such as the many Vitruvius editions of the Renaissance that often contained antique and modern visual interpretations of the city described in the lost original manuscript.

One of Calvino's references, to Campanella's concentric walled City of the Sun, allows to link the form of Leonia with images of built and not built fortified cities as the designs of citadels in the atlas of Lepoivre. This comparison is of interest since Calvino once considered a theme "Cities and Form" as well, but decided to merge it with those of other cities (Calvino 1983, 38). By extension, we can imagine a traversal through the space of city forms, following different exploration paths, Calvino, Campanella, Vitruvius, Lepoivre.

Figure 5. *Imaginary Cities* Z-text. Level 1 (left), 2 (top right), 3 (bottom right). Traversal through the space of forms, following multiple exploration paths and connecting imaginary cities in literature (Calvino, Campanella) and in architectural treatises and theory (Vitruvius) with imaginary representations of existing cities in design (Lepoivre).

(Birkets, 1994). This combination allows for the creation of multiple levels of meaning and supports a continuously process of reinterpretation from multiple perspectives, contributing this way in developing digital hermeneutic methods (Capurro, 2010).

Silva Portentosissima – Computer-Assisted Reflections on Bifurcativity in Stemmas

Armin Hoenen
hoenen@em.uni-frankfurt.de
Goethe Universität Frankfurt, Germany

Introduction

In 1928, the philologue Joseph Bédier explored contemporary stemmas and found them to contain a suspiciously large amount of bifurcations. He gave two potential reasons, one being that the editors constructing a stemma with a bifurcation below the root node, could freely choose the variants for their base text. The second reason termed *force dichotomique* postulates that constructing a stemma, because editors are always comparing manuscript pairs, they tend to overseparate. This is illustrated in Figure 1. The philologue would postulate a common ancestor for the closer pair and attach the third sibling together with this ancestor to the parent node producing two bifurcations, where there was a multifurcation originally.

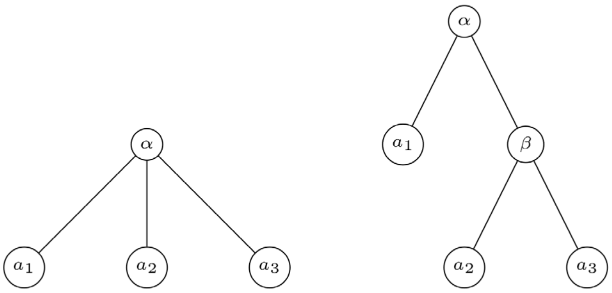

Figure 1. Force dichotomique, example. Left: true stemma. Right: probable philological reconstruction

(Maas, 1937) acknowledges a large amount of bifurcations in stemmas for recensions of Greek texts, but points out that this is rather unsurprising taking into account the number of possible stemmas and the proportion of bifurcations therein. (Felsenstein, 1978) computes the amounts of entirely bifurcating trees for *n* labelled leafs, which is certainly correlated with the number of predominantly bifurcating trees (and of root-bifurcating trees). As one can see, the proportion of bifurcating trees steadily declines, weakening Maas’ argument.

(Haugen, 2015) analysed collections of stemmas and found that Bédiers reason number two seems to hold independent of provenience. (Trovato, 2014) found that a realistic estimate of the percentage of lost manuscripts for medieval and earlier traditions ranges realistically above 73%. Related discussions and recent developments are reflected in projects such as Stemmaweb and the Parvum lexicon Stemmatologicum.

In this paper, the argument is introduced and investigated that, with a large amount of lost manuscripts, the amount of bifurcations in the true stemmas could naturally be high because of the transformations stemmas undergo when manuscript loss prunes away whole branches and leafs at a rate higher than 73%.

Distributions of outdegrees of manuscripts

Two basic distributions are most obviously historically interpretable, a normal distribution and an exponential distribution. In considering the outdegrees to be normally distributed, we assume, that there is one certain number of copies which is most probable, peaking the others; the more the outdegree diverges negatively or positively, the fewer manuscripts with this outdegree will be found. This could translate into a hypothetical historical projection, where many manuscripts of a tradition were copied and wore off at similar rates. Assuming an exponential distribution, things become more hierarchical. For instance, a powerful organization declares some of the manuscripts authoritative which would lead to certain manuscripts being copied many times more than others.

(Haugen, 2015) lists a table with the numbers of furcations (though not leafs) in two collections of stemmas for editions of Old Norse texts. Transforming these furcations into vectors, we conduct the Shapiro-Wilk normality test, (Shapiro and Wilk, 1965), and the exponentiality test by Kolmogorov-Smirnov (which are both robust even for smaller sample sizes) using the software R.[1] This results in an estimate on which distribution these stemmas entail for manuscript copying. However, stemmas with only identical values or only 2 furcations are skipped due to not being testable with the above chosen tests. Table 1 reveals a tendency towards exponentiality. Applying other tests for additional distributions, the weibull and log-normal distributions fitted the data best in terms of likelihood, suggesting a similar scenario.[2]

Value	Bibliotheca Arnamagnæna series	Editiones Arnamagnæna series
Normality	2	2
Exponentiality	11	9
Both	7	7
None	14	15
Stemmas	34	33

Table 1: Tests of distributions of furcations in the collections investigated by (Haugen, 2015). Tests at significance level 0.05

Experiment

In order to assess the above mentioned hypothesis, we need large numbers of underlying stemmas from which loss can be simulated and an appropriate model of manuscript loss. Then, we can simulate a large number of stemmas and manuscript loss, whereafter we count the number of bifurcations. Using simulations especially in large scale scenarios is sometimes the only possibility of assessing historical data, especially considering limits imposed onto empirical studies through data sparsity and other hindances.

Manuscript loss

Historical loss does not affect all manuscipts evenly. (Canfora, 2002) found private exemplars to be less affected whereas since libraries tend to be burnt in wars, public exemplars suffer loss more easily. Many other factors (climate, authoritativity, etc.) excert influence on manuscript loss most of which have never been made subject to generalizable quantifications and it is questionable if this can ever be done. Herein, we elaborate a simple model of loss using only two basic assumptions. We simulate loss of 73-100% where each node gets a probability related to its age (the older the more probably lost) and its outdegree (the more copied, the more probably kept in good conditions, the less probably lost). Since aging is considered to be stronger than preservational effort, we square the age dependent parameter. The probability of loss for each node is thus determined by

$$l_i^2 * slow(i)$$

where l is the height of the current node i incremented by 1 and slow(i) is the outdegree slowdown function:

$$slow(i) = \begin{cases} \frac{1}{o(i)} & \text{if } o(i) > 0 \\ 1 & \text{else} \end{cases}$$

where o(i) is the outdegree of node i. Note, that there is no distinction for nodes with an outdegree of one and leafs. This model of loss produced rather desirable loss probability distributions as is exemplified in the Appendix. However, we also use pure randomization of loss with equal probabilities among all nodes and randomization for probabilities as described but without squaring.

Simulation

For the simulation, we use R and Java.[3] First, for simulating normally distributed copying, we generate distributions randmonly drawn from a normal distribution using the R function *rnorm*. Since *rnorm* produces real numbers and negative numbers, we round all values and leave negative values and zeros aside. Since this may lead to a distortion of the so-sampled distribution deviating from a normal distribution, we test for the desired shape and only keep distributions which have a p-value above 0.05. This distribution is now our distribution of outdegrees in the to be simulated stemma, each value represents one outdegree. Starting with root, we randomly choose an outdegree (or make the node (not root) a leaf with a probability of 0.2) and add as many children to the actual node as this outdegree. For each of the so-generated children, we draw another outdegree and add as many children, recording them in the next generation. We iterate the process until all outdegrees are applied exactly once.This results in a differing number of leafs and a differing size of the tradition for each simulation. Since medieval traditions were probably not equal in size, the effect of this sampling is not controlled for further.[4]

With each tradition, loss is simulated in the three above described ways. We keep all nodes, which are on the path from root to any survivor but delete all other lost nodes. What remains is the true reconstructible stemma (TRS). Since philologues do not have sufficient information (and probably time) for the reconstruction of entirely lost branches, which would be too spurious an endeavour anyway, the stemma we simulated is the maximally faithful reconstruction given our simulated ground truth.

Distribution	Loss A	Loss B	Loss C
Normal (n=5, m=2, sd=1)	0.2 0.27	0.21 0.22	0.18 0.17
Normal (n=5, m=4, sd=1)	0.28 0.37	0.29 0.32	0.27 0.26
Exponential (n=5, r=0.5)	0.18 0.19	0.2 0.2	0.18 0.16
Exponential (n=5, r=1)	0.08 0.09	0.11 0.11	0.08 0.07

Table 2: Percentages of bifurcations and root-bifurcations given the parametricized simulations

Distribution	1	2	3	4	5	6
Normal (n=5, m=2, sd=1)	1216 2158	1740 546	1181 39	406 2	42 0	1 0

Exponential (n=5, r=0.5)	1509 1875	911 441	589 103	361 16	220 8	129 1
Exponential (n=5, r=1)	2052 1879	892 166	333 11	120 0	46 0	14 0

Table3: Furcations (1-6) before and after loss, Loss A

Results and discussion

Results can be seen in Tables 2 and 3. The simulated traditions ranged in size from 4 to more than 60 and after loss from 1 to around 20 manuscripts. Percentages of bifurations (even excluding leafs, as in Haugen (2015)) are below the observed values for the collections examined in the previous literature. Under more keeping nodes, which are on the path to root for any survivor as reconstructibles results in a much larger incidence of unifurcations, not bifurcations in the stemmas after loss has applied. Therefore, some model of contraction shall be applied in subsequent research. With a mean of 2 producing large numbers of bifurcations, after loss, their number is reduced sharply in contrast with unifurcations and leafs. Thus, *loss at high rates generally affects furcations of higher orders much more, leading to a naturally higher incidence of bi- and unifurcations and most of all obscuring an underlying distribution of original copies.* Aditionally, probably there are too few reconstructions of nodes with indegree and outdegree 1. In other words, philologues could tend to view a copy rather as sloppy than as a copies copy, which would contribute to making bifurcations more common in actual stemmas.

Conclusion

Although the simulation is an approximation, the values suggest, that indeed the proportion of bifurcations is suspiciously large in the collections in the literature. On the other hand, Maas was probably right in expecting a larger amount of lower order furcations. However, not their proportion among all possible stemmas, but the effect of massive loss of manuscripts leads to a large probable proportion of those in a pruned TRS.

Appendix

Notes

[1] Packages exptest and fitdistr have been used.

[2] The average mean of the furcation distributions was 1.95 and the average standard deviation 0.78.

[3] We used JgraphT and RCaller, (Satman, 2014).

[4] One could compare the proportion of surviving to lost nodes in the TRS and stemmas from the literature.

Live/Life Stories. The Uses Of Digital War Testimonies In Educational Contexts

Susan Hogervorst
susan.hogervorst@ou.nl
Open Universiteit Nederland, Erasmus University Rotterdam, Netherlands, The

Since the 1980s, under pressure of the definite 'disappearance' of the eye witness generations of WWII, a wide variety of initiatives has been undertaken to capture eye witness memories for the future. Multiple oral history collections have been created throughout the western world, in which ten thousands of interviews and life stories have been preserved on audio and video. Parallel to the quest for individual war memories to collect and preserve, there has been an increasing effort to transmit these memories onto younger generations. In my dissertation, I have referred to this process as the pedagogization of memory, with which I point at the transmission of WWII memories onto younger generations as a crucial way of giving meaning to the past, and, therewith, in creating and sustaining identities (Hogervorst, 2010, Proske 2012, Macdonald, 2013; 200). Both practices respond to, and express, a perceived shift from war memory towards war history, although in different contexts of historical culture (Erll 2011; Assmann, 1999, 2006). It is through the digital revolution that, at the beginning of the 21st century, both of these practices have become intertwined; the shift from memory to history is accompanied by, or expressed by, a shift from collecting and preserving to disclosing digitized interviews for a wider audience, also for education (Bothe/Lücke, 2013; Barricelli, 2009, 2010).

My paper presents the first findings of a case study of my postdoc research project, that addresses the central question how online portals to digitized WWII eye witness testimonies are used in educational contexts – both formal education in history or civics, and heritage educational projects. The case study focuses on secondary school history teachers' conceptions of digitized video testimonies as educational resource. Therefore, a group was composed of teachers interested in WWII, which was asked to explore different online interview collections. Through participatory observation and individual interviews with participating teachers, data was collected on expectations, desires and experiences regarding the use of digitized video interviews in history classrooms. The analysis focused on two different themes: (1) Participants' conceptions of differences and similarities between live and digitized testimonies as educational resource; (2) Their experiences using specific online portals to interview collections. The latter will be the focus of my paper.

Participants were asked to explore two different online portals to different interview collections: Getuigenverhalen.nl ('eyewitness stories') and IWitness. Getuigenverhalen.nl is a Dutch portal hosted by the Netherlands Institute of War- Holocaust- and Genocidestudies, giving access to about 500 quite recently conducted video interviews (2007-2010), all in Dutch. The interviews address multiple WWII related topics such as resistance, daily life, persecution, and forced labor. The majority of these interviews is searchable at fragment-level as the transcripts and time-based key words that have been attributed are indexed and aligned with the video. The other portal is IWitness, the worldwide educational program of the USC Visual History Archive in Los Angeles. Through IWitness, in which a selected part (1,500 interviews) of the Shoah interview collection is made available online in an open, but supervised community of teachers and students. Twelve of these interviews are in Dutch. The video interviews can be watched and searched. Moreover, a video-editing tool enables users to select, annotate, and share video fragments, or to combine them with other fragments, photographs or information from the built-in encyclopedia. Because of IWitness' theoretical fundament in constructivism as a learning theory, and the fact that it actively invites teachers (and students) to create their own learning materials with/within the program, it is unclear whether this program can be easily implemented in non-American education systems and practices.

In Dutch history education, oral history is not a common practice; neither as a source of information that pupils learn to assess, nor as a practice in which pupils are trained. Regarding WWII however, there is a modest tradition of inviting eyewitnesses in classrooms, mostly in the weeks prior to the yearly commemorations of the liberation in May. Video interviews are hardly being used in Dutch history education at this point. There seems to be a transition period, in which institutions disclose their interview collections for still undefined audiences, which are mostly unaware of the existence of such collections and their online accessibility, and continue current practices. It is this transition that is the background of my postdoc research project. Other case studies focus on video interviews in WWII exhibitions and educational projects.

The aim of the postdoc research project is, first, to gain insight in contemporary historical culture, and specifically in the effects of the digital in transmitting and appropriating war memories across generations. For instance it would be important to know whether there is some kind of digital 'streamlining' of testimonies with specific features considered to be suitable for educational purposes. The same goes for the eye witnesses as culturally constructed figure, that is already very familiar to us through the numerous films, documentaries, news reports, and exhibitions (Kansteiner, 2015; Keilbach, 2012; Gries, 2012). Which characteristics of the narrators are perceived as necessary or relevant for letting students learn from their testimonies, and why exactly? And how about the perceived historical realism and authenticity of the testimonies – are we perhaps more critical when we do not encounter the narrators in person?

The second objective is to explore and think through the needs of the educational and heritage field as users of digitized oral history collections. This corresponds to research such as the CLARIAH project Oral History Today, that has made the numerous oral history collections in the Netherlands available for scholarly research, in close cooperation with both computer technologists and scholars in the humanities. (Scaglioa et al., forthcoming; Kemman et al., 2013; De Jong et al., 2011). It is relevant to expand the gained knowledge about the scholarly uses of oral history collections, examining how digital technology can be applied to turn interview collections into a network of knowledge relevant to multiple audiences, including teachers and students.

Stylometry on the Silver Screen: Authorial and Translatorial Signals in Film Dialogue

Agata Hołobut

Monika Woźniak
moniwozniak@gmail.com
Sapienza University of Rome, Italy

Stylometry based on quantitative analysis of linguistic features such as most frequent words, lemmata, or parts of speech, is a time- and research-proven tool in authorship attribution and plagiarism detection, and is now also used in more general literary studies as part of the distant reading revolution. It has been particularly successful in grouping long texts by their authors in both supervised and unsupervised machine learning tests – and the appeal of this material to stylometrists is understandable in that novels are easily available and easily definable chunks of linguistic (and literary) material, and, despite rumors on the death of the author, most readily associated by the general reader with a single creative figure. And when they are not, discovering the fingerprints of more than one hand in collaborative works is another favorite pastime of stylometrists.

While perhaps equally avidly studied, the authorship signal in drama is often more problematic. This is probably why the most famous question, that of Shakespearean authorship, is so complex and so hotly contested – as evident, for instance, in a fairly recent debate (Craig and Kinney, 2009; Vickers, 2011; Hoover, 2012). Other difficulties in this genre include the "codification of … literary discourse" in certain literary periods and the fact that the same authors might write drama both in prose and in verse (Schöch, 2013, 2014); also, it may be supposed that, as dramatists create their characters through dialogue, there is a more or less conscious effort on their part to differentiate their style. This last phenomenon has also been researched in novels (Burrows, 1987) and translations of novels and drama, and the results could be equally problematic (Rybicki, 2006, 2007, 2008).

Even more distortion may be expected in a somewhat similar genre, that of film and TV dialogue – and its textual reflection in intralingual subtitles and interlingual translations. The final shape of filmic speech ascribed to a given screenwriter can be influenced by other agents, such as directors or actors. It can be further transformed in the process of intralingual subtitling, especially that performed by "fansubbers", who do not necessarily reflect the exact dialogue spoken onscreen. This becomes even more of a problem in the case of interlingual translations, which by nature condense (subtitles, voice-over) or rework (dubbing) the original message, being at times anonymous versions of questionable quality ("fansubs").

Quantitative methods have already found their way into audiovisual translation research (Pérez-González 2014; Baños *et al.*, 2013), as exemplified by such projects as Pavia Corpus of Film Dialogue, used to examine sociolinguistic and pragmatic features of dubbed Italian (Freddi and Pavesi, 2009), or Forlixt1, a multimodal corpus which helps to investigate the interplay of verbal and non-verbal semiotics of the film (Valentini, 2006, 2008).

In comparison with the above attempts, our research was done on a specialized corpus of historical films and TV (mini)series. This choice was based on the assumption that the subgenre has unique characteristics which find reflection in film dialogue: namely, it authenticates the represented reality and it also adheres to the codes of realism existing in particular countries. This, in turn, made us look for the same phenomena in (English) originals and (Italian and Polish) translations, since translated dialogue, too, is shaped by stylistic necessities of the genre, culture-specific images of the past dominant in the target context, but also by norms and conventions of audiovisual translation in a given language/culture/country. The exact composition of the corpus is given in the table below:

Original	**Polish voice-over**	**Polish "official" subtitles**	**Polish fansubs**	**Italian dubbing**	**Italian "official" subtitles**	**Italian fansubs**
The Tudors Season 1 (2005)	+	+		+	+	+
The Tudors-Season 2 (2007)	+	+	+	+	+	+
Elizabeth I (2005) (miniseries)		+			+	
Elizabeth (1998)	+	+		+	+	+
Elizabeth. Golden Age (2007)	+	+		+	+	+
The Other Boleyn Girl (2008)		+		+	+	+
The Private Lives of Elizabeth and Essex (1939)			+	+	+	+
Anne of a Thousand Days		+		+		
Wolf Hall (2015)						+

From the point of view of film and audiovisual translation studies, our research project explores the concept of film/television genre and its distinctive features, focusing on the functions of film dialogue and linguistic/stylistic strategies used by screenwriters to fulfil them (Kozloff, 2000; Jaeckle, 2013). The first stage of our investigation consisted in a contrastive stylometric analysis of the extended Anglophone corpus, composed of both historical and non-historical film scripts, in order to verify our preliminary hypothesis about the genre-related specificity of film dialogue. We proceeded, then, to the analysis of parallel corpora of scripts in all available translations into Polish (voice-over, official and amateur subtitles) and Italian (dubbing, official and amateur subtitles). All this was done with several quantitative methods previously developed and used on other textual material, i.e. literary texts. In particular, frequencies of words from various frequency strata were compared between texts in each of the languages studied using the Delta procedure (Burrows, 2002). The analyses were performed with *stylo* (Eder et al., 2013), a package for R, the statistical programming environment (R Core Team, 2014), later also postprocessed with Gephi network analysis software (Bastian et al., 2009).

On the basis of these tests several observations could be made. As concerns the screenwriters, they tend to adapt the dialogues to the requirements of historical genre and the presented epoch. This is visible in Fig. 1, where the authorial signal seems to disappear whenever a given writer worked on two films and/or series set in different eras or belonging to a different, i.e. non-historical genre.

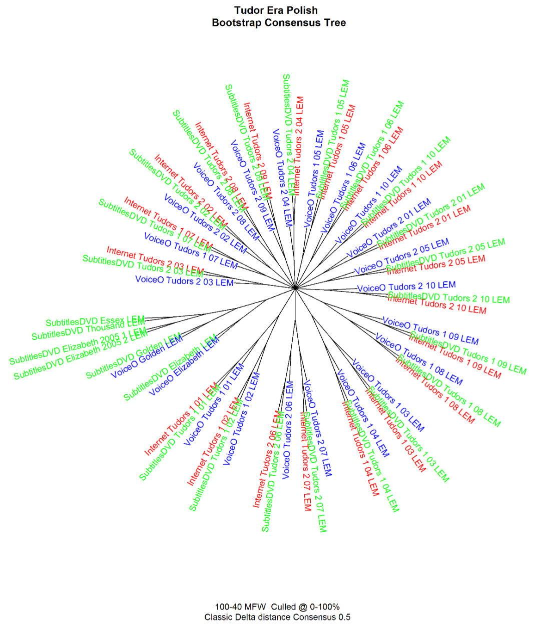

Figure 2. Bootstrap consensus tree for most frequent words in Polish subtitle and voice-over translations in a corpus of Elizabethan-era films and TV series.

As concerns audiovisual translations, we arrived at rather unexpected conclusions. We compared versions of individual episodes of TV series and films in Italian (dubbing, subtitles) and Polish (voice-over, subtitles) by analyzing frequencies of single words and part-of-speech 5-grams; the latter measure was a rough approximation

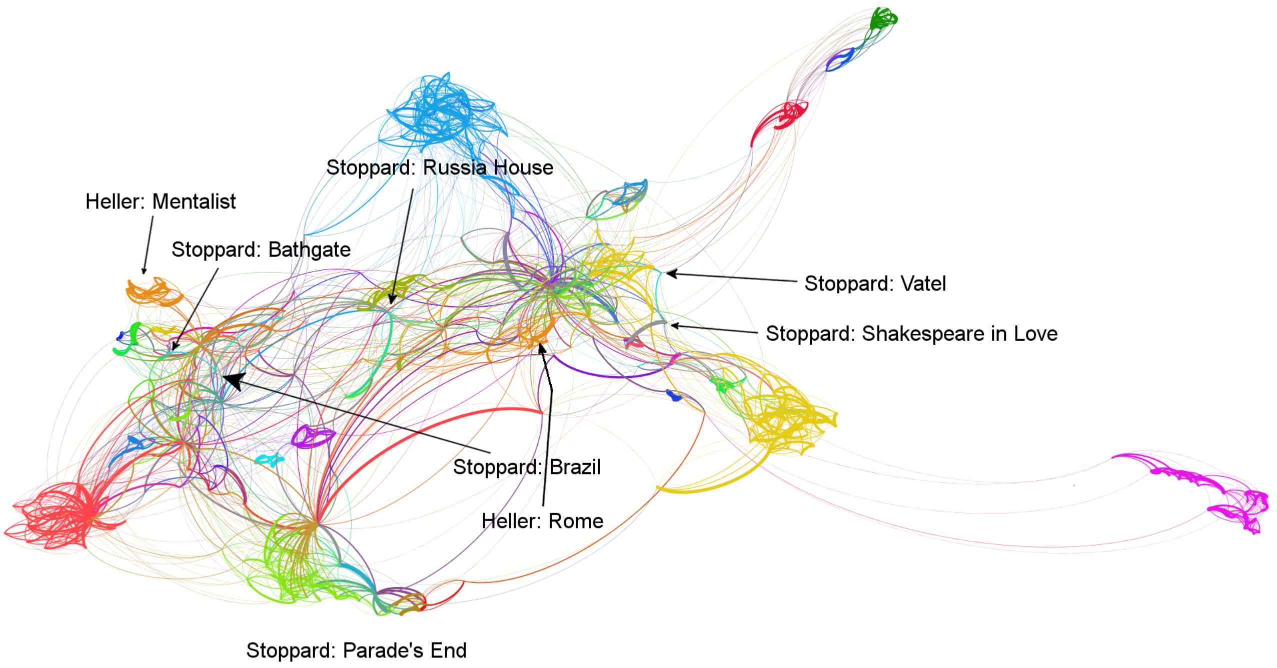

Figure 1. Network analysis diagram of historical and non-historical scripts.

of syntax (Górski et al., 2014). As far as Italy is concerned, we noticed an astounding uniformity of style regardless of technique, be it subtitles or dubbing: translations of individual episodes of TV series and films clustered together in analyses of both word and part-of-speech frequencies. By contrast, Polish subtitles and voice-over scripts of the same episodes clustered together for single-word frequencies, while the latter formed their own clusters in part-of-speech 5-gram analysis. This is shown in Fig. 2 and 3.

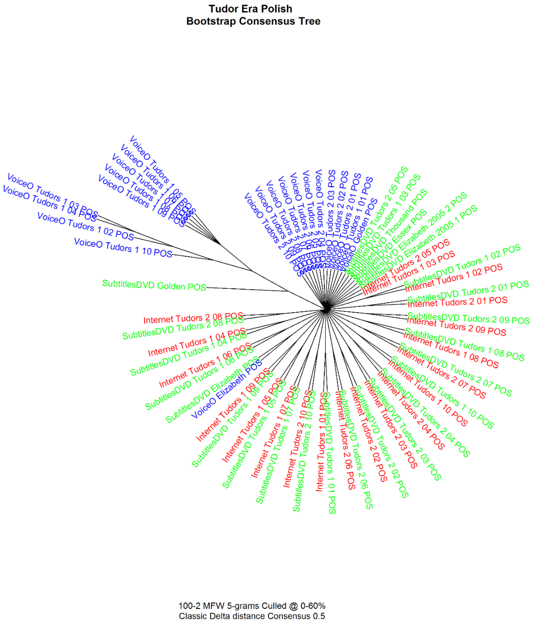

Figure 3. Bootstrap consensus tree for most frequent part-of-speech 5-grams in Polish subtitle and voice-over translations in a corpus of Elizabethan-era films and TV series.

Obviously, the similarities between dubbing and subtitles in Italian may stem from the fact that the latter are based on the former. However, the fact that even amateur subtitles, which usually are published before the release of the dubbed version, show a considerable affinity to dubbing, demonstrates high normalization of the formal language used in Italian historical films and television series.

All these results confirm our preliminary hypothesis that film genre influences the strategies of creating film dialogues and their translations. Although we believe that stylometric and computational analysis should not be the end in itself, it seems invaluable in audiovisual translation studies, encouraging closer qualitative analysis of the original and translated scripts. It invites further investigation of such issues as:

- the importance of cultural norms and conventions in film translation;
- significant intercultural differences in translation strategies used by subtitlers;
- complex relations between dubbing and subtitles, official and amateur subtitles, voice-over and subtitles
- cultural development of written / spoken language in a given country and the salient stylistic trends in audiovisual translation.

Identity Lenses in Analyzing Evolving Social Structures

John Robert Hott

In the effort to capture cultural dynamics, scholars have considered social networks, that is, a graph with people as nodes and their relationships as edges. These social networks are useful; however, to capture dynamics they must be considered over time. In the literature, Time-Varying Graphs (TVGs) have been defined (Aggarwal and Subbian, 2014; Casteigts et al., 2012; Casteigts et al., 2013). In our investigations, we have found benefit in defining TVGs with nodes as societal structures and people as the edges and then considering the dynamics of the societal structures evidenced in the TVGs (Hott et al., 2014; Hott et al., 2015). Here we consider two motivating applications for our extensions to TVGs: early Mormon marital structures and an arXiv.org citation network.

The societal structures represented in the marital and church structures of early Mormons in mid-1800s Nauvoo, Illinois, include binary, polygynous, and polyandrous marriages, as well as child and adult adoptions, and membership of individuals in the church organization hierarchy. In this time period the concept of "marriage" is in flux and part of our research is to consider various conceptualizations of "marriage" to better understand the relationship to the formation of the church structure. Each conceptualization we consider as a different "identity lens," a term we create to describe these different views.

We therefore define the *identity-lens function* that maps one evolving network to another evolving network. More specifically, given a TVG, $\mathcal{G} = (V, E, T, \rho, \zeta, \psi, \varphi)$ as defined in (Casteigts et al., 2012), the *identity-lens function* $f(i, \mathcal{G}) = \mathcal{G}_i$ maps the nodes and edges in $\mathcal{G}$ with a given identity definition to a new Time/Identity-Varying Graph (TIVG) $\mathcal{G}_i = (V_i, E_i, T, \rho_i, \zeta_i, \psi_i, \varphi_i)$. $\mathcal{G}_i$ is therefore the view of $\mathcal{G}$ under identity lens *i*.

In our marital network research (Hott et al., 2014; Hott et al., 2015), we represent marriages as the nodes, with the individuals connecting the marriages of their parents to their own marriages as adults. Every piece of this network is considered to be evolving, since marital relations change, new children are born, family members are adopted, and individuals change membership in the church organizational structure. Initially, this network $\mathcal{G} = \mathcal{G}_{binary}$ may be described as a binary-marriage network, in which each node depicts a marriage between two individuals and their biological children. This is one specific definition of node identity. However, we may examine this network in different levels of granularity: with different definitions of node identity. By extending the marriage definition to all individuals married to the same husband, we may redefine node identity to define polygynous marriages, creating $\mathcal{G}_{patriarchal}$. A related identity function that maps binary marriages to those with the same wife creates the TIVG $\mathcal{G}_{matriarchal}$.

Our second motivating example is the arXiv.org[1] citation network. ArXiv.org provides online open access to over one million cross-disciplinary papers, including papers in Physics, Mathematics, and Computer Science. We build a citation TVG from this dataset, linking authors as nodes based on the co-authorship of their papers. Similar to the Nauvoo application, we define multiple identity functions to map this TVG to multiple TIVGs. Under a node identity function combining authors within the same institution, we produce $\mathcal{G}_{institutional}$. Other node identity mappings include departmental affiliation $\mathcal{G}_{departmental}$, and $\mathcal{G}_{subject}$, in which authors are mapped to their subject areas.

Each of these TIVGs have characteristics that change over time. As we increase the complexity of the nodes through the use of identity lenses, we increase the dynamics of the characteristics, specifically those captured within the nodes. In the Nauvoo dataset, these characteristics include familial relationships among marriage members and church leadership positions held by the members of each marriage. Similarly, in the arXiv dataset, the characteristics include departmental and institutional collaboration. We want and need metrics that are sensitive to these changes within the evolving nodes as well as the overall evolving structure of the network. To capture and analyze these dynamics, we first define sampling methods to produce static graphs depicting the state of the TIVG during a fixed-size interval around each time point, then compute centrality measures over the graph across time for each identity lens. This process creates a distribution of the metric across time, which may then be compared between identity lenses. We conjecture that utilizing different-sized sampling intervals and comparing distributions across identity lenses will provide insights to understanding the TVG and the motivating application it describes.

We therefore define two methods to sample TIVG $\mathcal{G}_i$, in a λt-sized time interval around any given time-point *t* in *T*, to a static graph $G_i(t, \lambda t) = (V_i(t, \lambda t), E_i(t, \lambda t).)$They are given by the following node and edge set definitions:

1. The union of all nodes and edges extant at any time during the interval. ψ_i and ρ_i are the "presence" functions for nodes and edges, respectively, as defined in (Casteigts et al., 2012).

$$V_i(t, \lambda t) = \{v \in V_i \mid \exists t' \in [t - \lambda t/2, t + \lambda t/2] \Rightarrow \psi_i(v, t') = 1\}$$
$$E_i(t, \lambda t) = \{e \in E_i \mid \exists t' \in [t - \lambda t/2, t + \lambda t/2] \Rightarrow \rho_i(e, t') = 1\}$$

2. Only nodes and edges that exist throughout the entire interval.

$$V_i(t, \lambda t) = \{v \in V_i \mid \forall t' \in [t - \lambda t/2, t + \lambda t/2] \Rightarrow \psi_i(v, t') = 1\}$$
$$E_i(t, \lambda t) = \{e \in E_i \mid \forall t' \in [t - \lambda t/2, t + \lambda t/2] \Rightarrow \rho_i(e, t') = 1\}$$

As a simple example of these sampling methods, consider a correspondence network, where V is a set of individuals and E defines their correspondence; an edge connecting two individuals is present when a letter is in the mail between them. For an interval length, λt, of 1 year, the first sampling method would produce a graph containing connections between any individuals who corresponded by letter at any point that year. In comparison, the second sampling method would only leave connected those individuals with constant communication for the entire year.

Using the sampling methods above, we measure characteristics at time points throughout the lifetime of $\mathcal{G}_i$ and thereby evidence the dynamics. The harmonic centrality, C_H, is an indication of how close the nodes are to each other, while the betweenness centrality, C_B, is indicative of how interconnected the nodes are within the graph. They are defined as

$$C_H(G_i(t, \lambda t)) = \frac{\sum_{v_j \in V_i(t,\lambda t)} \left(\max_{\forall u \in V_i(t,\lambda t)} (C^*_H(u, G_i(t, \lambda t))) - C^*_H(v_j, G_i(t, \lambda t)) \right)}{[(|V_i(t, \lambda t)| - 1)(|V_i(t, \lambda t)| - 1)]/(2|V_i(t, \lambda t)| - 3)} \text{ and}$$

$$C_B(G_i(t, \lambda t)) = \frac{2 \sum_{v_j \in V_i(t,\lambda t)} \left(\max_{\forall u \in V_i(t,\lambda t)} (C^*_B(u, G_i(t, \lambda t))) - C^*_B(v_j, G_i(t, \lambda t)) \right)}{(|V_i(t, \lambda t)| - 1)^2(|V_i(t, \lambda t)| - 2)},$$

where $C^*_H(v_j, G_i(t, \lambda t))$ and $C^*_B(v_j, G_i(t, \lambda t))$ are the harmonic and betweenness point-centrality measures (Wasserman and Faust, 1994) for a given node $v_j \in V_i(t, \lambda t)$, respectively. For brevity, we will define here only C^*_H, using Boldi and Vigna's harmonic centrality definition (Boldi and Vigna, 2014), as

$$C^*_H(x, G_i(t, \lambda t)) = \sum_{\substack{d(y,x)<\infty \\ y \neq x \in V_i(t,\lambda t)}} \frac{1}{d(y, x)},$$

where $d(y, x)$ is the distance between $y, x \in G_i(t, \lambda t)$. As a concrete example of this measure, consider the graphs in Figures 1 and 2. In the graph of Figure 1, node A acts as the central connection point, or hub. The hub has the shortest distance to any node and therefore high harmonic point-centrality, C^*_H = 6. Other nodes must traverse at most two edges to reach any other node, giving them C^*_H = 3.5. The overall measure for this graph is C_H = 4.58. In comparison, the graph in Figure 2 has nodes that are distant from most of the other nodes, e.g., node A has C^*_H = 2.45 leading to harmonic centrality, C_H = 1.02. These two graphs demonstrate that the harmonic centrality of the graph is inversely related to the overall "closeness" of the nodes.

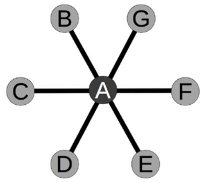

Figure 1. A star graph, with nodes shaded based on relative point-centrality, which has harmonic centrality C_H = 4.58

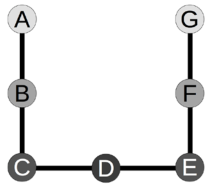

Figure 2. A linear graph, with nodes shaded based on relative point-centrality, which has harmonic centrality C_H = 1.02

Allowing *t* to range over the entire lifespan of $\mathcal{G}_i$ and considering multiple sizes for our λt interval, we generate distributions of the metric across time and with differing levels of temporal granularity. These distributions give a picture of the dynamics occurring within each TIVG. By comparing the metrics across TIVGs under different identity functions for the same TVG, we hope to more fully capture the dynamics of and understand the original evolving network, and provide insights into the motivating application at hand.

We have therefore defined a new conceptualization of Time-Varying Graphs, specifically the identity-lens function and resulting Time/Identity-Varying Graphs under each identity mapping. We also defined methods for sampling the TIVGs into series of measurable static graphs and provided metrics over those representations. At the conference, we will present visualizations that represent each of our applications from the various perspectives, as well as the findings of these measures: to better understand the definition of marriage in Nauvoo and its relation to church formation, and to illuminate patterns in author and departmental co-citations.

Exploring the Rules of Rhyme: Operationalizing Historical Poetics

Natalie M. Houston
Natalie_Houston@uml.edu
University of Massachusetts-Lowell, United States of America

Rhyme is a key feature of many verse forms used throughout the history of English poetry. In its simplest forms, rhyme in English poetry can be understood as a connection between words at the end of lines of poetry, due to the similarity in the sounds of their final syllables. Rhyme suggests and enacts relationships between sound and sense in poetry: "the equivalence of the rhyme syllables or words on the phonic level implies a relation or likeness or difference on the semantic level" (Brogan et al., 2012). Internal rhyme can also connect words located elsewhere in the poetic line, although that is less common in English poetry. Rhyme connects lines of poetry through sound patterns which contribute to the tone, pace, and emotional effects of a poem. Because a common printing convention in the nineteenth century indented lines of poetry to match the rhyme scheme, rhyme was also a visual feature of printed poems, perceptible to the reader's eye and cognition. Rhyme, along with meter, contributes to the memorable qualities of verse, and to the popularity of humorous forms like the limerick. Rhymed verse forms, such as the sonnet and ballad, were very popular in nineteenth-century British poetry, alongside unrhymed blank verse. Rhyme was used for different ideological and aesthetic purposes, as in the working-class ballads of the 1840s or Decadent revivals of French forms like the triolet and villanelle.

But the rules of rhyme are not fixed. Throughout the nineteenth century, poets and critics debated which kinds of rhymes were allowed in the best poetry. In particular, some critics argued that imperfect rhyme (also called near rhyme) was allowable because so many poets used such rhymes (such as "love" and "prove"), while others argued for a more restrictive definition of perfect rhyme. These debates about rhyme are part of larger nineteenth-century discourses about prosody, the patterning of sound in poetry. Recent work in nineteenth-century studies has focused on "historical poetics," the examination of nineteenth-century theories of prosody and their cultural impact (Hall 2011, Martin 2012, Rudy 2009). Such scholarship complicates transhistorical definitions of lyric poetry and its formal features by demonstrating how "prosody provided a way of thinking, a method of protest, of scientific argument and investigation, of negotiating gender, class, and national structures" (Martin and Levin, 2011: 153). But too often this work in historical poetics remains focused on theory separate from poetic practice: Yopie Prins, for instance, says bluntly that "practical application is not the point of historical poetics. There are other, more interesting questions" which for her encompass the relationship of prosody to larger philosophical and scientific discourses (Prins, 2008: 233). This paper offers an alternative, computational approach to historical poetics that will not only further our understanding of nineteenth-century theories of rhyme but also of their relationship to actual poetic practice.

Rhyming dictionaries, which serve as a resource to writers seeking rhymes for their compositions, serve as an importance source for understanding the changing rules of rhyme in the nineteenth century. In the eighteenth century, Edward Bysshe's *The Art of English Poetry* (1702) offered a small dictionary of rhymes, supplanted later in the century by John Walker's *A Dictionary of the English Language,* *Answering at once the Purposes of Rhyming, Spelling, and Pronouncing*, first published in 1775 with 41,000 words included in the rhyme dictionary. Walker's dictionary was expanded and reprinted many times throughout the nineteenth and twentieth centuries, and it is mentioned in the letters and papers of many writers and poets as a standard text. But in the second half of the nineteenth century the popularity of poetry writing as a leisure activity among the growing middle class led to the publication of many new rhyme dictionaries, each of which offered different definitions of acceptable rhymes. These included J. E. Carpenter's *A Handbook of Poetry* (1868); Tom Hood's *The Rules of Rhyme* (1869), later republished as *The Rhymester; Or, the Rules of Rhyme*; the American writer Samuel W. Barnum's *A Vocabulary of English Rhymes, Arranged on a New Plan* (1876); John Longmuir's *Rhythmical Index to the English Language* (1877); R. F. Brewer's *Orthometry: A Treatise on the Art of Versification* (1893); and Andrew Loring's *The Rhymer's Lexicon* (1905).

This paper presents my current work in progress in operationalizing these nineteenth-century rhyme dictionaries as R scripts that identify rhymes in poetic texts based on the rules of a specific dictionary. The entries in these rhyme dictionaries consist of rhyme syllables that serve as the entry headings, followed by a list of homophone syllables, and then examples of words that rhyme with the entry heading. The rhyme syllables and words listed may be subdivided into categories, such as perfect rhymes and imperfect or "allowable" rhymes. Many of the dictionaries provide supporting evidence for the use of imperfect rhymes in the form of quotations from the works of British poets. For this project, all of the rhyme syllables, rhyme words, and rhyme categories are stored in csv files for each dictionary, organized by entry headings. In the interest of fidelity to the original historical dictionaries, and to facilitate comparative analysis, conflicting entries have not been normalized. Thus one dictionary might give very different rhyme syllables or words for a given entry than those listed in another; it is precisely this kind of historical variation in the rules of rhyme that this project allows us to explore. The R package data.table facilitates querying and joining data files for multiple dictionaries so as to compare their entries for the same rhyme syllable.

The technical section of the paper describes the key components of these scripts:

- the last word of each line of the poem is extracted from the text and converted to reverse spelling;
- a series of regular expressions are used to enact the specific instructions each rhyme dictionary provides for its users to identify the rhyme syllable to look up, such as locating the vowel that precedes the consonant(s) of the final syllable ("ame"), unless the consonant(s) are preceded by a dipthong, in which case the first of the two dipthong vowels begins the rhyme syllable ("ound");
- a hash lookup for each rhyme syllable to the selected dictionary returns the perfect rhyme syllables, perfect rhyme words, imperfect rhyme syllables (if given), and imperfect rhyme words (if given);
- matches among these returned values and the other rhyme syllables and words in the poem are sought; when located, a capital letter is used to mark the rhyme pattern, as is traditional in literary criticism (ABAB, etc);
- for those dictionaries that include imperfect rhymes, the ratio of perfect to imperfect rhymes in the poem is also recorded.

This project expands our understanding of nineteenth-century rhyme theory and practice in three ways: by enabling the identification of rhyme patterns in large sets of texts, we can expand our understanding of historical verse writing practices beyond canonical literary texts; by operationalizing the rules instantiated in different dictionaries, we can compare how they would have evaluated the rhymes chosen by particular poets; and by creating a database of the words included in these dictionaries, we can examine the consistency and variation of the recommended rhymes.

The final section of the paper presents a case study in the application of these scripts to literary texts, an analysis of the rhyme patterns used in the 1274 poems included in Edmund Clarence Stedman's *A Victorian Anthology 1837-1895* (1895), as a sample dataset of poetry produced during the time when these rhyme dictionaries were circulating and when these rhyme theories were debated. Examining the frequency of different rhyme patterns and the vocabulary of rhyme common in Victorian poetry opens up new paths for analyzing rhyme practice, rhyme theory, and the lexical fields generated by the use of rhyme. This project thus contributes to current work in nineteenth-century studies and historical poetics by computationally analyzing the theory offered by rhyme dictionaries with the actual practices of nineteenth-century poetry.

From Keyword Search To Discourse Mining - The Meaning Of Scientific Management In Dutch Vocabulary, 1900-1940

Pim Huijnen
p.huijnen@uu.nl
Utrecht University, Netherlands, The

Juliette Lonij
juliette.lonij@kb.nl
Koninklijke Bibliotheek, The Hague, Netherlands, The

In this paper we present a technique to enable the historical study of ideas instead of words. It aimed at assisting humanities scholars in overcoming the limitations of traditional keyword searching by making use of context-specific dictionaries. The elaboration of this technique was the result of a successful collaboration between the History Department of Utrecht University (UU) and the Research Department of the Koninklijke Bibliotheek, National Library of the Netherlands (KB), executed by the authors of this paper during Huijnen's period as Researcher-in-residence at the KB in 2015.

The aim of this collaborative project was twofold: first, to create a method for dictionary extraction from a representative text corpus, based on existing methods and algorithms. Second, to find a way of executing dictionary searches in the KB's digitized newspaper archive and visualizing the results. Both components of the project were tested and evaluated by means of a case study on the impact of American scientific management theories in the Dutch public sphere during the first half of the 20th Century. Using the approach described here, we were able to discover and analyze shifts in the way the modernization of Dutch business and economy was discussed during this period. We would not have been able to achieve the same results by means of traditional historical scholarship alone.

Historical newspapers have traditionally been popular sources to study public mentalities and collective cultures within historical scholarship. At the same time, they have been known as notoriously time-consuming and complex to analyze. The recent digitization of newspapers and the use of computers to gain access to the growing mass of digital corpora of historical news media are altering the historian's heuristic process in fundamental ways.

The large digitization project the Dutch National Library currently runs can illustrate this. Until now, the KB has made publicly available over 80 million historical newspaper articles from the last four centuries. Researchers (as well as the wider public) are able to do full-text searches in the entire repository of articles through the KB's own online search interface Delpher (http://www.delpher.nl/kranten). Instead of manually skimming through a selected numbers of editions or volumes this functionality allows for the searching of particular (strings of) keywords within the entire corpus. As basic as it may seem, full-text searching completely overturns the way in which historians are used to approach newspapers. Instead of the successive top-down selections historians traditionally made in order to gradually isolate potentially interesting material, keyword searching treats the corpus as a singular bag of words and, therefore, enables researchers to immediately dive into the texts that meet their search criteria (Nicholson, 2013).

At the same time, keyword searching has some serious shortcomings for the use in (cultural) historical research. Historians commonly work with texts, but are rarely interested in language per se. Rather, they use written or spoken sources (be it correspondence, literature, diaries, or news media) to gain access to past cultures, ideas, or mentalities. The things that historians are mostly interested in, are often not made explicit (e.g. the Enlightenment attitude, generational conflicts) and difficult to abstract into singular keywords (modernity, secularization). Doing historical research with keyword searching is like painting a canvas using felt-tip pens: it loses every inch of subtlety.

We have successfully developed a technique of dictionary extraction and searching to address this problem. The use of dictionaries is able to bring greater subtlety and diversity into digital historical scholarship. The more elaborate these dictionaries are, the more they overcome the contingency that comes with the use of singular keywords in search strategies. Several research projects that have incorporated the use of highly domain- and time-specific word-lists ('dictionaries'), have already shown this. Text classification algorithms, for example, have helped find the most obvious indicator words for articles about strikes in the Dutch newspaper corpus (Van den Hoven et al., 2010). Implicit dictionaries based upon the MALLET (http://mallet.cs.umass.edu) package's topic modeling functionality has assisted in finding Darwinian motives in Danish literature (Tangherlini and Leonard, 2013). Topic modeling was also used in building a neoliberalism dictionary to study Colin Crouch's post-democracy thesis in German historical newspapers (Wiedemann et al., 2013; Wiedemann and Niekler, 2014).

From the wide variety of techniques scholars have developed to build and use dictionaries, this project found most inspiration in the topic modeling-based method of the ePol Projekt (Wiedemann and Niekler, 2014). However, rather than aiming at building an optimal infrastructure for dictionary extraction of our own, based on existing techniques, our project centered around practical usability. We sought to develop a (set of) tool(s) for working with dictionaries tailored to the computational expertise to be expected from, but also the specific needs of professional historians (and humanities scholars in general). One of the aims of the KB's Researcher-in-residence program, in addition, is that resulting tools and techniques are usable by the wider public searching the National Library's databases of historical newspapers, periodicals, and books. Our code is fully open source and can be found on GitHub (https://github.com/jlonij/keyword_generator). The ways in which we have tried to meet the specific demands this posed, can, in our view, be seen as exemplary for any Digital Humanities project aimed not at building highly specialized tools for individual projects, but at combining scholarly standards with the goal of generic usability.

There are a number of ways we have accounted for the targeted user groups in the development of our dictionary extraction and search techniques. On the one hand, for example, we aimed at agility and flexibility at the expense of the deployment of exhaustive computational means. Our algorithm is able to extract a dictionary of flexible length from a given source input of text files within minutes. Because the technique is intended for exploratory use, it is essential that iterations and experimentations are stimulated. Requiring too many preprocessing steps or demanding too much time would be counterproductive.

On the other hand, meeting the demands of tool criticism was crucial in every step of this project. Therefore, the risk of blackboxing was avoided wherever we could, while at the same time granting the user-expert as much control as possible. By varying the command, users decide over the segmentation of the source corpus, the number of topics to be generated, the number of words to be contained per topic, as well as the number of dictionary words required. Moreover, users may flexibly choose between Gensim's (https://radimrehurek.com/gensim) and MALLET's implementation of LDA, as well as a straightforward tf-idf implementation. When making use of one of the topic modeling packages, users are, just before the process of dictionary generation, given the option of excluding any number of (irrelevant) topics of choice from the equation.

An evaluation in terms of generic precision and recall for any of the variables is, in our view, contradictory to the principle of flexibility. Instead, we evaluated and improved the dictionary extraction by comparing automatically generated dictionaries with ones that were built manually, based on domain knowledge. Comparing the results of searches with different dictionaries in the KB's digitized newspaper archive was used as an additional evaluation method: dictionaries could be compared in terms of the ranking of some key articles about a particular topic, since the archive's Solr (http://lucene.apache.org/solr) search engine scores the results of an OR-query (the search string, in which we expressed the dictionaries) on the basis of the number of times query words appear in an article, amongst other things. The case study that was used to test, evaluate, and apply the tools and techniques under development was the impact of American scientific management ideas in the Dutch public media before WWII.

On the basis of this case study we would in our presentation like to show how our implementation of dictionary extraction, search, and visualization can assist the scholarly historical study of digital corpora in general. By visualizing the search results from different dictionaries we are able to show shifting discourses in historical news media. Plotting the number of articles containing a user-specified number of words from any given dictionary, we can present trends in discourse-specific vocabulary usage over time. Whereas existing historiography, for example, suggests a continuing use of scientific management vocabulary in the Netherlands since its introduction in the 1910s, our project presents a more differentiated picture. Dictionary searches in the KB's newspaper corpus show how the use of words in public media connected to the sphere of scientific management (based on context- specific literature) waned after the WWII and how they made room for a new vocabulary belonging to a new era.

At the same time, this case study illustrates how digital techniques like ours bring about conceptual innovations in the study of history. After all, our case study shows that (combinations of) ordinary words (in this instance, for example, 'time', 'work', or 'supervision') are more distinguishing to trace discursive discontinuities than the 'big' words (like 'taylorism' or 'neoliberalism') that historians traditionally have focused on.

Second World War on the Semantic Web

Data about wars is typically heterogeneous, distributed in the data silos of the fighting parties, multilingual, and often controversial depending on the political point of view. It is therefore hard for the historians to get a global picture of what has actually happened, to whom, where, when, and how. We argue that Semantic Web and Linked Data technologies are a very promising approach for modeling, harmonizing, and aggregating data about war history. Our goal is to make it possible, for both historians and laymen, to study history in a contextualized way where linked datasets enrich each other. The paper presents the in-use WarSampo[1] system, where massive collections of heterogeneous data about the (Finnish) history of the Second World War are harmonized using an event-based approach, and provided as a Linked Open Data service for applications to use. As a use case, a semantic portal WarSampo providing six different perspectives to the war based on events is presented.

There are several projects publishing data about the World War I on the web, such as Europeana Collections 1914–1918[2], 1914–1918 Online[3], WW1 Discovery[4], Out of the Trenches[5], CENDARI[6], Muninn[7], and WW1LOD (Mäkelä et al., 2015). War history makes a promising use case for Linked Data because war data is heterogeneous, distributed in different countries and organizations, and written in different languages (Hyvönen, 2012). Using metadata, also different opinions and conflicting information about the war can be represented.

Many websites also publish information about the World War II, the largest global tragedy in human history, such as the World War II Database[8] to name just one. However, such portal data is typically meant for human consumption, and there are only few works that deal with machine readable data about the WW2 for applications to use (Collins et al., 2005; de Boer et al., 2013).

Our work contributes to the related research above by initiating and fostering large scale LOD publication of WW2 data on the web, based on event-based data modeling. The idea is to publish Linked Open data, aggregated from distributed data silos, for Digital Humanities applications to use. In our case study, the data is related to the Finnish Winter War 1939–1940 against the Soviet attack, the Continuation War 1941–1944, where the occupied areas of the Winter War were temporarily regained by Finns, and the Lapland War 1944–1945, where the Finns pushed the German troops away from Lapland.

We first present and discuss the data modeling approach developed for the WarSampo LOD service. After this an application of the data, the WarSampo semantic portal, is presented where events are linked to related resources, such as photos, persons, and historical places. In conclusion, lessons learned are discussed and directions for further research pointed out.

The data service: modelling war events as Linked Data

Dataset	Name	Providing organization	Size
1	Casualties of WW2	National Archives	95,000 death records
2	War diaries	National Archives	26,500 war diaries of army units
3	Photos & films	Defence Forces & Military Museum	160,000 photos & films
4	Kansa taisteli magazine articles	Bonnier & The Assoc. for Military History in Finland	3,360 articles of veteran soldiers
5	Karelian map names	National Land Survey	35,000 places of the annexed Karelia
6	Karelian maps	National Land Survey	47 war time maps of Karelia aligned on modern maps
7	Organization cards	National Archives	War events of ca. 500 army units
8	War time events	Books etc.	11 300 war events in 1939-45

Table 1. Central datasets published and linked in WarSampo.

Data

The project deals initially with the datasets presented in Table 1. The casualties data (1) includes data about the deaths in action during the wars. War diaries (2) are digitized authentic documentations of the army unit actions in the frontiers. Photos and films (3) were taken during the war by the troops of the Defense Forces. The Kansa taisteli magazine (4) was published in 1957–1986; its articles contain mostly memories of the men that fought on the fronts. Karelian places (5) and maps (6) cover the war zone area in pre-war Finland that was finally annexed by the Soviet Union. Organization cards (7), written after the war, document events of military units during the war. War time events (8) extracted from various publications include, e.g., battles and political incidents. The data, over 5 million triples in total, has been transformed into RDF from database dumps, spreadsheets (CSV), and by applying OCR to documents. Named Entity Recognition (NER) techniques were used to link texts to data, e.g., to identify and disambiguate persons and places in the magazine articles and captions of the photos. In addition, new datasets are planned to be included in the system, such as the Finnish Broadcasting Company YLE's audio and film material recorded during the war or related to it ("Living Archive"), and a database of prisoners of war.

Metadata models

CIDOC CRM[9] is used as the harmonizing basis for modeling data, with events providing the semantic glue for data linking (Doerr, 2003). Our data model for WW1, presented in (Mäkelä et al., 2015), is used as the metadata model to start with. The model and data is documented at the data service[10].

Domain ontologies

The data is annotated using a set of domain ontologies, including: 1) an ontology of the troops and their hierarchies, 2) persons with their ranks and roles, 3) place ontology of historical places, 4) event ontology of battles, politics, and other war time incidents, 5) an ontology of time periods, and 6) a subject matter ontology. Ontologies on objects such as weapons, aircraft, and vessels remain topics of possible future work.

All WarSampo datasets are available as Linked Open Data (LOD) at the "7-star" Linked Data Finland service[11] (Hyvönen et al., 2014), based on Fuseki[12] establishing the SPARQL endpoint, and with a Varnish Cache[13] frontend for dereferencing URIs.

Application: perspectives to war history

The idea of the WarSampo portal is to provide a variety of different perspectives to war history. There are six perspectives available: Events, Persons, Army Units, Places, Kansa taisteli Magazine Articles, and Casualties (Hyvönen et al., 2016). The idea is that the perspectives enrich each other based on data linking.

Figure 1 illustrates the WarSampo Events perspective application to the WarSampo data. Events are displayed on a map, (a) in Fig. 1, and on a timeline (b) that shows here some events of the Winter War. When the user clicks on an event, it is highlighted (c), and the historical place, time span, type, and description for the selected event are displayed (d). Photographs related to the event (e) are also shown. The photographs are linked to events based on location and time. Furthermore, information about casualties during the time span visible on the timeline is shown alongside the event description (f), and the map (a) features a heatmap layer for a visualization of these deaths.

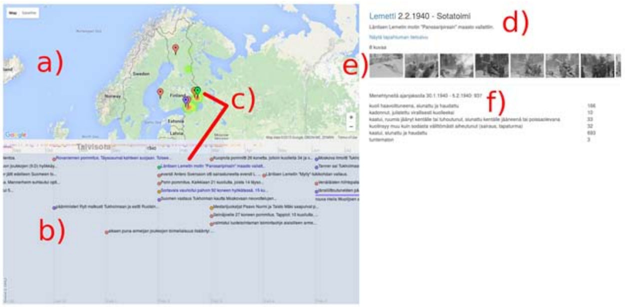

Figure 1. Event perspective featuring a timeline and a map.

The events can also be found and visualized through other perspectives. For example, in the Army Units perspective, the events in which a unit participated can be viewed on maps and in time, providing a kind of graphical activity summary of the unit. In the casualties perspective, military units of the dead soldiers are known, making it possible to sort out and visualize the personal war history of the casualties on historical maps that come from a yet another dataset in WarSampo.

The WarSampo semantic portal[14] was published Nov 27, 2015 at and has had tens of thousands of users. It is implemented solely on the SPARQL endpoint of the WarSampo LOD data service.

Discussion

Our first experiments, as illustrated in Section 3, suggest that heterogeneous datasets of war history really can be interlinked with each other through events in ways that provide useful insights for the historians. We have also learned that even in the rural northern parts of Europe, massive amounts of WW2 data can be found. We have initially dealt with tens of thousands of people killed in action. However, there is also data available about hundreds of thousands of soldiers who survived the war. In addition to historians, WarSampo data is very interesting to the laymen, too: every soldier's history is of interest at least to, e.g., his/her relatives. Managing the data, and providing it for different user groups, suggests serious challenges when dealing with, e.g., the war in the central parts of Europe, where the amount of data is orders of magnitude larger than in Finland, multilingual, and distributed in different countries. For example, solving entity resolution problems regarding historical place names and person names can be hard. However, it seems that Linked Data is a promising way to tackle these challenges.

Our work[15] is funded by the Ministry of Education and Culture and Finnish Cultural Foundation. Wikidata Finland project financed the alignment of the historical maps in WarSampo.

Introduction

Dealing with historical geographic places (Southall et al., 2011) is important in museums, libraries, archives, and media companies, but challenging: 1) Historical places change in time. 2) It is difficult to understand the spatial and temporal context of the places. 3) Historical place names can often be seen only on historical maps. 4) Historical geographic data is scattered across multiple sources that can be incomplete and/or mutually conflicting. 5) To preserve semantic interoperability across Cultural Heritage (CH) datasets, there is a need to find out how the same place is represented in different repositories. 6) If a place is nowhere to be found—a situation quite common—there should be a mechanism to suggest and share new place concepts among the CH community.

Dataset	Original Source	Place type	Size	Description
Finnish Municipalities 1939–44	National Archives of Finland	Municipality	612	Finnish National Archives research project "Finland, prisoners of war and extraditions 1939–1955" produced a map application, from where the war time municipalities were obtained.
Karelian map names 1922–44	Jyrki Tiittanen / National Land Survey of Finland	village, house, etc.	34 938	Historical places in the Karelia region of Finland and Russia.
Finnish Spatio-Temporal Ontology	SeCo	Municipality	1 261	A spatio-temporal ontology of Finnish municipalities.
Finnish Geographic Names Registry	National Land Survey of Finland	61 place types	800 000	The place name dataset comprises natural and cultural names whose spelling has been checked by the Institute for the Languages of Finland.
The Getty Thesaurus of Geographic Names	J. Paul Getty Trust	1800 place types	2 156 896	TGN is a structured vocabulary containing names and other information about places. Names for a place may include names in the vernacular language, English, other languages, historical names, names and in natural order and inverted order. Among these names, one is flagged as the preferred name.
Senate atlas	National Archives of Finland	Map	414	Series of maps of Southern Finland drawn by the Russian Army topographic troops in the end of the 19th and the beginning of the 20th centuries in scale 1:21 000.
Karelian maps	National Land Survey of Finland	Map	47	The National Board of Survey and Topografikunta produced four-colour topographic maps in scale 1:100 000 during 1928–1951.

Table 1. Datasets connected to Hipla.fi

To tackle these challenges, we have developed a Linked Open Data brokering service model HIPLA for using and maintaining historical place gazetteers and maps based on distributed SPARQL endpoints. Using Linked Data technologies, HIPLA provides a common search interface to historical geographic data like place names with coordinates and historical maps. Contextual information, e.g. historical events or photographs related to a geographic location, is provided to help the user to gain a deeper understanding of the historical place. HIPLA also serves as a sustainable and evolving repository of historical places by implementing Dynamic Ontology Services for Evolving Ontologies (Hyvönen et al., 2015). Cultural Heritage organizations can connect their legacy cataloguing systems to HIPLA using a widget or an API in the same vain as in the ONKI ontology service (Tuominen et al., 2009).

The general HIPLA model is being implemented to create and manage a national level gazetteer and map service Hipla.fi. Hipla.fi is based on four Finnish datasets in SPARQL endpoints totalling some 840,000 geocoded places, on 450 historical maps from two atlas series aligned on modern maps, and on the Getty Thesaurus of Geographic Names (TGN) SPARQL endpoint in the US.

This paper first presents Hipla.fi's user groups (section 2) and the end-user interface (section 3), complementing the crowdsourcing view to the system (Hyvönen et al., 2015). Then the system architecture is outlined (section 4), and finally lessons learned are discussed (section 5). Hipla.fi is available at http://hipla.fi.

HIPLA user groups

The audiences of HIPLA are 1) collaborative geo-ontology developers, 2) cataloguers of historical content, 3) information searchers, and 4) application developers. For group 1 HIPLA facilitates a sustainable model for aggregating historical place names in shared data repositories as time goes by. For groups 2 and 3 HIPLA provides a combination of historical and contemporary maps, linked contextual data, and semantic federated search to find and understand historical places. User group 4 can utilize distributed SPARQL endpoints, URI resolving services, and an autocompletion text search widget.

Finding and understanding historical places in context

Federated search

Our first focus in developing Hipla.fi has been on modeling, storing, and searching Finnish place names in multiple SPARQL endpoints, and on displaying them on historical and contemporary maps. The datasets used are stored in separate RDF graphs, which makes it possible to offer dynamic selection of data sources for the user interface or external data consumers. Table 1 presents the datasets currently connected to Hipla.fi, most of them available on the Linked Data Finland platform[1] (Hyvönen et al., 2014).

Figure 1 depicts the Hipla.fi user interface. For finding, disambiguating, and examining historical places, there is an autocompletion search input field (a). Place names can be searched from multiple SPARQL endpoints at the same time based on the user's choice (checkboxes above (b)) with the following functionalities:

1. Hovering the cursor over the search results shows where the places are: the corresponding marker bounces on the map.

2. A click on a search result label opens the info window of the place, showing its context (c).

3. A click of the menu button on a result row (a) shows the place data in a Linked Data browser for investigating the data in detail.

Map-based multiple dataset browsing

If the user does not know the name of the place, but has some idea where the place is located, she can pan and zoom the map view to the area. After this it's possible to use the "View all places on current map view" button. This way places from different datasets connected to Hipla.fi are rendered on the map, and the user can check if the place exists already in some of the datasets, and compare places in different gazetteers.

Fetch historical maps

The "Historical maps" tab (Figure 1 (b)) provides a list of old maps that intersect the current map view. The map images are fetched from the Hipla.fi's Map Warper service[2] and their metadata is queried with SPARQL from the map RDF graph of the HIPLA service. Each map has a checkbox for rendering the map on the main map view, a thumbnail image, information about map series, scale and type, and a link to view the map in Map Warper. All map series are visible by default, but with the series button it is possible to filter the maps by their series. Once one or more historical maps have been selected with the checkboxes, the opacity of the historical maps can be controlled with the slider that is located on the top right corner of the map. If the user pans or zooms the main map view, clicking the "Refresh map list" button updates the map list.

View contextual data

When the user selects a place, contextual data (Figure 1 (c)) is provided for connecting the place to other relevant data sources. This functionality is first piloted with the

spatial datasets of the WarSampo portal (Hyvönen et al., 2016), providing, e.g. 160 000 historical photos of the Second World War related to the places, and a timeline of historical events. In addition to this, the spatial perspective[3] of the WarSampo portal uses customized Hipla.fi user interface elements to visualize wartime places and their connections to other WarSampo datasets.

Extend with new gazetteers

The HIPLA model is adaptable to various geographic data models and both contemporary and historical gazetteers. The only requirement is that the gazetteer is published in a SPARQL endpoint. Because there is no standard for how to express the temporal extent of spatial data, the spatial dimension of gazetteer data can be utilized in the user interface (e.g. when disambiguating place names) by individual configurations.

System architecture

Figure 2 depicts the components of the HIPLA model. The Hipla.fi prototype is implemented using the Linked Data Finland platform (Hyvönen et al., 2014), based on Fuseki[4] with a Varnish[5] front end for serving the linked data. The end-user interface of Hipla.fi is a lightweight HTML5 single page map application, which provides access to multiple data sources with SPARQL queries and autocomplete search functionality using typeahead.js[6]. Embedded Google Maps view is used to visualize historical places. Hipla.fi's Map Warper is an instance of the open source Map Warper tool of the New York Public Library for georectifying old maps on top of modern ones.

Related work and discussion

HIPLA is an ontology library service (d'Aguin and Noy, 2012) for historical places. Complementing traditional gazetteers, HIPLA not only publishes the data for humans but also for machines using the SPARQL endpoint API. In addition, historical maps and contextual linked data about the places are provided.

Thesauri of historical places, published as Linked Data, include the Getty TGN[7] of some 1.5 million records, 'Pelagios: Enable Linked Ancient Geodata In Open Systems'[8], and Pleiades[9]. Pelagios and Pleiades are based on crowdsourcing volunteers' work in ontology development. The novelty of HIPLA from a user interface viewpoint lays in the idea of combining multiple geographic data sources, offering a unified view for examining and comparing them. In addition, HIPLA makes it possible to crowdsource the creation of the gazetteer to cataloguers of Cultural Heritage content, as a side effect of their daily work, as discussed in Hyvönen et al., 2015.

The Historical Gazetteer of England's Place-names[10] is a service of over 4 million names that can be searched and viewed on modern maps as well as on historical ones. HIPLA has a similar local flavor focusing on places in Finland, but is based on Linked Open Data. OldMapsOnline[11] is a search engine for finding historical maps covering a given area. In contrast to the systems above, HIPLA includes a map service for aligning and viewing georectified historical maps, as in the New York Public Library's Chronology of Place gazetteer[12]. HIPLA also publishes the metadata of the historical maps as Linked Open Data and the dynamic and transparent selection of data sources makes it possible to understand the origins of the data.

Our research was supported by the Finnish Cultural Foundation and Wikidata Finland.

Wired!: Collaborative Teaching & Critical Digital Making In An Art History Classroom

Hannah L. Jacobs
hannahlj@gmail.com
Wired! Lab for digital art history & visual culture, Duke University, United States of America

The Wired! Lab for digital art history and visual culture at Duke University comprises a group of faculty, staff, and students engaged in applications of visualization methods to studies of material culture and art, architectural, and urban histories. Members of the lab collaborate to develop critical digital research employing 3D modeling, mapping, and database tools. Art historians and digital humanists work together to integrate both digital and art historical methodologies in lab courses and projects.

In the Wired! classroom's collaborative teaching model, a digital humanist takes on a significant role in both course planning and implementation. She works with instructors, graduate assistants, and librarians to redesign syllabi and assignments for preexisting departmental courses that incorporate not only digital tools but also critical methods. She then attends class meetings to familiarize herself with courses' art historical content; she delivers workshops on digital concepts and tools; and she works with instructors and students to establish project workflows, to troubleshoot technical issues, and to critique student work. For students, this kind of collaboration can provide opportunities to make intellectual connections across two modes of inquiry as they apply digital methodologies to art historical topics. For instructors, this collaboration can enrich pedagogical practice as digital methods present different possibilities for student engagement.

While some educators have focused on pedagogical challenges such as, "How does one teach students the digital tools to address a wide variety of projects without neglecting traditional discipline-specific issues of research formulation and data collection?", (Johanson and Sullivan et al., 2012) the Wired! Lab's digital pedagogy focuses on only the digital knowledge required for a specific topic. This approach ensures that students intentionally engage art historical content via digital methods, prioritizing quality of digital interventions over quantity while also addressing very practical issues of scalability within a disciplinary context.

In this presentation, I will examine two cases in which Wired! Lab instructors and a digital humanist collaborated to design and implement project-based undergraduate courses. These examples will demonstrate how the different teaching teams worked in tandem to create these learning experiences and will discuss benefits and challenges of these pedagogical collaborations. I will also situate the Wired! Lab's pedagogical work within the larger digital humanities and digital art history ecosystem.

Introduction to Art History

In Spring 2015, Professor Caroline Bruzelius implemented a team-based teaching approach for her Introduction to Art History course. Together, we worked with a graduate assistant and librarian to redesign the survey course and student projects. We all attended class meetings, we each taught aspects of the course, and we assessed student projects as a group. Combining our variant expertise, we created a course in which students employed a digital humanities approach to performing art historical critical analyses of spatial, temporal, and cultural relationships that influenced the movement of raw materials and cultural objects across ancient and medieval Western and Mediterranean societies. The digital tools we chose to use in the course were Neatline, a spatiotemporal exhibit builder, and Omeka, a collection management system in which Neatline operates. We implemented Neatline first for visualizing the syllabus and second for developing students' visual narratives concerning specific pre-modern art historical objects and materials.

Fig. 1. Neatline syllabus for Introduction to Art History

The interactive visual syllabus (Fig. 1) introduces students to the course narrative: its units and lectures are shown in time and space accompanied by contextual maps, specific geospatial points of reference, and other relevant multimedia including hyperlinks to important objects' museum pages, lecture slides, and supplementary videos. The interactive visual syllabus makes explicit temporal, spatial, and cultural relationships that effected the development of art practices across pre-modern societies. Presenting the syllabus in Neatline also familiarized students with Neatline's affordances and interface in preparation for creating their own Neatline projects, in which they used critical understandings of spatiotemporal narrative to develop cohesive art historical arguments concerning particular pre-modern objects, their making processes, political influences, and economic and environmental impacts.

Visualizing Venetian Art

Dr. Kristin Lanzoni's upper level course on early modern Venetian art also employed a collaborative teaching model. She and I worked together to develop a syllabus and project in which students studied course material through processes of visualization. Students spent the semester not only learning about Venetian art, history, and culture but also working together to model a Venetian palace no longer extant and to design an immersive visual narrative about the palace's political and cultural significance (Fig. 2). The students worked with tools ranging from Adobe Photoshop to SketchUp to Unity3D to visualize the palace.

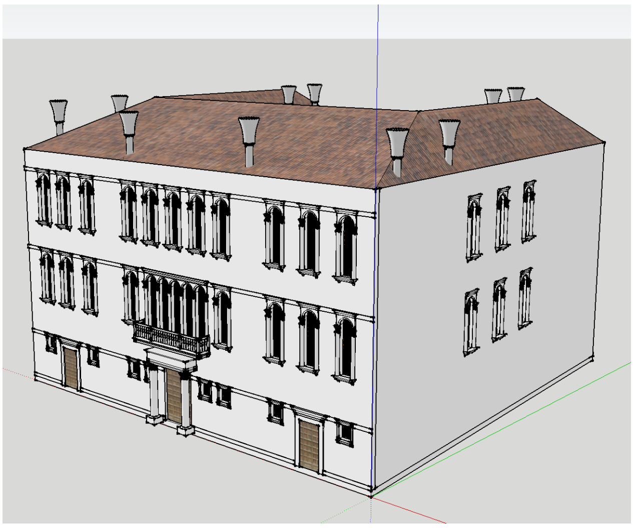

Fig. 2. Model of a Venetian palazzo created by students in Visualizing Venetian Art

As the semester progressed, Dr. Lanzoni and I worked closely with the students to troubleshoot a number of problems that arose as students strove to translate historical evidence into an historically informed 3D model. These issues stemmed from both primary sources, which give conflicting visual evidence for the palace's scale and appearance, and digital tools, which present challenges for modeling non-rectilinear structures and force compromises with regard to levels of detail. Students had to make joint decisions regarding model and narrative designs based on both historical research and the digital tools' affordances and limitations.

In both courses, students gained understandings of art historical topics through digital visualization processes. Wired! Lab teaching teams facilitate these types of learning experiences by combining their expertise in course design and implementation. While in the survey course, students were asked to create individual visual narrative projects, guided by an art historian, a graduate student, a librarian, and a digital humanist, the students in Visualizing Venetian Art worked together on a single topic from which their learning about early modern Venice radiated outward. While some digitally-inflected Wired! courses ask students to work individually, other courses model collaboration not only in the teaching but also in the learning. Overall, the majority of Wired! courses are not "Introduction to Digital Humanities" but rather art history courses redeveloped to integrate specific digital approaches that directly support course-specific content and disciplinary methods. The integration of a digital humanist in Wired! art history courses ensures that students' digital projects are informed not only by disciplinary knowledge but also by critical approaches to digital methodologies.

Motivation

Digital literary studies have embraced social network analysis as a powerful tool to formalize and analyze social networks in literary texts (Elson et al., 2010b, Hettinger et al., 2015). Extracting networks automatically from texts is still a challenging task with the following steps: identification of all character references (which is not identical to named entity recognition), coreference resolution (CR) and a final step defining the amount of interaction between the characters, for example by the amount of verbal exchanges or the co-occurrence in a text segment. In the following we will discuss different ways to solve this task using an annotated corpus of German novels. One of the related problems is the definition of an evaluation metric which connects the computational problem to literary concepts like "main characters" and "character constellation". Our goal is to find the best way to capture the intuition behind these literary concepts in a formalized procedure. For this purpose we introduce a new way of evaluating automatically extracted networks. We make use of carefully created and revised summaries of German novels, provided by Kindler Literary Lexicon Online[1]. Besides, this work is to the best of our knowledge the first to compare different methods of creating and evaluating automatically extracted character networks.

Related Work

Social Network Analysis (SNA) is a well-established discipline, e.g. in the social sciences, which literary studies can apply for the analysis of character networks (Trilcke, 2013). Approaches to automatic extraction of SNs from literary text using NLP techniques have been manifold.

Most works start by identifying entities in the text and connect them via CR. Park et al. (Park et al., 2013) extract SNs based on proximity of names in the text and define a kernel function to distinguish protagonists from less important characters. Celikyilmaz et al. (Celikyilmaz et al., 2010) use an unsupervised actor-topic-model to create SNs from narratives. Elson et al. associate speakers with direct speech passages in novels (Elson et al., 2010a) and create SNs from the dialogues to validate literary hypotheses like whether the amount of dialogues is inversely proportional to the amount of characters that appear in the novel (Elson et al., 2010b).

Moreover, three end-to-end systems for the extraction and visualization of SNs from English literary texts already exist: PLOS (Waumans et al., 2015) works similarly to the approach by Elson et al. by creating networks from dialogue interactions. He et al. use their own speaker identification system to detect family connections between entities (He et al., 2013). SINNET by Agarwal et al. (Agarwal et al., 2013b) finds different types of directed events in a text and creates a directed SN from these events.

Data

This work is based on a corpus of 452 German novels from the TextGrid Digital Library[2]. Expert plot summaries from Kindlers Literary Lexicon Online are available for 215 of these novels. As the following experiments are partly based on direct speech, we analysed the novels with regard to the direct speech they contain. We selected 58 novels with the highest possible amount of direct speech for which there was also a summary on hand.

Those 58 novels have been split into tokens and sentences with OpenNLP[3], POS-tagged and lemmatized by the TreeTagger (Schmid, 1995), further processed by the RFTagger (Schmid and Laws, 2008) and the morphological tagger from MATE-Tools[4]. Additionally, we use the dependency parser by Bohnet (Bohnet and Kuhn, 2012) to analyze the sentence structure. Named Entity Recognition is done with the tool by Jannidis et al. (Jannidis et al., 2015) and the rule-based component by Krug et al. is used for CR. The detection of the speaker and the addressee for each direct speech passage is also part of the CR (Krug et al., 2015). In the summaries from Kindler, Named Entities and Coreferences have been manually labeled by two annotators.

Methods

We use four different methods to identify the most central characters in the novels and evaluate their quality by comparison with the characters occurring in the Kindler summaries.

The first method relies only on the frequencies of the characters in the text: the most central characters are those appearing most often in the novel (coreferences resolved). The second methods counts only those entities that have at least once been detected as speaker or addressee of direct speech. The other methods each construct a different type of social network and make use of SNA to find the most central characters. The first network is based on co-occurrences of characters in the same window of text: an edge between two characters exists if they are mentioned in the same paragraph and the weight of the edge is the number of paragraphs in which this is the case. The second network is created using the dialogue structure of the text. For each direct speech for which both speaker and addressee could be detected, an edge is drawn between those two. Longer dialogues consequently lead to higher edge weights between the participants. Thus, both network types are undirected and weighted. Examples for networks that were created with those methods are shown in Figure 1.

To identify the most central characters we use the weighted degree of each node (i.e. the sum of the weights of all edges incident to a node) in decreasing order. This metric is most intuitively interpretable with regard to the importance of characters in a fictional world.

In the following paragraph, we compare the rankings with the summaries and discuss possible sources of error and their influence on the results.

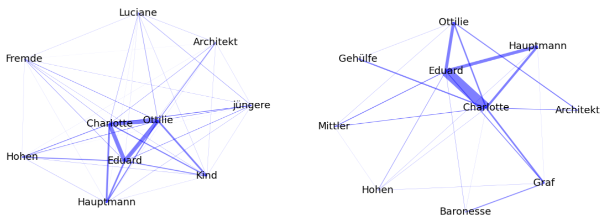

Figure 1: Automatically extracted SNs for Goethes: "Die Wahlverwandtschaften". The left picture shows the ten most connected characters when an interaction is created for a common appearance in a paragraph. The right picture shows the corresponding network when only direct speech is used as interactions.

Evaluation

Evaluating automatically extracted SNs is not a trivial task and there are no established practices. Elson et al. (Elson et al., 2010b) validate literary hypotheses, (Park et al., 2013) and (Waumans et al., 2015) analyze typical distributions that they expect of literary character networks. Agarwal et al. (Agarwal et al., 2013a) evaluate a machine-generated network of *Alice in Wonderland* against a manually conceived version by comparing typical SNA metrics like different centrality measures.

In this work, we want to compare the methods for identifying the most central characters as described in section 4. As a gold standard, we use the manually annotated Kindler summaries. The generated rankings for each novel, as well as the rankings from the summaries are first cleaned up so that only real names remain.

Our evaluation is based on the assumption that a summary contains all important characters. Since those summaries are carefully created and even revised by experts we propose that this assumption holds. For each summary, we create a ranking of the mentioned characters by [a] the number of occurrences (gold_count from here) and [b] the order of occurrence (gold_order from here). We relax the ranking assumption and only select the top 5 (top 10) figures from the summary rankings and compare them against the top 5 (top 10) characters in the automatically obtained rankings for the novels without respecting the particular ordering. If the name of a character from the gold standard is exactly found in an automatic ranking, there is a match. Table 1 shows the resulting correspondences with the two gold rankings, averaged over all 58 novels.

Results and Discussion

Table 1 displays first results for the identification of main characters in novels. Nevertheless, none of the methods yields very high scores for this kind of evaluation. Interestingly, the simpler approaches seem to be suited well for the task.

The low values can be explained by a variety of errors which can be grouped in three categories. Firstly, a character might not be among the top 10 of the relaxed ranking from Kindler. If automatic matches to lower positions in the ranking are allowed, the score in Table 2 can be reached.

Algorithm	DSN_Max	PN_Max	DSC_Max	Count_Max
gold_count	55.1%	56.6%	53.8%	57.3%
gold_order	58.0%	64.7%	55.1%	64.7%

Table 2: Accuracy of the matching, independent of the position in the automatic ranking

Algorithm	DSN_5	DSN_10	PN_5	PN_10	DSC_5	DSC_10	Count_5	Count_10
gold_count	40.5%	50.2%	39.3%	51.6%	38.9%	49.0%	40.1%	52.0%
gold_order	38.6%	45.1%	41.3%	48.6%	37.5%	45.3%	41.2%	48.5%

Algorithm	DSN_5	DSN_10	PN_5	PN_10	DSC_5	DSC_10	Count_5	Count_10
gold_count	40.5%	50.2%	39.3%	51.6%	38.9%	49.0%	40.1%	52.0%
gold_order	38.6%	45.1%	41.3%	48.6%	37.5%	45.3%	41.2%	48.5%

Table 1: Overview of the successfully matched entities between the two relaxed rankings from the summaries (gold_count, gold_order) and the generated relaxed rankings for the top 5 and the top 10 entities (DSN= Direct Speech Network; PN = Paragraph Network; DSC = Direct Speech Count; Count = simple frequency)

We can see that approximately 60% of the characters can now be matched unambiguously.

The highest percentage of errors is due to incorrectly resolved coreferences. Clusters of the same character that have not been merged during the CR do not only create redundant elements in the rankings, wrongly merged clusters also mean, that one character can never be matched correctly. If coreference errors are ignored, the results are as shown in table 3.

Algorithm	DSN_ Maxcr	PN_ Maxcr	DSC_ Maxcr	Count_ Maxcr
gold_ count	79.7%	81.2%	78.8%	81.2%
gold_order	58.6%	65.3%	55.6%	65.3%

Table 3: Accuracy of the matching, independent of the position in the automatic ranking, CR errors ignored

The third error type of originates from different spellings of the same name which make an unambiguous matching very difficult (e.g. "Amanzéi" vs. "Amanzei", "Lenore" vs. "Leonore"). Those kinds of errors are caused by different encodings, since the novels and the summaries originate from separate sources. Further reasons which render the matching more difficult or impossible respectively are missing or incorrectly detected Named Entities. The error analysis shows that future improvements are especially needed for the CR or procedures which avoid CR, since those have a better chance to succeed.

Conclusion

In this paper we showed work in progress to extract SNs from German novels. We compared four different approaches to the identification of central characters and evaluated against manually annotated summaries. Two presented methods rely on direct speech, the other methods can be applied to any novel. At least for this task, the more challenging approaches of determining speaker and addressee of direct speech and creating networks from the resulting interactions did score slightly lower than the simpler approaches. To improve the results, future work especially needs to be invested into the creation of a less error-prone CR system.

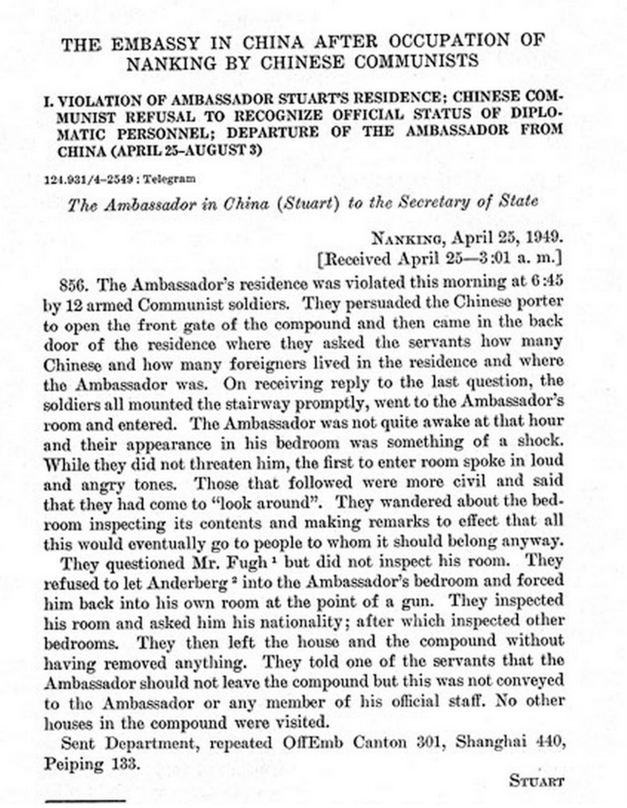
Diplomatic History by DataUnderstanding Cold War Foreign Policy Ideology using Networks and NLP

Eun Seo Jo
eunseo@stanford.edu
Stanford, United States of America

What is diplomatic culture or "rhetoric" and can we measure it?

This project is an attempt to understand quantitatively the language and structure of U.S. diplomacy as a bureaucratic institution through analysis of a large corpus of diplomatic papers. Since the "cultural turn" of History in the late twentieth century historians have produced cultural interpretations of American diplomacy that highlight gender and racial influences and justifications in diplomatic decision making but there have not been attempts to measure longue duree changes or to quantify them by a standardized measure.[1] This work hopes to fill this gap by introducing a new method of analyzing time-dependent bodies of text. I then apply these methods to a corpus of diplomatic papers to systematically chart changes in concepts and ideology detectable in diplomatic language.

The project has two aims. First, I am designing a method of measuring how a concept, as a fixed variable, evolves through a temporal corpus. Tools such as GloVe and Dynamic Topic Modeling are two existing approaches that can be used to understanding the linguistic shift and topic distributions over time.[2] I argue, however, that these tools are not adequate yet for time-sensitive tasks such as tracing concepts over time and attempt to design a new method optimized for this task. Second, mindful of the particular characteristics of this corpus as a set of diplomatic papers I want to apply the most appropriate methods of analysis and engage with the existing historiography on the Cold War to engage with claims historians have made about Cold War ideology. I am trying to answer: what is "Cold War rhetoric" in high level diplomacy? how did it evolve over the decades? and how did it become propagated within the diplomatic institution? I approach these questions from two methodological angles - networks and NLP.



THE EMBASSY IN CHINA AFTER OCCUPATION OF
NANKING BY CHINESE COMMUNISTS

I. VIOLATION OF AMBASSADOR STUART'S RESIDENCE; CHINESE COMMUNIST REFUSAL TO RECOGNIZE OFFICIAL STATUS OF DIPLOMATIC PERSONNEL; DEPARTURE OF THE AMBASSADOR FROM CHINA (APRIL 25–AUGUST 3)

124.931/4–2549 : Telegram

The Ambassador in China (Stuart) to the Secretary of State

NANKING, April 25, 1949.
[Received April 25—3:01 a. m.]

856. The Ambassador's residence was violated this morning at 6:45 by 12 armed Communist soldiers. They persuaded the Chinese porter to open the front gate of the compound and then came in the back door of the residence where they asked the servants how many Chinese and how many foreigners lived in the residence and where the Ambassador was. On receiving reply to the last question, the soldiers all mounted the stairway promptly, went to the Ambassador's room and entered. The Ambassador was not quite awake at that hour and their appearance in his bedroom was something of a shock. While they did not threaten him, the first to enter room spoke in loud and angry tones. Those that followed were more civil and said that they had come to "look around". They wandered about the bedroom inspecting its contents and making remarks to effect that all this would eventually go to people to whom it should belong anyway.

They questioned Mr. Fugh[1] but did not inspect his room. They refused to let Anderberg[2] into the Ambassador's bedroom and forced him back into his own room at the point of a gun. They inspected his room and asked him his nationality; after which inspected other bedrooms. They then left the house and the compound without having removed anything. They told one of the servants that the Ambassador should not leave the compound but this was not conveyed to the Ambassador or any member of his official staff. No other houses in the compound were visited.

Sent Department, repeated OffEmb Canton 301, Shanghai 440, Peiping 133.

STUART

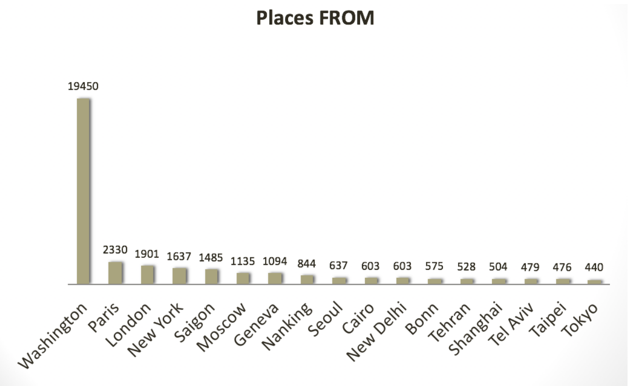
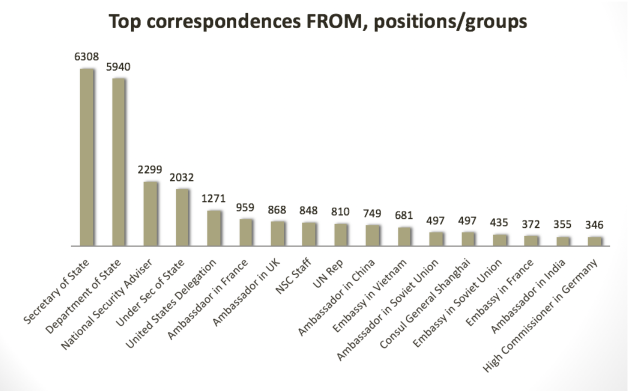
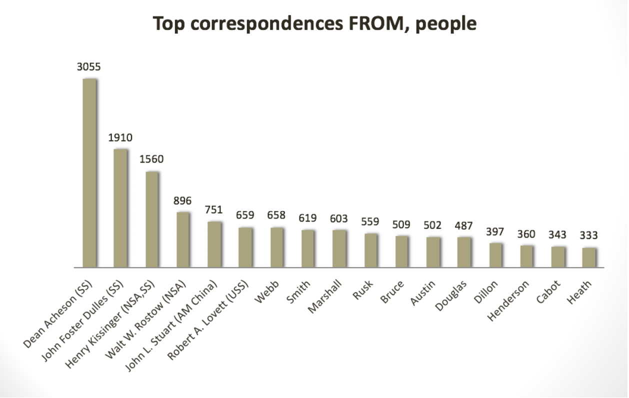


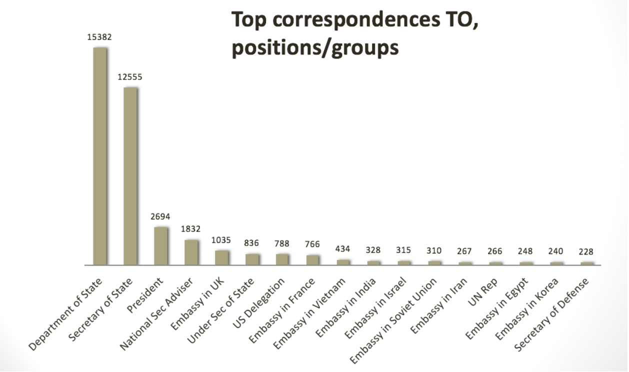
Graph 1A: Location of Correspondence Origin



Graph 1B: Top Correspondences sent from



Graph 1C: Persons that sent the most correspondences



Graph 1D: Top recipients of correspondences

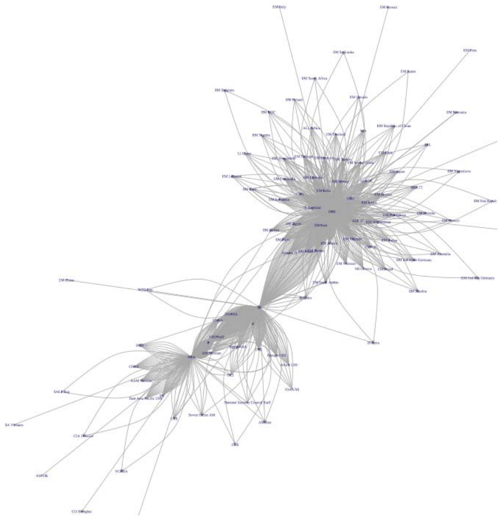
Dataset

The dataset for this analysis is the entire text corpus of the Foreign Relations of the United States (FRUS, 1861-1980), a collection of published declassified diplomatic papers. The FRUS collection is hand-curated by librarians at the Office of the Historian to be a representative and comprehensive sample of American diplomatic history and has been a dependable primary source base for historians and social scientists for decades. The document types include telegrams, airgrams, notes, and memoranda among others. Most documents have accompanying meta-data such as the name of the sender, name of the recipient, location of the sender, and date when applicable. So far, I have focused on a subset of this corpus, consisting of all papers from 1948 to 1980, to analyze the high Cold War era. This subset is also what is available in xml format online with hand-tagged meta-data and reliably edited text. About 92,000 documents were available for analysis. 3 A notable caveat of this work is that the corpus, while presumably a representative sample, is still a sample of non-random selection and could carry both deliberate and unintended biases of the librarians. The FRUS is a corpus that becomes publically accessible upon publication and has a fixed audience of social scholars. There is an inevitable feedback loop where the curators respond to the requests of the prime users of the collection such as adjusting the proportion of the most „useful" types of documents. For instance, as the Vietnam War is a highly contested field of scholarship curators may include a higher ratio of papers surrounding the Vietnam War thus distorting the overall representation of topics by exaggerating the war's significance. This possible limitation is something to keep in mind throughout the analysis of this corpus.

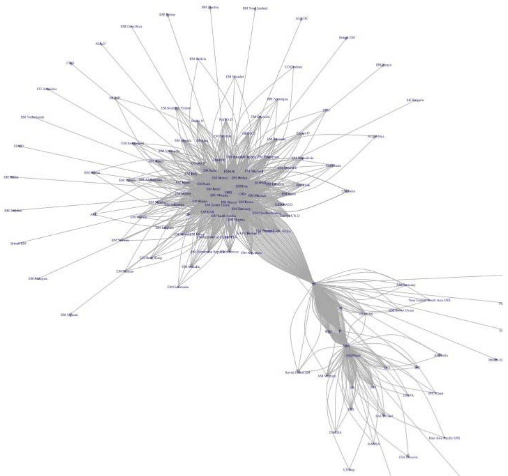
Analysis

Descriptive summaries of the meta-data from the corpus shows several clear distributive patterns. From the total set of all documents 42,000 were correspondences (have to and from agents) from which I parsed all available meta-data (name of sender, name of recipient, location of sender, date) and made inferences on missing data based on historical knowledge. The results show that the Department of State (DOS) as a bureaucratic institution is highly centralized around key actors. Not surprisingly, the prime location of correspondence origin is Washington and its overwhelming predominance indicates that the DOS correspondence system was used for sharing information from the center to the peripheries. Similarly, the top senders of the correspondents were concentrated in high administrative positions – the Secretary of the State (SS), Department of State (DOS) administrative center, and the National Security Advisor (NSA). The individuals that have the highest correspondence authorship are therefore those who have held SS or NSA positions such as Dean Acheson (SS), John Foster Dulles (SS), Henry Kissinger (SS, NSA), and Walt Rostow (NSA). The top recipients of correspondences are also SS and DOS confirming a much bilateral relation between central and peripheral offices.

I then mapped the network structure of correspondences to make the problem of bureacratic "culture" more concrete and visual. In this abstract, I have included images of correspondence networks from two discrete periods – when Kissinger served as Secretary of State from 1973-1977 and when Rostow served as National Security Adviser from 1966-1969. From the maps we can see the overall design of flow of information and transfer of knowledge based on the counts of correspondences and their directions. The maps confirm that indeed the bulk of the correspondence happens bilaterally between top administrative posts and peripheral agents. For instance, the DOS acts as the center point of correspondence for all embassies placed abroad and NSA as that for Washington based lower ranking administrative posts, such as the Under Secretaries of State. Further, two distinct communities emerge within the U.S. diplomatic institution. In both images, one can discern that the DOS and NSA act as distinct and separate focal points while the SS connects the two camps of correspondence and acts as a bridging agent of the two communities.



Graph 2A: Map of correspondence networks during the years Kissinger served as Secretary of State (1973-1977)



Graph 2B: Map of correspondence networks during the years Rostow served as National Security Advisor (1966-1969)

With this structural framework, I am using a combination of NLP methods to trace given "concepts" to see how they have changed in meaning over time. I identify concepts as individual terms, such as „liberty,“ or as a collection of related terms (topics). Word vectors are the most intuitive method of tracing changes in word meanings. Global vectors (GloVe) and other word vector models suppose a time stagnant corpus so I divided my corpus into decade-long chunks and worked with the assumption that language would not change in usage and meaning significantly enough to matter within ten-year time spans. My results comparing the nearing neighbors by Euclidean Distance of GloVe outputs of select concepts show there is a qualitative difference in conceptual meaning in the 1860s and 1950s. For instance, the concept „freedom“ in the nineteenth century was associated with more poetic and romanticized terms such as „triumph“ and „humanity“ whereas a century later it came to be linked with legal and defensive terms such as „right“ and „safeguard.“ Historians would contextualize this phenomenon in the American Civil War and the Civil Rights respectively. Then a question arises: Were diplomatic agents using terms that reflect the popularized lingo of their time or were their propagating it themselves? Who, in the DOS, initiated the usage of these concepts in such ways? Can we use the networks mapped above for to interpret this?

Discussion

This is a work in progress and there is still much work to be done in finding and developing new tools appropriate for time sensitive text data. Given history is a study of change and its significance, it is imperative that we do not assume a static distribution of words across time, eliminating many otherwise useful NLP tools. While Dynamic Topic Modeling considers time as a variable, it constructs a fixed number of topics based on a collection of words making it less favorable for corpora with minimal predictability and pattern as diplomatic papers. Unlike academic journals such as *Science* as Blei and Lafferty have applied their modelling on, diplomatic papers are much less consistent in topics. I have also discovered based on my experience of implementing these tools on the FRUS corpus that because in diplomatic papers certain topics predominate discussions at certain dates, I need to be aware of isolating these topics from purely semantic changes. For instance, in the 1940s, “communism” is closest neighbor based on GloVe results to “chinese” or “ccp” because of the Chinese Communist Revolution of 1949, which does not yield any surprising result about the meaning of “communism” in diplomacy.

Exploring The History Of The Qur’an Digitally

Tobias Jocham
jocham@bbaw.de
Berlin-Brandenburg Academy of Sciences and Humanities, Germany

Michael Marx
marx@bbaw.de
Berlin-Brandenburg Academy of Sciences and Humanities, Germany

Oliver Pohl
opohl@bbaw.de
Berlin-Brandenburg Academy of Sciences and Humanities, Germany

Markus Schnöpf
schnoepf@bbaw.de
Berlin-Brandenburg Academy of Sciences and Humanities, Germany

Initiated in 2007, the project Corpus Coranicum of the Berlin-Brandenburg Academy of Sciences and Humanities aims at building a comprehensive digital information system by providing access to relevant materials for the history of the Qur’an such as digitized versions of the oldest qur'anic manuscripts and their transliterations, comparisons of variant readings for each verse, texts from the environment of the Qur’an as well as providing commentaries for each sura, taking all the aforementioned elements into account. Both, manuscript evidence and variant readings, can be seen as the foundation for a future critical edition of the Qur'an. Following the German philological approaches to the history of the Qur'an before World War II such as the “Wissenschaft des Judentums” – a reform movement founded by Abraham Geiger (1810-1874) – and Gotthelf Bergsträßer's (1886-1933) “Korankomission” of the Bavarian Academy of Sciences, the Qur'an project in Potsdam is working on implementing a sustainable solution for exploring the history of the Qur’an, this time digitally.

This information system does not confine itself to the digital reproduction of the holy text but utilizes international standards like XML, Unicode and TEI to ensure the long-term readability and archivability of the conducted research, text analyses and editorial efforts. The print edition of the Qur'an produced in Cairo in 1924 is used as a reference for the documentation of the material for the textual history, since that print had a tremendous influence on following prints during the 20th century. following the analytical approach of Theodor Nöldeke (1836-1930), the project produces rich philological commentaries for each sura, exposing their chronological order and putting emphasis of the development of their literary forms across the 22 years of the prophet's proclamation.

Viewing the Qur’an as a text proclaimed in Arabia in Late Antiquity, the Corpus Coranicum project provides access to a collection of testimonies labeled as “Texte aus der Umwelt des Korans” (“Texts from the Environment of the Qur'an”). There, texts in Hebrew, Syriac, Greekt, Arabic, Ancient South Arabian, Ethiopian and others are being gathered, transcribed and translated, in order to highlight intersections and point out differences between and other documents from Late Antique culture, religions and traditions: Thus, the messages of the Qur'an can be viewed and understood in their respective contexts and in a new light.

Furthermore, the project gathers archeological evidence and conducts radiocarbon datings of qur’anic parchments in an ongoing German-French cooperation (2011-2014 Coranica, from 2015-2018 Paleocoran) to contribute substantially to the understanding of the Qur'an's history and the emergence of Islam. A joint goal of Corpus Coranicum and Paleocoran is to bring together all manuscripts that were originally kept in old Cairo and are now scattered around the world in a digital format for presenting them in their original form and order. On top of mere digitizations of the manuscripts, the Corpus Coranicum provides modernized transliterations of the original Arabic scripture. These transliterations are being shown in a self-developed font “Coranica” since other Arabic fonts like MS Typesetting or Amiri fail to display all the necessary characters occurring in the relevant texts of the project.

Next to commentaries, contextualization and analyzing manuscripts, the Corpus Coranicum project is building a corpus of variant readings on a word-level. Since the earliest time, the various readers of the Qur'an have recited the text in their own way. For each sura, each verse and word-coordinate in the Qur'an, the project compares the variant readings according to the written source with each other in order to show the varying tradition and interpretation of the holy text.

With the variant data accumulated so far the variances cannot only be analyzed on a word-to-word basis, but they can also be utilized to compute a general similarity measure between readers of the Qur'an by mapping the variant readings into a vector space which can be represented as a multi-dimensional matrix. For each word occurring in Qur'an, the Qur'an matrix is being assigned a dedicated row. Each variant reading of that word at this particular sura-verse-word-coordinate creates a column in that row, assigning the variant reading as its value. The same procedure is then applied to create matrices for each reader of the Qur'an. Whereas the Qur'an matrix can have multiple non-empty values in a row, a reader matrix can only have one: the corresponding coordinate of the variant reading the reader uses at that particular sura, vers and word position. Since the cutting angle between two vectors or matrices represents the similarity to each other, the Euclidian distance (see below) is being utilized to compute that similarity measure.

All the aforementioned branches of the Corpus Coranicum project, the history of the text, the manuscripts, analyses of variant readings, the literary and chronological commentary as well as the texts surrounding and having influenced the Qur'an are bundled together to develop a new perspective on the text. The website of the Corpus Coranicum goes beyond a traditional digital edition of the Qur'an and can better be described as a digital framework or digital information system for the Qur'an, as a variety of tools and different texts are present.

The project tries to pick up and go digitally beyond where German Qur'anic science tradition has left off. On top of the content created and functionalities implemented thus far, the projects aims at extending its range of features by providing internationalized versions of the website (English, French, Turkish) as well as integrating the Rafi Talmon (1948-2004, Arabist, University of Haifa) concordance to offer chrono-morphological and statistical analyses of the holy text.

The talk will give an overview about the current state of the project, will portray philological approaches and their technical applications as well as present results of the similarity computations mentioned above.

Adding Value to a Research Infrastructure Through User-contributed ePublications

Catherine Emma Jones
catherine.jones@cvce.eu
CVCE, Luxembourg

Lars Wieneke
lars.wieneke@cvce.eu
CVCE, Luxembourg

Introduction

The so-called 'web 2.0 revolution' heralded in the middle of the last decade has so far neither replaced the author as the source of genuine creation nor turned conventional production processes in research and industry upside down. Rather than blurring the boundary between experts and amateurs, it questions the role of the institution as a source of authority by empowering individuals, small groups and communities (Wieneke 2010). Even today, institutions struggle to turn the productivity and impulses of their respective user communities into clear added value that benefits the institution and the community alike. In this paper we present and discuss our experiences in the development, implementation and management of user-created content built using the MyPublications tool on CVCE.eu. MyPublications enables users to create and publish their own enhanced publications using documents and resources on the European integration process available on CVCE.eu.

The CVCE's goal is to contribute to a deeper understanding of European integration by developing a dedicated digital research infrastructure. One component of the infrastructure is a series of digital collections of publications (ePublications) on themes and topics associated with the European integration process, as curated by a researcher or team of researchers. The ePublications are themselves aggregations of diverse research objects (resources), including researcher-written contextual articles, historical documents, press articles, photographs, interactive diagrams and timelines as well as other multimedia material, each with a set of descriptive, publishable metadata and a unique and persistent identifier.

State-of-the-art ePublication frameworks are built upon a set of underlying principles encapsulated by the presentation of research knowledge alongside mechanisms for describing, sharing, discovering, reusing and repurposing the scientific content (Bechhofer, Roure et al., 2010). The CVCE's publication model is no different. It encapsulates the following principles: (1) the ability to provide aggregations of content derived from many different published objects; (2) the provision of a unique and persistent identifier, ensuring sustainability of access; (3) the possibility of tracing the steps a researcher took to produce the ePublication; (4) the potential to reuse objects in a different context; (5) the ability to change the way objects are used by repurposing them; (6) the ability to reuse objects in compliance with IPR constraints.

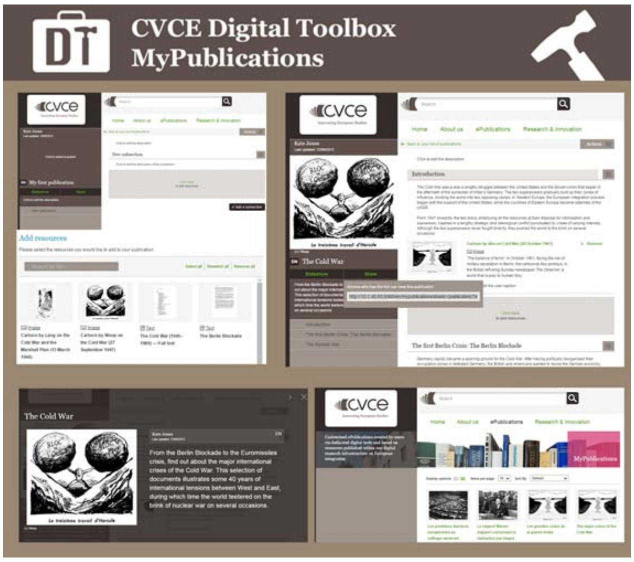
The current CVCE ePublication framework is expert-led, and research outputs are based on the centre's research questions and strategic topics. This approach leads to digital expert-curated ePublications based on themes and topics that are robust and reliable but — and this is both an advantage and a limitation — constrained by organisational priorities. On the other hand, the content itself can be combined and contextualised in different ways, both to highlight other perspectives and readings but also to address topics out of scope of the hosting institution. The challenge we face is therefore in the development of innovative tools and methods that offer new ways of reusing and repurposing historical objects by leveraging the potential of our user base to contribute knowledge themselves. This will in turn foster outputs that create a genuine surplus value for other users of the site by covering issues that we partially address or do not include at all.

The MyPublication tool empowers users to create tailor-made ePublications comprising resources in line with their personal needs, and encourages them to publish them on our website, thereby providing a plethora of different perspectives on the European integration process that ultimately enhance the value of our site for other users. The tool builds on the CVCE's multilingual ePublication model and infrastructure for research, teaching and learning activities in European integration studies.

The tool

MyPublications is the first instalment of the 'Digital Toolbox' at CVCE.eu. This suite of tools is designed to enable users to reuse or customise our resources for their own purposes. Using the MyPublications authoring tool, users can create ePublications that are personally curated collections of the many historical resources available on CVCE.eu alongside their own text, thoughts, ideas and critical analysis. The tool has been developed with the following workflow in mind: select, organise, structure, annotate, author (and edit), read, share and publish. The tool and its development are based on the CVCE's experience in building and maintaining a previous application called 'Albums', which was widely used by the teaching and learning community for assignments (e.g. 'build an album on the history of monetary union') or to document ongoing research (e.g. 'all resources related to the Rome Treaties').

Once a user is logged into the Digital Toolbox, they can browse collections of objects (referred to as 'resources' in the tool) or use the search facility to find and select relevant resources and add them to 'MyResources'. Users are then able to create a new publication using the MyPublication tool. They are asked to choose a cover picture, provide a short description and title and set the language. They then build a structure by creating subsections, add content to the different sections and write corresponding descriptions while being able to add, sort, organise and annotate the selected resources. Users can read the publication using a slideshow viewer, a simple interface that provides a sequential presentation of the narrative of an ePublication akin to a book. They can also share their publication with colleagues, peers and friends via a link. The publish/unpublish functionality enables users to make their publication accessible to the public in the MyPublications section of CVCE.eu (see figure 1). This should add new user-generated content to the research infrastructure.



From the Berlin Blockade to the Euromissiles crisis, find out about the major international crises of the Cold War. This selection of documents illustrates some 40 years of international tensions between West and East, during which time the world teetered on the brink of nuclear war on several occasions.

Figure 1: The MyPublications tool. Empty authoring interface (top left), MyResources section (middle left), slideshow view (bottom left), Share feature (top right), overview of publicly available MyPublications (bottom right).

The platform

The current CVCE data repository and ePublication framework uses the Alfresco document management system to manage, store and retrieve a wide variety of historical resources on the European integration process, such as interviews, treaties, legislation, photographs and cartoons, from an extensive array of archives and media outlets. The frontend and backend applications have been implemented in Liferay using HTML 5, CSS and JavaScript.

MyPublications was developed using the iterative design methodology Scrum, an AGILE development approach. This approach enabled us to involve our users in the development process on an ongoing basis, avoiding the need to predefine requirements for complex functionalities. The interface was designed with a focus on usability

(Shneiderman and Plaisant, 2005) and the aim of providing an easy-to-use, pragmatic environment. All the tools in the Digital Toolbox, especially MyPublications, were designed with a 'less-is-more' approach (Jones and Haklay, 2009) based on pragmatism and prioritising simplicity over complexity. As a benchmark we defined that it should be possible to explain how to use the tool with a two-minute help video. In-house users (historians, economists and political scientists) were engaged in testing, evaluating and providing feedback following each development cycle.

Conclusion

The simplicity of MyPublications enables a straightforward process of authoring and content creation for users with varying levels of digital literacy. Such facilities within research infrastructures also have the potential to increase accessibility to and reuse of existing objects to create new content. The tool provides a pragmatic solution for resources that have complex restrictions with respect to their licences for use. The content on our site is hosted by the CVCE, and full licences for permission to use the material on CVCE.eu have been acquired, so scholars, teachers and learners can avoid all the common problems associated with the use of weakly licensed material or unsustainable, transitory URLs. The option of publishing the publications in the CVCE research infrastructure increases the usability of the resources by enabling individual users, in various guises, to actively contribute to an international research infrastructure.

Following the release of the final tool in autumn 2015, we will reflect during our presentation at DH2016 on our experience of maintaining the MyPublications tool and user-created publications while particularly emphasising our lessons learned: how far have we succeeded in mobilising our user base to create and publish MyPublications? Is the incentive of being able to use licensed material, therefore avoiding copyright restrictions, strong enough, or is this not relevant for our users? What kind of content have our users created? Has the focus been on the final outcome (e.g. those publishing their own research) or has the process of creation been more relevant for them (e.g. those completing class assignments)? What tensions do we encounter between the institutional perspective and our user base regarding different perspectives and topics? And finally, what are the practical trials and tribulations of integrating user-created content in an institutional context?

Implementing Canonical Text Services in the Croatiae Auctores Latini Digital Collection

Neven Jovanović
neven.jovanovic@ffzg.hr
Faculty of Humanities and Social Sciences, University of Zagreb, Croatia

Alexander Simrell
arsimr16@g.holycross.edu
College of the Holy Cross, Worcester MA

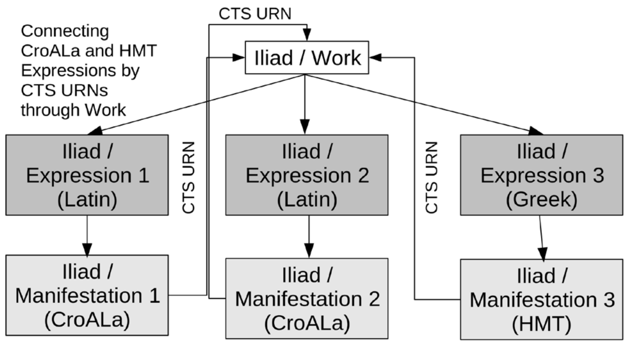
The Canonical Text Services (CTS) protocol (Blackwell and Smith, 2014) offers the scholarly community a way to use URNs for referring to two categories of propositional objects commonly called texts: to their ideal representations, **works**, and their specific realizations, **expressions** (International Working Group on FRBR and CIDOC CRM Harmonisation, 2015). CTS URNs point to complete texts and their subdivisions. CTS has a potential to transform scholarly practices. It supports the migration of our interpretations and knowledge from print to digital. It also forces us to reconsider what exactly we are doing when we refer or cite. It could, eventually, integrate into our referring and citing machine-driven comparisons across multiple versions of texts.

The CTS protocol is currently implemented in two projects: the *Homer Multitext* (Dué and Ebbott, 2015) and the *Perseus Digital Library* (Crane et al., 1987-). Both focus on texts which have traditionally been considered classical. Centuries, in some cases millennia, of appreciation and careful study have provided us with slightly different, but well-established citation schemes for such texts, and the main challenge to CTS up to now has been to reproduce these schemes. We put the protocol to a new test, by applying it to a non-canonical corpus of Latin texts published in the digital collection *Croatiae auctores Latini,* CroALa (Jovanović et al., 2009-).

CroALa collects and enables research of texts from a rich tradition of writing in Latin in Croatia. Latin was written through the Medieval and Early Modern periods up to modern times (our latest title is from 1984). The corpus includes a number of translations of Homeric poems into Latin, such as the partial one – an episode from the *Iliad* - by Janus Pannonius (1447), and a complete *Iliad* by Rajmund Kunić (1776). We wanted to connect

CroALa manifestations (digital editions) of these expressions to the *Iliad* as work, thus making possible a connection to manifestations of its other expressions, published elsewhere – in our case, to the Greek editions published by the *Homer Multitext*.

The process involved three stages: making the CroALa texts canonically referable through XML catalog records, validating and verifying the prepared editions, and establishing connections between editions prepared by different projects.



Connecting CroALa and HMT Expressions by CTS URNs through Work
CTS URN
Iliad / Work
Iliad / Expression 1 (Latin)
CTS URN
Iliad / Expression 2 (Latin)
CTS URN
Iliad / Expression 3 (Greek)
Iliad / Manifestation 1 (CroALa)
Iliad / Manifestation 2 (CroALa)
Iliad / Manifestation 3 (HMT)

Homer Multitext have produced URNs for each line of the *Iliad* as work; e. g. book 6, line 119 is described by urn:cts:greekLit:tlg0012.tlg001:6.119. A RDF triple connects this to URN of a line in the edition of the Venetus A codex (urn:cts:greekLit:tlg0012.tlg001.msA:6.119). Something similar is done for CroALa; you can see the work URN implied in the URN of a line our edition of Janus Pannonius' Latin translation (which is an expression fragment): urn:cts:greekLit:tlg0012.tlg001.croala-lat01:6.119. The same work URN is also implied by a line in the edition of Rajmund Kunić's complete Latin expression of the *Iliad*: urn:cts:greekLit:tlg0012.tlg001.croala-lat02:6.119.

The referencing happens through CTS Text Inventory (CTS TI), an XML catalog file. There Janus Pannonius' text is described by the following fragment:

```
<textgroup projid="greekLit:tlg0012">
 <groupname>Homer</groupname>
  <work projid="greekLit:tlg001">
    <title>Iliad</title> <translation xml:lang="lat"
    urn="urn:cts:greekLit:tlg0012.tlg001.croala-lat01"
    projid="greekLit:croala-lat01">
      <label xml:lang="lat">Diomedis et Glauci Congressus</label>
      <description>Jan Panonije [1447, Italia; Hungaria]:
      Diomedis et Glauci congressus, versio electronica,
      ed. Samuel Teleki
      Alexander Kovaczai</description>
      <online
      docname="/db/repository/greekLit/tlg0012/tlg001/
      tlg0012.tlg001.croala-lat01.xml">
        <citationMapping>
          <citation label="book"
          xpath="/div[@type="poesis-epica" and
          @n='?']" scope="/TEI/text/body">
            <citation label="line" xpath="/l[@n='?']" scope=
            "/TEI/text/body/div[@type='poesis-epica' and @n='?']"/>
          </citation>
        </citationMapping>
      </online>
    </translation>
  </work>
 (...)
```

The TEI XML guidelines allow multiple ways of marking up text structures (Schmidt, 2014). Therefore the most important sections in the fragment above are the XPaths which describe locations of individual books and linesin our editions. Books and lines can be encoded in a different way, represented by different XML elements, but through CTS URNs we are still able to connect the corresponding points, just as we refer to the same verse in the *Iliad*-as-work regardless of the fact that it is realised (printed or written) on different pages in different editions (Manifestation Product Types).

Our descriptions have also to be checked for correctness. Here the Homer Multitext project also can help; they have developed an excellent system for automated validation of editorial descriptions. We are adapting this to ensure that everything works in CroALa CTS, that no errors are introduced during the encoding process. Validation happens in a Virtual Machine which ensures that the entire process is replicable (Smith, 2015). But, since faithful replication of the process will only faithfully replicate systematic errors, a validation system was developed to assess our work in a different method, independent of how it was created.

The system first tokenizes all of the words. *Parsley*, a parsing machine for Latin morphology (Schmidt, 2015), checks that all tokens are valid Latin forms. Personal and geographic named entities do not parse automatically, so the system analyzes these separately. Named entities are checked for consistent markup and for compliance with our authority lists. The tokens that do not parse at either of these stages are analyzed by a researcher.

What has been validated has also to be verified as correct; our validation system ensures that all the tokens are acceptable Latin forms, but researchers have to ultimately decide whether the forms were correctly used.

Forms that are identified as being invalid are analyzed further for encoding errors, incorrect entries, problems with the parsing machine. One of recurring problems is that neo-Latin vocabulary is missing from the classical Latin dictionary used by the parser, so new words should be added to the lexicon. Even more numerous are neo-Latin forms that orthographically (sometimes morphologically too) violate classical Latin rules. Such forms have to be matched with the classical equivalents so that they can be accepted when the machine comes across these forms again. A similar approach would be required for all editions in which language differs markedly from the standard modern variant - e. g. for the Early Modern English as used in Shakespeare.

Once we have a text referenced by canonical URNs and tested as validated and verified CTS, we can serve the URNs and retrieve them from wherever we want. Connecting different editions - for example, linking Croatian Latin translations of Homer to editions of manuscripts prepared by the Homer Multitext project - is then a question of aligning the two sets of URNs. These aligned sets will enable us later, for example, to display in parallel the texts served behind each of them.

Though clear and simple in principle, the actual application of CTS to CroALa texts opened up a series of practical questions with certain theoretical implications. We mention only two.

First, a text and its translation are not always in a 1 : 1 relationship. A verse of the original can be rendered by verse and a half, or by a half verse, in the translation; a description ("Peleiades") can be glossed ("Achilles"). This had to be taken into account during the process of editorial verification. We had to introduce additional checks for translation alignments and establish a procedure for marking places where translation "shifts" equivalents forward or back in the textual structure (Latin equivalent of a Greek word appears elsewhere in the sentence, and therefore may appear in a different line).

Second, Croatian Latin translations of the *Iliad* are expressions of the Homeric work, but at the same time they themselves are of potential interest as authorial works, and they themselves exist in multiple manifestations (Kunić's translation was published in Rome 1776, Venice 1784, Vienna 1784, Firenze 1831 and 1838). To enable detailed scholarly study of translation as a work, the system has to take into account this additional level of multiplicity too: not only *Homer Multitext*, but also a *Kunić Multitext* (with the same underlying work).

Among the grand visions of digital humanities there is a dream of a world - or a space - in which different digital editions, carefully prepared, annotated and interpreted, mesh easily together, thus providing an especially rich and detailed groundwork for further annotations and interpretations. This space of interchangeability is today attained only rarely and with difficulty. The level of difficulty can be significantly lowered, as shown by CroALa's successful implementation of CTS and its automated validation and verification processes. A further step towards interchangeability will be wider acceptance of a digital canonical reference system such as CTS. For this to happen, a series of applications and "recipes" for specific usage cases is needed. We hope to have offered one such recipe here.

The Stanford Code Poetry Slam through Critical Code Studies

Melissa Kagen
mkagen@stanford.edu
Stanford University, United States of America

This paper reports on, analyzes, and contextualizes a project I have co-founded and run since 2013, the Stanford Code Poetry Slam (tinyurl.com/codepoetryslam). This is a series of international contests in which we solicit code poetry, whatever that means to our submitters, and then curate the best works. At each event, the best submissions are then “slammed” by human performers and (often) simultaneously by the computer programs that run them. The project explores the performative potential of computer languages, situates itself within the growing discipline of critical code studies, and has produced some fascinating work. In this short paper, I'll explain the project, analyze several of the poems as code and as poetry, and place the Stanford Code Poetry Slams in the context of recent conversations in critical code studies, particularly with reference to performance. How do humans perform code, and how does that differ from the way computers perform it? The connective aspect, I will argue, is based in the languages code poets use to write their works, each of which afford different performative possibilities. Through a close analysis of the linguistic choices our authors made, I will show in this brief presentation some of the commonalities between critical code studies and translation studies.

Many of our code poets have written and performed works that reference older poetic movements or forms, repurposing them for a digital medium. In Zak Kain's "Capsized," written in beautifully descriptive CSS, you can see a clear reference to imagistic works like William Carlos William's "The Red Wheelbarrow"; utilizing sparse but evocative descriptions, Kain's poem paints a harsh picture and simultaneously comes off as jokey and whimsical. This duality illustrates a fascinating, secretive aspect to code poetry, where the tone and content of the poem can imply one reading and the very language in which it's written (and the specific rules of that language) can inspire another reading entirely. In this case, the surrogate performer did a great job of presenting both aspects of the work, by starting sadly and then growing increasingly over-dramatic.

The code poem that won CPS 1.1 also played with performance to get across a profound point, in this case crossing seamlessly between aspects of performativity in digital, theatrical, religious, and social media realms. In "21st Century Prophecies," Hunter Bacot wrote a poem that calls the most recent tweet from seven "Prophets" (famous twitter users with huge followings) and strings those tweets together into a list of "virtues." In Keshav Dimri's performance, each line was intoned with the solemnity of a sermon ("Let KingJames be added to the list of virtues!") and the resulting poem (the 7 most recent tweets) was spoken like a biblical verse. "21st Century Prophecies" references movements like bricolage and found poetry by rearranging already extant text in new ways, and it gestures towards "Curation as Creation" and ideas found in the Digital Humanities Manifesto 2.0.

Other kinds of code poems make art out of the strenuous constraints imposed by coding languages, if one's goal is to write a text that actually compiles. Constrained texts reference much older poetic forms, like the sonnet, which require following a complicated set of rules about syllabic stresses and end rhymes. Many Perl poets write these kinds of texts. One of our best examples was Mike Widner's "A Pythonic Lament," which prints out "Alas! Alas!" when run.

Finally, in linguistic double coding, a sentence is readable in multiple languages at once. "Jean put dire comment on tape" reads in English (albeit a little ungrammatically) and, in translation from French, says "Jean is able to say how one types." Poems that are readable to humans and readable to computers perform a kind of cyborg double coding, and the ramifications of this possibility for translation studies are one of the themes the CPS series explores. Julian Bliss' "Polymorphism," the winning poem from CPS 2.0, took this idea to an incredible extreme, as he created a piece of text that, when compiled in multiple languages, produces a different poem in each. Moreover, each output poem parodies a clichéd English-language poem.

This presentation will analyze these and other works of code poetry we've slammed, showing how the languages in which they were written greatly affect their performative potential and demonstrate the performative nature of translation.

Trading Zones of Digital History

Max Kemman
max.kemman@uni.lu
University of Luxembourg, Luxembourg

As a subfield of the wider Digital Humanitiesdigital humanities, Digitaldigital hHistory is concerned with the incorporation of digital methods in historical research practices. Digital hHistory thus aims to do historical research using methods, concepts, or tools from other disciplines, making it a form of **methodological interdisciplinarity** (Klein, 2014){Formatting Citation}. However, how this interdisciplinarity affects the practices of Historyhistorians, on the methodological and the epistemological levels, remains underexplored. The PhD research presented in this paper aims to address this question by investigating the interdisciplinary interactions in which historians take part.

Three forms of interaction are of interest for this research, which are not necessarily an exhaustive list of digital history interactions. These forms are not mutually exclusive, but occur interchangeably and simultaneously, or one form could lead to another:

1. Digital history as collaboration with, among others, the computer science discipline.
2. Digital history as end-users of tools.
3. Digital history as building tools independently.

In order to look into such interactions, this PhD research will employ Galison's concept of **trading zones**, described as "an arena in which radically different activities could be locally, but not globally, coordinated" (Galison, 1996, p. 119).

When different groups interact with one another over a period of time in a trading zone, it is likely that the two groups will influence one another through **acculturation**: "the process by which the beliefs and practices of one community diffuse across the boundaries of another and subsequently alter the second community's practices and interpretations" (Barley et al., 1988). At the community level, acculturation involves changes of social structures, institutions, and cultural practices. At the individual level, it involves the behavioural repertoire of a person. By studying the acculturation of practitioners of digital history, as individuals and in groups, we may get a view of the types of trading zones and how these change over time. To model the different types of trading zones, we use three dimensions based on research by Berry (1997, 2005) and Collins et al. (2007):

1. Contact & Participation, i.e., how the two groups meet.

2. Cultural Maintenance (from homogeneous to heterogeneous), i.e., how the two groups define themselves and to what extent they aim to maintain their identity. On this scale, more homogeneous means the two groups become more alike to form a single group, while more heterogeneous means they remain two distinct groups.

3. Coercion (from collaborative to coercive), i.e., what the power relations in the trading zone are. On this scale, more collaborative means the two groups are both acting out of free will, while more coercive means one group is imposing practices upon the other.

The concept of trading zones has been used before to describe the digital humanities field. McCarty (2005) argues that humanities computing should rather be seen as a third space, neither belonging to one group nor the other, rendering it no longer a trading zone. However, in the terminology of Collins et al. (2007), this would constitute a collaborative-homogeneous trading zone, termed an inter-language. Svensson (2011, 2012a,b) suggests digital humanities is a collaborative-heterogeneous, termed fractioned, trading zone; a meeting place of two groups. Klein (2014) also describes digital humanities as a fractioned trading zone, and, like Svensson, emphasises that this may lead to a shared language, or jargon, between the different communities. Hunter (2014), without employing the concept of trading zones, describes digital humanities as a bridge or translation between two cultures, which we can describe as a collaborative-heterogeneous trading zone, termed interactional expertise. Rieder and Röhle (2012) use the concept to argue however that not the language should be central, but the interactions on the level of methodology, where not the terminology but the method itself is negotiated. In contrast to these authors, Mounier (2015) contends that there is a coercive political dimension underlying the field, which in the terminology of Collins et al. would suggest that digital humanities constitutes a coercive-heterogeneous, termed enforced, trading zone. This is not to say that this is how digital humanities will always be, but Mounier argues this should be better understood before we can move further and perhaps diffuse new digital methods into the wider humanities.

However, what is striking about these discussions of digital humanities as trading zones is that very little research into the **local** practices has been done, with the exception of Hunter (2014) who does not actually employ the concept of trading zones. Instead, digital humanities is discussed as a global phenomenon; this is in contrast with the original use of the concept by Galison as described above. This paper aims to reintroduce the concept of trading zones to describe local phenomena of digital humanities.

To this end, this paper investigates local manifestations of trading zones in digital history using the three dimensions described above. The analysis focuses on the first form of interaction described above, collaboration, and is based on interviews with practitioners of digital history, i.e., historians, computer scientists, and other collaborators, focusing on the diverse aspects of interdisciplinary collaboration. The interviews cover five distinct subjects, which together give an insight into the trading zones from each interviewee's perspective.

The first subject is that of **boundary work**, concerning how practitioners characterise their own discipline. Moreover, it is of interest how practitioners characterise the other disciplines in the collaboration. In previous research involving students of journalism, a lack of understanding what computer science is appeared to result in disinterest and performance anxiety (Cook, 2015). Furthermore, this subject covers the extent to which the practitioners aim to have their digital history research meet their discipline's values. This subject thus not only works towards the Cultural Maintenance dimension, but also already gives hints towards the Coercion dimension regarding how interested practitioners are in the collaboration with the other discipline.

The second subject is the **practice of research**, the research activities. This concerns a description of their research, both within and outside the trading zone, and the tools potentially used at different steps in their process.

The third subject concerns their **incentives** for practising digital history. In previous research on the collaboration between earth scientists and computer scientists, it was found that the two groups had different incentives for the collaboration (Weedman, 1998). This difference introduced difficulties for the collaboration and impacted the understanding of the other discipline. This subject thus works towards the Coercion dimension.

The fourth subject concerns the **organisation** of the collaboration. This concerns how often the groups meet, and where they are located, e.g., is it a collaboration between different departments at different places (or in different countries), or a sharing of office space. This subject thus works towards the Contact & Participation dimension.

Finally, the fifth subject concerns the **epistemological positions**. A criticism in the digital humanities debate is the incorporation of different epistemological positions such as positivism or objectivism in humanities scholarship (Drucker, 2011, 2013). It is therefore of interest whether practitioners in the trading zone (unconsciously) shift their epistemological position. A first question concerns their practice of reasoning; do they reason in a research question-driven deductive way, a more data-driven inductive way, or an abductive way to try to discover patterns (Dixon, 2012)? Other questions are related to epistemological positions. Roth and Roychoudhury (1994) developed a short qualitative questionnaire which allows to describe interviewees as more objectivist or more constructivist. Thus, this subject provides insight into the acculturation of practitioners, and works towards the Cultural Maintenance and Coercion dimensions on the epistemological level.

This paper will present preliminary findings of interviews held for this PhD research, focusing on the aspects of **incentives** and **organisation**. We will present a preliminary taxonomy of collaborations on the Contact & Participation dimension, and describe several digital history interactions on the Cultural Maintenance and Coercion dimensions. With these results, we aim to gain a better understanding of how digital history works as an interdisciplinary interaction, and how this impacts the practices of the involved groups and individuals.

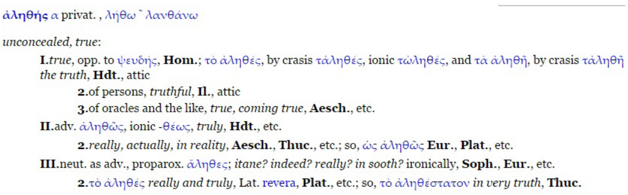
Introduction

The emergence and growing popularity of Linked Open Data (LOD) offers researchers a new range of possibilities when it comes to publishing datasets online (Hyvönen 2012, Oomen et al 2012); indeed not only does the success of LOD greatly facilitate the process of making scholarly data accessible and to a wider community but it also permits the enrichment of individual datasets by linking them to the other datasets available on the so called Linked Open Data Cloud. The advantages of Linked Open Data for teachers, academics and students in the humanities are obvious and are indeed manifold. However there is currently a paucity of linked open datasets in fields such as philology and literary studies, and in particular of datasets that deal with classical languages such as ancient Greek, Sanskrit, and Latin. This seems strange given the rich abundance of surviving works, of both a religious and secular character, that exist in those languages. A salient consideration here relates to the fact that even when such works have been digitised and made available in a format such as TEI-XML, a format which renders the structure and content of such texts more amenable to computer processing, the conversion of these resources into the Resource Data Framework (RDF), the standardised data model that underpins the Semantic Web, is not always straightforward.

In this article we describe ongoing work in the conversion of an important 19th century Ancient Greek resource the Liddell-Scott-Jones Lexicon, into RDF, part of a wider program of work that has been recently initiated at CNR-ILC in converting historical lexicons in languages such as Greek, Latin and Arabic into Linked Open Data.

Background

The Liddell-Scott-Jones lexicon (LSJ), or to give it its original title "A Greek-English lexicon", is a bilingual ancient Greek-English dictionary which since its first edition was published in the mid-nineteenth century has come to be regarded as amongst the most authoritative of modern day lexicographic resources dealing with the ancient Greek language, indeed it has the reputation of a standard in the field. As a result of its popularity the LSJ has been made available in a number of different versions differing in terms of the number of entries and the amount of data which they contain. For the work described in this paper we are using an abridged version of the LSJ which was originally published as "An Intermediate Greek-English lexicon," but which is more colloquially known as the "Middle Liddell" (ML). Fig. 1 shows the lexical entry for the adjective *ἀληθής* (alēthēs) in the ML. Entries in the ML are structured into different nested (sub-)senses, and each of these senses contain references (usually just the name of an author) attesting the use of the word as described in the sense's gloss.



ἀληθής α privat. , λήθω ˜ λανθάνω

unconcealed, true:

I.*true*, opp. to ψευδής, **Hom.**; τὸ ἀληθές, by crasis τἀληθές, ionic τὡληθές, and τὰ ἀληθῆ, by crasis τἀληθῆ *the truth*, **Hdt.**, attic

2.of persons, *truthful*, **Il.**, attic

3.of oracles and the like, *true*, *coming true*, **Aesch.**, etc.

II.adv. ἀληθῶς, ionic -θέως, *truly*, **Hdt.**, etc.

2.*really, actually, in reality*, **Aesch.**, **Thuc.**, etc.; so, ὡς ἀληθῶς **Eur.**, **Plat.**, etc.

III.neut. as adv., proparox. ἄληθες; *itane? indeed? really? in sooth?* ironically, **Soph.**, **Eur.**, etc.

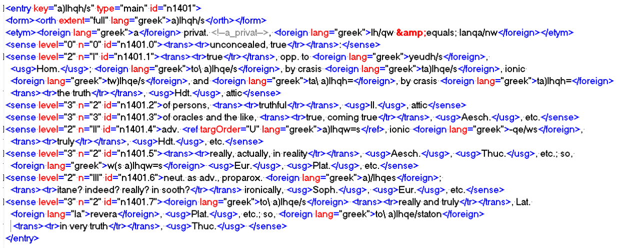
2.τὸ ἀληθές *really and truly*, Lat. revera, **Plat.**, etc.; so, τὸ ἀληθέστατον *in very truth*, **Thuc.**

Fig 1. An entry from the "Middle Liddell"

There were a number of motivations for choosing the LSJ as a starting point of our work into converting legacy lexical resources into linked data: aside of course from the question of its historical importance and continuing influence in the field of philology. Firstly we felt that given the lack of ancient Greek lexical resources in linked open data -- at the time of writing the Linguistic Linked Open Data cloud (Chiarcos et al 2011), that part of the LOD cloud that deals with linguistic data, contains no ancient Greek datasets -- there was an obvious necessity to ensure a presence on the cloud for a language that is absolutely foundational to the history of Western civilisation. Additionally there was also the challenge of converting a legacy resource like the LSJ which in its published form, and even in an abridged version like the ML, manages to condense a significant amount of lexical information in a relatively short amount of text, into linked data. In order to represent this information in the RDF model, and to stay close to the spirit of the Linked Open Data movement, a lot of what was implicit in the original text had to be teased out and rendered explicit.

Finally, one very important practical reason for choosing the ML was the fact that the conversion of the ML into XML using the TEI dictionary guidelines had already been carried out and made freely available under a creative commons license by the Perseus project (Crane et al 2013). This obviously saved us the trouble of digitizing the text ourselves and meant that we could work from a source file that was already annotated for lexical entries, senses, translations, etc.

In Fig 2 below we present the TEI-XML encoding of the ML entry for ἀληθής from the Perseus XML version of the ML which we used as our source dataset.



```

```

Fig 2. The TEI-XML encoding of the ML entry for ἀληθής.

The TEI-XML encoding for each entry already contains most of the information which we wish to represent in RDF marked up, and so the actual processing of the dataset was fairly straightforward. The part of the conversion which, however, did call for some thought was the use of the *lemon* model to structure the RDF translation.

Translating the Middle Liddell in RDF using *lemon*

For the conversion of the TEI-XML version of the ML we decided to use the *lemon* model for publishing lexicons in RDF (McCrae et al 2011, McCrae et al 2012). *lemon* has by now become a de facto standard for converting lexicographic resources into RDF and has been used to convert a number of important lexical resources such as Wordnet (McCrae 2014), UBY (Eckle-Kohler et al 2014), Wiktionary (McCrae et al 2012), and Parole/Simple/Clips (Del Gratta et al 2015). The Linked Open Data movement emphasises the re-use of general vocabularies and models in order to ensure semantic interoperability between datasets. And so given the widespread use of *lemon* in converting lexical resources into RDF, and given the lack of a more specific alternative specifically tailored for lexicographic resources like the ML, we decided to use it as the framework for our conversion. However using *lemon* for the conversion has not been without its challenges. One of the primary difficulties rests in the fact that *lemon* was originally intended as an onomasiological model, that it is, it was designed with the perspective in mind of enriching an already existing ontological or conceptual resource with linguistic information (Cimiano et al 2013). However in our case we started out with a very rich lexical resource but without any particular pre-ordained ontological or conceptual datasets in mind to which to link it. In fact we are not currently using the lemon:reference relation to link our dataset to others.

The ML in particular and the LSJ more generally represent lexical resources that have a specific and relatively complex way of encoding information and that contain a lot of philological and historical data alongside or in addition to "pure" semantic information. Therefore in in order to ensure a faithful translation we had to define a number of new classes and relations in addition to those in *lemon*. In what follows below we will briefly describe (most of) the additional classes and properties which were introduced in order to model the ML and which together make up the lemonLSJ module. Fig. 3 below is a diagram showing classes and properties in the lemonLSJ module and their relation to some of the main classes.

The new class lemonLSJ:Gloss represents the written text associated with each sense; the object relation lemonLSJ:gloss then links elements of this class to lemon senses. The lemonLSJ:usage relation links a sense to an ontological resource describing where that sense was used, e.g., by linking to an author or work where that sense can be found.[1] We have also added the relations lemonLSJ:senseChild, and lemonLSJ:senseSibling in order to represent the nesting of subsenses in ML entries.

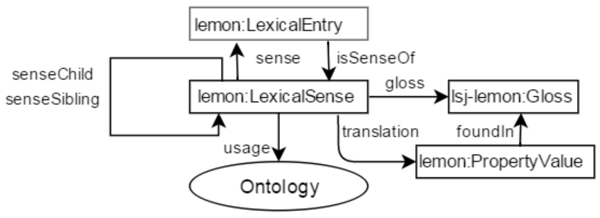

Fig. 3 The lemonLSJ module.

In Fig 4 we present an excerpt of the lemonLSJ RDF-Turtle encoding of the ML entry for ἀληθής with only two of the attached senses represented. Note that we have linked the second of the word senses in Fig 4 to instances in the VIAF dataset (in this case the entries for Herodotus and Homer).

The diagram in Fig. 5 shows how the nesting of senses is treated in the RDF encoding.

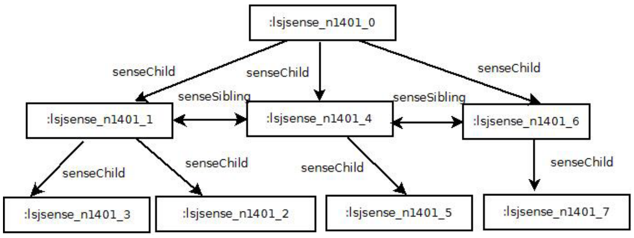

Fig. 5 Sense diagram.

Conclusions and future work

In this paper we have briefly described ongoing work in the conversion of an ancient Greek-English lexicon into RDF. Currently we are manually checking the RDF triples resulting from our conversion scripts and we also plan to additionally link the senses to Princeton Wordnet synsets by checking similarity of the glosses to synset glosses. The resulting dataset will soon be made available as an RDF dump together with other lexical resources of ILC CNR.

Acknowledgments

First of all we would like to thank Perseus project for converting the data and for making it freely available. Thanks also to the organisers of the *mylider* 2015 Summer Datathon, during which some of this work was carried out, for their advice.

Digital Criticism Platform for Evidence-based Digital Humanities with Applications to Historical Studies of Silk Road

Asanobu Kitamoto
kitamoto@nii.ac.jp
National Institute of Informatics, Japan

Yoko Nishimura
nishimura@toyo-bunko.or.jp
Hanazono University, Japan

Introduction

Source criticism is a scholarly process fundamental to many disciplines of humanities, especially in historical studies. However, it is mainly designed for a traditional way of research, namely human scholars read a textual source without producing structured evidences for reuse. Our proposal is to extend the traditional methodology of source criticism to digital research infrastructure on which scholars records the reasoning process from evidences to facts, and share them with other scholars so that the detail of the reasoning process can be transparently reproduced. Our approach, digital criticism, aims at realizing this idea on digital criticism platform (DCP) toward evidence-based digital humanities with the support of Semantic Web technology.

An evidence-based approach is also used in quantitative humanities, but digital criticism is a fundamentally different approach. Digital criticism focuses on reading sources in a critical manner, while quantitative humanities focuses on deriving numerical values from the collection of sources. Generally speaking, quantitative humanities tries to make abstraction of corpus through quantitative aggregation, while digital criticism tries to make critique of sources through digital analysis with support for the management of a layered abstraction process.

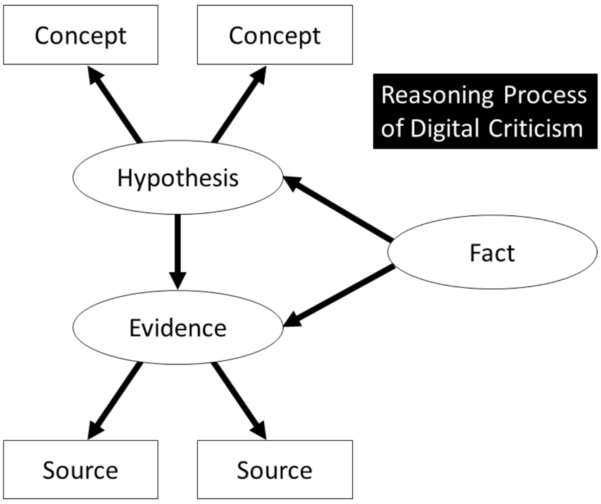

Figure 1 Schematic diagram of evidence network

Core concepts of digital criticism

The main contribution of the paper is evidence network on which digital criticism is performed. The network consists of four concepts, namely evidence, hypothesis, fact, and reliability. Those concepts have our own definition to organize the historical reasoning process into an explicit model.

1. Evidence is relationship between sources. If a photograph A takes the same scene with a photograph B, they are linked as an evidence with reproducible parameters of how photographs can be matched.

2. Hypothesis is relationship between historical concepts. If a ruin A and ruin B have different names but are believed to be the same ruins, they are linked as a hypothesis with supporting evidences and other descriptions on the reasoning process.

3. Fact is relationship between evidences and hypotheses to claim reusable knowledge for future research.

4. Reliability is an attribute of evidences and hypotheses to represent the degree of reliability estimated by the scholar on registration. Because the estimated reliability may be different for each scholar, evidences and hypotheses should always be linked to a user entity who made the action.

Figure 1 illustrates a schematic diagram of evidence network. A scholar can build up the network starting from each evidence and hypothesis. Another scholar who wants to reuse the knowledge can start from the fact, and track back to hypotheses and evidences to check the reliability of the reasoning process.

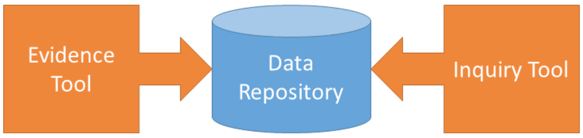

Figure 2 Three components of Digital Criticism Platform (DCP)

Digital Criticism Platform (DCP)

Evidence network is a directed graph with semantic annotation, and the graph structure is built using RDF (Resource Description Framework). Hence a search over a graph can be implemented using SPARQL, which is a query language for a RDF graph. To construct and study the evidence network, we develop Digital Criticism Platform (DCP) with three components, namely data repository, evidence tool, and inquiry tool as illustrated in Figure 2.

1. *Data repository* archives digital resources with unique IDs and metadata. We developed data repository using DSpace as infrastructure for its reliability and extensibility to Semantic Web environment.

2. *Evidence tool* works on various types of media for collecting evidences. We developed three tools, Mapping, Photofit, and MemoryHunt, for maps, photographs, and field work, respectively.

3. *Inquiry tool* is to study and sophisticate the evidence network using Semantic Web technology such as SPARQL. This component is now under study, and has not reached the development phase.

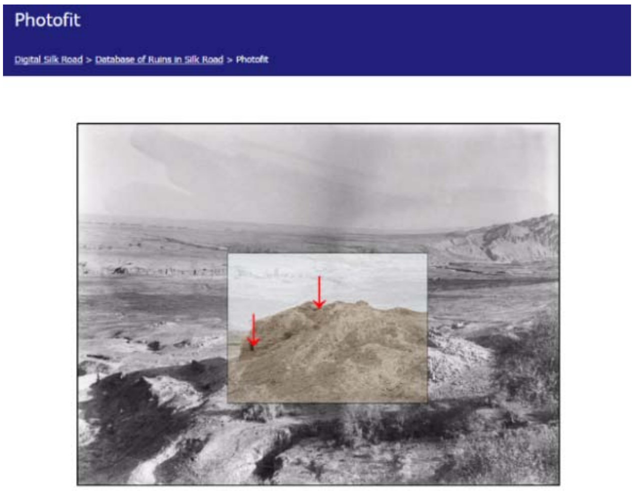
In the following, we focus on three evidence tools to describe more detail of the tools. Those tools should be integrated into data repository so that every evidence is registered as a part of evidence network. Three tools are already in operation, but only Photofit is fully integrated into data repository at the time of writing.

Mappining

Mappining (Kitamoto 2012) is a web-based tool for matching maps (Figure 3). This tool employs an idea of "interactive georeferencing" in contrast to geometric correction. Interactive georeferencing uses a pin to match two maps at a single point, in a similar way of pinning cloths. When we put a pin, two maps scroll together, while when we release a pin, only one map scrolls. Using this interface, any point on a map can be matched with another map for overlay-based comparison. Interactive georeferencing is advantageous for reading sources because geometric distortion is not introduced. A pin is an evidence to claim that each point on a map represent the same location on earth.

Photofit

Photofit is a web-based tool for matching photographs (Figure 4). The target of the tool is two photographs taken from similar locations but different angles at different time. It allows planar shift and zooming transformation for two photographs to find the best match. On success, it is an evidence to claim that two photographs take the same scene or the same object. This evidence may lead to a new hypothesis on the identity of historical concepts when the captions of two photographs represent different historical concepts.



Photofit
Digital Silk Road > Database of Ruins in Silk Road > Photofit

Figure 4 Matching two photographs on Photofits

MemoryHunt

MemoryHunt (Kitamoto 2015) is a mobile app for matching a photograph with the real world (Figure 5). It shows a target photograph on the viewfinder of a smartphone camera with controllable transparency, and the task of a user is to find the same location and the same direction that the photograph was taken. On success, a mobile app can record the location and direction as metadata of the photograph. This may lead to an evidence between an object appearing in the photograph and one in the present world.

Evidence network

The purpose of digital criticism is to build an evidence network in which historical sources are linked through evidence nodes, and historical concepts are linked through hypothesis nodes to derive fact nodes supported by evidence and hypothesis nodes. We start by a bottom-up process of registering evidences and hypotheses which are still fragmented. We then switch to a top-down process of viewing a graph structure as a whole to discover unknown relationships. In the following, we use our past results on Silk Road ruins as case studies to check the validity of our approach. Due to the incompleteness of DCP, the following diagrams were manually drawn.

Figure 5 shows a simple evidence network. A photograph in a book is matched with another photograph in another book using Photofit, and an evidence node is added with transformation parameters. We also know that, through captions, each photograph represents a ruin known by different names. We then add a hypothesis node based on the above evidence to claim that two ruins known by different names are the same.

Figure 6 shows a complex evidence network. Multiple tools are used for matching multiple sources, such as Mappinning, Photofit, and Google Earth. The evidence network suggests relationship among a Buddhist ruin

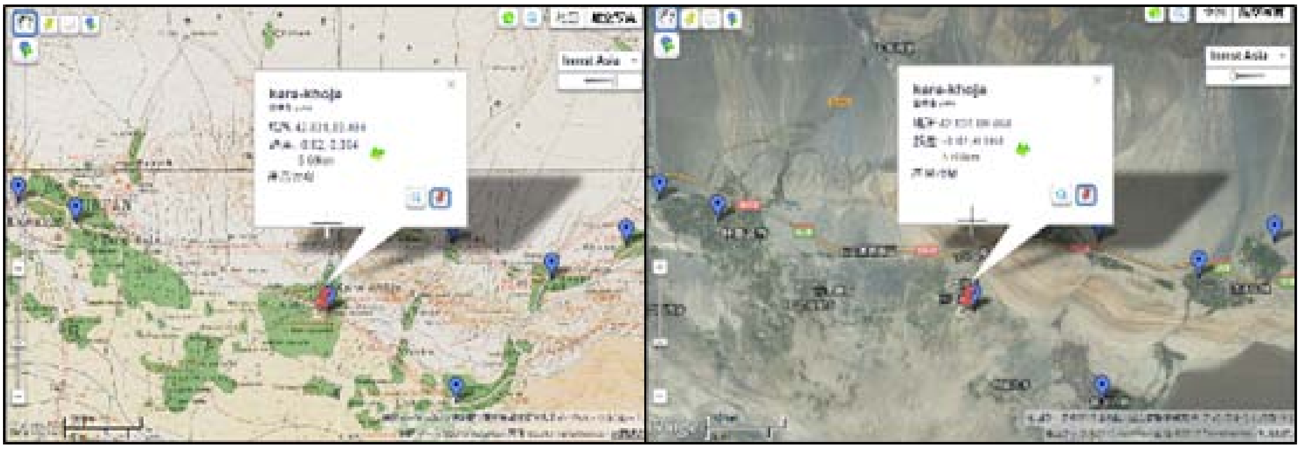


Figure 3 Matching two maps on Mappining

and a ruin known by the name Chikkan-kol and another ruin known by "七康湖遺跡." This relationship was our discovery previously reported in a paper (Nishimura and Kitamoto 2010), but digital publishing in the form of evidence network offers clearer representation of a compex reasoning process.

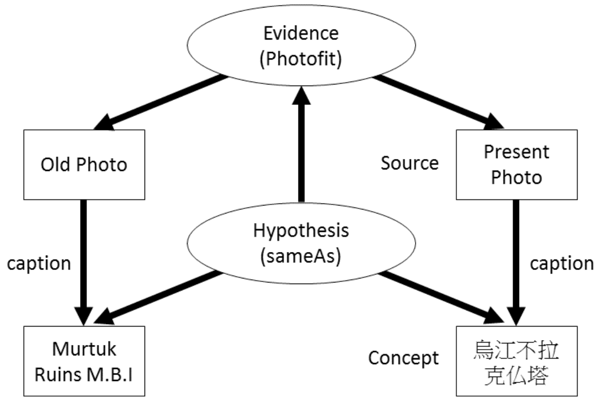

Figure 6 A simple evidence network

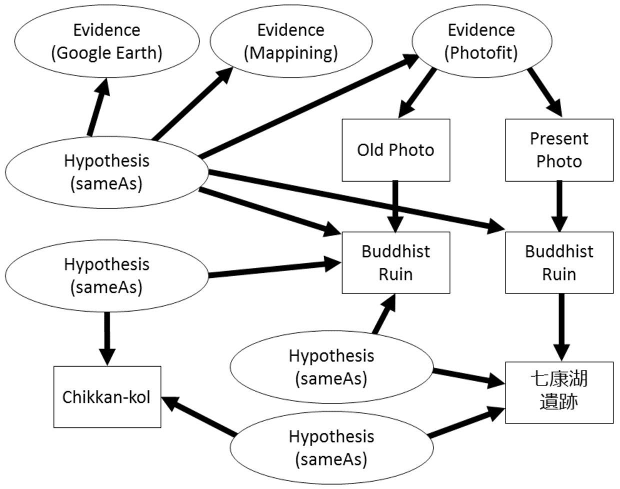

Figure 7 A complex evidence network

Conclusion

We proposed digital criticism platform (DCP) as a model of source criticism on a digital platform. Digital criticism tries to simulate the traditional method of source criticism and extend it to take advantage of digital research infrastructure. Digital Criticism is the upgraded version of our past proposal on "data criticism" (Kitamoto and Nishimura 2014), after shifting research focus on the type of sources to the way of digital scholarship. The methodology of criticism is also investigated in different approaches, such as algorithmic criticism (Ramsay 2011).

Knowledge representation of historical evidences has a large number of related literature. In particular, Pasin proposed the usage of factoid model for accumulating evidences for prosopography in the linked data world (Pasin and Bradley 2013), and linked data is also used for places such as Pelagios (Isaken et al. 2014). We also use the same concept of linking entities and uses sources as evidences, but digital criticism focuses more on accumulating structured evidences and hypothetical links. Another important work for the refinement of evidence network is knowledge representation for argumentation, such as CRMinf argumentation model, an extension of CIDOC-CRM (Paveprime Ltd and collaborators 2015). Finally, we are yet to make choices on metadata standards or vocabularies, which are open questions.

The long-term goal is to design a digital publishing platform for evidence citation. Historical facts can be tracked to evidences to clarify the reliability of evidences that support historical facts. This leads to increased transparency of research, and to realize better data management planning.

Introduction

An appeal to strengthen DH research using audiovisual collections has been repeatedly articulated in the DH community. Some of these collections are digitized museum collections of heritage objects. Many of these serve as repositories (sometimes for internal inventory purposes), some of the collections follow the rules of building digital scholarly editions and provide tools of analysis/summarizing and, sometimes, sources for critical interpretation.

Little is known, however about digitization practices within Museums in Russia, with no prior research into the number of Russian museum web sites, the amount of their collections digitized or put online or their digitization procedures. International research on digitization in museums has a comparatively long tradition and there is a significant literature on statistical data about digitization, digital preservation and online access to cultural heritage across Europe (ENUMERATE, 2015) and Northern America. Reports on digitization success stories in these geographical areas have been published (see among others ENUMERATE, 2015; Clough, 2013; Olsen, 2015) but there is no prior research regarding digitization uptake and practices in Russia.

This paper explores Russian museum digitization practices employing the standard method of surveying museums employed by the ENUMERATE project, allowing us to compare results to ENUMERATE. We also chose to augment our findings with the results from exploring the content of museum web sites to understand what parts of museum analogue collections are posted online. The paper seeks to answer a critical question about the size of digital collections as measured by the ratio of digital copies of unique museum objects to the number of unique objects from a museum collection (or the number of digital copies posted on the museum web site). We understand it very well that this can only serve as an imperfect proxy for digitization practices in Russian museums. However, in a situation when this is the only data that could be obtained, we judged it would be reasonable to start the discussion of digitization in Russian museums from this point.

Methods

In the early stages of our project we adapted the ENUMERATE questionnaire to our goals of obtaining answers from museum staff. We posted a survey with twelve questions online in October 2014 and we sent letters to 440 museums with a link to the survey. The email addresses were obtained from Museums of Russia web portal.[1] The database lists 3063 Russian museums including data on the number of visitors per year, the year when a museum was established and the number of curators among its employees. Our sampling method was to choose 130 museums located in Moscow and Saint Petersburg and 310 museums located in provincial cities and smaller settlements. Each of the 80 administrative districts in the Russian Federation was represented by 3-6 museums with one or two of them belonging to the group with the number of visitors per year more than 50,000 people. The other two groups included small museums (the number of visitors per year was fewer than 15,000 people) and medium museums with the number of visitors between 15,000 and 50,000 per year. This gave us an appropriate sample of museums to begin to understand different museum digitization practices across Russia.

Our next step was to study the web sites of large provincial museums and medium-sized provincial museums for 58 administrative districts (116 provincial museums as a total). Nineteen web sites for large museums and 23 web sites for medium-sized museums in Moscow and Saint Petersburg were also studied. The number of digital images on museum web sites was compared with the number of unique objects in their collections as reported in the Museums of Russia database (Museums of Russia, 2015).

Results and discussion

The response rate for the survey was a disappointing 6% (30 memory institutions completed the questionnaire and answered the most important question about the size of their digital collection). Such a response rate was very low compared to 30% response rate for the survey of library digitization projects in the USA in 2004 (Boock and Vondracek, 2006) and 51% for European cultural institutions in May 2007 and May 2009 (Poll, 2010). This result though is consistent with the finding that other Russian surveys tend to demonstrate low response rates with some studies reporting low level of trust to surveys among respondents (Kalinin, 2012), which has important methodological implications for those carrying out research within Russia.

In Table 1 we summarize the results for the survey of museum digital collections. Absolute average of the proportion of an analogue collection that was reported digitized for the 30 museums in the sample was 18,3%, in line with the results from ENUMERATE survey for 2012 (ENUMERATE, 2014).

ratio of digital images to unique objects (%)	number of museums in a sample	as % of a number of museums in a sample
0	8	26.3
10	8	26.3
20	8	26.3
30	3	10
50	1	3.3
80	1	3.3
90	1	3.3

Table 1. Distribution of parts of collection digitized (as reported by museums in our survey)

Tables 2, 3, 4, and 5 show the results for exploring the web sites of 158 Russian museums in the provinces and major cities to find out what parts of their analogue collections are posted online.

% of digital images representing museum collections online	number of museums	as % of large provincial museums in the sample
0	8	14
from 0 to 0,1	27	47
from 0,1 to 0,98	14	25
from 1 to 10	6	10
more than 10	2	3

Table 2. Parts of museum analogue collections published online. Large provincial museums.

% of digital images representing museum collections online	number of museums	as % of medium-sized provincial museums in the sample
0	13	22
from 0 to 0,1	11	19
from 0,1 to 0,98	21	36
from 1 to 10	9	15
more than 10	4	7

Table 3 Parts of museum analogue collections published online. Medium-sized provincial museums.

% of digital images representing museum collections online	number of museums	as % of museums in the sample
0	6	14
from 0 to 0,1	10	23
from 0,1 to 0,98	15	35
from 1 to 10	11	26
more than 10	1	2

Table 4 Parts of museum analogue collections published online. Museums in Moscow and Saint Petersburg

% of digital images representing museum collections online	number of museums	as % of museums in the sample
0	27	17
from 0 to 0,1	48	30
from 0,1 to 0,98	50	31
from 1 to 10	26	16
more than 10	7	4

Table 5 Parts of museum analogue collections published online. Overall results for 158 museums in the sample.

As shown in Table 5, a third of Russian museums in our sample publish less than 0,1% of their images online while another third of museums post digital images for a bigger part of their collection (but still less than 1%).

Large provincial museums are not enthusiastic about publishing their images online, with half of studied web sites demonstrating results which were lower than 0,1% of their analogue collections. Medium-sized museums show slightly better results, with a third of them displaying between 0,1 to 1% of their analogue collections online. They, however, have fewer objects to digitize and annotate. Museums in the two major cities seem more inclined to post their images online, with a quarter of museums publishing between 1% and 10% of their analogue collections on the Web.

Limitations

Unfortunately, the survey was designed so that respondents only had an opportunity to choose between 0% and 10% options when describing the parts of their analogue collections being digitized. This may have left many respondents with collections in between these figures indecisive on what option to choose, deteriorated the quality and accuracy of the results and may have influenced the response rate. The low response rate is also problematic, but, when combined with our survey of practice still gives us interesting insights to a hitherto undocumented area. Future work will be needed to work with museum bodies on gathering further data.

Conclusion

This work includes the survey results of thirty Russian museum digital collections to find out what part of their analogue collections is digitized. We also studied 158 museum web sites to count the number of digital images representing museum objects and to compare this number to the number of objects in the analogue collections. The average ratio of Russian museum digital collections in the sample of 30 museums compared to their analogue collections was 18,3% which is in line with the results from the ENUMERATE project (ENUMERATE, 2014), and aligns the work of Russian museums to the rate of digitization across Europe.

We have shown that half of large provincial museums in Russia publish an insignificant number of their images on the Web, and further work will allow us to establish why this is the case. Also (at a time when European Museums are being encouraged to adopt the Open Licensing Agenda), further work will pursue the opportunities of sharing digitized collections within Russian legislation.

Notes

[1] Museums of Russia web portal (http://www.museum.ru) includes detailed information on 3063 Russian museums, ranks their web sites, posts news, discussion threads and announcements for curators. Online since 1996, it was initiated by the State Darwin Museum and supported by the RF Ministry of Culture (see also Mikhailovskaya and Nasedkin 2002).

Tracking Online User Behaviour With A Multimethod Research Design

Martijn Kleppe
m.kleppe@vu.nl
Vrije Universiteit Amsterdam, Netherlands, The

Otte Marco
m.otte@vu.nl
Vrije Universiteit Amsterdam, Netherlands, The

Understanding users' online behaviour is of growing interest to academic researchers in a variety of fields. Traditionally, in the marketing domain commercial research companies map consumer behaviour to understand when and where customers decide to buy products. For this purpose, web metrics of individual websites serve as detailed source of information on when, how and at which section a user enters a website. Recently this type of data is also being used by cultural heritage institutes to understand the interest of their visitors (De Haan and

Adolfsen, 2008), to track where their digital content is being reused (Navarrete Hernández, 2014) or to understand the query's users perform in search systems by analysing the log files (Batista and Silva, 2002; Huurnink, 2010). In this type of research, the website is the central research object providing traces that Menchen-Trevino (2013) calls 'Horizontal Data sets'. These contain data that are 'organized around a specific type of trace, for example search terms, web browsing log files, tweets, hashtags, likes or friend and follower ties' (Menchen-Trevino, 2013: 331). An advantage of using this type of data is that they are not obtrusive to the respondents since they are created automatically as users are surfing the web. However, this also leads to an ethical disadvantage since users are not aware that their online behaviour is being examined, nor could they give their consent to have their data being analysed. While Horizontal Data Sets are organized around one type of trace, Vertical Data Sets are organized around research participants that deliberately 'give permission for researchers to collect their digital traces' (Menchen-Trevino, 2013: 331).

Since mid-1990s, commercial research agencies have started to collect these types of vertical data by building tools and panels of respondents whose online behaviour is monitored 24/7 to provide data on usage across media and purchase behaviour (Coffey, 2001; Napoli, 2010; Taneja and Mamoria, 2012). Similar to television viewing rates, these lists are mainly created to gain more insight in the background of website visitors in order to provide potential advertisers with information on how to reach their online target audience in the best possible manner. Obviously these commercial research data contain very rich information, also for academics who are interested in collecting real-world Web use data. However, apart from lists of the most popular domains that are published as open data by companies such as Alexa and Similarweb[1], data containing information about visits to each individual page and information about the background of the panel is not available. Main arguments of commercial agencies to not collaborate with scholars is to ensure the confidentiality of their respondents' identity and to prevent scholars to gain insight into the techniques applied by the companies.

Nevertheless, researchers in a variety of disciplines are interested in tracking online behaviour in a real-world situation. Especially in the communications science realm, scholars experimented with several techniques of tracking people's online behaviour (Ebersole, 2000; Tewksbury, 2003; Findahl et al., 2013; Findahl, 2009; Munson et al., 2013; Damme et al., 2015; Menchen-Trevino and Karr, 2012). Striking about these pioneering monitoring studies is its multi-method approach. By default each does not only monitor web use but also compares its outcome with either survey, diary or interview data. By triangulating the results, these researchers try to overcome the critique on classic studies on media consumption that often deploy either surveys or diaries registering self-reported media behaviour (e.g. Van Cauwenberge, d'Haenens and Beentjes, 2010; Schrøder and Kobbernagel, 2010; Taneja et al., 2012; Reuters Institute for the Study of Journalism, 2015). These methods strongly rely on the memory of the participants while several scholars found respondents often overestimate their media use (Ebersole, 2000; Prior, 2009; Robinson, 1985). Furthermore, since filling in diaries and surveys on news consumption is very labour-intensive, its outcomes mainly focus on *when* media have been consumed or on *which* devices, while it remains unclear *what* has been consumed. One way to gain insight in the consumed news content is focus on metrics of individual news organisations (Batista and Silva, 2002; Boczkowski et al., 2011; Lee et al., 2012; Usher, 2013) or the most clicked items (e.g. Boczkowski et al., 2011; Karlsson and Clerwall, 2013; Lee et al., 2012; Nederlandse Nieuwsmonitor, 2013). However, given the focus of these studies on individual websites or most-clicked articles it remains unknown which genres of news websites constitute users' 24/7 news menu. Do they e.g. visit news about sports mainly in the morning and news on politics mainly during the evening? Taneja at el. (2012) tried to overcome this problem by literally following 495 users throughout an entire day. However, even with this labour-intensive fieldwork it proved not to be possible to incorporate the genres of consumed news items.

Web monitoring tools such as the above mentioned examples, now offer a less labour-intensive and more precise way of registering digitally consumed news items. By deploying these techniques, we could overcome the knowledge gap of the 24/7 news consumption menu. Therefore, we created *the Newstracker*, a custom built system that collects web activities of specified and authenticated users, cleans the data by removing non-relevant data, extracts the associated content and stores this as a new dataset to be used for analysis. While most existing online tracking studies mainly report the visited websites, our set-up goes two steps further. We did not only monitor the website titles but also the actual visited URLs and crawled all textual and visual contents of the visited websites. Since one of the problems when monitoring a person's online behaviour is the magnitude of the data that is being collected (Batista and Silva, 2002; Manovich, 2012; Vicente-Marino, 2013: 43), we deployed automated content analyses techniques (Atteveldt, 2008; et al., 2012) to detect the topics that are being discussed in the news items. This enabled us to calculate the topical online news consumption during the day.

In this paper we will describe the set-up of 'The Newstracker' in a study on the online news consumption of a group of young Dutch news users and its applicability for other types of Digital Humanities research such as user studies focussing on formulating requirements based on existing user behaviour. We will demonstrate the workflow of the Newstracker and how we designed the data collection and pre-processing phase (see figure 1).

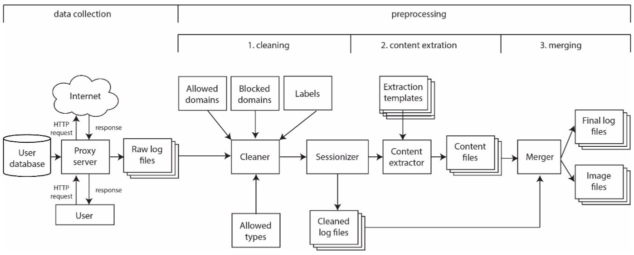

Figure 1. Workflow of the Newstracker application, illustrating the two main phases: Data Collection and Pre-processing. The latter consists of three stages: cleaning, content extraction and merging

By reflecting on the technical, methodological and analytical challenges we encountered, we will illustrate the potential of online monitoring tools such as the Newstracker. We will end our paper with discussing its limitations by stressing the need for a multimethod study design when aiming not only to register but also to understand online user behaviour.

Researchers to your Driving Seats: Building a Graphical User Interface for Multilingual Topic-Modelling in R with Shiny

Thomas Koentges
thomas.koentges@uni-leipzig.de
University of Leipzig, Germany

In this paper I will showcase the results of topic-modelling research undertaken during my 2015 visiting fellowship at Victoria University Wellington (VUW), New Zealand. This research was undertaken in collaboration with staff at the Alexander Turnbull Library, National Library of New Zealand (ATL), and was subsequently applied to the Open Philology Project (OPP) in the Department of Digital Humanities at the University of Leipzig, Germany, and to Classical Persian corpora in collaboration with the Roshan Institute for Persian Studies at the University of Maryland (UMD), USA. The paper emphasizes how humanities researchers, even those who do not have deep scripting knowledge, can be enabled not only to understand, but also to modify the topic-modelling process, adapt it to their corpus- or language-specific needs, and then use the results of this process for further qualitative research. Topic-modelling in digital humanities research is a means to an end that should always help to answer a specific research question. In this way the paper follows an alternative route to previous interactive topic-modelling research, for example Hu et al. (2014) at the University of Maryland. Instead of asking how the method of topic-modelling can be improved by user-input, the author of this paper focuses on the ways in which we can improve the results of topic-modelling while also improving the humanities researcher's understanding of the method and its variables.

After a brief introduction to the research projects in Wellington and Leipzig and to topic-modelling itself, the paper will summarize the limitations of topic-modelling with special emphasis on how to determine an ideal number of topics, as well as a short discussion of morphosyntactic normalization and the use of stop-words. It will then suggest a researcher-focused method of addressing these limitations and challenges in topic-modelling by introducing the Shiny topic-modelling application developed by the author based on R, Shiny, and J. Chang's LDA library and C. Sievert's LDAvis library. The paper will then briefly demonstrate the applicability to the different use-cases at ATL and OPP, which deal with very different fields and languages, including English, Latin, Ancient Greek, Classical Arabic and Persian. The paper will finish by stressing how digital humanities research results and practices can be improved by enabling humanities researchers who focus on more traditional and qualitative analyses of the corpora to use the quantitative method of topic-modelling as a macro-scope and faceting tool; effectively calling humanities researchers back to their driving seats.

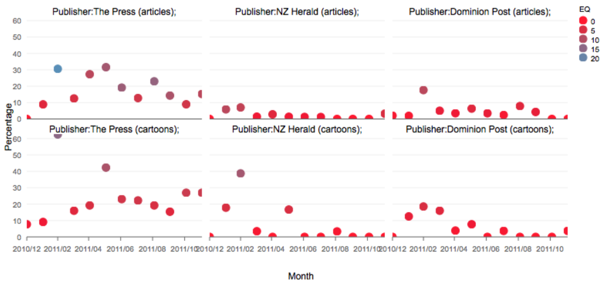

Figure 1: Percentage of earthquake-related articles and cartoons published in three New Zealand newspapers in the period from December 2010 to December 2011 generated using LDA-topic modelling. Also showing combined earthquake score.

During my research stay at VUW I worked with the Research Librarian for cartoons at ATL, Dr Melinda Johnston, on a mixed-methods-based analysis of the reactions of cartoonists and New Zealand print publications to the Canterbury Earthquakes in 2010 and 2011. ATL is part of the National Library of New Zealand, an institution that is interested in making the country's cultural heritage more accessible to a digital audience and researchers. Within the short project I attempted to automatize the detection and analysis of cartoon descriptions created by ATL and over 100,000 abstracts produced by Index New Zealand

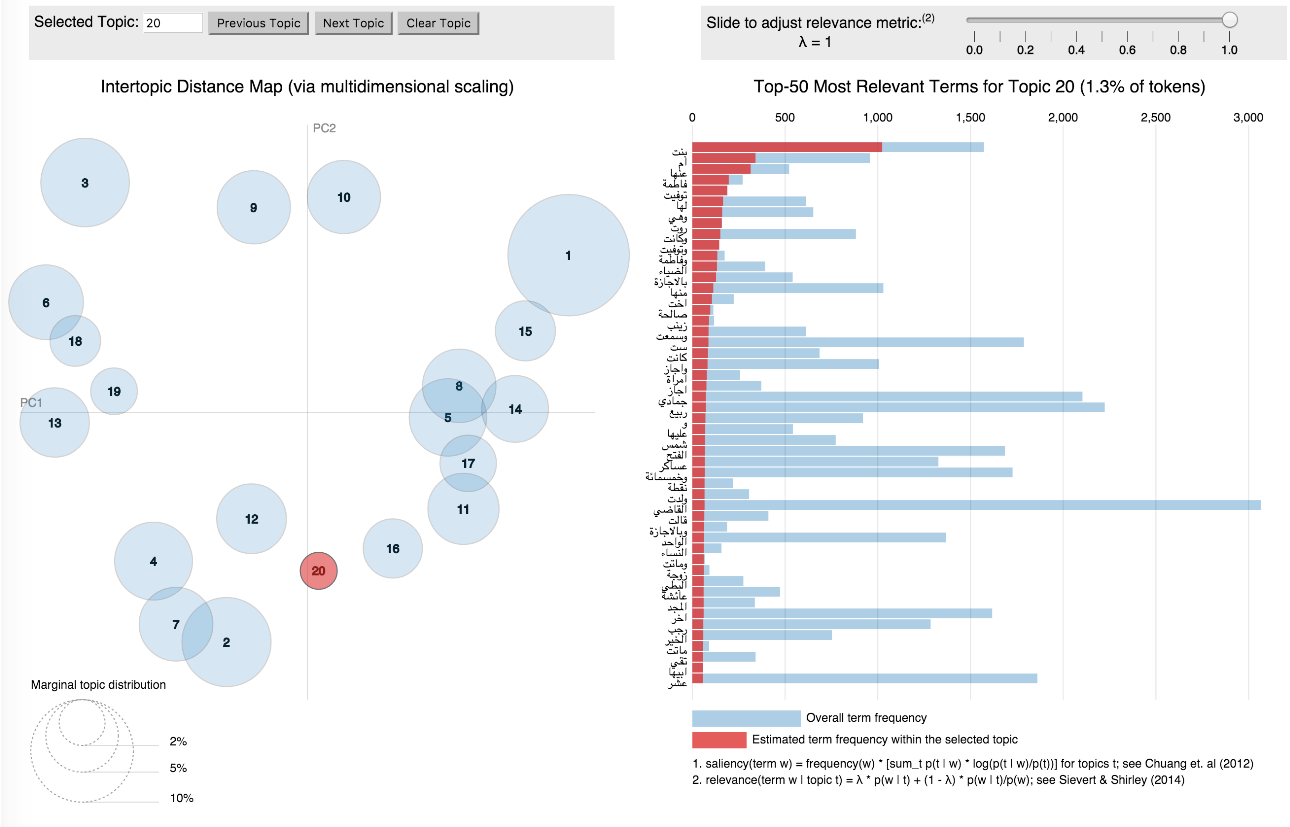
(INNZ); all items were published between September 2010 and January 2014. The INNZ-data could be retrieved as a double-zipped XML file from INNZ's webpage and ATL's item descriptions could be queried using the Digital New Zealand (DNZ) API. During the project it became apparent how a topic-modelling approach, first applied by the author in VUW's Digital Colenso project, could considerably speed up the finding of earthquake-related descriptions and abstracts.

The results were so impressive (see e.g. Figure 1 and forthcoming article by Johnston, M. and Koentges, T. in Alexandria: The Journal of National and International Library and Information Issues) that the author decided to apply it to Latin and Greek literature in Leipzig's OPP project. OPP has a text collection of over 60 million Greek and Latin words, and has recently begun to add Classical Persian and Arabic texts. It is one of the core interests of OPP to produce methods that can compete with more traditional approaches and that can swiftly generate results on big data. OPP is maintained and organized using eXistDB, the CTS/CITE-Architecture developed by the Homer Multitext Project, and additional web-based tools and services, including GitHub repositories and Morpheus, a Greek and Latin morpho-syntactic analyzer. This structure enables researchers to use a CTS-API to retrieve their desired text-corpora or specific texts. In a first evaluation run of the topic-modeller, 30,000 Classical Arabic biographies have been used (see Figure 2).

In both research institutions, OPP and ATL, researchers applying more qualitative methods complemented the process and evaluated results. In what follows the quantitative method topic-modelling will be explained briefly.

Topic-modelling is "a method for finding and tracing clusters of words (called "topics" in shorthand) in large bodies of texts" (M. Posner, 2012). A topic can be described as a recurring pattern of co-occurring words (M. Brett, 2012). Topic models are probabilistic models that are often based on the number of topics in the corpus being assumed and fixed (D. Bley, 2012). The simplest and probably one of the most frequently applied topic models is the latent Dirichlet allocation (LDA). Success and results of LDA rely on a number of apriori-set variables: for instance, the number of topics assumed in the corpus, the number of iterations of the modelling process, the decision for or against morpho-syntactic normalisation of the research corpus, and how stop-words are implemented in the process. Furthermore, its interpretation is often influenced by how the topics are graphically represented and how the words of each topic are displayed.

While Sievert has found already a very convincing solution for the latter (2014), the former is often out of the hands of the qualitative traditional researcher and any bigger modifications would have to be implemented by a computer-savy researcher. However, topic-modelling is often not an end in itself, rather it is a tool used to help answer a specific humanities research question or to facet



Selected Topic: 20

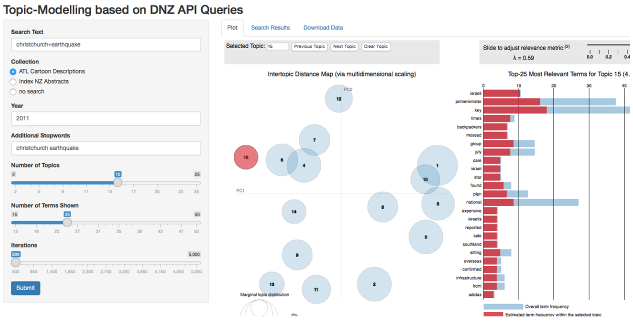
Slide to adjust relevance metric:(2)
λ = 1

1. saliency(term w) = frequency(w) * [sum_t p(t | w) * log(p(t | w)/p(t))] for topics t; see Chuang et. al (2012)
2. relevance(term w | topic t) = λ * p(w | t) + (1 - λ) * p(w | t)/p(w); see Sievert & Shirley (2014)

Figure 2: LDAvis visualization of the result of an LDA-topic model of 30,000 Classical Arabic biographies, showing a topic that can be used to detect biographies of women.

large text-corpora so that further methods can be applied to a much smaller selection of texts. Traditional researchers often have to continue to work with topic-modelling results, but may not always be aware of the bias that the apriori-set variables have brought into the selection process. One possible way to bridge this gap between researcher and method is to involve the qualitative researcher earlier by providing them with agency in the topic-modelling process.

The author of this paper used R and the web-application framework Shiny to combine Chang's LDA- and Sievert's LDAvis-libraries with DNZ/CTS API requests and language-specific handling of the text data to create a graphical user interface (GUI) that enables researchers to find, topic-model, and browse texts in the collections of ATL, INNZ, OPP, and UMD. They can then export their produced corpus and model, so they can apply qualitative methods on a precise facet of a large text corpora, rather than the whole text corpora itself, which contains texts that are irrelevant for answering the researcher's specific research question. On the left side of the GUI, the researcher can set the following variables: a) search term(s) or CTS-URN(s); b) the source-collection; c) certain stopword lists or processes; d) additional stop-words; e) the number of topics; and f) the number of terms shown for each topic in the visualization. The application then generates the necessary API-requests, normalizes the text as desired by the researcher, applies Chang's LDA-library, and finally presents a D3 visualization of the topics, their relationship to each other, and their terms using Sievert's LDAvis and dimension reduction via Jensen-Shannon Divergence & Principal Components as implemented in LDAvis. The researcher can then directly and visually evaluate the success of their topic-modelling and use the settings on the left like the settings of a microscope to focus on certain significant relationships of word co-occurrences within the corpus. Once they have focused their research tool, they can then export visualizations, topics, and their corpus for further research (see Figure 3) and teaching (see Figure 4).



Topic-Modelling based on DNZ API Queries

Search Text: christchurch+earthquake

Slide to adjust relevance metric:(2) λ = 0.59

Figure 3: GUI for Topic-Modelling ATL and INNZ descriptions.

The approach also enables educators to use the topic-modelling results to identify sight-readings for language-teaching purposes. The passages are paired based on the profile of their document-topic values and Perseid's Morpheus API is used to mark vocabulary not-yet-known by the learners. Unknown vocabulary links to an online dictionary, using markdown (see Figure 4).

The First World War in Perm Provincial Periodicals

Sergei Kornienko
kornienko@psu.ru
Perm State University, Russian Federation

Dinara Gagarina
dinara@psu.ru
Perm State University, Russian Federation

Regional newspapers' periodicals hold a firm place in the humanities among the sources of studying the First World War and its impact on the state and development of the countries and nations in the early 20th century. This kind of sources is especially significant at the level of micro-history and history of everyday life. At the same time, it is complicated to put provincial periodicals into scientific circulation due to problems of access, preservation, organization as well as effective search and analysis of information (Kornienko and Gagarina, 2015).

The source-oriented information system "The First World War in Perm Provincial Periodicals" (http://perm-newspapers.ru/) is an integrated solution to identify problems based on approaches, methods and technologies of Digital Humanities in general and Digital History in particular. The project is realized in the laboratory of historical and political information science of Perm State University in cooperation with the Perm Regional Museum (Russia).

The information system provides free access for scholars to images and full-texts of ten newspapers collections published in Perm province during the First World War. There are more than 2500 issues. Publications cover periods of Imperial Russia, the 1917 Revolution and the Civil War and represent different ideological political movements. These editions include:

- official periodicals of provincial administration of Imperial Russia: "Пермские губернские ведомости" ("Perm Province Bulletin");
- official periodicals of the 1917 Revolution and the Provisional Government period: "Вестник Пермского края" ("Herald of Perm Region"), "Пермский вестник Временного правительства" ("Perm Herald of Provisional Government");
- official newspapers of various levels councils:
- provincial level: "Известия Пермского губернского комитета" ("News of Perm Provincial Committee");branch level: "Известия исполнительного комитета Совета железнодорожных депутатов Пермской железной дороги" ("Proceedings of the Executive Committee of the Board of Railway Deputies of Perm Railroad");district (uyezd) level: "Известия Осинского исполнительного комитета Совета крестьянских, рабочих и солдатских депутатов" ("News of Osa Executive Committee of Peasants, Workers and Soldiers Deputies");
- official gazette of the Perm Province Zemstvo: "Пермская земская неделя" ("Perm Zemstvo Week").

Meaningful diversity and variety of publication's types are distinguishing features of the provincial newspaper periodicals. Official and unofficial newspapers published full texts of normative acts of different levels authorities, official announcements and telegrams, reference and information materials, articles, notes, satires, and others. There were treatments of government, laws and draft laws, regulations, diplomatic notes, information from the fronts of the First World War, reports on meetings of the Government, the Interim Committee of the State Duma, the State Conference and other agencies, including provincial and district authorities, as well as non-government organization. The newspapers published various materials on local history, geography, statistics, ethnography and cover topical issues of socio-economic, political, scientific and cultural life of the country and the region.

Such breadth of perspective and variety of publications leads to a high level of demand for local periodicals as a source of information for humanitarian studies in political, economic and social history, the history of printing and journalism, literature, linguistics, philology, cultural studies, political science, etc.

However, a variety of information submits special claims for its structuring in the information system, the search tools, representation and visualization of electronic versions.

The informational system "The First World War in Perm Provincial Periodicals" is structured based on metadata system that includes thematic fields (rubrics, headings, subheadings of publications), geographical, toponymical fields, personalities. This provides effectiveness of information retrieval and samples formation on various topics, issues, and other criteria at the level of the issue, single newspaper or their combination as well as whole collection. The system also gives possibilities to search keyword and context on titles and full texts for all editions and publications.

The informational system allows visualization of information at the level of newspapers, issues and publications. The results of search requests are displayed in the form of various lists and full-text publications. Each issue of newspapers is presented page by page in PDF format (text below the image), which help to preserve the text content and appearance of newspapers as much as possible. In addition, this method of representation allows text verification and editing as well as reading if OCR is found to be impossible. Texts of publications on the First World War theme are presented in HTML format. Both PDF files and texts as well as all other information and metadata on newspapers, issues and publications are stored in MySQL database.

Organization and structuring of sources data, search tools and visualization tools allow to obtain data on a wide range of issues related to the First World War, life and activities of the region's population in this period.

The information system "The First World War in Perm Provincial Periodicals" provides new possibilities for evaluating potential sources of information, completeness, representativeness and credibility of Perm newspapers periodicals, using computer processing techniques, obtaining new data for scientific humanities research.

Issues that can be studied by the system include attitude towards the war of different social classes and various persons in Perm, the evaluation of forces and the actions of Russia, its allies and opponents. It covers key war events, the role of various commanders, activities of Nicholas II, events in the Perm province and its districts related to the war and their consequences, the creation of images of the war, daily life in the rear and the fronts, etc.

Techniques and methods for solving research tasks are developed based on different types of database queries, which allow obtaining quantitative characteristics, samples for various themes and for specific items of publications. The implementation of these types of queries permits to determine the most common types and genres, subject focus of publications and their relation, generate text fragments and interpretation of the results in terms of the completeness and nature of the information source.

The study is supported by Russian Foundation for Humanities (grant 14-11-59003).

Language Attitudes of Twitter Users Toward New York City English

Nathan LaFave
nathan.lafave@nyu.edu
New York University, United States of America

New York City English (NYCE) has long been a stigmatized variety of English. In his seminal research on language use in the New York City dialect, the sociolinguist William Labov referred to New York City as "a great sink of negative prestige" (Labov, 1966)—a characterization that reflected the negative view of NYCE speech shared by non-New Yorkers and New Yorkers alike. Decades later, Preston (2003) elicited extremely low ratings of the New York City dialect on scales of both "correctness" and "pleasantness" by participants from across the US. While these studies present strong evidence of the prevalence of negative language attitudes toward NYCE speech, a more complete picture of linguistic ideology would include what speakers say about NYCE when they are not participating in an academic study. This project seeks to accomplish just that, by examining linguistic ideology with respect to NYCE as espoused by users of the social networking service, Twitter.

Twitter has been recognized as an important resource for humanists and social scientists alike. Scholars have collected and analyzed Twitter messages (tweets) in order to investigate numerous textual and linguistic phenomena such as *lexical variation* (differences in use of synonymous words and phrases, such as *pop* vs. *soda* vs. *coke*). Russ (2012) in particular (see also Bamman, 2011) illustrates the utility of Twitter for examining regionally defined lexical variation through comparison of the geographic distribution of word choices in *geotagged* tweets (with GPS coordinates from which they originated) to more traditionally collected dialectology data. All related research has focused on differences in production. However, I argue that Twitter represents an untapped resource for the investigation of *perceptions* of language use, particularly language attitudes toward regional dialects and differences in their phonetic features (which can be identified by non-standard orthography). Using Twitter solves a primary quandary for language attitude researchers—how to acquire naturally occurring data given the fact that participation in research decreases naturalness.

Tweets containing attitudes and ideology were collected using a range of strategies, including text mining for words—and, crucially, spellings—that reference individual features. To do this, however, it is necessary to determine which features get noted and then which lexical items—and which spellings—are used to signal them. For instance, *cawfee* (also, *cawffee*) is a common orthographic representation of the word "coffee" as pronounced with a raised-THOUGHT vowel, one of the signature dialect features of NYCE. Widely used spellings that reflect *r*-vocalization, another key feature of the NYCE dialect, include *New Yawk* and *fuhgeddaboudit*. In addition to collecting tweets containing orthographic representations of nonstandard features, Twitter search parameters included over 20 terms related to possible names for the dialect itself (e.g., *New York accent, Manhattan dialect, Brooklynese*). These were included in part to determine the extent to which the general public perceives a distinction among speakers from the five boroughs (a distinction which has not been borne out by linguistic analysis).

Repeated automated text mining of Twitter using a Python script to interact with the Twitter API yielded 6,384 tweets that match the aforementioned criteria. Elimination of retweets that did not introduce additional linguistic content and inspection to ensure the tweets reference NYCE produced a final corpus of 1,773 tweets. Relative frequencies of the borough-specific and pan-regional terms in the 1,315 tweets that explicitly reference NYCE by some name reveal that Twitter users most frequently refer to NYCE as the *New York accent* (N=805; 61.2%), though *Brooklyn accent* (N=359; 27.4%) accounts for more than a quarter, with *Bronx accent* (N=54), *Queens accent* (N=29, tied with *Brooklynese*—the most frequent *-ese* moniker), and *Staten Island accent* (N=10) being used much less often. Whether *New York accents* and *Brooklyn accents* are perceived as linguistically or socially distinct, or two names for the same dialect region, will be explored in the paper.

All tweets were manually coded to determine their sentiment with respect to NYCE.

- POSITIVE: *I swear girls from New York accent sound so sexy*
- NEUTRAL: *GAWGEOUS idea she said in her New Yawk accent*
- NEGATIVE: *If you have a Brooklyn accent I automatically want to punch you.*

Almost half of these tweets are neutral in sentiment (N=584, 44.4%); 378 were positive (28.7%) and 200 negative (15.2%). However, 154 tweets were classified as UNCLEAR (8.7%)—many are ambiguous as to whether they evaluate an imitation of an accent or the accent itself, such as when describing an actor's performance (which is common among these types of tweets):

- UNCLEAR: *his New York accent is so bad /:*

Examples such as these pose significant obstacles to automated sentiment analysis—which has been extended to Twitter data (see for instance Pak and Paroubek, 2010)—particularly of language attitudes. Automatic methods would simply code the tweet as negative without recognizing the need to differentiate its underlying meaning. It is noteworthy, however, that even if every UNCLEAR tweet is actually expressing negative sentiment, there would *still* be a greater number of tweets with positive opinions of NYCE speech than negative ones. Furthermore, when Twitter users reference a specific NYCE feature, their evaluation of it is more likely to be positive, regardless of whether they use standard (N=79) or nonstandard (N=568) orthography to represent the feature.

These findings portray a broader range of reactions to NYCE than the language attitudes speakers have presented when engaged in academic research. The paper will include discussion of both negative and positive language attitudes that Twitter users espouse concerning the dialect features associated with NYCE. For instance, any tweets with positive sentiment will be examined to determine if they represent instances of "covert prestige" (Labov 1966), whereby speakers use stigmatized varieties for in-group identification and solidarity. Additional discussion will focus on which regional features evoke the most metacommentary. Furthermore, I will explore the extent to which Twitter users draw (additional) attention to nonstandard forms they employ through capitalization (*NEW YAWK*), hashtags (*#newyawk*), and other orthographic means.

All in the Family: Testing Burrows' Delta on Robert Louis Stevenson's Collaboratively Authored Volumes The Dynamiter and The Wrecker

Anouk Lang
anouk.lang@ed.ac.uk
University of Edinburgh, United Kingdom

Robyn Pritzker
s1259282@sms.ed.ac.uk
University of Edinburgh, United Kingdom

Robert Louis Stevenson (1850-1894) is known to have co-authored several of his works, including *The Dynamiter* (1885), on which he collaborated with his wife Fanny van der Grift Stevenson (Stevenson and Stevenson 1885). Until recently, Stevenson scholars had comparatively little information about how the collaboration around *The Dynamiter* had operated, with one narrative claiming prominence: the preface to the 1905 edition written by Fanny (after her husband's death) which stated that she had invented the stories during an illness of his, and they had subsequently worked collaboratively to put them into written form (Stevenson 1905).

In this paper, we take insights gleaned from our previous work on the authorship of *The Dynamiter* (carried out with collaborators Mingyuan Chen, Carlos Fonseca, Laura McAleese, Alba Morollón Díaz-Faes and Elizabeth

Nicholas) to investigate another text, *The Wrecker* (1892). (At the time of submitting this abstract, the authorship analysis of *The Wrecker* had not yet been carried out, so we have supplied details about our previous study so as to demonstrate that the methods used are both appropriate and robust.) We used the R package Stylo (Eder et al. 2015) to apply Burrows' Delta (Burrows 2002) to two reference corpora containing works known to have been solely authored by Fanny or Robert Louis, and used these as comparators against the individual stories in *The Dynamiter*.

Visualizing the results in the form of a cluster analysis indicated that Burrows' Delta performed well at separating out texts known to be authored by Fanny from texts known to be authored by Robert Louis (Fig 1.)

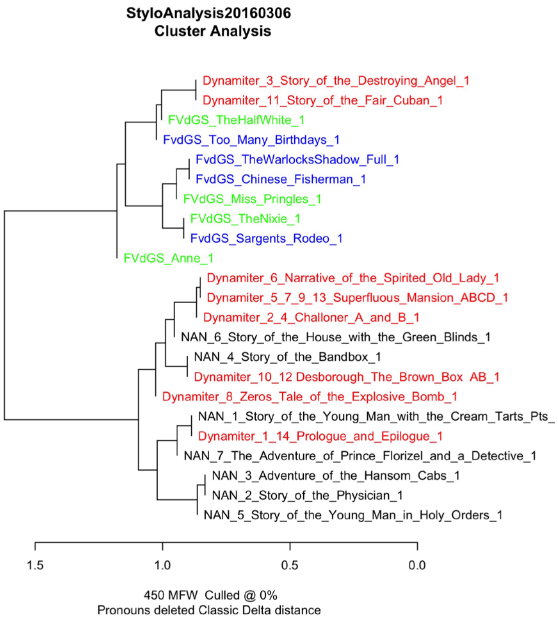

Fig. 1. Cluster analysis of Burrows' Delta scores of the 450 most frequent words in texts by Fanny, in green and blue, by Robert Louis, in orange and black, and *The Dynamiter*, in red (pronouns deleted, no culling).

Our interpretation of these results was that the stories Fanny was most likely to have authored from *The Dynamiter* were "The Story of the Destroying Angel" and "The Fair Cuban". However, it is important to note that while Fanny may well have had an originating role for the plot of many, if not all, of the stories – something which the Preface to the 1905 edition seeks to establish – when it came to the actual writing down of the stories, the "signal" from her linguistic signature was made less clear by the "noise" of her husband's heavy editorial hand (something which is known from biographical and historical writings about their relationship).

Building on this earlier work on *The Dynamiter*, the paper we propose here will examine another work co-authored by Stevenson: *The Wrecker*, also a volume of short stories, which Stevenson co-authored with his stepson Lloyd Osbourne. Stylo will again be used, as will insights from the many *Dynamiter* tests. These indicated, for instance, that deleting pronouns resulted in better separation of texts in the reference corpus, something we attributed to Stevenson's tendency to write about predominantly male characters, which resulted in the prevalence of male pronouns. With the experience gained from attempting to find a solution to the "signal" vs. "noise" problem caused by Robert Louis's proclivity to edit the work of his collaborators, we will also investigate how changes to additional parameters offered by Stylo – changes to the number of most frequent words considered, for example, and variations in text sample size – affect the results of the *Wrecker* tests.

As mentioned above, our earlier results suggested that Robert Louis's editing practices – he had a tendency to edit texts meticulously prior to publication – makes it hard to determine with certainty which sections were written, or initially drafted, by Fanny. A model of co-authorship in which the boundaries between one author and another are clear-cut – where the assumption is that one person is solely responsible for some sections and a second person is solely responsible for others – breaks down in a situation such as this, where the shared domestic space of two authors means that close consultation with – and iterative redrafting of the work of – one's familial collaborator is not simply possible but likely. It underlines the need for stylometric analysis to be complemented with careful literary historical analysis in order to arrive at any meaningful conclusions.

The broader significance of this work is that it is not only of relevance for the field of authorship attribution, but also for its recuperative potential in relation to figures who are less prominent within literary history, including women. Despite scholars' awareness of Fanny's involvement with her husband's writing, for instance, there is still minimal research into how she influenced his work, and how other women in similar positions influenced their famous husbands' legacies. In bringing to light the omitted literary contributions from women and other family members, what emerges is the need for theoretical approaches capable of evaluating the gendered practices of literary studies and book history in contributing to these omissions. In analysing letters and journals, combing through stylometric data, and assessing biographical accounts, there is a risk of overlooking collaborations in favour of other types of partnerships (amanuenses, muses, and the like). A woman like Fanny van der Grift, who history has recorded as a keen writer, diarist, and editor, surpasses the labels that book history has offered her. While authorship attribution analysis offers one set of useful tools for breaking down these barriers, further critical engagement with our own gendered scholarly practices is necessary to more clearly understand how and why certain works and canons have become established in the way that they have.

Morphology beyond inflection. Building a wordformation based dictionary for Latin

Eleonora Litta
e.littamodignani@gmail.com
Universita' Cattolica del Sacro Cuore, Italy

Marco Carlo Passarotti
marco.passarotti@unicatt.it
Universita' Cattolica del Sacro Cuore, Italy

This short paper describes the initial phases of a Marie Curie Research Project, *Word Formation Latin* (WFL), developed at the Centro Interdisciplinare di Ricerche per la Computerizzazione dei Segni dell'Espressione (CIRCSE), at the Università Cattolica del Sacro Cuore, Milan, Italy. The project consists in the compilation of a derivational morphological dictionary of the Latin language, which connects lexical elements on the basis of wordformation rules, through the use of computational linguistic methods.

In the past two decades there has been a considerable increase in the creation of computational language resources for the investigation of classical languages, which have updated the state of the art almost to the same level as that of the resources currently available for modern languages.

However, among the existing language resources, we currently lack, for Latin, a morphological derivational dictionary that connects lexical elements on the basis of Word Formation Rules[1] (WFRs).

A first attempt at constructing a lexicon based on wordformation for Latin was made by Marco Passarotti and Francesco Mambrini in 2012 (Passarotti & Mambrini, 2012). The WFL project has been awarded funding to expand on these efforts.

The project has three main aims:

1. the enrichment of an existing morphological analyser for the Latin language, LEMLAT (Passarotti, 2004), with wordformation information, and the integration of data within a interface similar to Word Manager (Domenig & ten Hacken, 1992), which has been already applied to other modern languages (English, German, Italian);

2. the integration of the information extracted from the resulting derivational morphological dictionary into the morphological layer of annotation the *Index Thomisticus* Treebank (IT-TB);[2]

3. offering the results of the project work via a user-friendly project website which will display the derivational morphological dictionary through a web based search interface. This will allow the lexicon to be accessed:

   1. by single lexical entry, which will show both the ancestors and their derived words;
   2. by morphological family;[3]
   3. by WFR.

The project relies on the automatic realisation of the linguistic resource both at the level of WFRs creation and to their application on the lexical items included in the morphological analyser LEMLAT. The LEMLAT lexical basis contains around 40.000 lemmas from three major Latin dictionaries (Georges, 1913-1918; Gradenwitz, 1904; Glare, 1982). We conceived WFRs according to the so-called Item-and-Arrangement model (IA), which follows a morpheme-based approach to morphology. In IA, word forms are analysed as arrangement of morphemes according to the following three axioms:

1. Roots and affixes have the same status of morphemes (Baudoin's single morpheme hypothesis);

2. They are dualistic, as they have both a form and a meaning (Bloomfield's sign base morpheme hypothesis);

3. They are stored in the lexicon (Bloomfield's lexical morpheme hypothesis).

The aim is to assign a WFR to each morphologically complex lemma (i.e. one morphologically derived from another lemma) and to link each complex lemma to its ancestor. The data are organised and presented according to a system similar to that for morphological dictionaries devised by Word Manager, in which relations between the members of the same morphological family are represented in a tree-graph.

WFRs are grouped in two classes: 1. compounding; 2. derivational. Derivational rules are divided in two categories: a. affixal (in its turn split into prefixal and suffixal), and b. conversive, a derivation process that does not imply any affix; these are manually defined.

This happens in two steps:

1. Phase A: Semi-automatic data-driven finding of WFRs:

1. lemmas are divided into two classes, according to their part of speech and inflectional category;

2. two lists are produced: an *incipitarium* and an

explicitarium, where lemmas are ordered according to a traditional alphabetical order, or to a right-to-left alphabetical order respectively;

3. prefixal and suffixal rules are created from the two lists respectively, part of speech and inflectional category of the lemma(s) are manually assigned to each candidate rule.

2. Phase B: Application (and evaluation) of the WFRs resulting from Phase A, and creation of the "morphological families". New rules are added in this phase by confrontation with data. Phase B is divided into two subtasks:

1. each complex lemma is assigned a WFR. This task is performed by assigning in semi-automatic fashion to each (possibly) complex lemma its most likely WFR according to the PoS of the lemma and the string of its initial (prefixal rules) and final (suffixal rules) characters;
2. morphological families are built.

All those (morphologically simple, or complex[4]) lemmas that share the same invariable part are automatically assigned to the same morphological family.

Finally, the members of each family are automatically linked to each other according to their PoS, inflectional category and affixes by means of the WFR assignment (2.a). The morphologically simple (i.e. not derived) lemma member is assigned the role of ancestor of the family.

Phase A finds the WFR, Phase B applies the WFR to data, obtaining input and output lemmas for each WFR.

Phase A is not to be considered exhaustive, but exploratory: the recall of WFR identified in Phase A is not 100%. The aim in the first phase of the project is to refine the data by tagging the highest number of lexemes using data driven WFRs, which will be increasingly complex, covering most well known wordformation issues.[5] Given the high number of homographs in Latin, this automatic procedure is regarded as non-ultimate for building the morphological families. However, it is helpful as it provides filtered data that must be checked manually.

This is why we need Phase B during which, by comparison with the evidence given by data, we can identify the rules that were missed in phase A. Manual hardcoding will be necessary for those lemmas produced by poorly productive WFRs, or morphotactically obscure wordformation processes. Evaluation of the language resource is performed by manual checking data organised into homogeneous groups based on WFRs (coverage of rules) and stemming (coverage of morphological families). Precision and recall are used as evaluation metrics in order to calculate the rate of positive and negative cases.

To date, 118 WFRs have been found automatically. Around 50 of these rules, those showing a certain degree of morphological transparency, hence easier to obtain through the automatic finding in the input-output relation (e.g. derivational, verb-to-verb, prefixal, etc.), have been added to a SQL database, and resulted in the tagging of some 9000 morphologically complex lexemes.

The final resource will be both a standalone dictionary accessible through its own website, and interconnected with the *Index Thomisticus*.

The integration with the IT-TB will be operated through the embedding of the dictionary data within the morphological layer of annotation of the treebank, using TEI (Text Encoding Initiative) P5 conformant XML encoding to favour data exchange and linking to other lexical resources. The data resulting from the dictionary, once encoded in XML, will be applied to the IT-TB data.

Notes

[1] Word formation is the creation of a new word from either the combination of two other words (*dish-washer*, compounding) or of adding one of more affixes to an existing word (*wash-er*, derivation), or from a part of speech change (*clean*, verb vs. *clean*, adjective).

[2] The *Index Thomisticus* (IT) is considered a pathfinder in digital humanities; started by Padre Roberto Busa in 1949. It is a database retaining the *opera omnia* by Thomas Aquinas (118 texts), plus works by other 61 authors related to Thomas

(61 texts). The size of the corpus is around 11 million tokens (150.000 types; 20.000 lemmas). The corpus is fully lemmatised and morphologically tagged. The IT-TB, based at CIRCSE, is the syntactically annotated portion of the IT, and it contains around 300.000 tokens for 15.000 syntactically parsed sentences.

[3] By "morphological family" we mean the set of lemmas morphologically derived from one common ancestor-lemma

[4] WFRs do not take in input morphologically simple lemmas only, but also complex ones. For example, the noun *excubatio* derives by suffixation from the verb *excubo*, which is morphologically complex, as it is derived (by prefixation) from the verb *cubo*.

[5] i.e. stem change featuring internal vowel alternation (*fac.io*, *per-fic-io*), assimilation of prefix (*fer-o* > **ob-fer-o* > *of-fer-o*), unclear segmentation (*cre-a-tor* or *cre-at-or*?), etc.

Analyzing the 17th Century Theatre Critique Texts with a Semantic Annotation Tool Driven by a Dedicated Ontology

Project "Haine du Théâtre"

This experiment takes place within the "Haine du Théâtre"[1] Project, which aims at analysing theatre debates in Europe by using scientific approaches and critical editions of polemical texts. The reflections of the team were primarily focused on the discovery of the circumstances and arguments used in theatre all across Europe, not limited to France, but including England, Spain, Italy, and the Germanic area. The timeframe encompassed the last decades of the 16th century up to the beginning of the 19th century. The purpose of the Project is to explore the grey areas of the controversies in order to outline a global overview of the situations which led to these polemics, discovering where and how they began, their chronological discrepancies in the different countries, and the links between them and their contemporary resurgences.

Corpus

The total collection of the Haine du Théâtre Project related to France made up of 300 texts in the PDF format. The XML/TEI critical edition of 27 texts has been achieved manually (examples of the main titles of this TEI corpus are D'Aubignac (1666), Conti (1666), Pierre Nicole (1667), Voisin (1671), Vincent (1647), cfr. <http://obvil.paris-sorbonne.fr/corpus/haine-theatre/>) and this small corpus is used for the semantic analysis we present here.

This collection is a homogenous combination of texts in which the different authors express their approval or their condemnation of theatre. Using the ontology we created, our interest was to discover to what extent the personal judgment of each author was celebratory or derogatory about theatre and, also, which arguments were mostly involved in their critiques.

In this direction, we had two main goals:

1. Organizing the knowledge about polemics in theatre and their vocabulary;

2. Use this structured lexicon for the corpus annotation and its analysis.

Building of the ontology

An ontology is a good way to automatically analyse many texts together along two parameters: documentary and linguistic. On the one hand, by improving a state of knowledge about 17th century French ; on the other hand, by refining the vocabulary linked to theatre controversy.

The ontology organizes the knowledge of our domain (polemical texts about theatre) as structured points of view (condemnation, defence, etc.) as well as 44 structured classes (concepts) related to critical controversies.

These classes report the axiological points of view (the judgment of the authors), their objects (such as *jongleur*, *actrice*, etc.), and the thematics of the polemics (*religion*, *emotions*, etc.).

To detect the salient terms pertaining to each concept, we realized that in most texts of the modern period, authors' judgements revolve around quoted authorities. The context and the deep knowledge of the corpus together with expertise in 17th century French constitute the cornerstones of our approach. It is very important to fully understand the contextual meaning (in the 17th century) of the selected salient terms.

The idea we came up was to look at the relative importance of the various semantic fields in each chapter of the collection, then extract a priori the content of a chosen text. We began to use this structured lexicon of outstanding terms related to theatre polemics for the corpus annotation and its analysis.

To our knowledge no other comparable ontology about theatre polemics exists; therefore, we will present the method we conceived keeping in mind that those classes are not exhaustive and that new questions will require the creation of new classes.

Despite the high specificity of the domain, this ontology model and the automatic annotator are deployable in other contexts, such as literary criticism and theatre critique in different languages. For this purpose we will translate the model into English (the set of the attributes useful for the annotator).

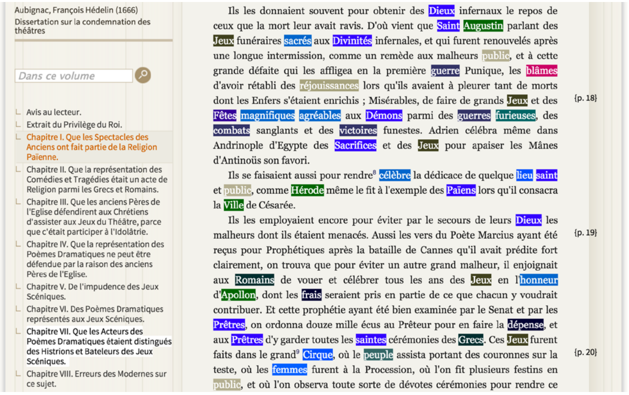
Snapshot of the TEI annotation (François Hédelin d'Aubignac, *Dissertation sur la condemnation des théâtres*, 1666, "Chapitre I. Que les Spectacles des Anciens ont fait partie de la Religion Païenne")



Aubignac, François Hédelin (1666)
Dissertation sur la condemnation des théâtres

- Avis au lecteur.
- Extrait du Privilège du Roi.
- Chapitre I. Que les Spectacles des Anciens ont fait partie de la Religion Païenne.
- Chapitre II. Que la représentation des Comédies et Tragédies était un acte de Religion parmi les Grecs et Romains.
- Chapitre III. Que les anciens Pères de l'Eglise défendirent aux Chrétiens d'assister aux Jeux du Théâtre, parce que c'était participer à l'Idolâtrie.
- Chapitre IV. Que la représentation des Poèmes Dramatiques ne peut être défendue par la raison des anciens Pères de l'Eglise.
- Chapitre V. De l'impudence des Jeux Scéniques.
- Chapitre VI. Des Poèmes Dramatiques représentés aux Jeux Scéniques.
- Chapitre VII. Que les Acteurs des Poèmes Dramatiques étaient distingués des Histrions et Bateleurs des Jeux Scéniques.
- Chapitre VIII. Erreurs des Modernes sur ce sujet.

Ils les donnaient souvent pour obtenir des Dieux infernaux le repos de ceux que la mort leur avait ravis. D'où vient que Saint Augustin parlant des Jeux funéraires sacrés aux Divinités infernales, et qui furent renouvelés après une longue intermission, comme un remède aux malheurs public, et à cette grande défaite qui les affligea en la première guerre Punique, les blâmes d'avoir rétabli des réjouissances lors qu'ils avaient à pleurer tant de morts dont les Enfers s'étaient enrichis ; Misérables, de faire de grands Jeux et des {p. 18} Fêtes magnifiques agréables aux Démons parmi des guerres furieuses, des combats sanglants et des victoires funestes. Adrien célébra même dans Andrinople d'Egypte des Sacrifices et des Jeux pour apaiser les Mânes d'Antinoüs son favori.

Ils se faisaient aussi pour rendre[8] célèbre la dédicace de quelque lieu saint et public, comme Hérode même le fit à l'exemple des Païens lors qu'il consacra la Ville de Césarée.

Ils les employaient encore pour éviter par le secours de leurs Dieux les malheurs dont ils étaient menacés. Aussi les vers du Poète Marcius ayant été {p. 19} reçus pour Prophétiques après la bataille de Cannes qu'il avait prédite fort clairement, on trouva que pour éviter un autre grand malheur, il enjoignait aux Romains de vouer et célébrer tous les ans des Jeux en l'honneur d'Apollon, dont les frais seraient pris en partie de ce que chacun y voudrait contribuer. Et cette prophétie ayant été bien examinée par le Senat et par les Prêtres, on ordonna douze mille écus au Prêteur pour en faire la dépense, et aux Prêtres d'y garder toutes les saintes cérémonies des Grecs. Ces Jeux furent faits dans le grand[9] Cirque, où le peuple assista portant des couronnes sur la {p. 20} teste, où les femmes furent à la Procession, où l'on fit plusieurs festins en public, et où l'on observa toute sorte de dévotes cérémonies pour rendre ce

Snapshot of the HTML highlighting of the annotation (François Hédelin d'Aubignac, *Dissertation sur la condamnation des théâtres*, 1666, "Chapitre I. Que les Spectacles des Anciens ont fait partie de la Religion Païenne"). The salient words of the religion thematic, very important in this chapter, are highlighted in dark blue ("Dieux", "Saint", "Divinités", "Démons", "Sacrifices", "Païens", "Dieux", "Prêtres", etc.)

The annotation tool

We created an annotator in order to markup all the forms of the outstanding terms, recorded as lemmas in the ontology ("horrible", "horribles", etc.), except when:

- the exact form matters: the tool annotates only the exact form ("Père" does not match "père", "pères");
- the gender matters: only the feminine forms, singular and plural ("courtisane(s)" which is a linguistic sign of the "Femme" concept in our ontology does not match the masculine forms "courtisan(s)").

The annotation tool enriches automatically the TEI files by setting down some <term> tags to mark all the forms, but also their lemma and the related semantic field.

Following this method we find a high density of salient terms (on average 9,5% of words in each the chapters) in our collection of texts. The combination of these linguistic signs and related semantic fields emerges as a semantic descriptor of the corpus content (e.g. http://obvil-dev.paris-sorbonne.fr/corpus/haine-theatre/vincent_traite-des-theatres_1647/vincent_traite-des-theatres_1647_6).

Semantic analysis

Without preconceived notions and previous knowledge of the corpus, it was possible for us to answer numerous research questions. By examining the intensity of condemnation in the corpus, we discovered that the most derogatory chapters belong to Nicole and Conti.

chapter_id	condemnation_ terms	defense_ terms	chapter_ length (words)	condemnation intensity (‰)
nicole_traite-de-la-comedie_1667_4	6	0	762	7,87
nicole_traite-de-la-comedie_1675_4	6	0	906	6,62
conti_traite-de-la-comedie_1666_14	21	1	4536	4,63

Examples of the condemnation intensity

By virtue of the possibility of making cross queries across multiple classes, we were able to obtain a list of the arguments developed by the authors – which can be confirmed by reading the chapters concerned. For instance, the most derogatory chapters about theatre were written by Nicole and Conti.

chapter_id	"Théâtre" and "Morale Négative" thematics relative stores 2(‰)
nicole_traite-de-la-comedie_1667_4	66,67
nicole_traite-de-la-comedie_1675_4	56,25

nicole_traite-de-la-comedie_1675_1	41,67
conti_traite-de-la-comedie_1666_14	41,24
nicole_traite-de-la-comedie_1675_13	40,75

The most derogative chapters

We can also compare the chapters more concerned with, for instance, condemnation and the thematic of "Women". We discovered that the chapters more concerned with misogyny belonged to Voisin, Conti and Nicole. The discriminant terms for woman are, in these derogatory chapters: "femme, fille, bouffonne, maîtresse, comédienne". Those are just examples of the queries we can construct with the annotation tool.

At this point, the results of the computational analysis reveal some critical conclusions about the textual tradition analysed. Continuing this kind of analysis for every concept present in the ontology, we found that some authors are more concerned with all the elements of theatrical debates, whereas others deal only with some of them.

In particular, we found a high concentration of annotated terms in Voisin, Conti, Nicole and Aubignac, whose chapters usually occupy the first 20 results for most thematics. On the contrary, authors like Vincent, Guillot-Gorju, Le Marcant and Gaule score high only when relating to economic issues.

chapter_id	**"Economy" thematic relative stores[3](‰)**
vincent_traite-des-theatres_1647_9	3.77
vincent_traite-des-theatres_1647_7	3.40
anonyme_honneur-theatre_1620_1	3.1
guillot-gorju_apologie_1634_1	2.75
lemarcant_conduite-du-vrai-chretien_1694_1	2.50
nicole_traite-de-la-comedie_1667_18	2.33

The concentration of the economic thematic. These results show that the economy is at the core of the descriptions by another group of authors: Vincent, Guillot-Gorju, Le Marcant.

For example, some very specific arguments are associated in the controversy, like women, passion and the economy. Moreover, results have shown that some authors of the corpus focus on only few topics of the polemics, whereas others, like Vincent, concentrate all the topics of the theatre polemic in his 11th chapter.

Conclusions

The HdT ontology organizes the knowledge about the theatre polemics and their vocabulary. In particular, it presents a hierarchical lexicon of salient terms and it reflects the points of view, objects and thematics of the polemic.

This ontology enables the exploration the corpus for research questions: the relative frequency of the salient terms (*lemma*) and of their related class (*catégorie d'indexation*) is a semantic descriptor of each chapter. Those descriptors can be exploited for the semantic exploration of the corpus, capitalizing on the ontology structure (terms / classes). The researchers can understand the intensity of the concepts they choose to analyse and thus can focus on the most significant chapters of the corpus.

[2] The score is the ratio between the theatre and the condemnation terms over the chapter length (number of words).

[3] The score is the ratio between the economy terms and the chapter length (number of words).

Méthodes computationnelles et analyse d'une langue de chancellerie: le logiciel d'analyse textuelle Machiato et la correspondance diplomatique et administrative de Machiavel

Corinne Manchio
corinne.manchio@gmail.com
Paris 8, France

Marc Lasson
marc.lasson@gmail.com
no affiliation

Cet exposé a pour vocation de présenter un projet en cours qui associe les méthodes traditionnelles des sciences humaines (philologie, histoire et histoire des idées) aux approches computationnelles et statistiques. La création et la mise en place du logiciel d'analyse textuelle MACHIATO (Lasson et Manchio, 2015) constitue le point de convergence de deux perspectives de recherche initialement séparées, celle d'un chercheur en informatique spécialiste de la formalisation mathématique et d'une doctorante en études italiennes, travaillant sur la correspondance diplomatique et administrative de Machiavel (*Legazioni e Commissarie, Scritti di governo*, 2002-2012). La mise en place du site internet relève donc en premier lieu d'une coopération, terme central pour tout chercheur en sciences humaines et sociales qui entreprend de se lancer dans un projet relevant des humanités numériques. En effet, la rencontre entre des champs disciplinaires, implique un constant pour créer un langage commun pour appréhender les textes, pour identifier le type de questionnements qu'il est possible de soumettre aux machines et pour dégager les potentialités et les limites de certaines procédures d'automatisation.

1. Question de méthodes

Nous avons suivi un cheminement complexe depuis la philologie traditionnelle, entendue comme combinaison de critique littéraire, historique et linguistique ou comme pratique d'établissement de texte à partir de sources différentes jusqu'à la philologie dite numérique. L'école qui a le plus influencé nos travaux est celle de Jean-Claude Zancarini et Jean-Louis Fournel et leur approche de ce qu'ils appellent « philologie politique ». Ils se sont attachés à historiciser la pensée de Machiavel, et plus généralement cette génération de la guerre, à travers une analyse minutieuse de son usage des mots dans le cadre de la traduction des textes politiques majeurs de la période des guerres d'Italie. Or, le fait de revenir à chaque usage pour parvenir à une élucidation sémantique est d'autant plus ardu que le corpus est important : pour exploiter nos 2214 lettres, nous avons donc rapidement pensé à croiser notre méthode initiale avec les potentialités des méthodes computationnelles et statistiques, qui nous ont ainsi permis de multiplier les points de vue sur le texte (diachronique, synchronique), de modifier l'unité de base de l'analyse (lemme, champ lexical, champ sémantique) et dégager les tendances générales du corpus et les spécificités de sous-corpus. De telles possibilités modifient inévitablement le rapport aux textes du chercheur en SHS qui ne peut parvenir à l'interprétation des résultats qu'à condition d'en comprendre le sens et les enjeux et donc, de suivre une formation (notamment en statistique et en visualisation de données).

2. Les mots et les nombres: MACHIATO

Le logiciel est commandé par une interface Web qui confère à l'utilisateur un accès facile aux ressources du programme avec son navigateur. Les analyses et les précalculs statistiques sont faits par un back-end mis en œuvre avec le langage de programmation Python dont le rôle est d'initialiser la base de données. Nous utilisons le Framework *open-source* Django pour générer du contenu HTML. Enfin, nous utilisons le langage de programmation Javascript pour afficher les données et les résultats côté utilisateur. Le corpus a tout d'abord été normalisé : différents types d'entrée permettent de le découper en fonction de nos besoins. L'index des lettres permet d'accéder à chaque missive en obtenant les indications de base sur chacune d'elles ; l'index des occurrences donne accès à chacune des 25 007 formes, permettant de cibler des graphies particulières, des noms propres ou des hapax) ; l'index des 6399 familles de mots (qui rassemble toutes les flexions d'un vocable, très nombreuses pour certains verbes du fait de leur emploi et de l'instabilité graphique très forte) consent de mesurer le poids d'un champ lexical. En outre, à chaque missive ont été associés son destinataire, sa date et son lieu de rédaction. Ce *tagging* préliminaires nous a ensuite donné la possibilité de formuler de nouvelles questions plus complexes et de croiser différentes variables (à titre d'exemple, quel terme est le plus employé lorsque Machiavel se trouve en mission auprès du roi Louis XII ?).

Nous avons repris une large part des outils proposés dans les logiciels d'analyse textuelle existants et utilisés par les linguistes à l'instar des concordances, particulièrement utiles pour dégager rapidement les nombreux homographes de notre corpus, et des cooccurrences indispensables pour repérer les cas de polysémie, voire de double isotopie typiques de la langue machiavélienne. Nous avons en outre emprunté un modèle d'analyse des cooccurrences multiples (Heiden, 2004) et les principes de mesure et de comparaison développés en statistique textuelle par Lebart et Salem. Les différents types de calcul permettent de décrire de façon toujours plus précise non seulement la nature des usages, mais aussi leur poids et les relations qui les lient les unités du texte entre elles. Nous utilisons trois types de calcul : les fréquences, l'indice de dispersion et l'indice de spécificité qui ont en outre permis de dépasser certains reproches récurrents faits aux méthodes computationnelles (dont celui de ne considérer la langue comme un ensemble d'unités abstraites, sans lien et décontextualisées). Nous avons fait le choix de limiter les types de visualisation pour des raisons de cohérence, de temps et de compétence. Nous proposons d'en donner quelques exemples tels que l'histogramme de répartition des fréquences, celui des graphies, les structures arborescentes (permettant de représenter tous les environnements immédiats en une image) et les histogrammes interactifs représentant la chronologie des missives. Toutes les visualisations de données sont exportables : nous utilisons Excel pour les tables, ainsi que le format SVG pour les données graphiques. Les critères de recherches avancées (permettent d'effectuer des recherches complexes en fonction du nombre d'occurrences ou/et de la fréquence et/ou des indices de répartition et de dispersion). À partir de l'index des lettres, il est aussi possible de questionner un sous-corpus particulier en vertu de critères variés tels que les bornes chronologiques ou la nature des missives (lieu de rédaction). Il est aussi possible de sélectionner un sous-corpus spécifiques et de procéder à une recherche précise en activant (ou non) les filtres sur les occurrences suivants : taille, nombre d'occurrences dans le sous-corpus interrogé, nombre d'occurrences dans l'ensemble du corpus, fréquence dans le sous-corpus, fréquence dans le corpus total, nombre de lettres, indice de dispersion et indice de spécificité. Enfin, nous avons ajouté une fonctionnalité pour comparer deux sous-corpus.

3. Premiers résultats

Le premier résultat que nous ayons obtenu est la réalisation du site internet en lui-même, à savoir la création d'une interface dynamique donnant accès aux textes et consentant de les interroger en fonction de différentes variables. En second lieu, plusieurs types de visualisation permettent de représenter l'évolution (dans une perspective globale) ou les rythmes (en fonction des lieux ou du contexte historique et politique de rédaction) des usages langagiers. Les données et leur visualisation permettent de vérifier ou d'écarter certaines thèses que nous avions postulées initialement mais elles ouvrent également la voie à une nouvelle approche des textes qui implique de nuancer certains phénomènes que nous avions identifiés au niveau local. Les tendances de l'écriture qui était invisibles apparaissent alors. L'analyse systématique des relevés d'occurrences et des mesures effectués mettent ainsi en exergue certaines micro-spécificités de la langue telles que le recours constant à la forme hypothétique et aux métaphores de l'incompréhension pour exprimer l'incertitude face aux événements en cours et à venir. L'examen des affinités lexicales a confirmé cette thèse et a permis de mettre au jour une caractéristique déterminante de notre corpus : l'extrême instabilité du monde politique pendant les guerres d'Italie, qui s'exprime à la fois par la centralité du champ sémantique du conflit (qui semble commander les autres champs sémantiques) et par la présence de différents éléments langagiers traduisant une précarité des temps et une fragilisation de la praxis politique.

"El Atambor de Plata Suena como Cascaveles de Turquesa". Reconstrucción de la Experiencia Sonora de la Colonización Europea (c. 1480-1650) a Través de un Glosario y un Tesauro Digital

Saúl Martínez Bermejo
saumarti@inst.uc3m.es
Universidad Carlos III de Madrid, Spain

El historiador del sonido se enfrenta a tres retos entrelazados: decodificar la información aural, clasificarla y establecer una sintaxis para dar sentido a la información acumulada (Smith, 2002: 311). Este segundo y tercer retos no deben afrontarse únicamente de un modo personal e impresionista, sino que pueden servir para establecer perspectivas metodologías compartidas, colaborativas y ampliables para la historia del sonido. En esta comunicación corta presentaré un glosario y un tesauro sobre la experiencia sonora en América central durante los siglos XVI y XVII, explicaré la metodología empleada en su creación y discutiré sus distintas aplicaciones.

"El tambor de plata suena como cascabeles de turquesa" es la traducción de un verso náhuatl en el que encontramos un instrumento musical extraño (un tambor hecho de un metal precioso) que se compara con otro artefacto sonoro igualmente complejo, como son los cascabeles de turquesa. El verso muestra tanto la densidad de la información existente en las fuentes, como la dificultad de reconstruir la experiencia sonora a partir de esa documentación. ¿Se trata de instrumentos puramente ficticios, nacidos de la voluntad del poeta, o rituales (pues nada impide que existiesen ejemplares de huethuetl decorados o incluso fabricados con metales preciosos)? Y el verbo frecuentativo *tzitzilica* usado en el original "Xiuhcoyoltzitzilica yn teocuitlahuehuetl" va más allá de un simple sonar y puede traducirse como repicar o repiquetear. El análisis de la poesía náhuatl (León Portilla 2011; Bierhorst, 1985; Damrosch, 1991) puede además ampliarse relacionándolo con otras descripciones de sonidos y paisajes sonoros de la época. Sin renunciar a una reconstrucción narrativa, en el que el verso del tambor de plata se explique en su contexto, un glosario y tesauro digitales ayudan a "clasificar" y "establecer sintaxis" más generales sobre las experiencias sonoras. Si se aprovecha su flexiblilidad para la comparación y el análisis, estas dos herramientas también permiten establecer nuevos modos de comprender y comunicar la información disponible en las fuentes históricas.

Todo glosario es un catálogo de palabras sobre una misma cuestión, con definiciones o comentarios. En su versión digital un glosario no sólo permite una consulta on-line, sino también estructurar la información en diferentes capas o niveles y recuperarla de modo flexible.

Un primer nivel del glosario recogerá las distintas definiciones y traducciones de términos relativos al sonido. Utilizaré para ello diccionarios y gramáticas de época, incluyendo obras bilingües o plurilingües, tales como el *Arte mexicana* del jesuita de origen mexicano Antonio Rincón (1595), el diccionario de Alonso de Covarrubias (1611) o el *Arte de la lengua mexicana* (1645), en el que Horacio Carochi publicó la primera traducción española del verso.

En un segundo nivel, que en realidad es una base de datos, se incluyen ejemplos del uso de estos términos en las fuentes de la época, autor, fecha, localización geográfica, asociaciones entre determinados términos y eventos históricos particulares, valoraciones sobre su significado, su intensidad o su frecuencia, y valoraciones sobre el estado emocional o sensorial que provocan o en el que aparecen. La información recogida en este nivel procede de fuentes como crónicas, las historias naturales, los relatos de viaje, las cartas y los diarios escritos por los participantes en los viajes y campañas militares. De este modo se puede contextualizar la información lexicográfica y se construyen herramientas para desambiguar los términos que aparecen en las fuentes (distinguir, por ejemplo, entre un *huehuetl* y un tambor de dos membranas de origen europeo) y establecer asociaciones entre términos y contextos de uso o entre términos y zonas geográficas.

El tesauro tiene por objetivo reducir las variaciones observadas en el glosario a una serie de categorías lógicas. Para ello se emplearán, naturalmente, términos unificados (campana, por ejemplo) clasificados dentro de una estructura de relaciones ontológicas o semánticas (sonido>artificial>instrumentos musicales>hechos de metal/largo alcance/uso público) A través del uso de estándares como ISO 25964-1 (aún en desarrollo) y de una estructura en XML se favorece la posibilidad de vincular este tesauro a otras clasificaciones previas de efectos sonoros (Chion 1983; Augoyard-Torgue, 1995) o expandirlo a través de colaboraciones de otros investigadores o instituciones.

La construcción del tesauro obliga a reflexionar críticamente sobre el uso de categorías (presentes o de época) para explicar culturas distantes en el tiempo, y se nutre de las perspectivas de la antropología del sonido y de la crítica postcolonial (Tomlinson, 1995; Feld y Brenneis, 2004; Faudree, 2012). Concretamente, plantea hasta qué punto un tesauro permite identificar sobre los cambios en los patrones sonoros o en los grupos de sonidos y sus valoraciones a lo largo de la historia. También pone en cuestión la predominancia de los materiales visuales y textuales y la predominancia de la vista en los modelos teóricos de los historiadores.

El formato digital del glosario y el tesauro ofrece una gran versatilidad a la hora de establecer reconstrucciones paralelas o comparaciones sobre distintas experiencias sonoras. Es posible comparar, por ejemplo, el catálogo de sonidos propio de los niveles perceptivos de un soldado (que no suele aportar muchos datos de carácter musical, pero que ofrece una información relativamente bien contextualizada y localizada en el tiempo y el espacio) con el mundo sonoro de un teólogo o misionero con conocimientos musicales y teóricos sobre el sonido (que categoriza de acuerdo a su propio esquema de división de sonidos y que puede ofrecer variaciones).

La información recogida en el glosario y el tesauro podrá consultarse de varios modos. Junto a una herramienta de búsquedas, una interfaz gráfica permitirá construir "mapas sensoriales" para visualizar la experiencia sonora del pasado. Esta representación novedosa utilizará un diagrama de base circular se colocan varios polos en los que se identifican la procedencia (animal, voz humana, música, artificial, medioambiental), los valores atribuidos a los sonidos (agradable-desagradable, tranquilizador-preocupante, importante-irrelevantes, etc.) y sus contextos (ritual, festivo, actividades diarias, guerra, rebelión, etc.).

Esta investigación es una parte del proyecto *Sound and Silence*, que actualmente desarrollo en la UC3M dentro del programa CONEX-UC3M. El objetivo general del proyecto es investigar los usos y la percepción del sonido durante la colonización portuguesa y española de la edad moderna.

El primer objetivo de *Sound and Silence* es ofrecer una aproximación innovadora y atractiva al estudio interdisciplinar del sonido (Bull & Back, 2003:1-9; Sterne 2012: 3-10; Schmidt 2000: 15-37) . Para ello resaltaré la importancia de la cultura oral (y de las mecánicas de choque e hibridación sonora y musical) en la edad moderna (Greenblatt, 1991: 86-118; Baker, 2008; Irving, 2010) y crearé mapas y/o visualizaciones de la experiencia sonora de un viajero o cronista particular. La página web asociada al proyecto ofrecerá mapas en los que se representarán los tipos de sonidos escuchados durante una expedición, campaña o acontecimiento particular a través de las descripciones existentes en las fuentes históricas creadas por los participantes. Algunos instrumentos, sonidos animales y de artillería y armas de fuego contarán con reproducciones históricas.

Un segundo objetivo del proyecto es investigar las posibilidades contemporáneas de definición semántica de documentación no textual. El texto ha sido y continuará siendo por algún tiempo la base y el centro de la web semántica y de todas las ontologías. En lo que respecta a archivos de música y voz humana la investigación se ha concentrado en los procesos de codificación y reconocimiento. El reconocimiento o la búsqueda por contenidos a partir de huellas sonoras de Shazam o Google se realiza a partir de bases de datos amplias pero limitadas. Sin embargo, el sonido, entendido como un paisaje o un entorno que va más allá la voz y la música plantea retos más amplios, tanto para la teoría historiográfica como para definir la frontera de lo transmisible o "legible" por máquinas.

Hoy día los archivos sonoros de cualquier tipo son accesibles en su gran mayoría a través de un número limitado de metadatos estandarizados referentes a su autor, título, fecha, etc. La identificación de documentos sonoros históricos no es en general mucho más profunda de la que ofrecería una biblioteca como la de iTunes. Herramientas algo más potentes como las folkosomias o la marcación social, permitirían recuperar información sobre el contenido y significado, pero no existe un equivalente histórico para esos modos de categorización. Mi hipótesis es que un glosario que recoja suficientes variaciones contextuales podría permitir de modo similar, comparar los distintos valores atribuidos a diferentes sonidos en determinada época y entender mejor como la gente clasificaba (y clasifica hoy día) el sonido. Un tesauro jerarquizado es, por otra parte, una base para una anotación más profunda de los registros sonoros. La clasificación de archivos sonoros por su contenido se beneficiaria de la existencia de una serie de categorías bien establecidas sobre los tipos de sonido. Ambas herramientas permiten reflexionar sobre los modos en que hoy día organizamos y recuperamos los archivos sonoros y abrir caminos para un tratamiento integral, y diferente, de la información contenida en los formatos de audio.

Remediations of Polish Literary Bibliography: Towards a Lossless and Sustainable Retro-Conversion Model for Bibliographical Data

Maciej Maryl
maciej.maryl@ibl.waw.pl
Institute of Literary Research of the Polish Academy of Sciences, Poland

Piotr Wciślik
piotr.wcislik@ibl.waw.pl
Institute of Literary Research of the Polish Academy of Sciences, Poland

Remediation 1.0.: "Printed database"

Polish Literary Bibliography (PBL) is a specialized bibliography which aims to map the totality of literary and cultural life in postwar Poland. It references primarily literary works and literary scholarship, however its entries also cover the related literary critique, adaptations, theatre performances, cinematography, radio and television broadcasts, as well associated events such as conferences or awards. At the heart of PBL lies its subject classification which orders the entries to reflect the domains, hierarchies and entities of Polish literary world, i.e. its ontology in the classical sense. PBL has been developed since 1954 and today covers the period 1944-2001. For most of its history it has existed in print, however since 2000 the data has been collected in the existing digital database which currently covers the period 1988-2001 what gives app. 600 000 records.

The vicissitudes of PBL remediations could be accurately captured through an urban planning metaphor. What definitely strikes every visitor to a large Moroccan city is a great contrast between *medina*, the traditional old town with centuries-long history, and *Ville Nouvelle*, new district built under the French Protectorate in the first half of the 20th century. The former reminds a maze with endless narrow streets, and buildings which are stuck densely next to each other with no visible order, whereas the latter is the essence of modern architecture with wide boulevards, large buildings and streets laid out in a grid pattern.

The current online database is quite exemplary for early bibliographical and cataloguing projects (in Poland as elsewhere) in that it is geared towards remediating the print form of the PBL instead of taking advantage of the new medium (cf. Antelman, Lynema and Pace 2006, 128). It is a tailor-made relational database developed in Oracle whose data model is built on a plethora of dataspaces for different types of records, accompanied by various catalogues of creators, contributors, associated institutions and subject headings. The former set reflects PBL's main entities: literary works in monographs and journals, adaptations in cinematography, radio and television and associated events. The latter represents an early digital take on the index card catalog, the traditional tool of the bibliographer. Furthermore each record has a special markup in order to assure that its display at the frontend follows the structure of the paper edition.

The result of this remediation is a *medina*-like database, very rich and complicated but not fit for modern uses. It makes perfect sense for people who built it, yet at the same time it is difficult to navigate by those lacking the local knowledge - be it a human or the machine. As it often happens with relational databases,[1] it does not comply with any of the common standards in terms of record structure or data formats, what eventually leads to serious problems with both preservation and interoperability of collected data.

Towards remediation 2.0

The aim of the research project we are currently pursuing (*Polish Literary Bibliography – a knowledge lab on contemporary Polish culture*) is to reestablish the PBL database project on Linked Open Data principles for its better reuse within and beyond the bibliographic domain (see e.g. Roszkowski 2013; Coyle 2010). However, we want to do better than the French colonizers of Morocco. The modernisation of PBL will be reflexive insofar as it will reconcile the OWL and the PBL's unique ontology of the literary world expressed through the structure of its entries and metadata. The main task of the current phase of the project is development and application of the new data model. This task involves (1) the choice of vocabularies and ontologies and (2) rendering of the subject classification structure.

(1) Vocabularies and ontologies (in the narrow sense used in information science) are needed to disambiguate the RDF triples (subject-predicate-object expressions). Here we need to balance two criteria. First the vocabularies and ontologies must enable widest possible sharing in the data cloud. Second they must be granular and complex enough in order to reflect the PBL data model, since adding too many heterogeneous elements would be counterproductive. The above applies to both metadata elements and their values.

Whereas the choice of value vocabularies was rather straightforward, using the geonames and Virtual International Authority File (VIAF) for disambiguating geographical, personal and corporate names, the choice of the meta-ontology,[2] or the vocabulary describing the metadata elements of the current PBL data model was much more difficult. It would be only natural to opt for one of the ontologies dedicated for describing bibliographic records, such as Functional Requirements for Bibliographic Records (FRBR) and its Resource Description and Access (RDA) and Bibliographic Framework Initiative (BIBFRAME) vocabulary variants (cf. Coyle 2016). Indeed, both contain a crucial distinction between "works" (a certain intellectual creation as such, regardless its edition, format or medium) and "instances" (expressions and manifestations of this intellectual creation) which in PBL is paramount for referencing editions, adaptations and critiques of a literary oeuvre of a particular author. For example, a review of *Don Quijote* refer to either Cervantes' literary achievement in general or to the newest translation of the Spanish original into Polish.

However, the FRBR-based ontologies are either not well equipped to handle theatre, cinematographic, radio and television instances of literary works, or (as in the case of FRBRoo) too complex to be easily handled by metadata producers in their everyday practice (Coyle 2016, 153).[3] Therefore, we opted for a solution that is more generic but robust enough - the schema.org ontology. However contestable due to its rather restricted vocabulary when it comes to describing books, this solution is not unprecedented in the bibliographic domain.[4]

This process of mapping is by no means mechanical. In many cases the PBL original methodology and the solutions of the first remediation entailed conceptual challenges, which will be addressed in more detail in our presentation. For instance, one needs to solve the tension between a minute bibliographic description on one hand, and the standard vocabulary on the other. Expressions entailing similar yet slightly different properties of the book such as "woodcut engravings"; "illustrations"; "drawings"; "reproductions"; "pictures"; "prints" need to be fit into the elements of the formal vocabulary of schema.org, properties such as "illustrator" and "artform."

(2) The second challenge of the new data-model involves the PBL subject classification structure. Here the option of using one of the existing and well-established subject headings/authority files published as Linked Data, such as the Library of Congress or German National Library Subject Headings was rather out of question, given the methodological uniqueness of PBL. Instead we will strive to create our own Linked-Data ready classification scheme while at the same time providing a partial mapping to existing resources.

To realize the scope of this challenge one needs to bear in mind that PBL has been an ongoing project for the last sixty years. During this time, not only literary life and its study have evolved (cf. the emergence of the online literary life, Maryl 2015), but also certain state entities disappeared (e.g. Yugoslavia or the Soviet Union). Given that the future database will be populated through retroconversion of the paper records in addition to the existing database records, we cannot take the current classification for granted, but also accommodate its historical evolution. A non-intrusive way to account for the historicity of PBL would be to add timestamps to subject headings. Whether a synthetic data-reconciliation layer is possible requires further analysis.

Conclusions

In the concluding remarks we will concentrate on the expected benefits of translating PBL into LOD.

- PBL datasets can be enriched through integrating other Linked Data collections (e.g. geographical data on places relevant to literary life).
- Data exchange protocols can be established between PBL and other bibliographies published as Linked Data.
- PBL data can be used for data-driven research in the humanities on such fields as reception history or transfer studies.
- The methodology and the production pipeline developed in this project can be reused for retroconversion of other disciplinary bibliographies.

Notes

[1] For a useful comparison of different approaches to data modelling, see van Hooland and Verborgh 2014: 11-70.

[2] Our understanding of "meta-ontologies" (as opposed to value vocabularies) is analogous to what the W3C Library Linked Data Incubator Group calls "Metadata Element Sets". An additional feature of a meta-ontology is that it " combines and organizes other ontologies to describe objects in a complex way." See: Stahmer 2015.

[3] In case FRBRoo is in fact widely adopted by the community of practice, we will be definitely interested in mapping it to our data model.

[4] For list of library-specific extensions proposed by the Schema Bib Extend W3C Community Group, see bib.schema.org. WorldCat.org uses a subset of schema.org terms for Linked Data (https://www.oclc.org/developer/develop/linked-data/worldcat-vocabulary.en.html). Updates on schema.org developments are frequently announced on Richard Wallis' blog dataliberate.com

The Digital Scholarship Training Programme at British Library: Concluding Report & Future Developments

Digital Scholarship Training Programme 2012–2015

Research libraries and cultural heritage institutions must be able to adapt to a changing research landscape and invest in the development of staff skills and core competencies to match if they are to continue to effectively support and engage with modern scholars (Adams, 2013). The Digital Research team at British Library, which includes the BL Labs project and the Digital Curator team, engages with those operating at the intersection of academic research, cultural heritage and technology to enable innovative use of our digital collections, and creates opportunities for library staff to develop skills necessary to support emerging areas of modern scholarship, particularly the Digital Humanities (DH).

This paper presents the final report on the pilot Digital Scholarship Training Programme delivered to staff at British Library between 2012-2015. It provides an evaluation of the skill-building initiative, incorporating preliminary findings from research into the current trends and international developments in the field of DH that will inform the next phase of staff training.

In 2012, the Digital Curator team embarked on a plan to design and deliver a bespoke training programme for staff (McGregor et. al, 2013). Four objectives were set to guide and ultimately measure the success of the programme:

- Staff across all collection areas are familiar and conversant with the foundational concepts, methods and tools of digital scholarship.
- Staff are empowered to innovate.

- Collaborative digital initiatives flourish across subject areas within the Library as well as externally.
- Our internal capacity for training and skill-sharing in digital scholarship are a shared responsibility across the Library.

In consultation with experts from within the Library and institutions on the leading edge of digital scholarship we designed and delivered in-house a catalogue of 19 one day courses suited to building the digital skills of information professionals in the research library and cultural heritage sector. Though much of the programme was rooted in and inspired by the field of digital humanities, the wider umbrella of Digital Scholarship was retained to future-proof the programme and to envelope developments in related fields like social and computer sciences. The following titles represent a cross-section of courses created:

- Behind the Screen: The Basics of the Web
- Crowdsourcing in Cultural Heritage (Ridge, 2015)
- Georeferencing and Digital Mapping
- Social Media: An Introduction to Blogging and Twitter
- Working with Digital Objects: From Images to A/V
- Information Integration: Mash-ups, APIs and the Semantic Web (Stephens, 2014a)
- Cleaning up Data (Stephens, 2014b)

The four-member Digital Curator team oversaw the running of 88 hands-on courses (or roughly 30 a year) between November 2012 and September 2015. Courses were delivered by a mix of internal and external trainers. Over 400 individual staff members came through the programme, on average attending two or more courses each.

Throughout the pilot we collected feedback formally via post-course evaluation forms, and informally through avenues such as a weekly Digital Research Clinic, and personal conversations that arose in the course of our daily work. Colleagues were asked to provide comments to help us improve the course, including what they enjoyed most out of the day, what they anticipated using in their work, and what was not clearly articulated.

Hands-on practical exercises were cited most often as the most enjoyable element, though not to the exclusion of the lecture and discussion time which participants felt provided necessary context. While many attendees cited specific technologies such as Open Refine as something they anticipated using in their work, they also tended to comment that having the technology underpinning innovative digital research projects demystified was helpful inspiration for future projects. Topics which could have been more clearly articulated centred on a lack of clarity on practical steps for turning aspiration into application.

Looking specifically at the objectives set, there is ample evidence to support the continuation of the training programme, such as the incorporation of the programme in staff induction for established Library projects such as Qatar Digital Library. As staff across all collection areas have become more familiar and conversant with the foundational concepts, methods and tools of digital scholarship, we have witnessed its profile increase across the Library. For instance three new PhD placements were offered this year specifically within the digital research domain (Sheperd, 2016) for the first time.

Staff have felt empowered to innovate, and collaborative digital initiatives have flourished. A particularly cogent example is that of curator Dr. Sandra Tuppen, who attended one of our courses on cleaning up data and went on to secure a £79,000 grant towards a research project which enriched and cleaned British Library catalogue data so that it could be successfully aligned with other printed music datasets in support of a big data approach to the history of music (Tuppen, 2014).

Our internal capacity for training and skill-sharing in digital scholarship has become a shared responsibility across the Library, with internal course instructors now outnumbering external instructors. With the increasing number of Library staff being involved in projects and other programmes that include digital research activities and methodologies, we have been able to integrate more in-house expertise to the courses offered. Additionally the Digital Curator team has prioritised our own upskilling through a monthly informal “Hack & Yack” where we work through online tutorials with a view towards incorporating them into training, as well as more formal courses such as Train the Trainer aimed at enhancing our teaching strategies, combining theory and practical methodologies in the planning and delivery of the courses.

Looking to the future

We will continue the Digital Scholarship Training Programme and for 2016/2017 will maintain 7 of the 19 courses in their current form:

1. 101 This is Digital Scholarship
2. 103 Digitisation at the British Library
3. 105 Crowdsourcing in Libraries, Museums and Cultural Heritage Institutions
4. 108 Geo-referencing and Digital Mapping
5. 109 Information Integration: Mash-ups, API’s and Linked Data
6. 116 Metadata for Electronic Resources
7. 118 Cleaning up Data

Focusing on delivering this smaller core of courses will free up resource to improve upon how we:

- Reach staff who are keen and could most make use of the information but have not yet engaged
- Providing guidance and support to staff who are looking to implement what they have learned
- Addressing more explicitly the challenges and opportunities for working with complex collection materials, such as with non-Western materials

We aim to provide a more diverse training offering to ensure that there are sufficient opportunities for staff in a variety of roles at the Library to engage with digital research. Often colleagues have said they would like to attend a course, but either their workload is such that they feel they cannot spare a full day for it or they work a rota, as is the case with our colleagues who staff reading rooms. Finding creative ways to articulate more clearly and succinctly the practical value of time spent on a course, for example through shorter more frequent taster sessions explaining how a digital tool or method might help solve a specific problem, may help to reach those who have yet to engage. We are also working in partnership with reading room staff on rota to develop new approaches for conveying the training (perhaps through short informational videos).

On the opposite end of the spectrum is the need to support increasing numbers of library staff who have engaged with the programme and are now looking to implement what they have learned. In an ideal world we could offer 'just in time' training to colleagues at the point of their immediate need. However, as Miriam Posner (2012) and others have discussed, each question a colleague asks may bring with it a hidden overhead of time taken to respond well. In some cases we may seek to hire existing trainers to support specific project needs but more practically, we will look to better promote and leverage our weekly Digital Research Clinic, a drop-in service for staff to get guidance on any aspect of digital research. A collection of practical 'Getting Started' guides will be further developed and shared via an internal wiki. Additionally, Digital Curators sit on key infrastructure development projects so as to directly inform the development of these in support of digital research.

Finally, digital scholarship is a complex and global affair, as evidenced by the rapid expansion of DH centres around the world. Our courses to date have tended to deal with relatively simple forms of digitised material such as digitised printed English language books. However for colleagues working with non-Western texts for instance, knowledge of cutting edge developments in transcription and Optical Character Recognition would be highly beneficial in helping ensure these materials can be leveraged by digital scholars. Our collections are as global and diverse as the DH communities interests worldwide, and future staff training provision must more accurately address the complexities and opportunities of working with our vast non-Western materials.

Building Large Persons' Networks to Explore Digital Corpora

Giovanni Moretti

Introduction

Although representing large corpora through the network of persons' interactions has become quite popular in the Digital Humanities community (Elson et al., 2010), several parameters can have an impact on the resulting network, especially when it is automatically extracted. In this work, we present a step-by-step procedure to extract persons' networks from documents and select possible configurations in order to increase readability and ease

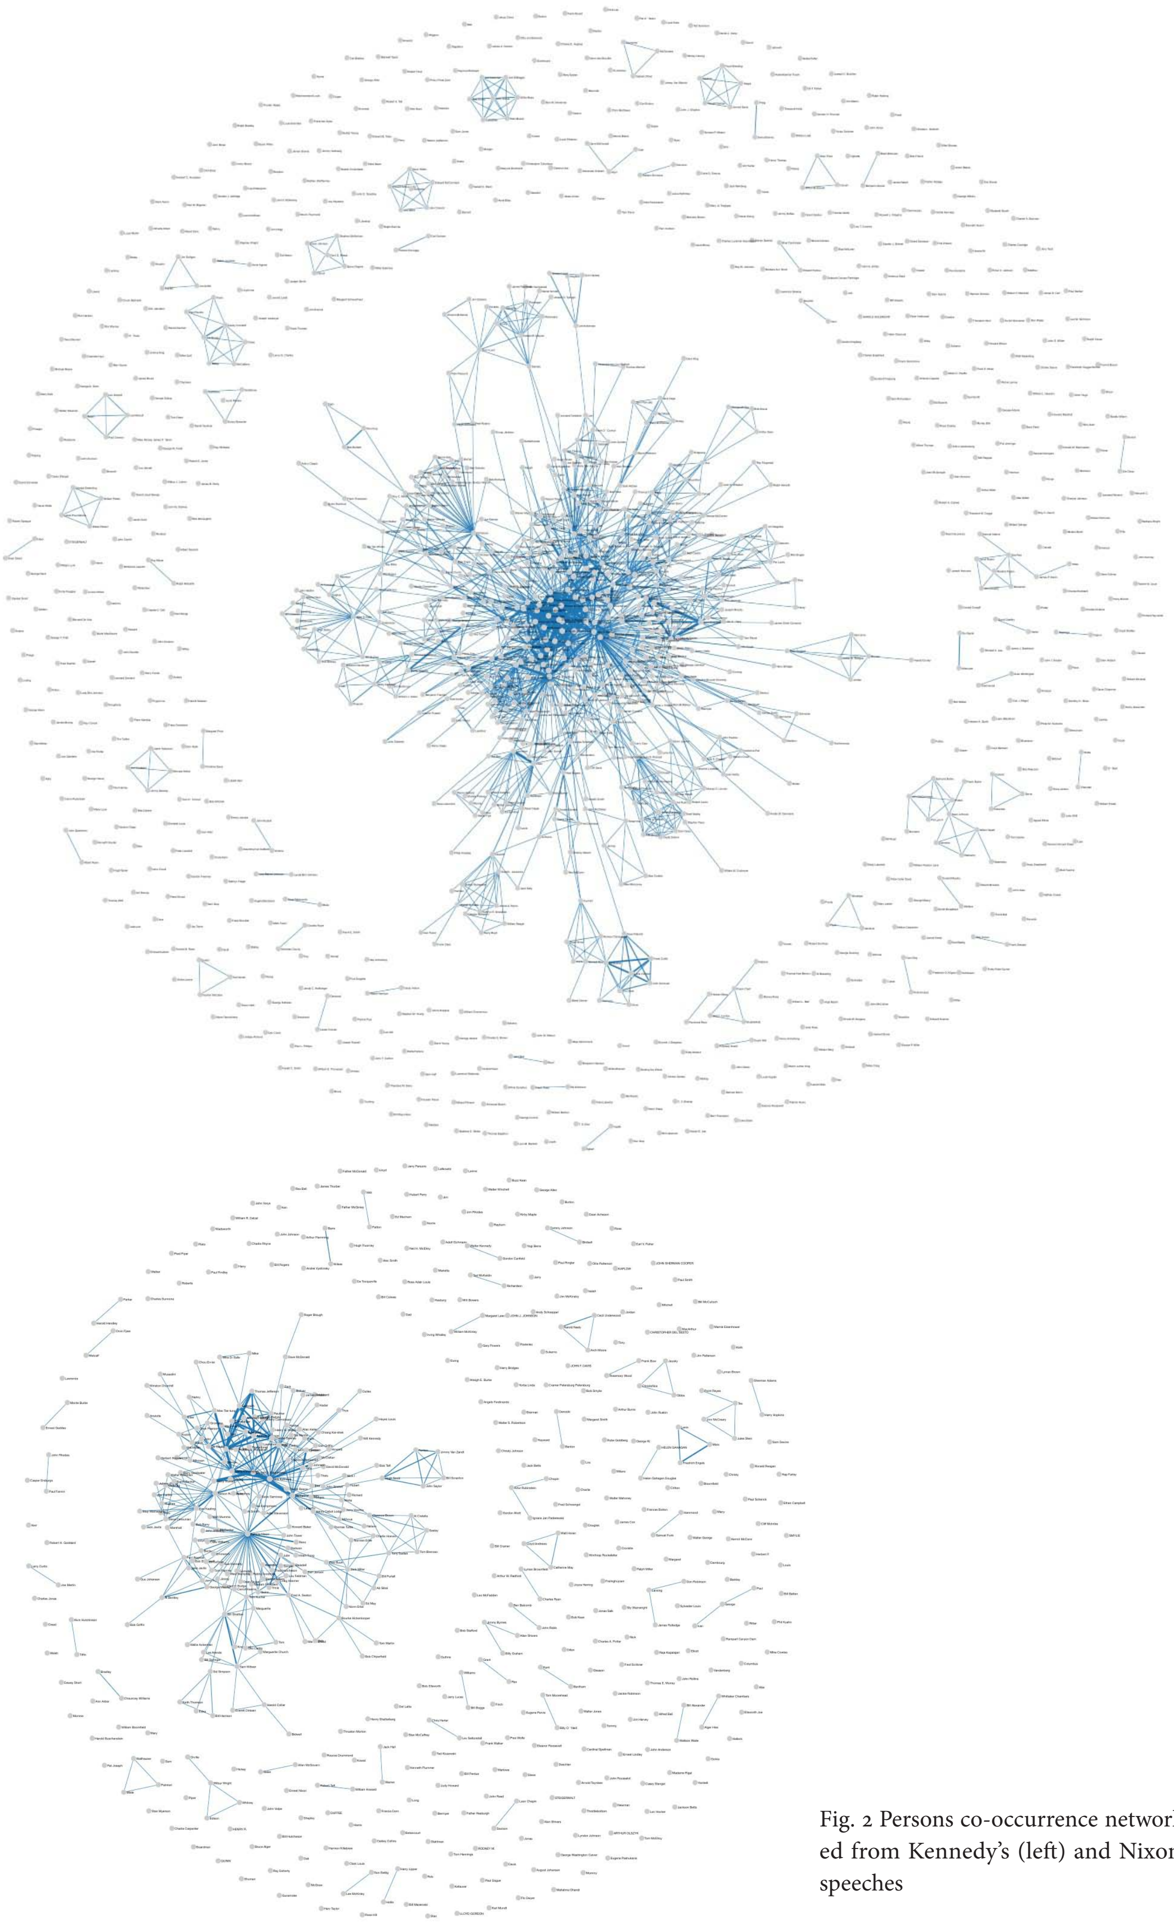

Fig. 2 Persons co-occurrence network extracted from Kennedy's (left) and Nixon's (right) speeches

the interpretation of the obtained information. We also discuss some open issues of the task.

We rely on the same assumption as for word co-occurrence networks: *two persons who tend to be mentioned together in a corpus share some commonality or relation from the author's perspective.*

The Methodology

We implemented a novel tool for the automated extraction of a persons' network from a corpus in the online ALCIDE platform[1] (Moretti et al., 2014). The module is based on the following steps: *i)* the corpus is first analysed with the Stanford named entity recognizer (Finkel et al., 2005), in order to recognize persons' mentions (e.g. *John Kennedy*, *F.D. >Roosevelt*, etc.). In the network representation, we assume that persons correspond to nodes and edges express co-occurrence within a given token window; *ii)* We build a person-person matrix where we assign an edge weight of 1 every time two persons are mentioned together within a certain context window. Every time a co-occurrence is repeated, the weight is increased by 1; *iii)* The final output is a weighted undirected network where edge weights are the co-occurrence frequency. In the default configuration, name mentions are collapsed onto the same network node only if they have an exact match. In order to allow a more flexible creation of the network, a "Person Management" functionality (Fig. 1) has been implemented, through which users can collapse nodes referring to the same person (e.g. *J.F. Kennedy* and *John Kennedy*). This manual check is done through an interface, without the need to access directly the underlying matrix.

From a technical point of view, the information is stored in a relational database management system, in order to grant multi-user access, good performances and high flexibility regarding the queries. The persons' co-occurrence matrix is visualized as a network by means of the d3 javascript framework[2]. During the conversion of the matrix in the json used by d3, the nodes are enriched with additional information, such as the list of documents containing the corresponding entity and the number of connections.

Some settings such as the co-occurrence window type (sentence or token) and width (number of sentences/tokens) are arbitrary, although they have a relevant impact on the extracted network and on its readability. Therefore, the system gives the possibility to change such settings and regenerate the co-occurrence matrix at runtime. In the following sections we will discuss some of these parameters and explain their impact in the light of a use case related to Nixon and Kennedy's speeches of the 1960 presidential campaign. The corpus consists of 282 documents by Nixon (830,000 tokens) and 598 documents by Kennedy (815,000 tokens)[3]. All networks displayed in the following sections are screenshots of the system output and are dynamically displayed.

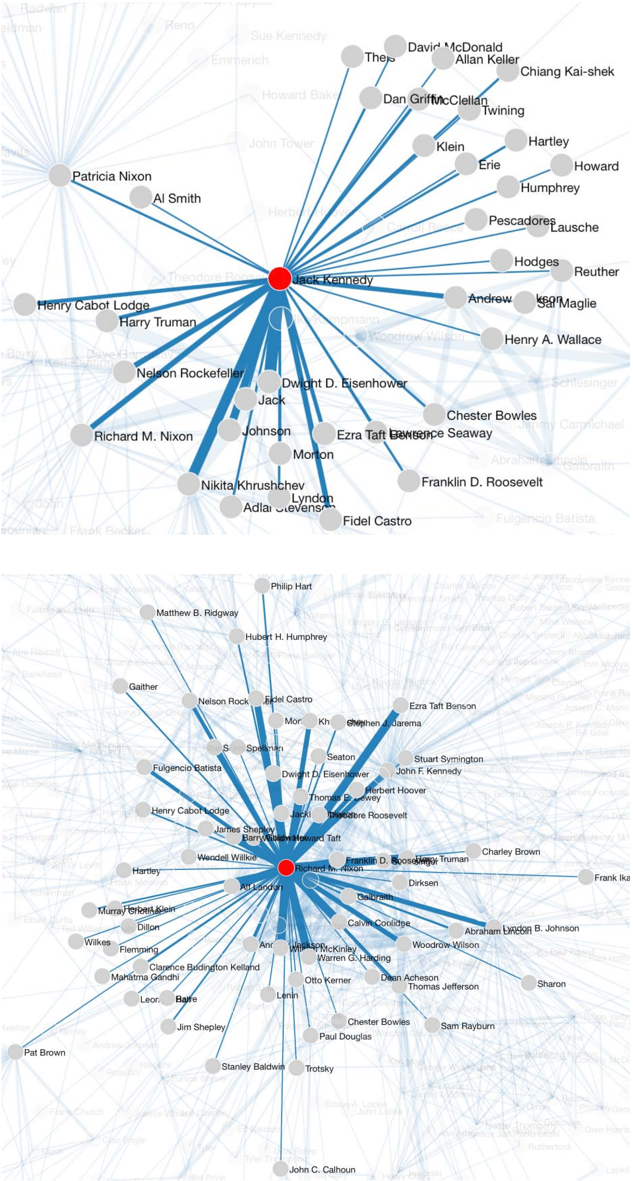

Fig. 3 Co-occurrence network of "Nixon" mentions extracted from Kennedy's corpus (left) and of "Kennedy" mentions from Nixon's (right) speeches

Default configuration

In our default configuration, the tool extracts persons' networks using 1 sentence as a co-occurrence window and collapsing on the same node only name mentions with an exact match. As shown in Fig.2, this basic configuration is enough to highlight the differences between Kennedy's and Nixon's networks: the first is much larger and much more connected, with several cliques that tend to emerge from the overall picture. Nixon's network, instead, is smaller (i.e. less persons are mentioned in his corpus) and less dense.

By zooming in the pictures, it is possible to focus on single nodes of interest. For example, if we compare Nixon's mentions appearing in Kennedy's speeches, and the other way round (Fig. 3, left and right resp.), we observe that in both cases the opponent is frequently mentioned with 'enemies' of the time such as Fidel Castro and Khrushchev. However, this association with negative figures is much more frequent in Kennedy's speeches (e.g. Nixon is mentioned also with Trotsky and Lenin), probably because Nixon had already a prominent role in US foreign policy being Vice-President.

Changing configuration parameters

The tool allows users to move from the default configuration to a more customizable one, where it is possible to change the type (sentence or token) and the size of the context window taken into account for the co-occurrences as well as set a threshold to the edges' weight (number of co-occurrences). By tuning these parameters, it is possible to transform the networks presented in Fig. 2 to obtain a more readable representation, filtering minor nodes and emphasizing information previously hidden by the large amount of information.

Reducing the co-occurrence window increases the probability to extract persons that are more strictly related. At the same time, by increasing the minimum edge weight threshold, we reduce the information visualized, filtering out all the persons co-occurring only once in favour of persons co-occurring consistently through the entire corpus.

Fig. 4 shows the networks, obtained from the data in Fig. 2, generated by setting the maximum token range to 10 (thus, on average, less than the sentence length adopted in Fig. 2) and the minimum edge threshold to 2. The result is a visualization with less but more readable data. In Nixon's network, we can easily spot some well-defined clusters such as the one grouping the leaders of the communist world (i.e Khrushchev, Stalin, Mao Tse-tung), the cluster of the main representatives of international politics in 1960 (e.g. de Gaulle, Nehru, Adenauer) or a cluster reflecting Nixon's attitude to refer to previous U.S. Presidents (e.g Andrew Jackson, Thomas Jefferson). Also the network from Kennedy's corpus is more understandable, including a cluster with prominent Communist politicians (e.g. Khrushchev, Castro, Kadar), but also clusters defining local democratic representatives, for instance those from California (e.g. Pat Brown, John Moss) or those from Pennsylvania (e.g. David Leo Lawrence, Joseph S. Clark).

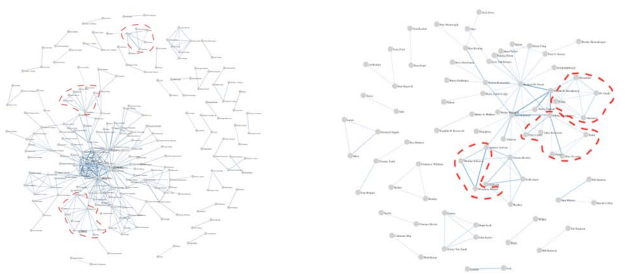

Fig. 4 Persons co-occurrence network extracted from Kennedy's (left) and Nixon's (right) speeches using a 10 tokens windows and a minimum threshold of 2.

Discussion

As shown in the above examples, building a persons' network in an automated fashion implies making some a-priori choices that strongly affect the outcome of the analysis. Such choices are influenced by the type of analysis required by the user. If *distant reading* is the main goal, the parameters proposed as default by our tool, as shown in Fig. 2, seem to be appropriate. This analysis gives an overview of the overall network dimension and density, and makes it possible to compare two networks at a glance. Instead, if *close reading* and a qualitative analysis of the connections are more relevant, reducing the window width and displaying only the most connected nodes is necessary. Since in a typical research scenario distant and close reading are both present, and users need to zoom in and out frequently, a tool that changes the network on demand in real time should be implemented. In this respect, Gephi (Bastian et al., 2009), probably the most widely used tool for network analysis in the Digital Humanities community, shows some limitations. Although it provides useful in-built metrics for analysing a network structure, it does not offer the possibility to test different parameters on the fly. Also its integration in an online, browser-based environment is quite complex, as well as the connection to a text analysis pipeline.

Other issues related to the automated creation of persons' networks are worth mentioning. Since natural language processing tools are involved in the pre-processing step, users should be aware of the possible mistakes introduced by this pipeline. In particular, Named Entity Recognizers may label as persons other types of entities, wrongly introducing nodes in the network. Other possible mistakes are more difficult to spot and concern homonyms (i.e. nodes that should be split). Such cases can be solved only resorting to a cross-document entity coreference system, where mentions can be resolved by linking them to the entities they refer to. A finer-grained outcome could be achieved integrating also an intra-document coreference system, able to link mentions referring to the same person in a text. Cross- and intra-document coreference would be necessary to ensure that all persons mentioned in a corpus are included in the extracted network. Nevertheless, the impact of automated processing on the quality of the network needs to be further investigated.

Many pre-print texts emerge from an authorial context that was collective rather than individual. Pre-print texts may be the result of an accretive process, where portions of the work were added or subtracted to conform to the needs of copyist or audience, and where the surviving versions can reflect the contribution of many different minds (Fisher, 2012). A truly sensitive translator of a text from the past must take into account the historical setting of the written product, what has been called the *social logic of the text* (Spiegel, 1990) to interpret the words for the reader and convey the meaning for those who wrote them and for their contemporary audiences (Paul, 2008).

Just so, the job of the translator has become increasingly complex as our notion of text also expands. Ideally, the process of translating pre-modern texts would mirror their progressive creation, incorporating multiple voices and layers of interpretation. With the integration of digital modes of thinking and acting into our daily lives, what some digital theorists have called "eversion" (Jones, 2014), new textual communities in some way mimic those that participated in the collective process of pre-print text creation. Digital tools have made it possible to assemble voices in a virtual community of textual reception, one in which participants need not be in the same physical space to exchange ideas in real time about the meaning of a text.

Scholars at Fordham University have embarked upon two different translation projects that are sensitive to elements of pre-print textual creation and that aim to forefront the process in ways understood by digitally-inflected communities. The projects emerge from a pragmatic vision of work-sharing, yet simultaneously co-opt our increasing comfort with virtual communities to recreate the collective context of pre-print texts. These projects come from unrelated disciplines and cultural contexts: the first brings together scholars with linguistic, literary, and art historical expertise to produce a new translation of the Codex Aubin, a manuscript written in Nahuatl created between 1576 and 1609 by indigenous scribes in Mexico City; and the second, led by the French of Outremer Legal Texts Working Group, brings together nine scholars to examine and translate three thirteenth-century legal texts written in a type of Old French from the Holy Land.

Although digital tool-builders have recognized the power of the collective translation process from the standpoint of a division of labor, most translation platforms are designed to manage work-flow, not to accommodate incertitude, discussion, or to express a plurality of interpretations (Gambier, 2014). Using the norms of crowdsourcing as a point of departure, Fordham scholars have worked with program-developer Ben Brumfield to substantially extend his open-source digital edition tool FromThePage (http://www.fromthepage.org/) to allow groups of scholars to translate selected texts in a communal fashion. For example, since the 1841 editions of the French-language legal texts were digitized by the Internet Archive, the existing FromThePage-Internet Archive integration was extended to ingest the OCR produced by the digitization process as a starting point for page transcripts (Beugnot, 1841). The translation process itself required modifying the data model to support parallel texts for each transcribed page, as well as new user interfaces for editors to toggle between transcript and facsimile while translating. Since users may be unfamiliar with Old French or Nahuatl, the presentation interface was revised to support a translation-first experience.

Translation teams working on both Fordham FromThePage projects include language specialists, historians, and content experts who bring their proficiencies to the discussion, but who will nonetheless disagree along the way. The assembled communities are closed and highly selective; our end product will be a curated conversation that reflects the specialization of each team member. Using FromThePage gives us the option to make the deliberations transparent to our end-users in a way that remains epistemologically true by mapping the process of consensus necessary for a final translation. Reaching an agreement on our final versions, for example, may be the result of one scholar arguing for a reading according to his or her own expertise, or of a collective ignorance and the need to choose the most neutral term possible; our final translations will expose this decision-making process and situate our users in the midst of communal textual production.

Achieving this transparency required a number of unanticipated changes. The first concerned the commenting mechanism: while editors transcribing a manuscript often need to discuss unclear handwriting, translators' discussions of variant readings need to be surfaced for readers. In addition, parallel texts required a total re-write of the full-text search mechanism to handle verbatim text of the original, editorial emendations, and English translations. Finally, the nature of the sources revealed fundamental challenges in the representation of text within FromThePage; since the page division of the *Assises* is an artifact of 19th-century typesetting, semantic divisions had to be de-coupled from the facsimile pages for online readers and consumers of the exported TEI-XML documents. All of these enhancements were re-incorporated into the FromThePage source code, allowing other digital edition projects to benefit from the new translation and OCR correction features. The projects underscore the communally-crafted nature of our chosen texts by marking conflicting opinions, and the results will serve as a test-case for other kinds of collaborative textual projects, particularly those that contain non-standard languages or terminologies.

Linguistic Variation In The Hebrew Bible: Digging Deeper Than The Word Level

Martijn Naaijer
m.naaijer@vu.nl
Vrije Universiteit Amsterdam, Netherlands, The

Dirk Roorda
dirk.roorda@dans.knaw.nl
Data Archiving and Networked Services

One of the most discussed issues in Biblical studies in the past 15 years is the history of Biblical Hebrew. Standard works on this issue assume that one can distinguish between Archaic Biblical Hebrew, Early Biblical Hebrew and Late Biblical Hebrew (Saenz-Badillos; 2004, Hurvitz; 2013). This position has been challenged in a number of recent publications, in which the authors state that the variation that can be found in Biblical Hebrew is better explained by assuming that there have been different styles of Biblical Hebrew (Young, Rezetko and Ehrensvärd, 2008) in use throughout the biblical period, which is roughly the whole first millennium BCE. A complicating factor in the research on the biblical texts is that we know relatively little about their transmission in the centuries after their composition.

In general the manuscript used for research on Biblical Hebrew is the Codex Leningradensis, which was created in 1008/1009 CE. There exist older manuscripts of the Hebrew Bible; by far the most important ones are those found in the Qumran Caves which can be dated to the beginning of the Common Era, but many of these manuscripts survive in a fragmentary state.

Many studies on the diachrony of Biblical Hebrew are concerned with Hebrew vocabulary. These have resulted in long lists of early lexical items that were supposed to be replaced gradually by late alternatives. These late alternatives can often be identified as loans from languages like Aramaic and Persian (Young, Rezetko and Ehrensvärd, 2008).

One of the problems of studying vocabulary as a gauge of linguistic change is that the vocabulary could have been manipulated easily during the process of transmission. Scribes could change words, thereby consciously archaizing the language of a text.

In order to solve this problem, we study syntax instead of vocabulary. Forming sentences takes place on a less conscious level than choosing words, and therefore this is a better way of studying continuity and change in the history of Biblical Hebrew. In our study we investigate the use of prepositions accompanying a whole range of verbs. In the literature on linguistic variation in Biblical Hebrew the use of prepositions and other function words in various contexts has been studied before, but this has always been done in a very restricted way. Sometimes only a few biblical texts had been studied or the data had been extracted from one manuscript exclusively (Hornkohl, 2014:218-38).

In our research we will focus on verbs of motion and on stationary verbs. In the former category we find verbs like אוב (bōʔ, to come), הלע (ʕālā, to go up) and אצי (yāṣā, to go out), in the latter we find verbs like בשי (yāšav, to sit) and דמע (ʕāmaḏ, to stand). These verbs have in common that in most cases they have a locative as complement, which is often introduced by a preposition (Oosting, Dyk and Glanz, to be published). It is known that various prepositions can be used with a given verb and this variation can be found in parallel texts in the Codex Leningradensis, within specific biblical books and between different manuscripts (Kutscher, 1974).

The use of function words like prepositions is well known in authorship attribution (Argamon and Levitan; 2005, Garcia and Martin; 2007, Segarra, Eisen and Ribeiro; 2013), but in the case of ancient religious texts, detecting the author of a text is a controversial issue. Not only could texts have been adapted during the transmission of the complete text, also the composition of a text may have had a long history. Therefore we do not try to find the supposed author of a text, but based on the study of prepositions accompanying verbs of motion we would like to find out what is the main factor of the variation in the use of these prepositions. Is it related to diachronic development of the Hebrew language or to the way the texts were transmitted or both or are there still other options? We investigate these issues by comparing the thousands of instances of prepositions accompanying verbs of motion and stationary verbs in:

1. different books in the Codex Leningradensis (Genesis, Exodus, etc.)

2. different manuscripts (e.g. compare Isaiah in the Codex Leningradensis with the Great Isaiah Scroll)

3. parallel texts.

This kind of research can only be conducted in a proper way if the textual data is in place, not only for the research proper, but also for those who want to reproduce this research later on. Therefore we base our research on the Amsterdam Hebrew Text Database (Van Peursen et al., 2015). This database is Open Access and can be downloaded from DANS, a national research archive in the Netherlands. Without downloading, the material in the database can be accessed through the website SHEBANQ (https://shebanq.ancient-data.org and Roorda, 2015b). Here the text of the Codex Leningradensis can be browsed, and while doing so, the user has access to a wealth of annotations that represent linguistic information and additional observations. In particular, there is an extensive set of cross-reference annotations between virtually all parallel passages (Roorda, 2015a). With the help of clustering techniques and entropy calculations we are investigating the challenge of linguistic variation in Biblical Hebrew and the transmission of the biblical texts. Results of others (Hornkohl, 2014:218-38, Rezetko and Young, 2014:380-83) and ourselves show that this approach leads to significant progress in our understanding of these issues.

The relevance of this research for digital humanities in general is that it explores challenges such as working with ancient languages of which we have only fragmentary evidence and (religious) texts with a long history of composition and transmission. While there is a lot of literature on these issues in traditional studies, it is clear that digital methods of research have not been pursued to their full potential yet.

Introduction

Humanities scholars have experimented with the potential of different text mining techniques for exploring large corpora, from co-occurrence-based methods to sequence-labeling algorithms (e.g. Named entity recognition). LDA topic modeling (Blei et al., 2003) has become one of the most employed approaches (Meeks and Weingart, 2012). Scholars have often remarked its potential for distant reading analyses (Milligan, 2012) and have assessed its reliability by, for example, using it for examining already well-known historical facts (Au Yeung, 2011). However, researchers have observed that topic modelling results are usually difficult to interpret (Schmidt, 2012). This limits the possibilities to evaluate topic modeling outputs (Chang et al., 2009).

In order to create a corpus exploration method providing topics that are easier to interpret than standard LDA topic models, we propose combining two techniques called Entity linking and Labeled LDA; we are not aware of literature combining these two techniques in the way we describe. Our method identifies in an ontology a series of descriptive labels for each document in a corpus. Then it generates a specific topic for each label. Having a direct relation between topics and labels makes interpretation easier; using an ontology as background knowledge limits label ambiguity. As our topics are described with a limited number of clear-cut labels, they promote interpretability, and this may help quantitative evaluation.

We illustrate the potential of the approach by applying it to define the most relevant topics addressed by each party in the European Parliament's fifth term (1999-2004).

The structure of our work is as follows: We first describe the basic technologies considered. We then describe our approach combining Entity Linking and Labeled LDA. Based on the European Parliament corpus (Koehn, 2005),[1] we show how the results of the combined approach are easier to interpret or evaluate than results for Standard LDA.

Basic technologies

Entity Linking

Entity linking (Rao et al., 2013) tags textual mentions with an entity from a knowledge base like DBpedia (Auer et al., 2007). Mentions can be ambiguous, and the challenge is to choose the entity that most closely reflects the sense of the mention in context. For instance, in the expression Clinton Sanders debate, Clinton is more likely to refer to DBpedia entity Hillary_Clinton than to Bill_Clinton. However, in the expression Clinton vs. Bush debate, the mention Clinton is more likely to refer to Bill_Clinton. An entity linking tool is able to disambiguate mentions taking into account their context, among other factors.

LDA Topic Modeling

Topic modeling is arguably one of most popular text mining techniques in digital humanities (Brauer and Fridlund, 2013). It addresses a common research need, as it can identify the most important topics in a collection of documents, and how these topics are distributed across the documents in the collection. The method's unsupervised nature makes it attractive for large corpora.

However, topic modeling does not always yield satisfactory results. The topics obtained are usually difficult to interpret (Schmidt, 2012, among others). Each topic is presented as a list of words. It generally depends on the intuitions of the researcher how to interpret these tokens in order to propose concepts or issues that these lists of words represent.

Labeled LDA

An extension of LDA topic model is Labeled LDA (Ramage et al., 2009). If each document in a corpus is described by a set of tags (e.g. a newspaper archive with articles tagged for areas like "economics", "foreign policy", etc.), Labeled LDA will identify the relation between LDA topics, documents and tags, and the output will consist of a list of labeled topics.

Our approach

Labeled LDA has shown its potential for fine grained topic modeling (e.g. Zirn and Stuckenschmidt, 2014). The method requires a corpus where documents are annotated with tags describing their content. Several methods can be applied to automatically generating tags, e.g. keyphrase-extraction (Kim et al., 2010). Our source for tags is Entity linking. Since entity linking provides a unique label for sets of topically-related expressions across a corpus' documents, it can help researchers get an overview of different concepts present in the corpus, even if the concepts are conveyed by different expressions in different documents.

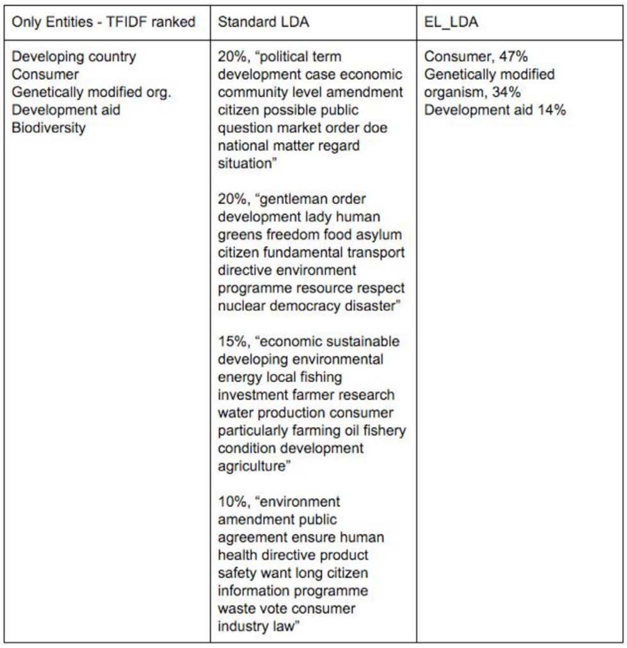
Our first step is identifying potential topic labels via entity linking. Linked entities were obtained with DBpedia Spotlight (Mendes et al., 2011). Spotlight disambiguates against DBpedia, outputting a confidence value for each annotation.[2] Annotations whose confidence was below 0.1 were filtered out. We also removed too general or too frequent entities (e.g. Country or European_Union)

We then rank entities' relevance per document with tf-idf (Jones, 1972), which promotes entities that are salient in a specific subset of corpus documents rather than frequent overall in the corpus. Finally, we select the top five entities per document as per tf-idf. These five entities are used as labels to identify, with Labeled LDA, the distribution of labeled topics in the corpus.

Experiments and Results

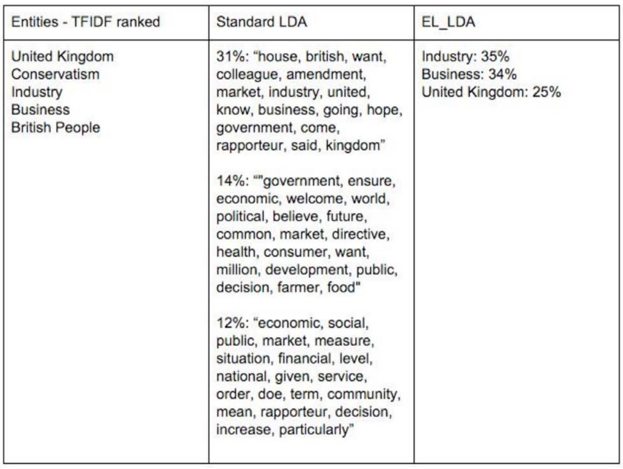
Using the Stanford Topic Modeling Toolbox,[3] we performed both Standard LDA (k=300) and Labeled LDA (with 5 labels)[4] on speech transcripts for the 125 parties at the European Parliament (1999-2004 session). The corpus contains 125 documents, representing one party each. Documents were tokenized and lemmatised; stop-words were removed. DBpedia entities were detected with Spotlight and ranked by tf-idf, as described above.

We present the outputs of Labeled LDA with entity labels (EL_LDA) for three parties, compared to both Standard LDA and to the top-ranked entities for each party (by tf-idf). In each case, we show topics with relevance above 10%. Results for the remaining parties are available online.[5]



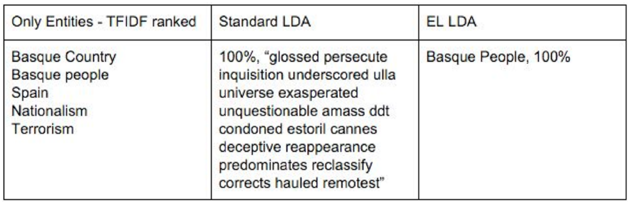
Only Entities - TFIDF ranked	Standard LDA	EL_LDA
Developing country Consumer Genetically modified org. Development aid Biodiversity	20%, "political term development case economic community level amendment citizen possible public question market order doe national matter regard situation" 20%, "gentleman order development lady human greens freedom food asylum citizen fundamental transport directive environment programme resource respect nuclear democracy disaster" 15%, "economic sustainable developing environmental energy local fishing investment farmer research water production consumer particularly farming oil fishery condition development agriculture" 10%, "environment amendment public agreement ensure human health directive product safety want long citizen information programme waste vote consumer industry law"	Consumer, 47% Genetically modified organism, 34% Development aid 14%

Figure: Linked entities (tf-idf-ranked), standard LDA topics and EL-LDA topics for speeches by Les Verts (France).



Entities - TFIDF ranked	Standard LDA	EL_LDA
United Kingdom Conservatism Industry Business British People	31%: "house, british, want, colleague, amendment, market, industry, united, know, business, going, hope, government, come, rapporteur, said, kingdom" 14%: ""government, ensure, economic, welcome, world, political, believe, future, common, market, directive, health, consumer, want, million, development, public, decision, farmer, food" 12%: "economic, social, public, market, measure, situation, financial, level, national, given, service, order, doe, term, community, mean, rapporteur, decision, increase, particularly"	Industry: 35% Business: 34% United Kingdom: 25%

Figure: Linked entities (tf-idf-ranked), standard LDA topics and EL-LDA topics for speeches by the Conservative Party (UK).



Only Entities - TFIDF ranked	Standard LDA	EL LDA
Basque Country Basque people Spain Nationalism Terrorism	100%, "glossed persecute inquisition underscored ulla universe exasperated unquestionable amass ddt condoned estoril cannes deceptive reappearance predominates reclassify corrects hauled remotest"	Basque People, 100%

Figure: Linked entities (tf-idf-ranked), standard LDA topics and EL-LDA topics for speeches by Partido Nacionalista Vasco (Spain).

Discussion

Labeled LDA combines the strengths of Entity Linking and standard LDA. Entity Linking provides clear labels, but no notion of the proportion of the document that is related to the entity. Standard LDA's relevance scores do provide an estimate to what an extent the topic is relevant for the document, but the topics are not expressed with clear labels. Labeled LDA provides both clear labels, and a quantification of the extent to which the label covers the document's content.

An advantage of Labeled LDA over Standard LDA is topic interpretability. Consider the UK Conservative Party's topics. In each standard LDA topic, there are words related to the concepts of *Industry* and *Business* in general, and some words related to the UK appear on the first topic. However, in each topic, some other words (e.g. *government, directive, decision, measure, health, consumer*) are related to other concepts, like perhaps *Legislation* or *Social policy*. A researcher trying to understand the standard LDA topics is faced with choosing which lexical areas are most representative of each topic: is it the ones related to *Industry*, *Business*, and the UK, or is it the other ones? The clear-cut labels from Labeled LDA are more interpretable than a collection of words representing a topic.

The Labeled LDA topics may be more or less correct, just like Standard LDA topics. But we find it easier to evaluate a topic via questions like "is this document about *Industry*, *Business* and *the UK*, in the proportions indicated by our outputs?" than via questions like "is this document about issues like *house, british, amendment, market, industry, government,* (and so on for the remaining topics)"?

The topics for French party Les Verts illustrate Labeled LDA's strengths further. Most of the Standard LDA topics contain some words indicative of the party's concerns (e.g. *environment* or *development*). However, it is not easy to point out which specific issues the party addresses. In Labeled LDA, concrete issues come out, like *Genetically modified organism*.

Topic label *Development aid* shows a challenge with entity linking as a source of labels. Occurrences of the word *development* have been disambiguated towards the entity *Development_aid*, whereas the correct entity is likely *Sustainable_development*. These errors do not undermine the method's usefulness. Efficient ways to filter out such errors exist; this is conceptually similar to removing irrelevant words from Standard LDA topics. However, we need to be aware of and address this challenge.

Regarding Partido Nacionalista Vasco (Basque Nationalist Party), the Standard LDA topic misses the word *basque*, which is essential to this party. Labeled LDA identifies *Basque people* as a dominant concept in this party's interventions.

Outlook

Our method performs Labeled LDA using Entity Linking outputs as labels. Its main advantage is providing a specific label for each topic, that improves topic interpretability, and can simplify human evaluation of topic models.

More evaluation is needed to fully assess the approach. We will consider two possible complementary evaluations: first, a crowdsourced task where participants evaluate the coherence of Labeled LDA topics with the corpus documents. Second, an assessment of our topics by political science experts. We're mostly interested in evaluating the approach for diachronic comparisons.

Visualising Cultural Spheres – Virtual Tours and Epigraphical Data

Anna Neovesky
anna.neovesky@adwmainz.de
Academy of Sciences and Literature | Mainz, Germany

Max Grüntgens
max.gruentgens@adwmainz.de
Academy of Sciences and Literature | Mainz, Germany

Introduction

Today, cultural heritage sites, museums and other places of historical or societal value can often be visited on the Internet. Panoramic images and virtual tours allow the user to access distant sites from home via handheld devices as well as conventional desktop devices. In this way, these applications strongly reduce the threshold for getting acquainted with various cultures, their respective artefacts and unique heritage.

But can this popular and usually touristic way of presentation be used to introduce valid scientific information to a broad public? This question has been posed at the Academy of Sciences and Literature | Mainz regarding its project "Die Deutschen Inschriften".

The research project "Die Deutschen Inschriften"

The long term research project "Die Deutschen Inschriften" is a joint undertaking of six German Academies of Sciences and the Austrian Academy of Sciences. The research focuses on collecting, editing and interpreting medieval and early modern Latin and German inscriptions. They often occur in conjunction with figurative elements or spatial as well as architectural features. The inscriptions themselves are mostly in medieval Latin or in historical or regional varieties of the German language. The geographical area of research consists of Germany, Austria and South Tyrol. The inscription records range from approximately 500 AD to 1650 AD (Brandi, 1937; Kloos, 1973; Nikitsch, 2008). The project's scholars carry out their research within a wide scope of interests ranging from art history, philology and linguistics to the history of ideas. The research results are published in 90 volumes. More than 43 of these volumes, including over 17.000 records, are currently accessible through the online database "Deutsche Inschriften Online" (German Inscriptions Online, www.inschriften.net).

Virtual cultural heritage

Observing an item within a cultural heritage site in isolation frequently limits the understanding of it. This is due to its removal from the big picture of the entire ensemble in its historical, cultural and spatial context.

Two different approaches of representing historical sources in their spatial context are being explored by the projects "Inschriften im Bezugssystem des Raumes" (Inscriptions in their Spatial Context, IBR) and the virtual tours through St. Stephan in Mainz and St. Michael in Hildesheim. Project IBR utilised methods of laser scanning and semantic web technologies, in this regard aiming at a more specialised target audience. The virtual tours of St. Stephan and St. Michael on the other hand were developed as a means to visualise the spatial cultural sphere for an audience with a lower degree of specialized knowledge. In doing so the applications were generally aiming at a broader audience (Lange/Unold 2015; www.spatialhumanities.de/ibr/startseite.html; www.inschriften.net/hildesheim/ rundgang.html)

The virtual tour's objective was to arrange the scientific edition's epigraphical items in their spatial context and to put the scientific sources on display to a diverse audience in an easy accessible and comprehensible manner.

In Hildesheim, the interrelation between the church and bishop at the time of construction, Bernward of Hildesheim, is shown and emphasised through the inscriptions and their placement. (Kruse, 2012). So, the visualisation of this connection and the importance of inscriptions as biographical evidence as well as general historic sources are a further aim.

Generic virtual tours

Several software applications for creating virtual tours already exist that enable everyone to build virtual tours. The software offers the modelling of the views, their arrangement within a tour, the navigation, interactive elements as well as the display on a map. Images, short text and links can be added to describe selected objects. The lack of possibilities to import and embed detailed textual information and to load them from external repositories, limits the benefits in a scientific context. Thus, a software for generic virtual tours was developed to integrate and provide a generic approach for adding content from external repositories (databases, text documents, etc.).

Taking the tour to St. Michael in Hildesheim as an example for the possibilities: the virtual tour enables the user to navigate within the church accessing several fixed viewpoints, to look around and to zoom in on interesting looking spots. Interactive elements indicate the possibility of switching to a different viewpoint, provide information about specific points of interest, most of them inscriptions on stone tablets or tomb slabs or other (art-)historic artefacts. Pop-up windows can contain general information about the inscriptions, a full transcription, as well as a translation of the inscribed texts. Furthermore, images of the inscription, historical sketches, or old photographs as well as audio information can be provided. All this information is displayed in the context of the tour, without exiting the panoramic visualisation. Links to the critical edition of the inscriptions in “Deutsche Inschriften Online” provide easy access to the full scholarly content including scientific apparatus and further bibliographic introductory material.

The software allows for subdividing the information about the epigraphical and pictorial agenda utilized throughout the church into multiple sub-tours. Each tour is therefore enabled to concentrate on a specific topic and by this means to weave a unique narrative of the site and its cultural sphere. Furthermore, various preservation stages and relocations of objects and decorations can be pointed out. The conception of such thematic tours prevents the user from "getting lost" in the virtual environment and from overlooking the content's contextual conclusions and messages. Throughout the tour the viewer receives information in structured order, e.g. the events are sorted chronologically as is the rule in the context of historical information (Rizvic, 2014; Tan/Rahman, 2009).

Cultural coding = generic coding

Creating digital code in the public sector is by necessity an open source process. In contrast to coding in the realm of the competitive private sector, in the cultural realm it is not—and must not be—imperative to shield digital products, project data and know how. Open source software enables people from outside the project to reuse and adapt the outcome as well as to contribute. A generic approach increases the reusability of the code and the application.

Hence the virtual tour was designed as browser-based and implemented as a generic JavaScript application using HTML5, WebGL and the Three.js framework. (Neovesky/Peinelt, 2015). An encapsulated package was released that enables others to build their own virtual tour without programming knowledge. A simple JSON file is used for configuration and data exchange. Adaption of this core JSON file makes it possible to create a custom virtual tour. All the cultural institution has to add are suitable images, positions and texts which can for example be received via data interfaces and web APIs. The generic virtual tour and the user manual are available on GitHub (https://github.com/digicademy/virtualTour).

Conclusion

The virtual tour to the inscriptions of St. Michael’s Church in Hildesheim was born from the idea of combining a popular visual representation with unrestricted access to scientific research and publications.

By means of using a generic approach to the technical implementation, the software is not limited to any specific set of circumstances and does not represent a single-use scenario. Although the application was developed with a specific object in mind, it can easily be adapted to fit other projects within the fields of research, education and visualisation.

Even though the application focuses upon a broad audience, the visualisation can also be of interest to researchers from diverse academic background and disciplines. In this manner scholars are able to receive an impression of a distant site’s or compound’s spatial context. They are as well enabled to present their research in an easy to use, appealing and low-threshold way. The distribution under a free license (GNU GPL V3) enables users to use, adapt and extend the software.

Stefan George Digital: Exploring Typography In A Digital Scholarly Edition

Frederike Neuber
frederike.neuber@uni-graz.at
Graz University, Austria

Introduction

The digital scholarly edition *Stefan George Digital* (StGD) is, as its name implies, dedicated to the oeuvre of the German author Stefan George (1868-1933).[1] As part of my PhD thesis, StGD is concerned with the role and application of typography within the printed collections of George's poetry and the formal canon, and development of the so-called *Stefan-George-typeface (St-G-typeface)*. To capture typographical information within the digital edition, I have tested two approaches that this short paper will discuss: the application of a TEI-based model and the development and the integration of an ontology.

Subject matter

More than any other poet in modern German literature, Stefan George (1868-1933) engaged with writing – particularly typography[2] – in exceptional ways. From 1897 on, he almost completely abandoned his cursive handwriting, using instead highly stylized block letters. From 1904 on, this individual book hand was transferred into metal:[3] the third edition of *Das Jahr der Seele* (*The Year of the Soul*) was the first volume printed in the so called *St-G-typeface*, a Sans-Serif typeface which emerged when the German dispute between Serif and Black Letter typefaces was in full swing. Accordingly, St-G forms a third, alternative typeface, strongly inspired by modern Sans-Serif typefaces such as the Akzidenz-Grotesk of the Berthold foundry. Furthermore, St-G includes letter shapes of Roman and Carolingian scripts as well as of the Greek alphabet (Kurz, 2007). Between its inception and 1927, the *St-G typeface* was changed several times, so that it now exists in various versions.

Problem statement and project goals

George linked his poetry and his understanding of aesthetics to the design of his books by introducing an individualized typeface. He broke with typographical conventions at the time by applying a Sans-Serif typeface, by basing the design on his own handwriting, and by referencing historical script models in its formal features. The extraordinary design of St-G and the fact that the author himself was involved in its creation calls for special attention in a scholarly edition. However, previous editions neither include a detailed recording of the printed publications nor their typographical analysis. StGD aims to close this gap by providing a digital scholarly edition that allows for exploring typography in George's poetical work.

In the first phase of research, I will create a digital edition of printed poetry collections by George. I will develop a model to identify and describe typographical forms as well as to allow for citing them. In a second phase of research I will enhance the corpus of StGD with handwritten drafts, thereby allowing further investigations of the relationship between George's book hand and the typeface.[4]

The digital edition

The corpus of StGD consists of 29 printed editions of Stefan George's poetical works published between 1890 and 1933. Individual works are represented in the corpus variable numbers of times according to their textual and typographical variation.[5] Currently all volumes are encoded according to a customized XML/TEI schema and enriched by bibliographical metadata through FRBR (Functional Requirements for Bibliographic Records) and METS (Metadata Encoding and Transmission Standards). The full texts will be enhanced by corresponding facsimiles, provided via a IIIF (International Image Interoperability Framework) compliant image server using the OpenSeadragon viewer. At the end of the project (April 2017), all contents of the digital edition will be openly available through a Creative Commons (CC-BY-NC-SA) License via the FEDORA-based asset management system

GAMS (Geisteswissenschaftliches Asset Management System)[6].

Focus of the paper

Due to the significant role of typography in George's work, the creation of a digital scholarly edition calls for special attention to graphical features within the documents. This means that typography needs to be classified (i.e. typeface family, font) and its features need to be modelled. The latter includes the description of typographical forms, the identification of stylistic models, and the definition of the semantic function of types in the text. Such typographical enrichment is particularly challenging since neither a commonly shared vocabulary to describe typographical features nor a widely accepted type classification system exists. With regard to this lack of a common standard, StGD has mainly tested out two methods of typographical enrichment which will be discussed in this paper: the application of a TEI based model and the development of an ontology to describe typography.

Typography and the TEI

A distinction can be drawn between two different purposes of encoding features of writing: representation and information enrichment. The first purpose is covered to a great extent by the TEI gaiji module[7] and the application of Unicode. Recent editing projects like *Hugo von Montfort: the poetical work*[8] demonstrate the potentials of these methods, even if they also show that performing them throughout a complete edition is work-intensive and impractical. Concerning the capture of information about writing, especially about typography, the possibilities offered by the TEI are more restricted. Although the element <typeDesc>[9] as part of <msDesc> allows for a description of types in prose, there is no TEI vocabulary to describe types and their features in a formalized way. The paper will report on the benefits and drawbacks of the already implemented elements and attributes and demonstrate their application to material at hand.

Typography and Ontologies

There are barely any digital projects dedicated to the modelling of typography. Those that exist include the *Type Repository of Incunabula*[10] at the Berlin State Library, a database which identifies and catalogues incunabula types. It applies a relatively flat project-customized XML schema that describes types in prose. However, the digital modelling of handwriting has made significant progress over the last decade, since Arianna Ciula coined the term "Digital Palaeography" (Ciula, 2005), and the modelling of typography can benefit from this research. Recent research projects like *DigiPal*[11] and *ORIFLAMMS*[12], though not created in the context of digital scholarly editions, emphasize the strong tendency towards the application of semantic web technologies for the modelling of handwriting (Stokes, 2011 and 2012; Stutzmann, 2013). This paper will discuss their advantages for the identification, formal description and citation of typographical forms. Moreover it will give an overview of the technology or modelling language (i.e. RDFs, UML, SKOS) that might be the most suitable for the purpose of StGD. In this context, the paper will strongly take into account aspects of practicability and re-usability of the model.

Research questions

By modelling and analysing typographical information, the digital edition opens up Stefan George's poetical work for the following research questions: (a) Which formal features does the St-G-typeface contain and what are they referring to?; (b) How has the formal canon of the typeface developed between 1904 and 1927?; (c) Is the development of the book design across George's work linear or is it marked by any significant breaks?; and (d) How are text and typography interrelated in George's work, and how is typography applied as a stylistic device?

Context in Digital Humanities

StGD is contributing to the field of digital scholarly editing, the focus of which is shifting increasingly to the materiality of the edited documents. This tendency has been encouraged by movements such as New Philology as well as by textual concepts such as the "material text: (Shillingsburg 1997) and the idea of text as interaction of "bibliographical" and "linguistic code" (McGann 1991). In this context writing – as the interface between the text's message and its documentary carrier – plays a significant role and is particularly difficult to capture (Schubert, 2010). The goal of StGD is to aid in the development and promotion of a future best practice method for the modelling of typography in digital scholarly editions. Furthermore, the project's thematic focus contributes to the field of digital book history. By putting typography in its focus, StGD represents a first step towards the burgeoning and as-yet-unexplored field of Digital Studies of Typography.

Introduction

In the ever-expanding world of digital libraries and cultural heritage collections, bibliographic metadata standards provide a structured approach to managing resources. The capture of additional contextual information further supports the identification, selection, and use of the resources described. As the problem spaces and areas of study of Humanities scholars are increasingly diversified (Henry and Smith, 2010) and supported by digital material and methods, existent approaches and systems are falling short of the needs of users (Fenlon et al., 2014; Varvel and Thomer, 2011). In short, research agendas and investigations have begun to evolve beyond searches based on traditional metadata parameters (author, date, publication place, genre).

Semantic Web technologies have been identified as a potential solution (Bair and Carlson, 2008). They augment keyword-based, full-text approaches to discovery, with methods that rely on named entity identification, relationships between entities, and the potential to leverage interlinked data from a variety of repositories and corpora. A number of different, well-defined ontologies (structural frameworks capturing domain information) created by various bodies within the wider context of the Digital Humanities (DH) have emerged (Isaac, 2013; Stead, 2006). A critical evaluation and comparison between these different structures has, however, been lacking.

In this paper, we provide a summary of four bibliographical metadata ontologies, and expand on an earlier initial comparative analysis between them. What follows is a more in-depth discussion of complementary differences and parallels in terms of expressiveness, rather than domain, focus, or perspective. The strengths and weaknesses of these vocabularies are of interest and importance to anyone working with any type of Humanities dataset or research output, whether it be interacting with metadata that describes the resource, features that have been extracted from it, or the resource itself.

Bibliographic Ontologies

To date digital libraries have relied heavily on traditional library bibliographic standards, such as MARC[1]. As new research questions have arisen in DH, the limitations of earlier standards have become more pronounced (see Ramesh et al., 2015; Sfakakis and Kapidakis, 2009; Park, 2006; Cantara, 2006; Shreeves et al., 2005), and a number of ontologies designed to map the entities and relationships inherent in bibliographical metadata have emerged.

Rather than aiming to provide a comprehensive analysis of all known examples, we extended a preliminary evaluation of a small number of bibliographic ontologies. Earlier research[2] bridging the large general corpus of the HathiTrust Digital Library[3] with the specialist Early English Books Online - Text Creation Partnership[4] assessed the different needs of three distinct case study examples and analysed the suitability of existing ontologies to adequate capture associated information, including publication facts and object biographies (Nurmikko-Fuller et al., 2015a). This preliminary analysis examined four ontologies: MODS RDF[5]/ MADS RDF[6], BIBFRAME (Miller, et al., 2012), Schema.org[7], and FRBRoo (Bekiari, et al., 2013). BiBo[8] was originally considered, but excluded from the final comparison as it operates on a finer level of granularity.

In this paper, we elaborate on that initial analysis, and provide access to the entirety of the comparative table (Nurmikko-Fuller et al., 2015b)[9] of which only a representative sample has previously been made available. We summarise the main characteristics of each structure in order to provide context for the detailed discussion outlining the parallels and differences between the models.

Methodology

Based on available documentation and extant examples, we conducted an extensive review of the expressiveness of each ontology. Comparing each property and class against possible alignments in the other three led to the identification of parallels and differences between these models. One revelation was the differing extent to which documentation had been left incomplete, highlighting the lack of workflow standardisation in ontology-development even within a shared domain. At times the absence of extensive documentation complicated our ability to confidently assert parallels between the models.

The comparative analysis led to the insertion of all classes and properties of each ontology into one cohesive table, aligned wherever the same data could be represented regardless of how the mapping was achieved, and resulting in a table of exactly 500 rows. Five types of alignment were identified:

- equivalent, where the same data can be mapped in each ontology using a single class. An example of this is location information (such as publication place), captured via madsrdf:Geographic, bf:Place, sc:Place, and frbroo:F9_Place (equivalent to cidoc:E53) in MODS/MADS, BIBFRAME, Schema.org and FRBRoo respectively.
- alternative, which encompasses situations where properties were used in one ontology, but classes in another to talk about the same attribute. An example of this is Schema.org's sc:birthDate. It takes an entire grouping of entities and relationships to express this same information in FRBRoo (frbroo:P98B_wasBorn frbroo:E67_Birth frbroo:P4_hasTime-Span frbroo:E52_Time-Span frbroo:P78_isIdentifiedBy frbroo:E50_Date).
- parallel, where the same data can be mapped using a combination of classes and properties. In the case of the date of creation for a work, MODS/MADS, BIBFRAME and Schema.org all have a single property (mods:dateCreated, bf:creationDate, CreativeWork:dateCreated), whilst FRBRoo necessitates a cluster of classes and properties: F1_Work R19b_wasRealisedThrough F28_ExpressionCreation P2_hasType E55_Type{"Earliest known externalisation"}. We consider these approaches as aligned because the same data can be mapped against them, but parallel rather than exactly equivalent due to different approaches.
- partial, where the same data could be mapped using different ontologies to a greater or lesser extent. As an example of this, we cite the assignment of a unique identifiers, captured using a single property in MODS/MADS (modsrdf:identifier) and FRBRoo (which uses a CIDOC property cidoc:P48_hasPreferredIdentifier), but through several possible options in Schema.org (Thing:sameAs, Book:isbn, Periodical:issn), and via a total of 13 possible properties in BIBFRAME (such as bf:doi, bf:isbn, bf:uri).
- granular, which captures differences in levels of granularity. This is illustrated by entity types such sc:CreativeWork and sc:Book, and showcases how categorical alignment across all four ontologies is not always possible. In the case of frbr:F1_Work (a conceptual version of a work, of which digital and physical manifestation are carriers), an equivalent alignment can be drawn to bf:Work,

but MODSRDF/MADSRDF has no entity type that fulfills the role of representing that notion.

Comparative Analysis

The bibliographic metadata ontologies discussed here differ in their approach and expressiveness. Of the four, MODS RDF/MADS RDF was found to be most descriptive, with FRBRoo an event-based model, and BIBFRAME bridging the two by virtue of containing characteristics typical of either. Schema.org stands out as an ontology that promulgates a model at the crossroads between the other four; however, its focus on instrumenting marketplace transactions also detracts from much of its descriptive power and leaves it orthogonal to the purposes of the others. It has some generic properties that are useful in each of the other ontologies, but also possesses properties and classes that end users do not require outside of point of service systems.

From the perspective of a DH user of these ontologies, each is (to some degree) a victim of its provenance and the motivations of its designers. The benefits and failings of each are different, and they all incorporate a number of idiosyncrasies:

- MODS/MADS has a data structure that replicates the XML serialization format and is frequently realized in RDF as empty nodes.
- Schema.org affords humanists with a vocabulary that combines events and descriptions but differs from the other models in its focus.
- FRBRoo spans beyond the remit of bibliographical metadata by mapping relationships via temporal entities; this results in greater complexity for the representation of the same data, often necessitating a cluster of classes and properties.
- BIBFRAME adopts a different method, recreating MARC in RDF using methods and approaches more in line with graphical thinking, as well as extending beyond that format.

Conclusion

Our review examines the structure and scope of four ontologies designed for the representation of bibliographic metadata as applied to cataloguing digital source material in the Humanities. From this analysis direct equivalences, parallels, and complementary differences have emerged: there are many similarities in aim, scope, and expressiveness, but none of the considered ontologies completely satisfy scholarly needs on their own. Moving between them is feasible, but not achievable without some lossiness, as illustrated by the examples for granular alignment (see **Methodology**). For the comprehensive mapping of all the aspects of a given dataset, these models need to be supplemented with less bibliographically-focused ontologies. Our analysis has highlighted the need to formalize the mappings, best practices, and transformations, as these are key to the correct (re)use of ontologies across projects and domains.

We have provided DH researchers with a window into the digital corpora design process. Knowing the requirements of domain scholars to have interactions with finer-grained research objects, we will be looking at standards like BiBo, Web Annotation, and others during the next round of research.

Digging the Aboveground: Visual Archeology of an Asylum

Burcak Ozludil Altin
bozludil@njit.edu
New Jersey Institute of Technology, United States of America

Augustus Wendell
wendell@njit.edu
New Jersey Institute of Technology, United States of America

Psychiatric practice during the nineteenth century was closely engrained in the spaces of the asylum. Envisioned as "therapeutic instruments" in and of themselves, asylums boomed all around the world: some were purpose-built, some were existing buildings repurposed as asylums. But how did these institutions really function? How was psychiatry practiced here?

Our proposal reports a work in progress that visualizes the evolution and workings of a nineteenth century Ottoman asylum. Located in Istanbul, the capital of the Ottoman Empire, it was used as the state mental hospital between 1873 and 1922. The building is originally a sixteenth century imperial complex by the famous Ottoman court architect Mimar Sinan (1489-1588) and is still standing albeit currently under heavy and damaging restoration. Research shows that during the time of its use as an asylum, the building changed significantly to enable its medical function. Indeed, it is precisely through the changing of the building one can demonstrate the medicalization and modernization of Ottoman psychiatry during this period. In this sense, our case study does not visualize an "ideal" asylum nor is it a search for the "original" complex; on the contrary, it analyzes a neglected and messy phase of an existing building's life. Traditionally perceived as a "corruption" in the original structure, we take the period it was used to treat the insane as a story worth being told.

The information is gathered from a detailed research of primary archival and printed sources involving multiple disciplines: medicine, psychiatry and architecture. These sources include: (1) Ottoman and Turkish official documents kept in the Prime Minister's Archives: Correspondences between state departments giving details about the running of mental institutions, spatial interventions, and concerns over public health; (2) Medical publications of the period: Visitor accounts by physicians, medical writings discussing approaches in psychiatry, and comparative reports on the current conditions of asylums around the world; (3) Popular media: Newspaper articles and travel accounts.

The project is located at the intersection of architectural and medical history; however, it is primarily using the toolset of architectural history. Partly stemming from the demands of the field and partly due to the nature of the project itself, one of the major concerns is the visualization of findings. In line with architects' particular understanding of visualization, the first resort was experimenting with various 2D and perspectival illustration techniques. 2D depictions (i.e. plan, façade, elevation) have been the mode of representation for centuries in the field of architecture. Perspective was a welcome addition with the development of linear, or mathematical, perspective in the fifteenth century. Computational 3D modeling and visual simulation (rendering) has become the norm starting from the 1990s. Despite its popularity in architectural practice and education, the use of 3D computation has, until recently, been relatively underutilized in architectural history.

Scholars in architectural history and in the neighbouring fields of art history and archeology have recently been using methodologies and approaches to integrate innovative technologies in historical research. From virtual reconstruction to web-based panoramas, geospatial modeling to photogrammetry, the virtual creation of static environments to interactive ones, these studies appear in multiple platforms and venues related to digital humanities, digital art history, architectural computation etc. In the mainstream publications of architectural history, an important milestone was the publication of an article that featured real-time interactive simulations of the Roman Forum presenting a hypothetical reconstruction of a funeral ceremony in the Journal of the Society of Architectural Historians (JSAH) (Favro and Johanson, 2010). Another outstanding project that addressed issues of time and movement was "The Virtual Monastery" that focused on a single structure to analyse the workings of a building type through ages (Bonde et al., 2009).

Visualizing the findings

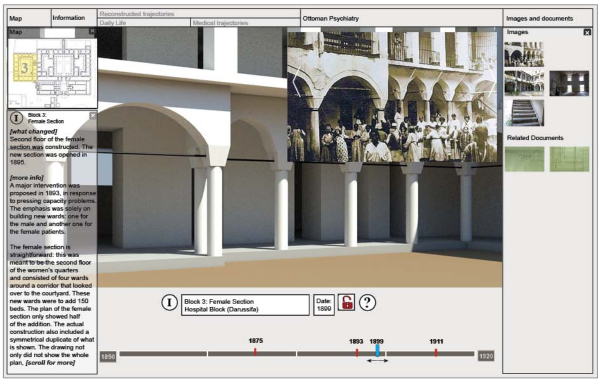
In our project, we faced several challenges to demonstrate the findings with methods traditionally used in architectural history. Ottoman mental facilities in general, and our case study in particular (especially the period that we are focusing on), is largely understudied compared to the aforementioned examples of the Roman Forum or monasteries. All the findings come from primary sources that are incomplete in nature. Moreover, the sources are predominantly textual with limited visual resources describing various states of the building. The historical layers added to the building render conventional visualization methods ineffectual. As a response to these challenges and the resulting complicated presentation of findings, the project employs an interactive 3D simulation toolset built within Unity 3D that allows visualizing hypothetical spatial reconstructions and trajectory tracking all continuously referring to temporal data and incorporating primary documents. Our interactive simulation framework builds on these efforts creating the ability to navigate in four dimensions simultaneously and without restriction:

1 **Temporal dimension:** Instead of the traditional interest in finding out about the "original" building, this approach looks at the **life of a building** and how it changed over time. The method we propose for Unity is to implement a time slider component into the viewing user interface (UI). This component controls the visibility of architectural changes at distinct time periods. In this project, we have identified four specific points in time wherein primary sources identify distinct architectural states. The timeline UI is enabled by including time data within the model data. In the 3D modeling or 3D data acquisition phase, model elements are tagged with custom properties coded to our tool. These custom properties represent abstract metadata defining the start and end date for the object(s) (for temporal properties), the orientation point for the object(s) (for geospatial locating), as well as any descriptive information all of which become native to the file.

2 **Reconstructed trajectories:** Instead of treating space as an isolated entity, this approach captures the **life in the building**. By tracing the movement of the occupiers of the space, we know more about their lives. The everyday life in the asylum consisted of the acts and movements of its occupiers, in this case, patients, doctors and the staff. By tracing their movements and visualizing them, it becomes possible to have a better understanding of the daily routines (eating, cleaning, sleeping etc.) in addition to the medical treatments that took place through a certain reorganization of space and time. This setting is particularly illuminating as it was assumed at the time that the life and routines of patients in the asylum were crucial components of the healing process.The user interface (UI) enables diagrammatic circulation indicators for each of the four points in time to be visible at the viewer's discretion.

3 **Cross-referencing data:** In addition to the ability to preview time and movement, the interactive functionality in Unity allows the viewer to select the information relevant to the simulation viewed at any time. The ability to combine text as hyperlinked visual overlays and graphic information enables important reference texts and images to be associated with spatial and temporal elements and viewed when desired. One advantage of this presentation method is the ability to break free from the linear structure of a textual manuscript. One can interact with the information presented in a nonlinear way (albeit guided). By cross-referencing various types of information, we aim to create a system that binds or connects these documents and data sets in meaningful ways.

We do not intend the spatiotemporal model to be the **primary** outcome, but rather a platform inviting interpretation and scholarship through the combined textual and visual data. In line with the ontological approach adopted in digital humanities, the ever-evolving outcome is a "knowledge representation, a hypothesis" not a recreation of reality (Bonde et al., 2009). The relationship between the representation and its referent also calls into question producing knowledge with partial data, which is not uncommon in (conventional or digital) historical scholarship. Both possibilities and risks exist in 3D visualization with partial data. 3D models give the opportunity to relate to the building without the trained eye to "read" 2D representations. Risk is related: 3D creates a sense of absolute masking the hypothetical elements within. Being aware of this danger, the project aims to visually clarify the "known" versus "unknown" using graphic coloration indicating the extent of "known" detail.



[what changed]
Second floor of the female section was constructed. The new section was opened in 1895.

[more info]
A major intervention was proposed in 1893, in response to pressing capacity problems. The emphasis was solely on building new wards: one for the male and another one for the female patients.

The female section is straightforward: this was meant to be the second floor of the women's quarters and consisted of four wards around a corridor that looked over to the courtyard. These new wards were to add 150 beds. The plan of the female section only showed half of the addition. The actual construction also included a symmetrical duplicate of what is shown. The drawing not only did not show the whole plan, [scroll for more]

Block 3: Female Section
Hospital Block (Darussifa)

Figure 1: Simulation User Interface Mockup (B. Ozludil, U. Thompson, A. Wendell). Photograph source: Sihhat Almanaki, 1933.

The tool we propose visualizes temporally-located spatial data that allows multiple readings and interpretations, and that is open to manipulation, rather than a mere representation of a space. Doing so will open the approach to more disciplines and interested parties, and while still technical in nature, will provide a platform for historical spatial research. This work can be shared with other digital humanities scholars employing Unity or similar tools. Integrating innovative technologies in historical research has the potential to change the ways in which we conceptualize and tackle the problem at hand. In other words, rather than being "tools" to accomplish what is predetermined, they open up new ways to think and to produce knowledge.

Data Praxis in the Digital Humanities: Use, Production, Access

Thomas George Padilla
tpadilla@msu.edu
Michigan State University, United States of America

Devin Higgins
higgi135@msu.edu
Michigan State University, United States of America

While there have been numerous efforts at framing the history of the Digital Humanities, no study has concretely characterized the extent to which Digital Humanities research is data driven (Gold and Klein, 2012; Schreibman, Siemens, and Unsworth, 2004; Nyhan, Flinn and Welsh, 2015; Terras, Nyhanand Vanhoutte, 2013). Debates related to this topic periodically crop up along the Hack/Yack divide, as recurrent waves of scholars reflect on the varied histories, projects, and positions that comprise the Digital Humanities (Nowiskie, n.d.; Ramsay, n.d.; Cecire, n.d.; Alvarado, 2012). While these debates will likely continue, it is clear that current theoretical and historical contextualization stand to benefit from a more granular evaluation. The benefits of this evaluation hold potential to shed light on data driven research practices across disciplines and academic ranks, distribution of this output by institution type and geographical location, relative research data accessibility, as well as illumination of the scope of data resources utilized to further Digital Humanities research, which in turn holds the potential to inform library efforts to augment Digital Humanities support with more nuanced focus on acquisition, preparation, and provision of data that is more readily usable to Digital Humanists (Bryson et al., 2011; Sustaining the Digital Humanities, n.d.; Rockenbach, 2013). In order to realize these benefits the present study focuses on Digital Humanities praxis that is expressly data driven and computationally contingent. The study of this praxis is achieved through analysis of nearly 500 articles drawn from seven years of Oxford University Press' Digital Scholarship in the Humanities (formerly Literary and Linguistic computing), seven years of Digital Humanities Quarterly (the full run of the journal), as well as the full run of the Journal of Digital Humanities.

In order to evaluate data praxis, it was necessary to come to a working definition of "data" scoped to the level of concrete usage patterns in the Digital Humanities. The conclusion that a particular article utilized source "data" was based on whether or not the material under analysis played a role in supporting research claims predicated on the affordances of the digital object itself. A close reading of a digital version of *Jane Eyre* therefore would not meet the criterion of data driven, but topic modeling *Jane Eyre* would, as this is a form of analysis that is uniquely possible given digital instantiation of the object under study. Articles which were understood more as reports on data-oriented research, rather than active analysis were typically excluded. Assessments, historiographies, and other meta-analysis of computational research represented elsewhere are not treated as data driven for the purposes of this study as the work in question can move forward without leveraging the affordances of a digital object. Even where these types of articles are held to not contain source data under a process of direct computational analysis or representation, they are still considered against a rubric of research data production. Research data is understood to encompass any non-rhetorical, primarily structural data generated as an output that is used to validate research findings (Federal Register Notice Re OMB Circular A-110, n.d.). This might include tabular data, computer code, or survey responses.

Research data production is evaluated in order to come to an understanding of how Digital Humanists provide or do not provide access to generated data they use to support their arguments. The authors sought to focus on this aspect of research given a growing movement by scholars, operating primarily outside of the Humanities, to make their data and code accessible to support reproducibility and transparency (Stodden, Leisch, and Peng, 2014). If research data was produced in a given article, the authors proceeded to evaluate whether or not it was accessible. Research data is only considered to be accessible if the data in question is made available in a format that is machine processable. Therefore, a table of research data or an image of a line graph included in an article as a JPG is not accessible because the format renders the data intractable. Furthermore, a subset of a larger set of data, mainly used to illustrate an aspect of an argument rather than providing access to the unmediated source dataset is held to be inaccessible. Collectively, researchers, librarians, and publishers can use this portion of the study to inform assessment of the extent to which current research and publication practice are in line with how the field aims to articulate the integrity of its research claims.

On the whole, article level analysis is supported by capturing up to 48 descriptive elements for each article in the target corpus. In aggregate this dataset captures the number of data sources used in a given article, the provider of the data, type of provider, data collection name, content type, format, extent, size, publication pre or post 1923, whether research data is produced, whether research data is accessible, the method of access provided if it is accessible, research data URL, research data type, and a range of demographic data that allows disciplinary characterization of data driven practices by scholars and students, the type of institutions they work in, and where in the world they work. Collectively this data will enable the Digital Humanities community to gain a concrete sense of what proportion of Digital Humanities Scholarship as represented in a core set of journals is data driven. This study indicates that current research and publication practice provide insufficient access to research data. Because the evaluation of a data driven article's argument requires access to research data, this scarcity seems especially troubling. Additional pragmatic gains to be had from this study include ready access to all data sources utilized over the past 7 years in core Digital Humanities journals. Ready access to this data holds potential to increase awareness of data for Digital Humanities research and pedagogy in addition to informing library acquisition, preparation, and provision of data that can used to support the Digital Humanities. Through its concrete focus on data praxis, this study provides newly comprehensive insight into data driven practices across the Digital Humanities.

Depuis 2014, la bibliothèque de Sciences Po développe une offre de service à destination des laboratoires de recherche de l'Institution. Traditionnellement assez éloignée de ces publics, elle essaye d'adapter ses pratiques et de trouver de nouvelles méthodologies de travail pour accompagner les chercheurs dans leurs travaux.

La révolution numérique a introduit un bouleversement dans la constitution des fonds des bibliothèques: comment rendre compte de l'état d'un sujet d'actualité pour les générations à venir lorsque le discours ne se bâtit plus uniquement dans des médias coutumiers, mais dans le flux des réseaux ? La bibliothèque peut-elle opérer des carottages thématiques du web et concevoir les dispositifs qui en conserveraient la trace ?

Les corpus web tentent de répondre à cette double problématique documentaire et de recherche en s'appuyant sur des techniques d'exploration et de visualisation de réseaux web. S'inscrivant dans la lignée des corpus d'étude outillés proposés par Corinne Welger-Barboza, ils permettent de structurer et d'identifier les discours sous-jacents, tout en apportant des moyens d'appropriation adaptés.

De la construction des données aux premiers constats scientifiques, cette communication dresse un bilan de ce travail, expérimental pour la bibliothèque tant au niveau des outils mobilisés et développés que des processus documentaires mis en œuvre, à travers l'exemple d'un corpus des acteurs de la question des changements climatiques.

Construction

En 2015 se tient à Paris la Conférence des Nations Unies sur les changements climatiques, la COP21. Sciences Po a retenu cette année ce sujet d'actualité comme thème fort de l'institution; le contenu des enseignements, des manifestations scientifiques et de vulgarisation, des expositions en est irrigué. La bibliothèque et le médialab[1], partenaires de ce projet, l'ont choisi comme problématique de leur premier corpus. Quels sont les acteurs de la discussion autour des changements climatiques? Quelle est leur position quant à la responsabilité de l'homme? Qui parle avec qui? Faut-il réduire les émissions de gaz à effet de serre? Voici la liste des questions que nous avons posées. Pour y répondre, nous avons développé un processus en 3 temps: construction, exploration et exposition des données.

Le crawler Hyphe est l'outil qui nous permet de constituer les données. Pour cette opération, itérative, deux types d'actions sont mises en œuvre : identifier, sélectionner. La première consiste à trouver des sites (entités) pertinents pour la thématique. C'est le cœur du corpus[2]. Les crawlers parcourent les liens hypertextes de ce cœur afin d'identifier de nouvelles entités. La seconde à distinguer ceux qui sont pertinents et qui seront crawlés, de ceux qui ne le sont pas. De proche en proche, nous prospectons le web et de nouveaux sites apparaissent. De 60 entités de départ, 40.000 ont été identifiées et 600 ont été conservées. Ce sont ces dernières qui forment le corpus (Jacomy, 2015).

Cette étape repose sur des pratiques à la fois connues et nouvelles pour la bibliothèque: l'analogie entre la sélection d'ouvrages à partir de sources fiables (ici pertinentes) est assez aisée à comprendre. En revanche, crawler, et ainsi automatiser l'opération d'identification reste une action assez éloignée des processus traditionnellement mobilisés en bibliothèque. D'autant plus que le crawler utilisé, Hyphe, conserve l'empreinte des liens qui unissent les entités constitutives du corpus: le réseau. Au-delà de la liste des sites de référence sur les changements climatiques, Hyphe nous permet donc de garder la trace des discussions en ligne. La compétence méthodologique sur les réseaux est apportée ici par le médialab.

Exploration

L'exploitation envisagée nécessite que les entités web soient enrichies. Les métadonnées des sites ne sont pas standardisées, à l'inverse des objets traditionnellement traités en bibliothèque (ouvrages, revues, documents audiovisuels) qui sont, eux, décrits avec des langages contrôlés. C'est pourquoi une série de catégories a été créée: type d'acteur, responsabilité de l'homme dans le changement climatique, nature des actions soutenues (atténuation, adaptation).

Ce travail est la combinaison de compétences documentaires et scientifiques. Le chercheur spécialiste de la thématique propose, et valide les catégories choisies, mais il aide également à circonscrire le périmètre du corpus, en optant par exemple pour la conservation de sites anglophones uniquement. Les catégories sont construites sur des index élaborés par la bibliothèque qui les éprouve lors des phases de test. De plus, pour chaque site, un résumé est rédigé afin de garder une trace de son contenu et ainsi pallier la nature éphémère du web (Corey, 2010).

En l'absence d'outil de catégorisation pour ce type de corpus, le développement d'une solution ad hoc est nécessaire. Elle doit répondre à des contraintes claires, dont le travail collaboratif synchrone et le maintien de l'intégrité des données entre Hyphe et le site web.

La phase exploratoire ultime est celle de la visualisation: « faire parler » le réseau en s'appuyant sur la catégorisation[3].

Exposition

Le troisième temps est celui de l'exposition: comment dépasser la liste, par laquelle une bibliothèque présente traditionnellement les ressources web sélectionnées? En proposant un outil d'exploration en ligne, qui permet à l'utilisateur non seulement de consulter les sites du corpus, mais également de se les approprier. En combinant les catégories au graphe, l'usager peut jouer la partition écrite par la bibliothèque: si la liste, rassurante, car connue, est toujours là, il est en plus possible de visualiser, par exemple, les acteurs institutionnels qui soutiennent les mesures d'atténuation des émissions de gaz à effet de serre et de les confronter à celles des blogueurs climato-sceptiques en manipulant la visualisation. Le graphe ajoute de la profondeur à la liste en faisant apparaître la dimension de connexion entre les entités: c'est un atout du corpus.

Les interfaces web existantes exposent rarement cette dualité liste/visualisation. C'est pourquoi, une nouvelle fois, une solution adaptée aux besoins des utilisateurs a été développée[4]. Ce projet entre dans un cadre de libération du code et d'ouverture des données.

Conclusion

Ce travail est le fruit d'une collaboration étroite entre les différents corps de métiers inhérents aux Digital Humanities. 11 personnes ont participé à cette expérimentation : 1 chef de projet, 4 bibliothécaires dont le référent « environnement », 1 développeur, 2 informaticiens spécialistes des réseaux web, 3 chercheurs du domaine. Il aura fallu une année pour mener à terme ce projet qui avait valeur de test: la bibliothèque a-t-elle les moyens de proposer un service d'accompagnement des chercheurs pour l'étude des réseaux web? Répond-elle également à la question de l'archivage du web ?

Le premier constat, positif, est celui de la faisabilité : le collectif a été en mesure de finaliser ce corpus. Le deuxième, tout aussi engageant est celui des premiers résultats scientifiques basés sur la visualisation du réseau. L'équipe de recherche a été surprise de voir que les climato-sceptiques sont encore très actifs sur le web, alors même qu'ils semblent minoritaires dans les discussions physiques. Qui sont-ils? Comment interagissent-ils avec les institutions, les entreprises et la société civile? Pourquoi ne forment-ils pas un groupe à part, mais apparaissent-ils comme parties prenantes de la conversation en ligne? Ces questions doivent maintenant être analysées en profondeur. D'objet documentaire, ce corpus sur le changement climatique est devenu objet d'étude outillé. Chaque carte peut entériner ou infirmer les problématiques initiales et parfois générer des intuitions, interrogations qui doivent être vérifiées et prouvées scientifiquement.

Ce projet a permis à la bibliothèque de collaborer avec un laboratoire de recherche et ainsi d'aller au-delà de ses logiques traditionnelles de documentation. De nouvelles méthodes de travail ont été identifiées. Il s'agit maintenant de les fixer et de voir s'ils sont opérants sur d'autres thématiques en achevant la conception de la chaîne d'outils et en faisant monter en compétence les équipes sur leur utilisation et la connaissance des réseaux web. La phase suivante est également celle de l'archivage: la documentation du processus de construction et d'exploration de chaque corpus est une étape nécessaire pour garder une trace pérenne des ressources web et assurer les conditions de réutilisation des corpus.

S'appuyant sur la décomposition du travail autour de la construction, l'exploration et l'exposition des données, l'équipe a su répondre à la double problématique à laquelle l'institution est confrontée. Et ainsi, comme une valse, la bibliothèque est entrée en trois temps dans la danse des corpus web.

In questo lavoro descriviamo un progetto di ricerca, attualmente in corso, dedicato all'analisi dell'universo linguistico e semantico della musica rap, con particolare attenzione rivolta alla realtà italiana. L'obiettivo del lavoro è quello di arrivare ad offrire una mappatura panoramica, una "distant reading" della lingua usata dal rap italiano.

La scelta di questo genere è motivata dal fatto che il rap è tra i fenomeni più vitali e dal maggiore impatto socioculturale della musica e delle sottoculture giovanili degli ultimi decenni (Lena, 1995; Toop, 1999; Forman and Neal, 2004; Pinkney, 2007), esteso ormai ben oltre gli originari confini statunitensi per divenire fenomeno globale (Androutsopoulos and Arno 2003; Osumare, 2007; Alim et al., 2008) e all'interno del quale è possibile riscontrare una ricchissima produzione testuale ed un alto tasso di innovazione e sperimentazione di forme linguistiche (Cutler, 2007; Bradley, 2009; Terkourafi, 2010).

L'idea alla base del lavoro è quella di ottenere una "cartografia" della lingua del rap, che permetta di osservare e analizzare nel suo complesso un settore della produzione culturale contemporanea estremamente diffuso e popolare anche in Italia (Pacoda 1996; Filippone and Papini, 2002; Attolino, 2003; Scholz, 2005). In questo lavoro focalizziamo l'attenzione principalmente sulla dimensione testuale del rap piuttosto che su quella musicale, pur trattandosi di un genere in cui il rapporto tra parola e ritmo è inestricabile (Bradley, 2009). In ogni caso, è possibile affermare che la componente testuale nel rap occupa un ruolo centrale e che la specificità del vocabolario, dei temi, della capacità di invenzione linguistica nonché l'importanza dell'aspetto narrativo (Attolino, 2012) fanno dei testi del rap un corpus linguistico interessante da analizzare in sè.

A tal fine, piuttosto che soffermare l'attenzione su di un numero limitato di testi da analizzare in profondità, mettiamo in campo una metodologia di lavoro multidisciplinare - in cui convergono web data-mining, linguistica e information design – con l'obiettivo di giungere alla costruzione di un database testuale molto ampio da sottoporre ad analisi mediante strumenti di text-mining e di linguistica computazionale e da rendere esplorabile mediante una serie di visualizzazioni interattive elaborate ad-hoc.

In una prima fase si è proceduto all'individuazione di alcune web-repository contenenti le trascrizioni dei testi delle canzoni rap in lingua italiana. Non essendo le fonti ufficiali (siti personali degli artisti, siti delle etichette, libretti dei CD, ecc.) particolarmente ricche di informazioni, sono stati individuati alcuni popolari siti di text-sharing, dove fan e ascoltatori forniscono spontaneamente le proprie trascrizioni dei testi degli artisti.

Sulle fonti selezionate è stato addestrato uno script di web-scraping, sviluppato appositamente, in grado di estrarre, per ogni brano presente sul sito, il testo e i meta-dati di riferimento (titolo brano, nome autore, collaborazioni, album). Una volta addestrato lo script si è passati alla fase di estrazione dati vera e propria che ha portato alla costruzione di un database di circa quindicimila brani. Il risultante database è stato poi sottoposto ad una prima fase di pre-processing e data-wrangling per renderlo disponibile all'analisi successiva. Sul testo estratto dal web è stata effettuata una profonda ripulitura con metodi semi-automatici in modo da ottenere un corpus omogeneo di testi trattabili computazionalmente.

Alla fase di estrazione e standardizzazione del dataset segue la fase di analisi linguistica. In questa fase teniamo conto di alcuni studi precedenti condotti nell'ambito del MIR - Music Information Retrieval, in particolare quelli rivolti all'analisi automatica dei testi delle canzoni (Mahedero et al., 2005; Kleedorfer et al., 2008; Hu et al., 2009) e dei testi rap in particolare (Hirjee and Brown, 2009; Hirjee and Brown, 2010; Malmi et. al, 2015).

Il corpus è processato usando l'intera pipeline di analisi linguistica (Manning and Schütze, 1999) già ampiamente nota nei task di NLP: tokenizzazione, lemmatizzazione e pos tagging. Successivamente si è passato ad un'analisi statistica per ottenere le frequenze assolute dei termini, le frequenze relative per autore, le collocazioni, i bigrammi e i trigrammi ricorrenti e la forza di associazione tra le parole espressa in termini di PMI (Pointwise Mutual Information). Gli strumenti utilizzati per effettuare queste analisi sono basati sulla libreria NLTK in Python (Loper and Bird, 2002). Una volta estratti i Lemmi con le rispettive frequenze, viene calcolato il valore di Term Frequency/ Inverse Document Frequency (TF/IDF) per ogni lemma in modo da estrarre le parole più significative per ciascun autore. Una matrice di co-occorrenza, precedentemente costruita su un corpus di circa 3 milioni di parole, attraverso l'applicazione di un algoritmo di Distributional Semantics chiamato HAL - Hyperspace Analogue to Language (Burges and Lund, 1995), è utilizzata per estrarre le parole con valori di similitudine semantica maggiori per ogni lemma, allo scopo di creare un network di significati che identifichi lo spazio semantico di ciascun autore e permetta la loro classificazione attraverso algoritmi di machine learning (clustering).

I dati risultanti dall'analisi linguistica sono strutturati in un database adatto all'elaborazione dei software e dei processi di data visualization. L'obiettivo di questa parte del progetto è quello di costruire un tool interattivo che utilizzi tecnologie web (html, css, javascript) per rendere il dataset esplorabile, comunicabile e analizzabile ulteriormente. Per l'elaborazione del sistema di visualizzazione prendiamo in esame le specifiche problematiche poste dalla visualizzazione di grandi corpora testuali (Wise et al., 1995; Fortuna et al., 2005; Alencar et al., 2012; Sinclair et al., 2013; Kucher, 2014; Brath and Banissi, 2015) e le soluzioni approntate da alcuni lavori precedenti sulla visualizzazione di database composti da testi di canzoni (Labrecque, 2009; Baur et al., 2010; Oh, 2010; Sasaki et al., 2014).

Il tool di visualizzazione si compone di una serie di "viste" e di filtri di navigazione che permettono di osservare il dataset da più angolazioni e attraverso diversi livelli di dettaglio, secondo il classico pattern Overview first, zoom and filter, then details-on-demand (Shneidermann, 1996). Oltre agli approcci classici dell'Information Visualization, la progettazione delle visualizzazioni tiene conto dell'approccio maturato dal design della comunicazione nell'ambito delle Digital Humanities (Uboldi and Caviglia, 2015) in paritcolare per quanto riguarda la definizione della user experience.

Una serie di layer di visualizzazione sono combinati in delle viste panoramiche che offrono uno sguardo complessivo su diversi aspetti del database: statistiche di base come le frequenze e le distribuzioni dei termini più utilizzati; la varietà complessiva del vocabolario; una serie di ranking; reti bipartite tra autori e termini; reti tra parole e relativi cluster semantici più evidenti.

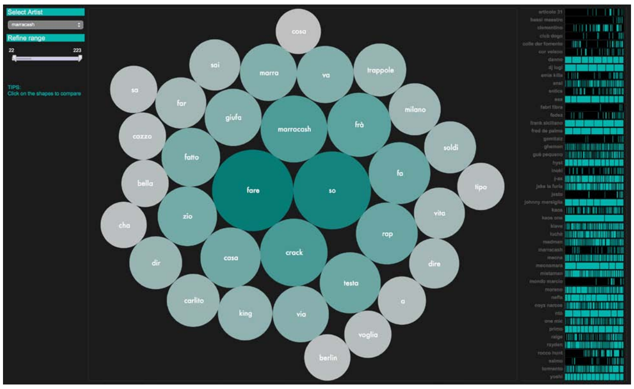

Fig : Rapscape: Single Artist Explorer view

Filtri e viste secondarie sono progettati invece per muoversi rapidamente tra diversi livelli e prospettive sul dataset e di scendere nel dettaglio per analizzare i dati relativi al singolo autore (termini più frequenti, temi dominanti, ecc) o al singolo brano. E' inoltre possibile operare comparazioni tra autori (o gruppi di autori), o tra brani (o gruppi di brani). La visualizzazione è progettata dunque principalmente come strumento esplorativo in modo tale da rendere possibile l'analisi dell'universo testuale del rap a diversi livelli di profondità e granularità.

Metaphor Mining in Historical German Novels: Using Unsupervised Learning to Uncover Conceptual Systems in Literature

Stefan Pernes
stefan.pernes@uni-wuerzburg.de
University of Würzburg, Germany

Figurative language poses a challenge to Natural Language Processing systems, while being a ubiquitous phenomenon that is deeply ingrained in every-day language. As corpus studies suggest, figurative language devices appear on average in every third sentence of general-domain text (Shutova, 2015), thus making the development of automatic recognition and interpretation systems play an important role in many text mining use cases, especially those aiming for a deeper semantic understanding of texts. Furthermore, acknowledging the pervasiveness of such language forms - and of the emblematic device of metaphor in particular - allows for a change in perspective, not conceiving it as a merely rhetorical device but as a genuinely cognitive mechanism that manifests itself in language in the form of surface metaphorical expressions. Such surface expressions usually follow a directionality principle common in figurative language which is to project one domain of experience (the source, e.g. war) onto another (the target, e.g. argument), the first one typically being more concrete and the second one being more abstract. Taken together, such surface expressions (e.g. She shot down all of my arguments) consitute a conceptual metaphor argument is war, a cognitive phenomenon that can be studied through its expression in language. This line of thought has been established as Conceptual Metaphor Theory (Lakoff and Johnson, 1980), by now a widely adopted and empirically grounded approach (e.g. Gibbs, 2008) that has opened up a interdisciplinary field of research, not least with involvement from computational linguistics.

Analysing metaphorical language use from a (cognitive) anthropologic and psycholinguistic point of view has various possible applications: The approach qualifies for research questions from the fields of critical discourse analysis, media studies, and philosophy, as it sheds light on a collective subconscious, encompassing ideological subtexts, and maybe even pre-discursive existential territories (Guattari, 2008) as traced out in late 20th century philosophy. Another area of application is text classification in literary studies: Found metaphorical expressions and conceptual mappings can be used as features to describe the relative similarity of observed texts and thus lend themselves to genre identification and authorship attribution (Lodge, 1988).

The research described here takes up this theoretical framework and builds upon a computational metaphor identification and aggregation approach as proposed by Shutova and Sun (2013). Unsupervised machine learning, namely a hierarchical soft clustering strategy known as Hierarchical Graph Factorization Clustering (HGFC), is employed to build up a graph of concepts that reflects aggregate metaphorical mappings. Using conceptual metaphor as a unit of observation allows for a sensible aggregation and tracing of surface metaphorical expressions in large scale corpora, and in this case is also used to follow diachronic developments in a corpus of historical German literature. Furthermore, as a correlate of cognitive processes it should provide an empirically grounded access to the conceptual systems, e.g. cultural and moral models, of examined texts and their times.

The main idea of the approach is to cluster nouns - which are taken to be concepts - according to their selectional preferences, that is, "the tendency for a word to semantically select or constrain which other words may appear in a direct syntactic relation with it" (Roberts and Egg, 2014). In the resulting clustering, figurative language use becomes visible as violation of the most frequent selectional preferences representing the normal, non-figurative case. It is an approach that determines the metaphorical in relation to the normal, which also entails that a sufficient amount of non-metaphorical language use needs to be present in the data. In the case of a diachronic corpus of literature that means to balance the corpus using historical dictionaries and encyclopaedias in order to introduce more prosaic language use.

The dataset is drawn from a large text collection (The Digital Library, 2016) and contains up to 1700 German novels from the early 16th up to the beginning of the 20th century. Preprocessing consists of POS-tagging, lemmatization, and dependency parsing, allowing for an extraction of nouns and their corresponding verbs according to certain grammatical relations - subject, direct object, and indirect object relations. Verbal constructions are only one type of realization, but they do cover a significant part of metaphors usually encountered in the wild. Furthermore, it should be straightforward to generalize the approach in order to include adjectival constructions and similes, which would allow to cover most of the possible metaphorical expressions. Preprocessing is performed using a modular pipeline (Jannidis et al., forthcoming), tailored to the processing of book-length German texts. Subsequently, a number of most frequent nouns (e.g. 2000) and corresponding verbs are extracted. The verbs act as features for the concept clustering and can come from various sources, not necessarily the same corpus as the most frequent nouns. This could be used as a way to introduce balancing text types into the model, without altering the concept graph as derived from the literary corpus. The resulting noun-verb feature matrix is then normalized for each noun vector to sum to 1 and the Jensen-Shannon divergence between pairs of noun vectors is used as a measure to calculate the similarity matrix (the initial concept graph).

With the similarity matrix in place, clustering methods can be applied in order to generate a suitable tree of concepts. Different approaches were tested at this point (using implementations from Python machine learning library scikit-learn, cf. Pedregosa et al., 2011): 1) connectivity-based or agglomerative clustering, which includes average, complete, and - the baseline from Shutova and Sun (2013) - Ward linkage 2) density-based clustering, namely DBSCAN and HDBSCAN, and 3) for subspace-based methods, spectral clustering, as well as spectral bi- and co-clustering. Results where manually reviewed and an internal evaluation measure, the silhouette coefficient, was used to assess the quality of generated clusterings. Results indicate that in this setting, spectral clustering performs very similar to the baseline, while the other methods produce clusterings of inferior quality. This exploration of readily available methods shed some light onto the requirements for unsupervised metaphor identification and aggregation. In addition, tests with balancing and pruning were performed on smaller development corpora: Solely using encyclopedias produces a model that contains mostly synonym and antonym relations but no metaphorical mappings. Similarly, models consisting only of literary texts can lack non-figurative uses for concepts. What can also be observed is that the balancing leads to deeper models, e.g. concepts accumulate more features and aggregate better.

To give an intuition, example clusters from the baseline results on a subset of 383 novels are reproduced here, showing the top ten features for each concept:

IDEAS ARE FOOD

education / bildung (10): geben-dobj beanspruchen-dobj taxieren-dobj voraneilen-subj überstrahlt-dobj ausspräch-subj nahestehen-subj heraustreiben-dobj ermangelnd-dobj abschöpfen-dobj

memory / erinnerung (48): geben-dobj wachzurufen-dobj stören-dobj mahnen-dobj aufgrischen-dobj verlöschen-subj wiederzuerwecken-dobj neubeleben-dobj frischen-dobj hervorschießen-subj

hunger / hunger (10): geben-dobj erweren-dobj büssen-dobj schaben-subj überhen-iobj verschmachten-dobj stärkern-dobj bittern-subj hinausgetreiben-subj trainieren-iobj

EMOTIONS ARE PLANTS

flower / blume (47): pflücken-dobj liegen-subj lieben-dobj begießen-dobj welken-dobj duften-dobj duftet-subj durchhauten-subj hingesenken-subj erblüht-dobj

emotion / gefühl (90): liegen-subj ersticken-dobj abstumpfen-dobj hervorraufen-dobj halten-iobj entspinnen-dobj hinausdehnen-dobj aufwekken-dobj anhielen-subj arten-subj

In principle, cluster labels are manually assigned using categories from Lakoff's master metaphor list (Lakoff et al., 1991). Such is the case with the first example, IDEAS ARE FOOD, while the second one, EMOTIONS ARE PLANTS, is not present in the list and was created to appropriately describe the cluster.

Pending work includes testing HGFC and providing means to include metadata for modeling the diachronicity of the data. Considering the time span covered by the corpus, some orthographic and lexical variation will have to be handled, either by use of a specialized spelling normalization system or a more rigoros treatment such as stemming. It can be noted that HGFC combines some of the characteristics exhibited by the surveyed approaches and running it on the full size corpus will significantly improve on the baseline in terms of the amount of metaphorical expressions and conceptual mappings induced. The system will be evaluated using either a small gold standard of annotated sample sentences or manually compiled conceptual mappings in a confined domain (e.g. using Lakoff et al., 1991), which should give some indication of its precision in the domain of historical German literary texts.

Introduction

The work described in this paper came about as a result of reflections made within the “Clavius on the web” Project[1], which studied the correspondence between the Jesuit mathematician and also astronomer and some important scientists of his century, such as Galileo and Brahe[2]. One of the main aims of the project is to make it possible for students and scholars to access the texts on a semantic basis, in order to allow a deeper understanding of the often complex content, they convey.

Texts are often the unique source that scholars have at their disposal in order to be able to reconstruct and more completely understand the past author’s thought.

In order for technology to come to the aid of scholars in this effort, the concepts evoked within the text, as well as the terms representing these concepts need to 1) have a structured organization 2) be explicitly and univocally represented and 3) be defined through the relationships that unite them. In order to achieve this, we chose to adopt an ontologybased model, as ontologies are a de facto standard for knowledge representation.

Interestingly, the choice to use ontologies raised some issues, also with regard to theoretical aspects: indeed, standard ontological formalisms usually static and crisp proved to be inadequate in modelling the complexity of the knowledge conveyed by the analysed texts. As a result, more refined models as well as appropriate graphical representations needed to be introduced so that computers would be able to process these ontologies and visualize them in a way that students and scholars could understand and work with them.

The ontological model

Here we list and briefly describe the main aspects of the knowledge conveyed by the Clavius’ corpus that our ontological model should capture.

- **Explicit** versus **implicit knowledge** : our ontology is designed to structure both the entities explicitly evoked in the text (typically denoted by terms) and the entities implicitly entailed as belonging to the background knowledge that the writer implies (which can be possessed by the reader themselves only in part).
- **Shared** versus **individual knowledge** : different authors can share, and in fact do share, some aspects of conceptualising the domain, as clearly they have certain theories and beliefs in common. However, our ontology must formally structure the author’s own conceptualisation of the world, as it emerges from specific textual passages of the analysed corpus.
- **Certain** versus **uncertain knowledge** : in the case where the authors express confidence in some theories or reject and advance doubts towards others. It is therefore essential for each entity which populates the ontology (a class, an instance, a property) to be associated with a degree of certainty.
- **Static** versus **dynamic knowledge** : correspondence implies sharing information and knowledge, which can lead to changes in the way the correspondents view the world, sometimes significant. This is particularly the case

with scholars. As a result, the ontology needs to be dynamic and temporal, so that it is possible to illustrate the evolution of the author's conceptualization over a period of time. The specific time is either explicitly indicated by the author in his/her work or reconstructed from other sources.

Other parameters could be considered, such as vagueness, ambiguity and sincerity. The validity of these aspects is not limited to these kinds of texts (i.e. scientific letters), but it applies to any text such as essays, scientific journals, diaries, which expresses an author's firmly-held or evolving opinion. Consequently, as a case study (see Section 4), we chose Galileo's Sidereus Nuncius(Galilei, 2001), to prove the applicability of the model outside the epistolary corpus. In the present paper, we will mainly focus on dynamic knowledge and its representation.

Models for representing dynamic knowledge

In literature, the problem of representing dynamically evolving information in ontologies has been addressed by adopting several different approaches (Flouris et al., 2008). A very simple solution is to create a version of the ontology for each temporal event that has to be represented (ontology versioning). However, a versioning algorithm is necessary in order to access the different temporal variants of the ontology. Other proposals aim to extend OWL ontologies in order to provide binary relation instances with a time reference. Related approaches are: (Welty et al., 2006) encoding a perdurantist/4D view in OWL, (Krieger, 2008) interpreting original entities as time slices, and (Manola et al., 2004) reifying original relations. For an exhaustive list of works, see (Krieger and Declerck, 2015). However, all of these approaches typically invalidate standard OWL reasoning, and they do not allow the representation of the change in subsumption and instantiation. In (Rizzolo et al., 2009) time semantics is added also to resources by providing temporalvarying classes and individuals, but only for RDF(S) ontologies, by extending the model presented in (Gutierrez et al., 2005). However, domain expertoriented tools for manipulating RDF(S) do not currently exist.

Against this background, we chose to conduct our first experiments with a reification-based approach and SKOS[3], the latter providing the best compromise between temporal aspects representation, availability of tools, querying and reasoning capabilities.

A case study

We propose here a possible representation of the evolution of Galileo's conceptualization of Jupiter's moons over a specific week in 1610, reconstructed on the basis of the Sidereus Nuncius.

The first observation of the planets dates back to 7th January 1610, when Galileo first saw what he thought were three fixed stars near Jupiter. After several observations on 11 th January, he noticed that their position relative to Jupiter changed in the same way as wandering stars. Two days later, he observed that there existed four satellites orbiting around Jupiter and not three.

Here we present the preliminary version of the ontology which structures the content of portions of the Sidereus Nuncius where Galileo describes his observation of Jupiter's moons.

We first identified the key terms of the text as the terminology (in bold in Fig. 2) upon which we defined the explicit entities of the ontology. In addition we specified the necessary implicit entities to add to it (eg. *Galilean moon*). The ontology was built using Protégé 5.0.0 (Musen et al., 2000) and the plugins Skos Editor[4] and Chronos (Preventis et al., 2014), the former to implement an SKOS ontology and the latter to add the diachronic component. The process is described in the following steps:

1. Structuring of the concepts via the skos: broader relation; the concept *Galilean_Moon* has been set as a subconcept of both *Fixed_Star* and *Wandering_Star* (Fig. 1.a);

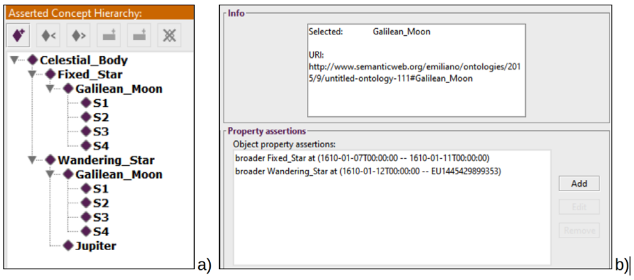
2. Definition of the properties *isNearTo* and *revolvesAround;*

3. Instantiation of these two properties between the four moons (*S1*, *S2*, *S3*, and *S4*) and *Jupiter;*

4. Conversion of the properties broader, *isNearTo* and *revolvesAround* into temporal;

5. Attribution of the correct time interval to each property instantiation.

As a result of this representation, the concept *Galilean_Moon* became narrower than *Fixed_Star* during the time interval between 7th and 11th January 1610, then it changed to narrower than *Wandering_Star* (Fig. 1.b). Analogously, each of the three moons progressed from being simply "nearTo" *Jupiter* to "revolvesAround" *Jupiter*. Finally, starting from 13th January, the relation broader also links *S4* and *Galilean_Moon* (i.e. Galileo spots a fourth object).



Asserted Concept Hierarchy:

- Celestial_Body
  - Fixed_Star
    - Galilean_Moon
      - S1
      - S2
      - S3
      - S4
  - Wandering_Star
    - Galilean_Moon
      - S1
      - S2
      - S3
      - S4
    - Jupiter

Info

Selected: Galilean_Moon

URI:
http://www.semanticweb.org/emiliano/ontologies/2015/9/untitled-ontology-111#Galilean_Moon

Property assertions

Object property assertions:

broader Fixed_Star at (1610-01-07T00:00:00 -- 1610-01-11T00:00:00)
broader Wandering_Star at (1610-01-12T00:00:00 -- EU1445429899353)

Fig. 1: a) The concept hierarchy shown in the "SKOS view" tab of Protégé; b) the temporalized relation "broader" applied to Galilean_Moon.

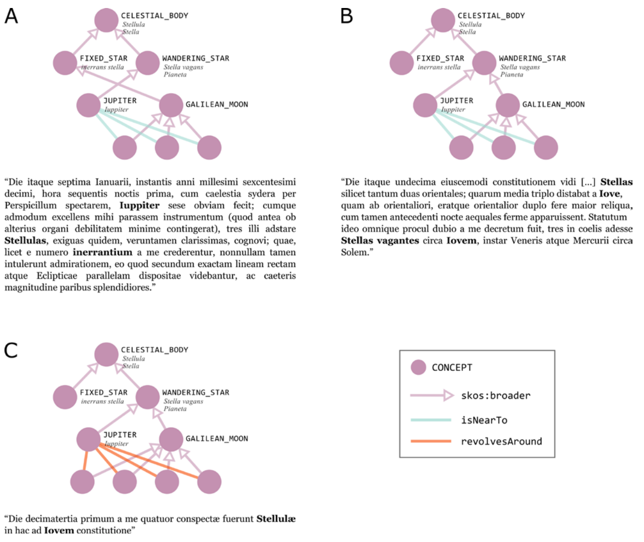
Browsing the constructed dynamic ontology allows to answer to complex queries such as: "how did Galileo's vision of Jupiter's moons evolve in time?" or "which had been Galileo's main changes of perspective about Jupiter in January of 1610?".

Visualization of the ontology

A visualization can be described as an artefact that helps humans to make decisions, learn and communicate, acting as a visual cognitive support (Card et al., 1999). A visual representation of ontologies can therefore be developed to ease their comprehension by both scholars and non-expert users. In our case, a suitable graphical display allows to make visual comparisons between the different time frames of a dynamic ontology, capturing the evolution of the author's ideas. Among the available visualization techniques, we adopted the node-link diagram, which is particularly well suited for exploring the topology of a network and for locating paths (Munzner, 2014).

We wanted to automatically produce visualizations with a quality resembling that of hand-made diagrams (Dwyer et al., 2006; Kieffer et al., 2013). To do so, we observed the work of experts sketching some ontologies on paper, and derived a series of geometric constraints for an automatic placement algorithm. Since the skos:broader relationship defines a *quasi-hierarchy*, i.e., a tree with a reasonably small amount of nodes having multiple parents, the constraints we implemented were intended to produce a familiar, tree-like representation.

The input for the layout algorithm is the entire SKOS graph, and the output is a single layout for all the time frames. Comparison is then made possible by displaying a series of juxtaposed views, each showing only the items of a specific time frame (Fig. 2). This technique ensures that the same item is given the same position in each view, while differences create easy-to-spot “holes”', thus leveraging the user's spatial memory to carry out the comparison task (Munzner, 2014).



“Die itaque septima Ianuarii, instantis anni millesimi sexcentesimi decimi, hora sequentis noctis prima, cum caelestia sydera per Perspicillum spectarem, **Iuppiter** sese obviam fecit; cumque admodum excellens mihi parassem instrumentum (quod antea ob alterius organi debilitatem minime contingerat), tres illi adstare **Stellulas**, exiguas quidem, veruntamen clarissimas, cognovi; quae, licet e numero **inerrantium** a me crederentur, nonnullam tamen intulerunt admirationem, eo quod secundum exactam lineam rectam atque Eclipticae parallelam dispositae videbantur, ac caeteris magnitudine paribus splendidiores.”

“Die itaque undecima eiuscemodi constitutionem vidi [...] **Stellas** silicet tantum duas orientales; quarum media triplo distabat a **Iove**, quam ab orientaliori, eratque orientalior duplo fere maior reliqua, cum tamen antecedenti nocte aequales ferme apparuissent. Statutum ideo omnique procul dubio a me decretum fuit, tres in coelis adesse **Stellas vagantes** circa **Iovem**, instar Veneris atque Mercurii circa Solem.”

“Die decimatertia primum a me quatuor conspectæ fuerunt **Stellulæ** in hac ad **Iovem** constitutione”

Fig. 2: A prototype visualization of the case study presented in section 4. Scholars or students can see the evolution of Galileo's concepts after each observation of Jupiter's moons. The automatically computed diagram layout ensures comparability while preserving a familiar, tree-like appearance.

Picture to Score: Driving Vector Animations with Music in the XML Ecosystem

Stephen Ramsay
sramsay.unl@gmail.com
University of Nebraska-Lincoln, United States of America

Brian Pytlik-Zillig
bzillig1@unl.edu
University of Nebraska-Lincoln, United States of America

Audio can be united with video using a number of different techniques. Among the most common are "score to picture" and procedural generation.

"Score to picture" is a feature of most modern DAWs (Digital Audio Workstations), such as *Pro Tools, Logic, Cubase,* and *REAPER*. A composer plays forward the video—usually in the very advanced stages of post production—and sets cues within the software around which a musical soundtrack can be structured. Thus a composer might set a cue to indicate suspense leading up to a particular moment, or the beginning and end of a romantic scene that should be accompanied with incidental music.

Procedural generation goes the other way. Here, a composer creates music—often in a sophisticated audio synthesis environment like *Max/MSP, Pd, Impromptu,* or *SuperCollider*—and uses properties of the audio signal or of the overall program flow to cue events in a video presentation. Since these are full-fledged (if visual) programming languages, driving video with them often means combining the complexity of software engineering with the complexity of handling audio and video signals.

In this short presentation, we describe our experiments with a method of uniting audio and video that lies somewhere between these two approaches. Unlike the practice associated with contemporary filmmaking, our method begins with a musical score and uses events indicated within it as the set of cues for an animation. Rather than use procedural programming or digital signal processing to inform the creation of cues, we use the ordinary conventions of Western musical notation.

To accomplish this, we first represent the score in MusicXML. This might seem an odd choice, given that the MIDI (Musical Instrument Digital Interface) standard was designed precisely to indicate performance events over time. MusicXML, by contrast, was primarily conceived as a way of providing interoperability among software for rendering musical scores as printable objects. Yet MusicXML contains, as one explanation of the standard puts it, a "MIDI-compatible part" concerned with how the music should sound (as opposed to how it should look) (MakeMusic, 2016).

Our system exploits these MIDI-compatible elements—along with several other features of the markup—in order to indicate where a change might occur in an animation. In this way, we are able to use such things as rehearsal marks (sectional markings intended to make it easier for conductors to refer to particular passages), tempo markings, indications of changes in volume (amplitude), emphases, articulations, orchestration, and other aspects of musical notation as cues. And since everything about the duration of a piece and the relationship of the cues within the piece are discernable from the MusicXML file alone, we are able to produce SVG animations that are perfectly in sync with the music from which they are "generated". In the simplest case, this might involve simple changes in color or the movement of shapes, but the system is fully capable of quite advanced 2D animation.

From an artistic standpoint, our way of doing things hearkens back to the earliest days of animation when popular short films were synced to the music of Wagner, Rossini, and Dukas. In this sense, ours is perhaps a new way of doing an old-fashioned thing. But unlike earlier eras, artists today have access to very sophisticated tools for producing digital art. Digital artists regularly use vector graphics programs (like Adobe *Illustrator* and the free *Inkscape)* that can generate SVG, and scoring programs (like *Finale, Sibelius,* and the free *MuseScore)* that can generate MusicXML. What is missing, we think, is a robust way to bridge these two technologies.

Our system provides a very sophisticated bridge in the form of *Indigo*—an SVG animation system developed at CDRH that we have recently re-engineered along the lines we illustrate above. In this presentation, we briefly explain how Indigo works and demonstrate how it can facilitate interoperability between SVG and MusicXML (perhaps with the world premier of an original animated score in honor of this year's conference theme).

Our presentation requires only the most rudimentary knowledge of musical notation and SVG.

Git-Lit: an Application of Distributed Version Control Technology toward the Creation of 50,000 Digital Scholarly Editions

Jonathan Reeve
jonathan.reeve@columbia.edu
Columbia University, United States of America

Distributed version control technologies, the most popular protocols of which are git, subversion, and mercurial, have long been popular among computer programmers for their abilities to track changes in a codebase and foster collaboration among coders. When combined with code management platforms such as GitHub, Bitbucket, or GitLab, they become even more powerful, enabling sophisticated bug tracking, project planning, and open-source code publication. Although these technologies have not yet been in widespread use in the humanities, their potential for use with corpus creation and textual editing is far-reaching. This paper describes Git-Lit, an open-source, community-centered initiative to parse, version control, and publish to GitHub roughly 50,000 scanned public-domain books from the British Library, thereby facilitating decentralized, open-access, and democratic scholarly editing.

The Git-Lit initiative addresses these problems:

- **Electronic texts are difficult to edit.** Traditional text repositories like Project Gutenberg and the Oxford Text Archive maintain central, canonical versions of their texts that, in most cases, are virtually immutable. If a reader spots an OCR error in an ebook, he or she must rely on contacting the publisher to propose a correction. Even with an infrastructure such as Project Gutenberg's Distributed Proofreaders, the process of releasing a corrected edition may take months or years. Git-Lit aims to radically streamline the improvement of an electronic text in two ways. First, ease of editing is achieved through GitHub's push-button forking (making a copy of a repository in one's user account) and in-browser editing---a reader may spot a mistake, correct it, and submit a pull request for the change in mere seconds, all without leaving the browser. Second, the decentralized model ensures that no single text may be considered unquestionably canonical, although *de facto* canonicity might be democratically achieved through repository voting mechanisms such as GitHub's stars.
- **Electronic texts often lack editorial history.** Owing, in some cases, to the age of an electronic text, its editorial provenance is often lost. Many Project Gutenberg editions, for instance, are transcribed from unknown print editions, and the history of their revisions is similarly opaque. Version control mitigates these problems by recording every edit, editor, and edition in the history of the text. When two editions diverge, git provides sophisticated tools for analyzing the differences between these editions. Sites like GitHub further provide graphical network charts, showing the genealogy of each version. Since contributions to a given text are logged according to individual contributor, credit for a given edition may be assigned according to the individual's percentage of total contributions, minimizing the danger, for instance, that a professor may take credit for his or her graduate student's work.
- **Textual corpora are difficult to assemble.** With some exceptions, notably the download function of the NLTK corpus module, downloading a text corpus involves compiling texts from diverse and heterogeneous sources. A would-be text analyst must click through a sequence of web pages to find the corpus he or she wants, and then either download a number of .zip files, or email the corpus creator to request a copy. With multiple texts, this can be a labor-intensive process that is not easily scriptable or automated. Git provides an easy way to solve these problems: by making texts available through the git protocol on GitHub, anyone that wishes to download a text corpus can simply run the command git clone followed by the repository URL. Parent repositories can then be assembled for collections of texts using git submodules. A parent corpus repository might be created for nineteenth-century *Bildungsromane*, for instance, and that repository would contain pointers to individual text repositories. These categories would not necessarily be mutually exclusive, and would allow for arbitrary curation of custom corpora. This provides a major advantage over the traditional directory structure model, where the existence of overlapping datasets necessitates the storage and maintenance of redundant data.
- **ALTO XML is not comfortably human-readable.** ALTO XML, the OCR output format used by the British Library texts, as well as texts created by the Library of Congress, is extremely verbose. It encodes the location of each word on the page, and often gives the OCR certainty for each word. While this format is useful for archival purposes, plain text editions are more useful for reading and for most brands of computational text analysis. Git-Lit parses the British Library's ALTO XML, and creates markdown versions of each text that are easily edited. Since markdown is readily converted to other document formats using tools such as Pandoc, this allows each text to be easily exported to PDF, EPUB, LaTeX, Docbook, and others. Additionally, Git-Lit is currently working on a system that leverages GitHub's built-in Jekyll HTML compilers to convert each text into a web page hosted on github.io, effectively creating 50,000 readable web editions. These new editions will exist as git branches in parallel with the markdown and ALTO XML editions. Since git maintains efficient copies of every historical version of the text, no information about the text is lost in these conversions. Anyone that wishes to improve the conversion script and create newer, better editions of the

original files may freely do so by branching the text from an earlier git commit.

Git-Lit software works by first parsing the XML metadata included with each text. This metadata is used to programmatically generate a repository name and a README.md file that describes the text, a document which GitHub will automatically render into a web page at the repository root. This file, along with standard CONTRIBUTING and LICENSE files, is then committed to local git repositories, initiating version control of the texts. The resulting local repository is then uploaded to GitHub via Python bindings to the GitHub API. Parent repositories are then created using git submodules for each collection of texts based on the their associated Library of Congress subjects. This enables a text analyst interested in 19th century poetry, for instance, to download all of the British Library's released works in this genre simply by running git clone https://github.com/git-lit/19th-century-poetry.git && git submodule update --init --recursive.

Since British Library texts are not the only ones being published to git-based platforms like GitHub---notable version-controlled corpora on GitHub include texts from the Text Creation Partnership and the early modern corpus Shakespeare His Contemporaries---git provides a common protocol for sharing, modifying, and distributing texts and textual corpora. Anyone may aggregate these corpora into parent repositories using git submodules. The Git-Lit project will soon launch a web application that will routinely scrape GitHub and other open repository sites for any textual corpus, thereby automating the process of discovering and indexing available corpora. This mechanism will also serve to democratize the curation of corpora, since the corpus index will be sorted by the number of GitHub "stars", or votes, a repository has engendered from the community.

The 50,000 British Library texts processed by Git-Lit, as well as many of the other open corpora described here, are currently being integrated into DHBox, the cloud-based Digital Humanities software suite. Soon, these corpora and many others will be available for download by selecting them from a web-based interface, where they will then be available for analysis using pre-installed versions of the Python NLTK, R, and other textual analytic tools.

This paper discusses how Git-Lit's methods might be used by other digital humanities projects involved in the creation or analysis of large text corpora, and how digital humanists may contribute to the Git-Lit project. (As an open-source project, Git-Lit welcomes contributions in the form of bug reports, feature requests, or code.) The paper also discusses some of the storage and computation limitations of electronically publishing texts via code repositories, and some of the technical problems encountered by the Git-Lit project. Finally, it suggests pedagogical uses of git-based collaborative digital editing, such as classroom compilation of anthologies or digital scholarly editions. The applications of these technologies are wide-ranging, and are neither proprietary to this project nor to services such as GitHub, but remain concepts of openness and collaboration with powerful implications for the digital humanities.

Researchers' perceptions of DH trends and topics in the English and Spanish-speaking community. DayofDH data as a case study.

Defining the "state of the art" in Digital Humanities (DH) is a really challenging task, given the range of contents that this tag covers. One of the most successful efforts in this sense has been the international blogging event known as "DayofDH" or "A Day in the Life of the Digital Humanities" project, promoted and sponsored by centerNet (http://www.dhcenternet.org/), which has put together digital humanists from around the world to document once a year what they do (Rockwell et al., 2012). The websites of DayofDH were hosted in North America until 2015, when it was coordinated in Europe by LINHD (http://linhd.uned.es), the Digital Innovation Lab, at UNED in Madrid. Participants belong to several countries around the world.

The relevance of DH in non-English speaking countries has been quick and important in the last decade, and especially important in the Spanish-speaking world (Spence and González-Blanco, 2014; González-Blanco, 2013; Del Rio Riande, 2014a; Del Rio Riande, 2014b; Galina et al., 2015). Technological projects for humanities have existed in the Spanish world for many years; however, the discipline called "Digital Humanities" arose in 2011 with the first meeting that originated the Spanish Digital Humanities Association, HDH. This relevance is reflected in the creation of a parallel version of the DayofDH in Spanish, the "DíaHD", which was hosted by the UNAM in Mexico in 2013 and 2014 and converged in the last initiative at UNED transforming both blogging events into a bilingual version of the Day.

Although there have been general studies about the information on participation in those events (Priani et al., 2014), there has not been an automated data analysis using NLP (Natural Language Processing) or Big Data tools to extract and classify the relevant information gathered in blogs (Webb et al., 2004). More technical details about these aspects can be found in (Tobarra et al., 2014b).

According to this, the main goal of this paper is to develop a dashboard that allows us to get more insight about interest topics and leaderships of this community during the period of time in which this event has been developed. With the "dashboard" word, we mean the analysis and presentation of results, not a tool. In this sense, the topic characterization process deals with the detection of the most relevant topics which are employed in the publication tools of these kinds of virtual communities (Tobarra et al., 2014a).

In order to achieve our aforementioned objectives, this work is focused on the datasets corresponding to four years of DayofDH (2012, 2013, 2014 and 2015 editions), and the Spanish version of the event in DíaHD 2013. This work strives at showing the evolution and trends in the last four years in order to give account of the presence of the Hispanic communities in the field. The information of the Spanish 2014 edition has been discarded, as it is not any more available online due to technical problems at the organizing institution. All editions of DayofDH employ WordPress, which has an associated SQL database, including several general tables and a specific set of tables per blog, defined in the project and common to all editions. The CMS is combined with the Buddypress social plugin, which lets users register, create communities and forums and interact among them. For the last edition of the Day, LINHD included also the bilingual plugin WPML to make it available the possibility of including translation in Spanish and English. This feature was, however, just used for the general website and its blog entries.

The data employed in this proposal has been obtained by using web scraping techniques (Fredheim, 2014) in the DayofDH websites for the previously mentioned editions. In particular, humanists' blog data, and their associated posts in the website have been gathered in this phase. All information scrapped from blogs is public and accessible from the Internet and, also, they have been anonymized for ethical issues. For validation purposes, the conceptual information about the database schemas have been compared with the extracted dataset, concluding the extraction process has been satisfactory.

Since the data obtained are huge enough to be efficiently processed, the use of big data techniques have been considered for this work (http://social-metrics.org/analyzing-big-data-with-python-pandas/). In order to achieve the main goals of the project, all the information related to the textual content in DayofDH have been processed, so that the most significant tokens are selected. Then, these tokens have been characterized by two parameters; first, it has been used the direct frequency which characterize if a token is used regularly in all DayofDH blogs. Secondly, the inverse frequency of the token that give information of how significant the token is in the context of digital humanities in a semantic way.

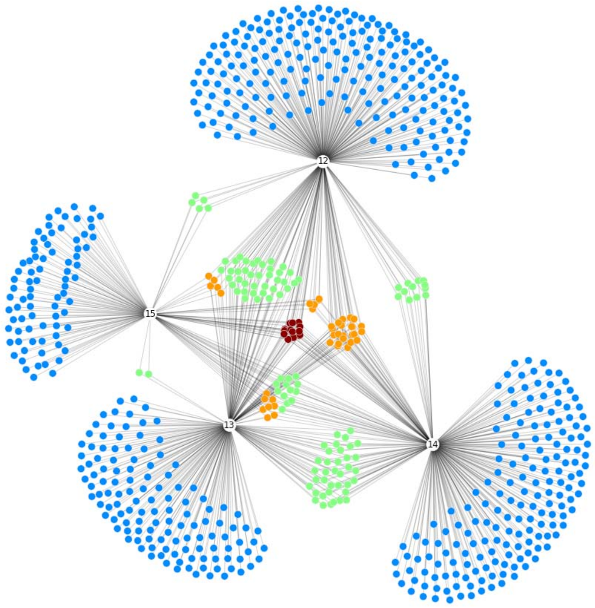

Fig. 1. Social network generated for 2012-2015 editions of DayofDH

These parameters have been used to observe the interest and evolution of the characterized tokens along the time, either in a global and individual way. The interest of the global analysis is to find how the knowledge has evolved during the years of the study. From the point of view of a personal analysis, the interest is to build individual profiles that show the main interest of the researchers in the humanist community. Finally, the leadership relations have also been explored by using disease propagation techniques in the generated social network, taken into account the different editions of the DayofDH. For instance, Fig. 1 shows the social network according to the amount of authors' participations.

The resulting graphics and visualizations (Tobarra et al., 2014b) let users make a quick idea of how the DH focus has been moving and distributing across the time through the different Academies in the different countries, but also how topics and interests change from one country to another and it is strongly related to their perspectives and disciplines, which are not independent from their origin (as an example, see Figs. 2 and 3). This approach will enlighten future studies on DH perspectives with real and precise data on the current state-of-the-art on DH perception and its evolution. Data of the years 2009, 2010 and 2011 are not used at the moment, as the same information is not available through web scraping. They will be incorporated to this study as a future work.

Mnemosyne: A Smartlibrary for Rare and Forgotten Texts

Dolores Romero-López
dromero@filol.ucm.es
Universidad Complutense de Madrid, Spain

José Luis Bueren-Gómez-Acebo
jlbueren@hotmail.com
Universidad Complutense de Madrid, Spain

In recent decades European libraries have taken a giant step towards the mass digitization of their historical collections and the opening of their contents for the use of the global digital society. However, researchers and teachers experience great difficulties using, enriching or sharing that content. Our project aims to explore the new needs of the users of European digital libraries, databases and repositories in order to evolve the "traditional digital model" towards the *SmartLibrary* model, which proposes the compilation, integration and downloading of contents according to the needs of users and in order to enrich the European uses of the history.

Mnemosyne, for the ancient Greeks, was the personification of Memory. In our project the concept of memory comprises two uses:

1. **The recovery of historical memory** through European texts we consider rare and forgotten. We will analyse these concepts as conceptual categories in cultural studies (Alonso, 2008; Romero Lopez, 2014). This new paradigm will cover the analysis of a large and complex network of literary manifestations. We aim to record the history of the losers, looking for it in popular and mass culture texts that have been marginalized until now (Labanyi, 2003). This recovery requires making those digitized texts accessible and bringing together their interpretations so that the axes that have governed their oblivion within European cultures can be underlined.

2. **The rewriting of historical memory**. Once we have compared texts digitized in the *Scriptorium*, researchers and teachers will begin an enrichment of these texts through their collaborative annotation. This reinterpretation will allow historical memory to be restored by setting new categories of knowledge for the understanding of European cultures under common tendencies.

The prefix **SMART**- has been used as synonymous to agility, safety, ecology and sharing (Doran, 1981). It is a prefix that has been applied to phones, cars, houses and cities. So far, it has not been applied to libraries. The creation of a European *SmartLibrary* implies:

- **S**imple access to integrated European databases on contemporary and alternative European literatures
- **M**otivational search based on specific research content or didactic objects
- **A**ppropriate results based on the semantic Web search
- **R**esults discharged in a personal *Scriptorium* to be enriched with the specific tools
- **T**ransference of new digital objects to be shared with the global community

As a "smart digital model", exportable to other areas of the digital humanities, we have been developing *Mnemosyne: A SmartLibrary for Rare and Forgotten Texts*, based on the research that the LEETHI, LOEP and ILSA (see below) research groups in the Faculties of Philology and Information Technology of the Complutense University of Madrid (Spain) are jointly developing. Thanks to the collaboration of specialists in different European literatures and computer experts in the course of several national research projects, we have designed a new model of *Scriptorium* which allows for the integration of metadata and the enrichment of digital objects with new tools such as *Clavy* –an import/export tool for metadata- and *@Note* – a collaborative annotation tool.

About *Mnemosyne. Digital Library of the Other Silver Age* (Beta version):

1. *Mnemosyne. Digital Library of the Other Age of Silver* **is already accessible** on the Internet (http://repositorios.fdi.ucm.es/mnemosine/). As you can see *Mnemosyne* contains authors' data, access to digitized works and research collections. The field of study is rare and forgotten Spanish literary texts (1868-1939). The work is still in progress. Our current project ends by 06/31/2016.

2. *Mnemosyne records* show the metadata imported *by our tool Clavyfrom Biblioteca Digital Hispánica and from HathiTrust with the support of theComplutense Library*.

3. The *Mnemosyne* database works as **a laboratory** in which we experiment with *Clavy* the importation/exportation of metadata, and the tool *@Note* and practise collaborative annotation. *@Note* promotes the collaborative creation of free-text and semantic annotation schemas on literary works by communities of researchers, teachers and students and the use of these schemas in a very flexible and adaptive model for the definition of annotation activities.

4. As *SmartLibrary, Mnemosyne* **will integrate** @Note **and other digital** tools (forthcoming). Of course we are very much interested in DARIAH tools and its research infrastructure and we would like to collaborate with this European consortium. Besides, our *SmartLibrary* could be an extraordinary field of study in which to experience the development and integration of new digital tools. *Mnemosyne*, as a *SmartLibrary*, could become a field of international experimentation for the practice of tools with semantic interoperable networks.

5. The Spanish *Mnemosyne* is the first example of what we would like to build. We would like to regrow our *smart* model in the international environment with the support of other European projects, interested, like the authors, in rare and forgotten texts and the uses of the past.

Mnemosyne: SmartLibrary for Rare and Forgotten Texts **needs transnational collaboration**. This project involves the integration of specialists in different European literatures and researchers in computer science to develop new research and resources for the common use of European citizens.

The research developed in *Mnemosyne* is being financed by: 1) Ministerio de Economía y Competitividad. Research Project: "Escritorios Electrónicos para las Literaturas-2". Some Problems in the Non-Traditional Authorship Attribution Studies of the Dramatic Canon of William Shakespeare: Are they Insurmountable

Joseph Rudman
jr20@heps.phys.cmu.edu
Department of English, Carnegie Mellon University, United States of America

William Shakespeare is arguably the greatest dramatist of all time. Yet, the man and his works are shrouded in mystery and uncertainty. This paper posits that a man named Shakespeare wrote the First Folio. It is this First Folio that provides the "most certain" body of Shakespeare's plays.

The makeup of the Shakespeare dramatic canon has prompted more attribution studies (traditional and non-traditional) and caused more controversies than any other canon – by far. This paper looks at the several hundred non-traditional studies (and concomitant "flame wars") and points out some of the more serious problems. There is no doubt that it is a canon in disarray. Most of the scholars involved in the controversies are the "heavyweights" of Shakespearean studies – e.g.:

- Rasmussen (1977) vs. Hope (1994)
- Vickers (2011) vs. Craig and Kinney (2009)
- Taylor (2015) vs. Stern (2004)
- Craig vs. Vickers and Jackson (Hirsch and Craig, 2014)

But the most famous controversies involve (1) Donald Foster vs. Ward Elliott and (2) Robert Valenza and Donald Foster vs. the world.

In a recent article (Rudman, 2016) I pointed out many caveats to scholars working on authorship attribution on the canon of William Shakespeare. Among these are:

- Reproducibility
- Input Texts
- Genre
- Editing
- Controls
- Isolation of Variables
- Choice of Style Markers
- Statistical Tests
- Sample Selection and Size
- Treatment of Errors
- Collaboration

In this paper, I expand on one of these caveats (Genre), look at and cite examples from many of the non-traditional studies of the Shakespeare canon in order to highlight these problems, and suggest solutions.

- Each genre is governed by different linguistic rules and rhetorical purpose – a practitioner should not mix genre.

- Drama – Comedy, History, Tragedy, Romance – how far down should these be catagorized
- Verse within the drama – rhymed verse within the verse – how far down should this be broken
- Music
- Dialogue vs Dramatic Monologue

Also in this paper, I address the conundrum of using what I deem as seriously flawed studies to show problems with other studies – e.g. if a practitioner mixes genres (history and tragedy) but shows that Shakespeare's style changes over time, I cite this change as evidence that chronological constraints must be employed.

No matter how flawed I consider a study, there are parts of that study that are correct – there is no non-traditional study (of the hundreds conducted) that is completely without merit. By invoking the *etiam si non est verum* paradigm, I show how almost all of the necessary steps in a valid study exist in the literature. We can look at all of the links in he chain (even the broken ones) and try to piece together what we should do to move the field forward. The evidence in this paper reinforces my conclusion from the *JEMS* article that any attribution results are problematic at best.

The Conclusion reached (and I believe supported by very strong evidence) is that all of the non-traditional studies are seriously flawed and that as of today we do not have a valid Shakespeare text to conduct non-traditional attribution studies.

The following bibliography is only representative. There are more than 200 non-traditional studies on the Shakespeare canon. My working bibliography for this study is well over 1,000 entries.

Introduction

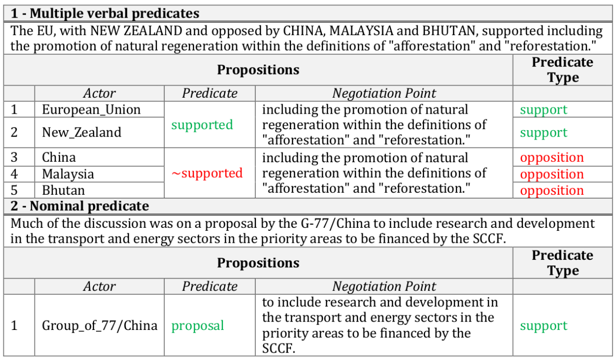
Text analysis methods based on word co-occurrence have yielded useful results in humanities and social sciences research. For instance, Venturini et al., (2012) describe the use of concept co-occurrence networks in social sciences. Grimmer and Stewart (2013) survey clustering and topic modeling applied to political science corpora. Whereas these methods provide a useful overview of a corpus, they cannot determine the predicates[1] relating co-occurring elements with each other. For instance, if *France* and the phrase *binding commitments* co-occur within a sentence, how are both elements related? Is France in favour of, or against *binding commitments*?

Different natural language processing (NLP) technologies can identify related elements in text, and the predicates relating them. A recent approach is *open relation extraction* (Mausam et al., 2012, among others), where relations are derived from the corpus in a data-driven manner, without having to pre-specify a vocabulary of predicates or actors. We are developing a workflow to analyze the Earth Negotiations Bulletin (vol. 12)[2], which summarizes international climate negotiations. A sentence in this corpus can contain several verbal or nominal predicates indicating support and opposition (see Table 1). Results were uneven when applying open relation extraction tools to this corpus. To address these challenges, we developed a workflow with a domain model, and analysis rules that exploit annotations for semantic roles and pronominal anaphora, provided by an NLP pipeline.

Our system identifies points supported and opposed by negotiating actors and extracts keyphrases and DBpedia[3] concepts from those points. The results are displayed on an interface, allowing for a comparison of different actors' positions. The system helps address a current need in digital humanities: tools for the quantitative analysis of textual structures beyond word co-occurrence.

The abstract is structured as follows. First, related work and the corpus are presented. Then, our system is described. Finally, evaluation is discussed.

Material supplementing the paper and access information to the system will be available on the project's website.[4]



1 - Multiple verbal predicates				
The EU, with NEW ZEALAND and opposed by CHINA, MALAYSIA and BHUTAN, supported including the promotion of natural regeneration within the definitions of "afforestation" and "reforestation."				
Propositions				**Predicate Type**
	Actor	*Predicate*	*Negotiation Point*	
1	European_Union	supported	including the promotion of natural regeneration within the definitions of "afforestation" and "reforestation."	support
2	New_Zealand			support
3	China	~supported	including the promotion of natural regeneration within the definitions of "afforestation" and "reforestation."	opposition
4	Malaysia			opposition
5	Bhutan			opposition
2 - Nominal predicate				
Much of the discussion was on a proposal by the G-77/China to include research and development in the transport and energy sectors in the priority areas to be financed by the SCCF.				
Propositions				**Predicate Type**
	Actor	*Predicate*	*Negotiation Point*	
1	Group_of_77/China	proposal	to include research and development in the transport and energy sectors in the priority areas to be financed by the SCCF.	support

Table 1: **Typical corpus sentences**. Sentence 1 has predicates *supported* and *opposed*, with several actors each. Example 2 shows a nominal predicate (*proposal*). For Sentence 1, five ‹*actor, predicate, negotiation point*› propositions are extracted by the system, and the opposing actors (*China, Malaysia, Bhutan*) are assigned a proposition which is a negated version (with *~supported* as the predicate) of the proposition for the main verb *supported*.

Related work

Venturini et al., (2014) created concept co-occurrence networks for the ENB corpus, using Cortext Manager[5], a corpus cartography tool. This analysis does not cover which predicates relate concepts and actors. Salway et al., (2014) used *grammar induction* on ENB to identify recurrent actor/predicate patterns; it could be tested whether results with that approach complement ours.

Some studies have used syntactic and semantic parsing for text-analysis of social sciences and humanities corpora. Diesner (2012, 2014) examines the contribution of NLP to the construction of text-based networks. Van Atteveldt (2015) used dependency parsing to apply co-occurrence based methods within sentence elements related to an actor or a predicate. These studies rely mostly on syntactic dependencies and verbal predicates. We are using semantic role labeling as the basis for relation extraction, and treating nominal predicates besides verbal ones. We also developed an interface to navigate the results.

Finally, a relevant resource for text-mining on climate corpora is *climatetagger* API[6], which links concepts against a domain-specific thesaurus (Bauer et al., 2011). This thesaurus could complement our concept-linking results (based on DBpedia, a general ontology).

Corpus

Each ENB issue is a 2000 word summary for one day of negotiations. The issues are written by domain experts, who strive for an objective tone and, to avoid biases, use similar expressions when reporting about all participants' interventions (Venturini et al., 2014). The COP meetings are covered in 255 ENB issues, with ca. 35,000 sentences. The original corpus format is HTML, which we preprocessed into clean text. We dated each issue based on ENB's table of contents.

System description

The system helps analyze patterns of support and opposition between negotiating parties, and the issues about which parties agree or disagree. To achieve this, the system extracts propositions of shape ‹*actor, predicate, negotiation point*›,[7] based on a domain model containing actors and predicates, and applying analysis rules on the outputs of an NLP toolkit. Keyphrases and DBpedia concepts are also extracted from the negotiation points. All extractions, and the corpus itself, are made navigable on a user interface (UI).

NLP toolkit

We used the IXA Pipes library[8] (Agerri et al., 2014), with default models for **tokenization** and **part-of-speech tagging**. We resolved some types of **pronominal anaphora** based on *CorefGraph*[9] coreference chains.

Semantic Role Labeling (SRL) (Surdeanu et al., 2008) identifies a predicate's arguments and their semantic functions or roles (e.g. *agent*). SRL was performed with ixa-pipe-srl[10], which tags against the PropBank database (Palmer et al., 2005) for verbal predicates and against NomBank (Meyers et al., 2004) for nominal ones.

Keyphrase Extraction: YaTeA[11] was used (Aubin and Hamon, 2006). This library performs unsupervised term extraction using syntactic and statistical criteria.

Entity Linking (EL): The tool from (Ruiz and Poibeau, 2015) was used. It combines outputs from several public EL services, selecting the best outputs with a weighted vote.

Domain-specific components

The **domain model** contains actors (negotiating countries and groups) and verbal or nominal predicates. Verbal predicates (from PropBank) can be neutral reporting verbs (e.g. *stated*), or verbs related to support and opposition (*recommended*, *criticized*). The nominal predicates (from NomBank) express similar notions to the verbs (e.g. *proposal*, *objection*). The model also specifies a predicate type: *report*, *support*, or *oppose*.

Analysis rules were implemented to identify propositions based on the semantic roles of predicates' arguments, previously obtained with SRL. Most domain predicates involve an agent and a message expressed by the agent (who agrees with the message, objects to it, or just reports it). Thus, actor mentions in a predicate's A0 argument[12] represent the actor who expresses the message, and the predicate's A1 argument 12 often represents the negotiation point addressed by the actor. The generic rule to identify propositions is in Figure 1.

```
Rule: Generic proposition

for each predicate p :
  · resolve negation (see below)
  for each pronoun he, she, it in p's A0 argument :
    · apply anaphora resolution (see below)
  for each actor-mention am in p's A0 argument :
    · create a proposition ‹am, p, point›, where point is a concatenation of p's A1 arguments
```

Figure 1: **General rule to create a proposition**

Sentences with *opposed by* constructions require a different analysis (e.g. *China, opposed by the EU, recommended…*) In such sentences, a different rule creates, for the opposing actors, propositions where the predicate contradicts the main clause's predicate (see Table 1 for an example). Proposition-creation rules for more specific cases have also been implemented.

Nbr 18 - COP-01 More Like This

... will be a second round with three cities and, if necessary, a third round with two cities.

Estrada then noted that budget implications and the need to establish a Secretariat without doubts about administrative arrangements made a decision imperative. Canada disagreed that this was the appropriate time to decide. He said that INC-11's intent was for COP-1 to select a candidate city only if there was consensus. He urged delegates to consider using the survey later at a neutral site. Responding to a question from Iran, the Chair said the survey would be informal and confidential as a means of reaching consensus, not a binding vote.

Switzerland said it was not the time politically to pursue these consultations. He said it would also be a bad UN precedent. The decision should be made on ... ... neutral ground, possibly at the CSD meeting in New York. The US said he was persuaded by the Canadian and Swiss concerns.

Italy, supported by Poland, said he was impressed by the Chair's suggestion, and that Article 8.3 of the Convention says COP-1 should designate a Permanent Secretariat. Germany said now is an appropriate time to take a decision. Nigeria, Costa Rica, Ethiopia, Mali, Trinidad and Tobago, Togo, Cape Verde, Niger, Mauritius and Djibouti supported the Chair's proposal. Burkina Faso said that COP-1 should take the decision, but the question should be put before the Ministerial Segment.

Canada said Article 8.3 did not require COP-1 to decide on the location. He called for a substantive discussion, including budget figures comparing costs for the four locations. The Chair ... ... said the figures had been presented in consultations on the Convention budget, and participating delegations have had an opportunity to review them. The Chair said deferring the

Figure 2: **Main view of the interface.** The left panel gives access to the search workflows (Actors, Actions, Points). It also shows propositions for a query (e.g. the actor *Canada*), and gives access to the *AgreeDisagree* view. The right panel shows the documents in the Docs tab, as well as aggregated keyphrases and DBpedia concepts for the query or for selected propositions, in the other tabs.

The treatment of **negation** relies on finding *AM-NEG* roles (see footnote 12) attached to a predicate, or negative items (*not*, *lack*) in a window of two tokens preceding a predicate.

Pronominal anaphora was treated via custom rules operating on the output of a coreference resolver (see footnote 9). We created custom rules since, in the corpus, *he* and *she* (besides *it*) can refer back to a country (pronoun gender depends on the country's delegate).

To facilitate searches by date-range, propositions are assigned their documents' date.

User interface

The UI (Figure 2) helps analyze actors' negotiation positions. It allows searching for documents matching a text query (Text search box), and for propositions matching a given actor (Actors box) or a given predicate (Actions box). Propositions matching a query are displayed on the left panel, documents for a query on the right. Aggregated keyphrases and DBpedia concepts for the content matching a query (documents or propositions) are displayed in tabs on the right panel. The AgreeDisagree view provides an overview of keyphrases and concepts from propositions where selected actors agree or disagree. Simultaneous access on the UI to the corpus and the annotations helps researchers validate results.

The implementation framework is Django[13], with Solr search.[14] We're working on allowing the user export results and edit the model's actors and predicates.

Evaluation

It is important to assess whether the system can help domain-experts gain insights they would not have otherwise obtained, e.g. detect previously unnoticed generalizations (see e.g. Berry, 2012). This type of evaluation is ongoing; we are collaborating with political scientists, whose initial feedback on the tool has been positive. User validation of the interface is also ongoing.

The system's NLP components were evaluated in literature cited above. Results are state-of-the-art or competitive, and available on our project's website (sites.google.com/site/nlp4climate).

To evaluate the model and analysis rules that create domain-relevant propositions, we have manually annotated a set of corpus sentences with propositions. Details about the test-set, evaluation metrics and results are on the website. We consider the results satisfactory.

Outlook

A useful feature would be an annotation confidence score, that users could employ to establish priorities in manual result revision. A useful application of the propositions extracted would be creating network graphs with different types of edges representing support and opposition among parties, and between parties and issues.

Acknowledgements

We thank Tommaso Venturini, Audrey Baneyx, Kari de Pryck and Diégo Antolinos-Basso from the Sciences Po médialab in Paris for domain-expert feedback on the system. Pablo Ruiz is supported by a PhD grant from Région Ile-de-France.

Modeling as Discourse: The case for 3D

Marie Giltner Saldaña
marie.saldana@gmail.com
University of North Carolina, Chapel Hill, United States of America

Introduction

In 2004, Willard McCarty characterized the Digital Humanities as “an experimental practice”, with modeling at its core: “the way to a computing that is *of* as well as *in* the humanities: a continual process of coming to know by manipulating representations” (McCarty, 2004). McCarty’s proposition embraced the open-endedness of models, yet this quality tends to be forgotten in the face of 3D’s sensory immediacy, with the result that such models tend to be perceived as static. Diane Favro, a longtime proponent of 3D modeling for architectural historical research, has acknowledged that “while observers intellectually acknowledge that the virtual re-creation is an approximation, not a *doppelgänger* for a past reality, this concept is almost immediately subsumed by the experiential power of the presentation” (Favro, 2006). This seems to hold true regardless of the model’s realism. Recent attempts to mitigate this effect emphasize the metadata and decision making processes behind 3D models, whose claim to scholarship is substantiated by virtue of their being supported by a database of textual, graphic, and quantitative sources (Saldaña, 2015). Anyone who has worked on 3D historical models, however, can attest that the act of compiling and layering of source data only reinforces the ultimate inability of such multiplicitous archives to present a coherent picture of the past on their own terms, let alone generate a truly representational or mimetic 3D model. Despite this, it is difficult to prevent even the database-driven 3D model from slipping back to the mode of uncritical simulation.

Simulation intentionally obscures the digital means of production in order to present a more convincing version of reality, in the service of a predetermined purpose. The origins of virtual reality simulation are coincident with the post-WWII military-industrial complex, with military training schemes being some of the primary instigators and funders of computer graphics simulation research (Penny, 2004). The anti-discursive nature of simulations is embedded in their interfaces, which invite the observer to experience the space in as natural a manner as possible, whether through embodied movement or the abstracted kinesis of mouse clicks. The pedagogical implications for academia are clear. VR training programs used in medicine, aviation, and the military rely on the repetitive, unthinking response of users to train them in a particular behavior (Penny, 2004). But what of the open-endedness of the humanistic modeling project? The automatic assumption that 3D space maps real space obscures the relationship of 3D modeling with critical theories of modeling practice in the humanities. Can 3D models be recouped from the totalizing logic of simulation?

This paper attempts to access this underexplored theoretical potential of 3D by proposing a reconceptualization of 3D modeling in the Foucauldian sense of *discourse,* rather than representation. Foucault’s idea of discourse was not meant to uncover an underlying definitive meaning of a given text or object, that elusive “knowledge” to which so many scholarly 3D models aspire. Rather, discourse is meant to uncover the “rules that are revealed when an object of discourse is modified and transformed”, which often involve implicit power structures (Philp, 2013). 3D digital models, which embed and incorporate many types of information, have the capacity to bring these layers of knowledge into dialogue with each other so that the underlying assumptions inscribed in them are revealed.

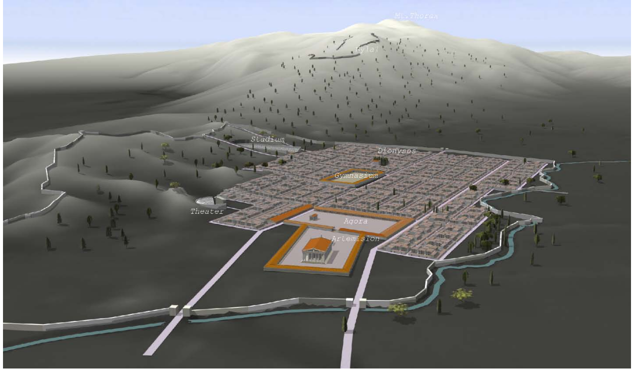

Fig.1 3D procedural model of the Hellenistic city of Magnesia on the Maeander

Case Studies

This paper will examine two of the author’s projects as ongoing attempts to mine the discursive power of 3D modeling in different ways. The first case study is an exploration of the vocabularies of ancient Roman architecture at Magnesia on the Maeander. The project directly engages with the concept of ‘rules’ that allow the formation of discourse as a “system of possibility for knowledge” (Philp, 2013). In the context of procedural modeling, the methodology used here, *rule* is a technical term denoting the scripts that generate 3D visualizations, and it also accurately describes the heuristic process of modeling. In writing the procedural rules, the modeler seeks to match a proleptic model with a mimetic one, continually negotiating the gaps between conjecture and representation. This process becomes discourse when the rules that result begin to delineate the shape of knowledge formation itself. Procedural modeling goes part of the way towards formulating a discursive approach to the process of modeling. As a finished product, however, 3D procedural models are indistinguishable from their non-discursive counterparts (Fig.1). Another possible answer involves dissolving the link between 3D space and representational space. The second case study is an application built in the Processing development environment that takes as its object of study the *Manhattan Transcripts* by Bernard Tschumi (Tschumi, 1981). Like the archaeological data behind the 3D city model of Magnesia, the *Manhattan Transcripts* comprises different representational modes to form a narrative that leaves many gaps open to interpretation. Originally displayed as an exhibition and later published as a book, Tschumi's work contains 24 sets of 3 images for the same event, expressed as plan, diagram, and rendering. The digital application attempts to bring these images into dialogue with each other through the medium of 3D space by separating them and recombining them in various ways (Fig.2). 3D space here serves the discursive function of exposing the images' areas of overlap and discordance in combinations and sequences not possible on the printed page or gallery wall. The sets of photographs, drawings, and movement diagrams can be viewed side-by-side or as semi-transparent layers thus making it easier to investigate the correspondences and differences between each representational mode. In addition, the images can be viewed all together or sorted by medium. Using the keyboard, the images can be cycled like frames in a film, highlighting Tschumi's own references to the medium of cinema.

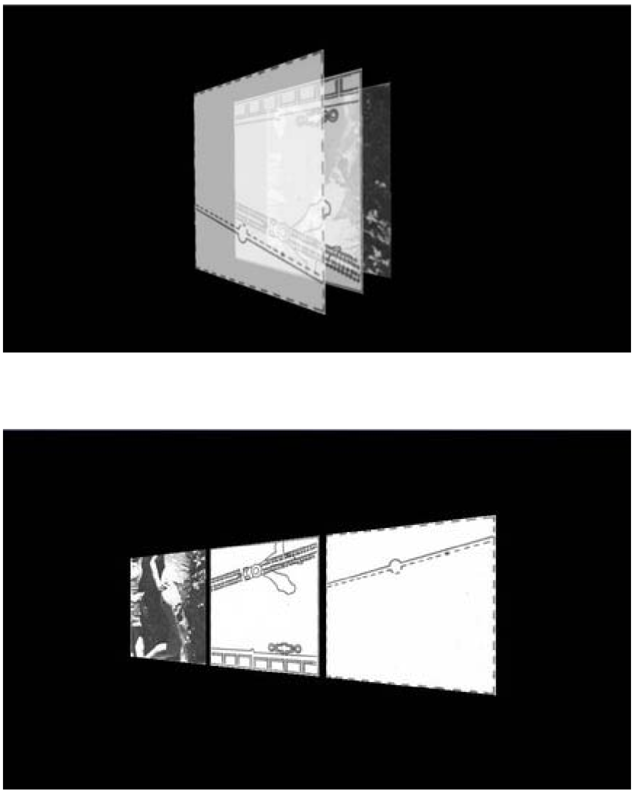

Fig. 2 Screenshots from the 'Manhattan Transcripts' 3D environment

Conclusions

The use of 3D media in the humanities has come of age in the last 15 years and its function as a critical apparatus is still in the process of development. Projects that treat 3D models as more than representational tools have the capacity to expand and illuminate this increasingly widespread form of digital culture. Particularly important is the need for theoretical discourse that resists the intentionality of 3D simulations and provides alternative modes of generative, non-determinant modeling. The case studies mentioned in this paper are but two partial answers to this challenge, part of a growing effort by a contingent of artists and researchers interested in the critical potential of 3D models.

Agents of Change: Women Editors and Socio-Cultural Transformation in Europe, 1710–1920 is a five–year humanities research project funded by a European Research Council (ERC) Starting Grant (2015–2020), directed by Marianne Van Remoortel from the Department of Literary Studies at Ghent University, Belgium. It examines a neglected aspect of the social and cultural life in Europe in the modern period: the impact of women editors on public debate. From the 1700s on, European women actively participated in the cultural arena through the journals that they edited. *Agents of Change* advances the hypothesis that periodical editorship enabled women editors to take a prominent role in public life and as a result influence public opinion and shape transnational processes of socio-cultural change. By examining how these processes unfolded in the press through practices of textual transfer both among women and in the larger publishing landscape, *Agents of Change* will not only initiate a shift in our thinking about the participation of women in society and print culture, but also pave the way for pan-European research on the periodical press.

In order to trace these networks of intellectual exchange, *Agents of Change* is using NodeGoat, a web-based integrated data management, network analysis, and visualisation platform, developed by Lab1100, a research and development company, based in The Netherlands. NodeGoat allows us to collaboratively gather our research data about women editors and their periodicals, and enables us to visualise and analyse the linkages (both biographical and bibliographical) between them. By gathering evidence to prove connections between people and publications across languages and state borders, we will be able to identify the dynamics of cultural prestige at work in Europe. For example, how knowledge and fashion radiated outward from a few trendsetting periodicals across the pages of myriad publications which translated, adapted, or reprinted them either in part or in their entirety. The data that we collect in NodeGoat will also be invaluable as a descriptive index of periodical editors, a role which traditional print culture studies has tended to overlook, especially when it comes to women periodical editors. For this reason, we are developing a web front-end that will act as a catalogue interface to make this descriptive index freely available online.

In order to fully capture these transnational networks of intellectual exchange it is important to strive for the most comprehensive coverage possible of the period and region at hand. Our multilingual and multidisciplinary team of six researchers will pay particular attention to practices of textual transfer (including translation, adaptation, reprinting and reviewing) across language boundaries and historical periods. However, six researchers cannot cover every language across the 1710–1920 period. In order to make our data as rich as possible, we will be inviting researchers from outside our research team to contribute missing data. We will develop an online workflow, based as far as possible on existing crowd-sourcing initiatives, for managing this community-sourced content. The workflow will enable the community-sourced data to be reviewed by the research team before it is added to the *Agents of Change* dataset. An important aspect of the workflow will be to ensure that such contributors are properly credited for their work.

Alongside the collection of our research data, we are also requesting retrospective assignment of International Standard Serial Numbers (ISSN), a unique identification code for serial publications, for the periodicals which do not currently have one. These ISSNs will be used as stable identifiers for the periodicals we store within our database. Similarly, we are working on establishing authority records via the Virtual International Authority File (VIAF) for those women editors that do not have one yet. We will use use their VIAF IDs as stable identifiers within our NodeGoat dataset.

Our ultimate goal is to create a Virtual Research Environment (VRE), as an essential tool for establishing the research field of European Periodical Studies. The VRE will bring together primary sources and secondary literature, as well as the original scholarship that is produced as a result of the research data that we collect. Additionally, we would like the VRE to enable researchers outside the project team to contribute to the field, which we hope, step-by-step, will become a research community for European Periodical Studies.

We want to ensure that *Agents of Change* becomes a sustainable research tool beyond the end of the project funding by working closely with the local digital humanities centre. The Ghent Centre for Digital Humanities (GhentCDH) is an interdisciplinary centre facilitating digitally-enabled research in the arts, humanities and social sciences at Ghent University and beyond. GhentCDH also plays an active role in the coordination of Belgium's participation in DARIAH, the Digital Research Infrastructure for the Arts and Humanities. Within the framework of DARIAH, Ghent University, along with the universities of Antwerp and Leuven, has received startup funding from the Research Foundation Flanders, to develop a Virtual Research Environment Service Infrastructure (VRE-SI).

The VRE-SI is being developed by focussing on the infrastructural needs of existing humanities research projects in Flanders and Belgium that have a 'digital focus'. Now that the first year of the DARIAH-Flanders project has drawn to an end, the project team have gained a better understanding of how DARIAH Partner Institutions can sustainably support digital scholarship in the humanities. For example, at Ghent University, it has been identified that the establishment of a *digital humanities expert team* including humanities researchers, library staff, IT professionals and digital humanities experts would help to institutionally embed digital humanities research support.

The role of this interdisciplinary team is to both support the realisation of the digital humanities aspects of existing humanities research projects as well as providing advice and guidance in the development of new project proposals. To date, it has been identified that a missing element in the existing service provision is a *digital humanities scientific programmer*, whose role is to combine an understanding of the humanities research questions with the skills of an IT professional to realise the tools and services needed. It is possible to use the DARIAH funding to temporarily recruit such a member of staff and to demonstrate the value of such a post to the Faculty Management Team, with the view to, such a position being structurally funded by the university, in the medium to long-term.

Considering the curation and management of the research data both during the project funding and beyond, is a further crucial aspect of the project. As it is intended that *Agents of Change* will become a sustainable digital humanities research tool thriving beyond the fixed-term project funding, the establishment and implementation of a Data Management Plan (DMP) has been anticipated from the start of the project. The Faculty Library of Arts and Philosophy, as a result of their Arts and Humanities Research Data project, coordinated by their LibraryLab, is providing support to researchers in the faculty in the development of DMPs. Within DARIAH-BE, the intention is that every 'DARIAH pilot project', is strongly recommended to consider research data management from the outset. Finally, the GhentCDH is working closely with Lab1100 to explore how NodeGoat could be offered as a DARIAH-service. In the medium to long-term, the possibility of facilitating the development of an open source community around NodeGoat to further extend the environment for the needs of the digital humanities research, is being investigated.

The aim of this short paper is to firstly, to present some initial research results, based on the analysis of the data gathered by the *Agents of Change* on tracing the networks of intellectual exchange across temporal, geographic and linguistic borders through women editors and their periodicals. Secondly, this paper will demonstrate how working together with the local digital humanities centre and participating in DARIAH is helping to facilitate *Agents of Change* in becoming a sustainable digital humanities research tool that will thrive beyond the end of the fixed-term project funding.

Erlebter Raum im Rom der späten Republik - eine digitale Forschungsumgebung

Thema dieses Beitrags ist der Aufbau und die Nutzung einer digitalen Forschungsumgebung zur Analyse und Visualisierung textueller, individueller und gruppenbasierter Raumwahrnehmung und Raumordnung der Stadt Rom im ersten vorchristlichen Jahrhundert. Neben einer grundlegenden kurzen Einführung in die historische bzw. raumwissenschaftliche Fragstellung sollen insbesondere der Umgang mit unscharfen bzw. unsicheren räumlichen Daten sowie der technischen Umsetzung einer digitalen Forschungsumgebung, in der unterschiedlichste Daten und Anwendungen miteinander kombiniert werden können und so ein genuin digitaler hermeneutischer Prozess ermöglicht und dokumentiert werden kann, im Fokus stehen.

Theoretische Grundlage

In den letzten Jahren haben die sich neu etablierenden Raumwissenschaften besonders für die Neuzeit ein Modell entwickelt, welches den historischen Raum von einem vermessbaren „euklidischen" oder auch einem positivistisch erfassten Natur- bzw. Kulturraum unterscheidet. Es konnte herausgestellt werden, dass Raum nicht die Summe und Relation der Objekte zueinander, sondern dass er erst im Aneignungsprozess durch die historischen Akteure generiert wird. Raum kann also nicht mehr von seinem Inhalt getrennt angesehen werden, sondern fungiert als dessen Ordnungsgefüge [PARNREITER 2013 S. 46] oder wie Ernst Cassirer es bereits 1930 programmatisch in seinem Vortrag „Mythischer, ästhetischer und theoretischer Raum" auf den Punkt gebracht hat, die Substantialität ist durch die Funktion, das „Was" durch ein „Wie" ersetzt worden [CASSIRER 2009/1931 S. 95]. In Bezug auf das Verhältnis von Geschichte und Raum bedeutet diese Öffnung des Raums vom Absolutum zum Betrachtungsgegenstand, a) dass die Vorstellung von Geschichte im Raum, bzw. der Raum als Behälter von Geschichte in eine Raum-

Geschichte umgewandelt werden muss, b) dass es nicht Eine Raum-Geschichte, sondern eine Pluralität von Raum-Geschichten gibt, welche vom Standpunkt bzw. der Lebenswelt des Betrachters abhängig sind und c) dass innerhalb dieser historischen Raum-Ordnungen Platz für Widersprüche, Leerstellen und Ungereimtheiten bestehen darf, ja muss. Denn in der Konstitution dieses „Wie“, dieser Raum-Ordnungen der Lebenswelt, spielt neben der sensorischen Wahrnehmung die individuelle Erfahrung des bzw. der Wahrnehmenden ebenso eine Rolle wie auch das kollektive Gedächtnis der jeweiligen Gesellschaft [LYNCH 1960/2001 S. 13]. Ziel einer historischen Raumwissenschaft muss es also sein, diese Pluralität von Raum-Ordnungen in ihrer vernetzten Struktur zu erfassen und auf ihre individuellen und gruppenspezifischen Anteile hin zu untersuchen. Konventionelle historische Karten können für die Analyse dieser Prozesse nur eine Grundlage bilden, auf welcher die mentalen Karten der historischen Akteure aufbauen, die wiederum die Basis für das Handeln Letzterer darstellen.

Historisches Szenario

Aus diesen grundlegenden Überlegungen zum Raum ergibt sich für eine Untersuchung der antiken Raumordnungen von Städten im Allgemeinen und der Stadt Rom im Speziellem als erstes Ziel der Aufbau der vermittelten Räume, aus den auf uns überkommen Quellen – in diesem Fall besonders den Texten. Zu Beginn müssen also, in dem hier vorgestellten Projekt vom lateinischen Autor Marcus Tullius Cicero (106-43v.Chr.) präsentierten Räume erfasst und dargestellt werden. Praktisch bedeutet dies zu fragen, welche räumlichen Objekte genannt werden, welcher Stellenwert ihnen zugemessen wird und wie sie zueinander in Verbindung gesetzt werden.

In einem zweiten Schritt muss ferner die Frage gestellt werden, welche individuellen Aneignungen und welche kollektiven Vorstellungen der Räume durch diese vermittelten Räume zutage treten und welchen Charakter diese besitzen. Handelt es sich um staatlich bzw. durch zentrale Akteure geplante, um alltägliche oder auch um symbolische Räume? Können diese klar voneinander getrennt werden oder überlagern bzw. bedingen sie sich und, sollte letzteres der Fall sein, auf welche Weise?

Die Quellenbasis für diese Analyse besteht in 1300 Nennungen von insg. 255 Raumobjekten der Stadt Rom in den Werken Ciceros, welche in einer relationalen Datenbank gesammelt und georeferenziert wurden. Ein zentrales Problem hierbei bestand in der Unschärfe der genannten Räume, da a) nicht alle Orte, die Cicero nennt, heute genau zu lokalisieren sind, b) die Nennungen, die der Autor macht, nicht immer exakt sind und c) manche Verortungen in der Zeit der Entstehung der Werke nicht mehr oder nur sehr vage bekannt waren (z.B. wenn sie sich auf die Zeit der Gründung Roms beziehen). Als Referenzdaten für eine räumliche Analyse wurden der archäologische Befund zur Stadt Rom in der späten Republik kartographisch aufgenommen sowie Nennungen bei für Cicero zeitgenössischen Autoren (Varro, Caesar, Sallust) und die historischen Daten zur Stadt Rom in der späten Republik.

Technische Umsetzung

Zentral für die Umsetzung eines solchen Ansatzes ist es, ein dynamisches kartographisches System aufzubauen, indem unterschiedlichste archäologische, philologische und historische Daten zusammengeführt und unter Nutzung verschiedenster Analyse- und Visualisierungswerkzeuge (kartographisch, netzwerkanalytisch, word-Clouds …) dynamisch miteinander in Beziehung gesetzt werden können. Es bedarf hierfür einer digitalen Forschungsumgebung, in der unterschiedliche Medieninhalte miteinander über streng definierte Programmierschnittstellen kombiniert werden.

Einen Schlüssel für die Verbindung unterschiedlicher digitaler Analyseverfahren bei freier Manipulierbarkeit der Daten bildet die Webble-Technologie [TANAKA 2003], eine Schnittstellentechnologie, mit der versucht wird, philosophische Konzepte der Wissensevolution in innovativen Werkzeugen des Wissensmanagements umzusetzen. Webbles erlauben Nutzern, vorhandene Wissensressourcen, welche als Medienobjekte gekapselt – „gewrapped“ – sind, weiterzuverarbeiten und zu distribuieren. Benutzer können einzelne Medienobjekte durch direkte Manipulation, wie „drag“, „drop“, „copy“, „paste“, miteinander zu neuen Objekten kombinieren, ohne Programmierkenntnisse zu besitzen. Aus technologischer Sicht handelt es sich bei der Webble-Technologie um eine Middleware, die insbesondere für Web-basierte Anwendungen geeignet ist und die intuitive Verbindung von nahezu beliebigen Funktionen und Dienstleistungen erlaubt. Dies gilt für die Verbindung von Methoden der qualifizierenden Datenanalyse mit denen der Bildverarbeitung gleichermaßen wie etwa der Verbindung von GIS-basierten Visualisierungssystemen mit digitalen Methoden der Netzwerkanalyse. Die Webble-Technologie erlaubt die intuitive Kombination von Medienobjekten, die im Ergebnisse neue Sichten oder gar Einsichten repräsentieren können.

Introduction

The use of Semantic Web Technologies in Digital Humanities projects has increased over the years, but only recently annotation tools and research environments have started to create and use semantic graphs (e.g. Pundit[1], Grassi et al. 2013, or CWRC[2], Rockwell et al., 2012). While the sharing of annotations and data into a formalized Web of Data is a central part of these projects, in this paper we would like to focus on capacities for qualitative research by using semantic graphs and linking these with quantitative data. Qualitative research approaches have thus far not been positioned at the core of Digital Humanities (Drucker, 2012). However, recent discussions about close and distant reading e.g., (Moretti, 2013) point out a manifestation of a strict opposition between qualitative and quantitative research on the level of data. We would like to reconfigure this separation between qualitative and quantitative data by taking into account its epistemological practices and apparatuses. Qualitative and quantitative data can be regarded as "thin descriptions". Both need an interpretative act to become "thick descriptions" (Love, 2013). This involves a broad range of research capacities, whereby a semantic graph addresses parts of it and creates a link between both paradigms by connecting the different data. This main argument of the paper will be demonstrated through examples from ongoing Digital Humanities research projects based on the semantic research environment Semantic CorA[3], where we experimented with epistemological apparatuses which were developed through participatory design approaches and collaborative ontology engineering.

Re-Configuring the apparatus of qualitative and quantitative research

The recent focus in Digital Humanities on epistemological apparatuses, including their materiality, performativity and relation to theory, offers the possibility to sharpen the respective analytical concepts for data and research apparatuses. Ramsey and Rockwell (2012) describe tools as a "telescope for the mind" and offer a materialistic epistemology. Concerning the opposition of qualitative and quantitative research, Manovich (2011) describes the potentials of big data by contrasting quantitative methods (i.e., statistical, mathematical, computational) with qualitative methods (i.e., as used in History, Literature Studies, Anthropology, qualitative Social Sciences and Psychology) and the different kinds of underlying data. While quantitative approaches commonly rely on surface data, qualitative data are described as deep data. Manovich posits equivalent epistemological depth of both kinds of data but hints to the different scale of contact points with the object of interest.

Venturini and Latour (2010) point to the micro/macro distinction in Social Sciences, which corresponds to the qualitative/quantitative separation at the methodological level. The new capacity of digital, computerized methods, they point out, are quali-quantitative methods, which do not rely on the opposition of statistical analysis and ethnographic observation. Love (2013) concretizes this link between qualitative and quantitative approaches as well and takes into account the epistemological apparatus by comparing Literature Studies and ethnographic research. Instead of placing thin description in opposition to "thick description" (Geertz, 1973), Love (2013: 403) argues for the significance of thin description, which she considers as an integral part of thick description, and demands for a reflective engagement with the full range of empirical methods. In this sense the epistemological apparatuses are per se boundary-making practices, which "enact what matters and what is excluded from mattering" (Barad, 2007: 148) and demand an accountability of this material-discursive practice of epistemological apparatus design.

Designing Semantic CorA

The realization of Sematic CorA was driven by a participatory design and agile development approach of both the software components as well as the ontology. A main goal was to enable classical qualitative researchers to realize their research by using the potentials of a semantic graph. The design followed the research practice though an evolutionary process, which was initiated by an analysis of needs and requirements (i.e., site visit, artefact analysis, interviews) and was followed by nearly weekly meetings with requirement articulations and prototype testings. Semantic MediaWiki[4] was used as a technological platform, which was extended with newly developed tools (extensions) to address the needed research capacities.

Linking qualitative and quantitative Research with Semantic CorA

Openness and flexibility: In qualitative research, the openness of the research object and the flexibility to adjust the knowledge base play a central role in grasping the complexity of the phenomenon of interest (Bauer, Aarts, 2007). Using a semantic graph as an epistemological tool offers the possibility to create new entities, add properties or relate these to other entities. In this way, a network is created step by step based on the research material, which can be extended and re-arranged in the research process. So an all-encompassing fixed schema is not a precondition when starting a research project. The semantic graph consists of pages (representing entities), which are described by properties or links. Figure 1 demonstrates the schema of the semantic graph for exploring historical educational lexica (ranging from 1774 to 1945). Integrated bibliographic data (e.g., lexicon, article, author) and digital images of the lexica from a digital library[5] build the data basis for the graph, whereby the syntax supported by the SMW platform and data edit forms offer to enrich the graph. For example, a researcher establishes the relation `Is About´ between the article and a person and adds further properties (date of birth/death, gender, nationality, domain of mattering). In this respect, a thin description has been created, indicating a network of the phenomenon with more than 6 million values and 100,000 pages.[6]

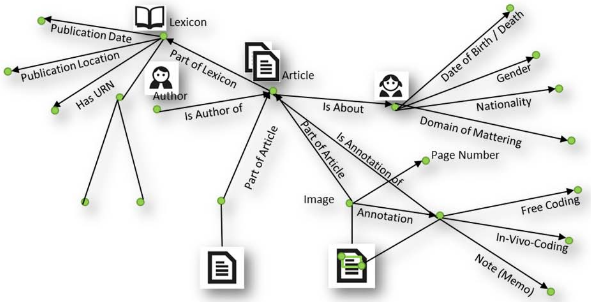

Figure 1: Schema of the semantic graph for exploring educational lexica

Balancing particularities and formalizations: In qualitative research it is necessary to balance formalization with respect to the particularities of the phenomenon of interest and the research material. Star describes this balance as achieved through facetted classifications in the methodological approach of the grounded theory (Star, 1998: 227). As previously described, a semantic graph offers the possibility to create a network, which calls for formalization and sets the boundaries of the phenomenon. To enable a more `fuzzy´ or qualitative thin description, each node and property of the graph can be described in an unformalized way using the classical text tools of a wiki. Additionally, an open approach for qualitative content analysis is followed to enable annotations of the text (Figure 2). In this way, the annotation is connected to the article on the basis of the semantic graph (Figure 1), providing links between the annotations of the qualitative content analysis and the further network of the semantic graph. This constitutes a thin description based on qualitative data (e.g., through close reading and annotations) and quantitative data (e.g., bibliographic data), where an interpretative act is needed for the description to become a thick description.

Figure 2: **Annotation tool with data edit form** (i) and **a**ggregated annotations in a dynamic table (ii)

Ongoing data analysis and graph creation: Another main aspect of qualitative research is the ongoing iteration between grasping the research material and creating new connections or qualities. This intensive work with research data can be done by comparing, following associations, close reading, or – as previously described – by distant reading of aggregated or related elements. While using a semantic graph as a network of the phenomenon, two different examples can be demonstrated which use the linkage between qualitative and quantitative data: Semantic browsing and querying the network. To represent relevant parts of the graph, aggregations and inferences are created for main entities (e.g. 1,200 aggregated descriptions of persons) to thickening the research data and browsing through the network (Figure 3, i). Additionally, a query tool enables to query and aggregate the semantic graph (Figure 3, ii).

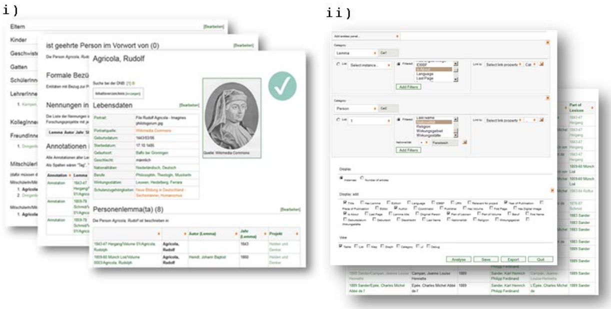

Figure 3: Semantic Browsing through the aggregated information on page about person (i) and analysis tool with results in dynamic table (ii).

Discussion and outlook

This paper demonstrates the possibility of linking qualitative and quantitative data by using semantic graph technologies to create thin descriptions. Therefore, the advantages of the interpretative act of thick descriptions are considered by allowing for ongoing iterations of analyzing the research material and creating the semantic graph in a formalized and unformalized way (enrichments, annotations, text descriptions). With semantic browsing, aggregations of information, annotation and querying the semantic graph, aspects of close and distant reading are addressed, thus offering new techniques for grasping the research material for qualitative research.

For the Digital Humanities, the focus on mattering of apparatuses offers the possibility to open the design space for digital tools to the diversity of epistemological practices in Humanities. Thereby, an engagement with the diversity of the Humanities comes to the front, enhancing the accountability of boundaries and possibilities of epistemological apparatuses in Digital Humanities.

Acknowledgements

The authors would like to thank the research group around Semantic CorA, especially Marc Rittberger, Lia Veja, Kendra Sticht, Anne Hild, and Anna Stisser. The initial realization of the research environment Semantic CorA was supported by the German Research Foundation (DFG) and its further development is supported in the context of CEDIFOR by the eHumanities program of the German Federal Ministry of Education and Research (BMBF) no. 01UG1416C.

The MONK system uses shape-based feature vector methods that have very few assumptions concerning the content or style of the material. It avoids the traditional OCR approach (optical character recognition) which assumes that individual characters are essentially legible. That assumption only holds for a tiny fraction of handwritten material and a limited number of scripts. The only assumptions MONK makes are that pictorial and textual segments are separated by white spaces; and that the layout, of underlining, etc. in a specific document, is consistent throughout the document. In MONK, classification methods are used that allow for a fast bootstrap from single example instances (nearest-neighbor search) (Gast et al., 2013). With larger numbers of labeled examples, models can be computed, varying from nearest-centroids to support-vector machines and neural networks in a continuous learning process (Krizhevsky et al., 2012; Liu et al, 2015; Guo, in press). A challenging topic from the technical point of view is the relation between existing semantic knowledge (ontologies) and the statistically inferred semantics using Google's *word2vec* and current deep-learning neural networks. Can the underlying structure and style in a collection of a common and realistic size be detected by such algorithms? Can the proposed enrichment system profit from generally available text corpora? The processing power required by the proposed architecture is substantial. For this project, algorithmic optimization of the image processing and recognition system is necessary in order to create the necessary speed and flexibility of the system for use by non-technical end users. In order to tackle this challenge the consortium will make use of the combined knowledge and expertise of ALICE in Groningen, and the Leiden Institute of Advanced Computer Science (LIACS), where multiple supercomputers and high performance computing experts are present.

Because of its visual approach, MONK can handle the diversity of material that we encounter in our use case and in historical collections in general: text, drawings, and images. MONK also does not require a language model nor fully transcribed samples to quickly assess the contents of an archive page. The human-in-the-loop approach of MONK is currently 'label' oriented, but will be enhanced by providing the user and the system with ontologies for bootstrapping the learning process. The system will understand handwritten corpora to such an extent that the visual and textual content on individual pages is categorized, determined and networked to other pages in the archive and external sources. To construct training examples for MONK, biologists and historians of science will manually label documents to the machine learning software by means of a human in the loop approach. In addition, a crowdsourcing approach will be used to further expand this corpus of examples. Our consortium will here build on the expertise of ALICE and Naturalis Biodiversity Center, the Leiden-based National Museum of Natural History. Eventually, the computer-assisted recognition of words and visual information on a page will thus allow users to search, filter and group arbitrary archive items and enables connections with external databases. Last but not least, MONK lays the groundwork for full transcription of any handwritten-illustrated archival collection.

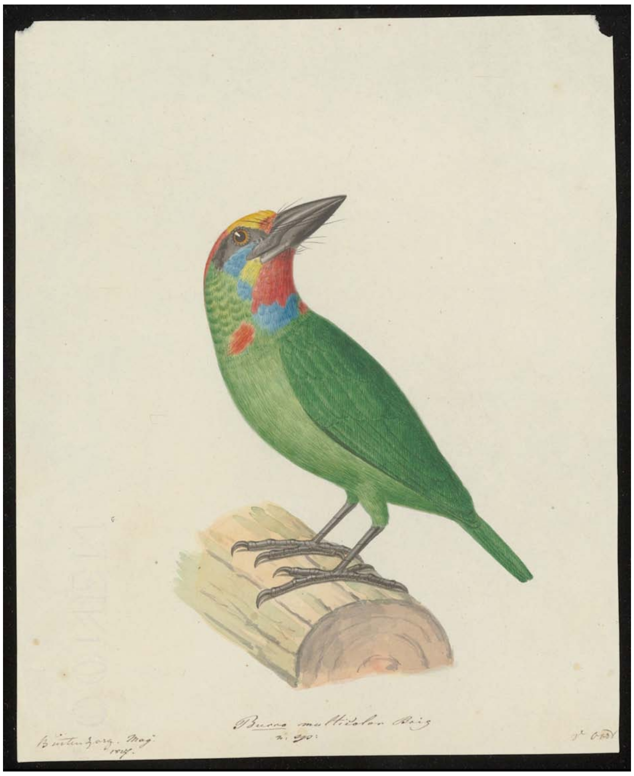

Figure 2. Drawing of Burro multicolor created in Buitenzorg, Java in 1827 by Pieter van Oort. Source: Naturalis Biodiversity Center, Archief van de Natuurkundige Commissie voor Nederlands-Indië. Copyright: Public Domain Mark 1.0

The central use case of our research project is the collection of the *Natuurkundige Commissie voor Nederlandsch-Indië* (hereinafter NC). It is one of the top-collections of Naturalis. From 1820 to 1850, the NC charted the natural and economic state of the Dutch East Indies and returned a wealth of scientific data and specimens which are now stored in archives in the Netherlands and Indonesia. The collection comprises thousands of handwritten notes and drawings and tens of thousands biological and geological specimens. While these archival items have all been digitized, the individual pages in the notebooks, diaries and reports are not catalogued nor labeled separately. Many of the field notes combine different textual and visual elements on one page. Our short paper presentation is based on the processing of an initial set of understudied handwritten field notes which we carried out in early 2016. By doing so, we will demonstrate the efficiency of the MONK system and our approach.

Owing to the different 'hands' and languages used in the documents, links across handwritten field records and notes, drawings and specimens cannot be made in an efficient way. Our corpus contains material from at least seventeen different writers and the used languages range from German *(Kurrentschrift)* to Latin, French, and Dutch. The labels of related historic specimens only provide very general information on collection localities and collectors. Hence, the typical use case of a scholar wishing to retrieve information on a certain species, person, drawing, or collecting locality is limited. Owing to its sheer dimension and its weak structure, it is impractical to disclose and network this archive manually. Its current inaccessibility hampers research into Southeast Asian natural history and the history of (scientific) knowledge production. Knowledge extracted from the documents will be structured and served as Linked Open Data. This will allow interlinking of content and also enable interoperability with other cultural heritage resources, for example, the physical specimens obtained during expeditions, or other historically significant data collections from the same area.

The multi-layered character of the material makes it a perfect use case for developing a technologically advanced and usability engineered digital environment for interpreting and connecting illustrated-handwritten collections. In our consortium data scientists from the Universities in Leiden and Groningen work closely together historians of science from the University of Twente and taxonomy experts from Naturalis. Fueled by an investment from BRILL publishers in a national funding scheme, this project will not only result in the disclosure of the NC archive, but will also enable the integrated study of underexplored scientific manuscript collections and archives in general.

Digital History "From Below": a Call to Action

Anelise Hanson Shrout
anshrout@davidson.edu
Davidson College, United States of America

Humanists – inclusive of digital humanists – are preoccupied with telling stories. Some of our most interesting subjects, however, have left only the barest of marks on historical records. Their stories are among the most captivating, but also some of the most difficult to access. This paper knits together recent trends in digital humanities practices that have helped us to elevate unrepresented voices with a discussion of how to elevate the marginalized within the DH community. It showcases select projects that undermine archival silences.[1] It then argues that digital humanities practitioners should add these theories to the collection of tools currently used to forward social justice projects in DH spaces.

Elevating the Archivally Silenced

Various methodologies have been adopted to address the problem of how to tell stories about people who left behind few records. In the 1970s and 1980s, practitioners of "history from below" worked to elevate narratives about "people with no history," by chronicling the everyday lives of peasants and non-elites. At the same time, practitioners of the "new social history" turned to cliometrics – and adopted methods that would be familiar to those who work with "big data" today – to highlight trends about marginalized peoples from historical data like censuses, probate records and financial documents.

There have been various resurgences and developments in these methods in the intervening four decades. These include practices of reading archives "against the grain" to get at the unstated assumptions that historical actors made about those they held power over. They also include theoretical approaches that advocate the reading of silences to understand those whose voices were intentionally obscured by official recorders and gatekeepers.

Marginalizations Within DH

Questions about whose voices are elevated and whose are silenced have also long been a theme in DH scholarship and discourse. These questions seek to unpack the ways in which DH as a field is exclusionary. This former is a much (though still not enough) referenced problem in panels at former DH conferences, which have asked how DH research can address (and remedy) social problems.

Digital humanities scholarship has also begun to address problems of access within the broader DH community, and the barriers erected to women and people of color in particular. For example, Adeline Koh has argued that we need to examine the ways in which DH publics are constituted, in order to better understand the creation of "limits of the discourse that defines the idea of a digital humanities 'citizen.'" Similarly, Tara McPherson has argued that we must see the evolution of DH as a field shaped by structural inequalities – of race, class and gender – which accompanied the rise of computation technologies.

A Knitted View

These are much needed interventions, and help us to understand the evolution of our field as one in which certain groups have been marginalized and others have been centered. These conversations also mirror methodological debates within history about whose voices to elevate, and under what circumstances. This paper complements extant work by arguing that theoretical interventions concerning current structural inequalities must be brought to bear on the past, and that digital methodologies are ideally suited to elevating subsumed voices in the present. It further demonstrates that these projects, the theories that underlie them, and current work to make DH more equable should be read together to further the practice of digital history and humanities "from below.

by slaveholders to argue for the agency and tactical prowess of enslaved people (http://revolt.axismaps.com/map/); and Michelle Moravec's use of metadata to "unghost" lesbian women in the past (http://michellemoravec.com/).

Change, Transition and Governance: Lessons from a Long-Term, Large Scale DH Collaboration

Lynne Siemens
siemensl@uvic.ca
University of Victoria, Canada

Digital Humanities (DH) is becoming increasingly a collaborative community of practice, a move encouraged both by the scale, scope and complexity of projects (L. Siemens and Burr, 2013) and by granting agencies with programs such as Digging into Data (2013), the new Bilateral Digital Humanities Program between the National Endowment for the Humanities' Office of Digital Humanities and the Deutsche Forschungsgemeinschaft, Germany's research office (2014), Canada's Social Sciences and Humanities Research Council's Partnership Grants (2013), and many others. This trend is further supported through efforts such as Fair Cite (2012) and the Collaborators' Bill of Rights (Off the Tracks, 2011) to more fully recognize project contributions through multi-authorship citation practices, University of Virginia's Praxis Program which provides collaborative project experience for graduate students (The Praxis Program at the Scholars' Lab, 2011a, 2011b, 2012, nd), and individual DH project charters outlining guidelines for team work (Hjartarson, Fast, and Hasenbank, 2011; Ruecker and Radzikowska, 2007).

These are all exciting developments that will reap long-term contributions at the individual, project, and DH as a community of practice levels and beyond. At the same, more work is needed to understand how these teams function and the types of supports which are needed to coordinate the research, people and tasks to ensure successful outcomes at these levels (Dombrowski, 2013; Lyall, Bruce, Marsden, and Meagher, 2013). With this knowledge, DH teams will be better able to anticipate benefits and challenges associated with collaborations and develop processes to maximize benefits while minimizing associated challenges.

At present, much of the body of knowledge about academic team functioning and best practice guidelines has been developed through a reflection process at a project's completion (For example, see Bracken and Oughton, 2006; Bryan, Negretti, Christensen, and Stokes, 2002; Kishchuk, 2005; Lawrence, 2006; National Endowment for the Humanities Office of Digital Humanities, 2010). These reviews often focus on the actual research work accomplished with little discussion of associated processes that supported the work, communication patterns, and other factors that supported (or not) successful outcomes. As a result, some hard-earned lessons are forgotten or minimized through the passage of time, but might be captured if this type of reflection occurs during a project's life.

As a large project in terms of team membership, budget, scope, disciplinary perspectives, and project length and research integration, Implementing New Knowledge Environments (INKE) provides a unique perspective to explore the nature of collaboration (INKE, 2012a). INKE's primary research focus is the exploration of e-books and their potential from a variety of perspectives, including interface design, modeling and prototyping, user studies, and textual studies (INKE, 2012b). Further, this collaboration is examining the "understanding, creating, and evaluating research structures that will allow academic and non-academic (including industry partner) members of our research team to work together in ways that meet the needs of the research and development cycles of the entire INKE group" (R. G. Siemens, Siemens, Cunningham, Galey, Ruecker, and Warwick, 2012, p. 7)[1]. To that end, INKE has undergone yearly reflections on the nature of collaboration within the project with an objective to better understand the ways to support large-scale research collaborations as they unfold and communicate these lessons to other projects for consideration.

This paper contributes to our understanding of how research teams function by reviewing INKE's six years of experience in collaboration and with a view to articulate best practice guidelines (L. Siemens and INKE Research Group, 2010, 2012b, 2012c, 2012d, 2012e, 2013).

Members of the administrative team, researchers, graduate research assistants and others are asked about their experiences collaborating within INKE on an annual basis in order to understand the nature of collaboration and ways that it may change over a grant's long-term life. The interview questions focus on understanding the nature of collaboration, advantages and challenges associated with it within INKE's context. These interviews allow the researcher to explore topics more fully and deeply with probing and follow up questions while participants reflect on their own experiences and emphasis those issues which are important to them (Marshall and Rossman, 1999; McCracken, 1988; Newell and Swan, 2000; Rubin and Rubin, 1995). This paper focuses on a summary of the first 5 years of the grant-funded work.

At the time of writing this proposal, final data analysis is being completed, but clear patterns are emerging and, after final analysis, these will form the basis of my presentation.

While the grant application suggested a stable team of active researchers and partners, the reality has been very different. Due to a variety of reasons (L. Siemens and

INKE Research Group, 2012a, 2013), change and transition have been constant within INKE, which has led to sub-research group re-organizations and the creation of new ones. Concurrently, new researchers, administrative leads and partners joined the team. And as is always the case when working with student research assistants and post-doctoral fellows, sub-research areas were continually recruiting and training new ones as others moved on to other opportunities.

Grounding this change has been several constants that have ensured the research has been able to continue effectively and efficiently despite the transitions. First, the governance documents outlined clear articulation of roles and responsibilities which became especially important for ensuring that new researchers, partners, and administrative understood and enacted the nature of collaboration and accountability within INKE. At the same time, these documents provided guidance for ensuring that processes for change, transition, planning and reporting, and decision making were considered and thoughtful while remaining responsive to changing circumstances (L. Siemens and INKE Research Group, 2012c). The use of basecamp, an online project space, and an updated project website further reinforced these processes by providing an ongoing repository for messages, documents, data, and publications, all important knowledge for current and new researchers and partners. Second, multiple communication channels, such as annual birds-of-a-feather gatherings, attendance at other conferences, both formal and in-formal face-to-face administrative and sub-research area group meetings, conference calls, and online project spaces, ensured that team members met on a regular basis to exchange information about and participate in research projects with the other sub-research areas, ensuring highly collaborative work.

As INKE nears the end of its 7 years of funded research, the team is anticipating both winding down this focused work on e-books and exploring next research steps, building from its successes (INKE, 2014). While the research has been intellectually challenging and not without its administrative issues, INKE team members report positive experiences in terms of the collaboration, associated outcomes, and connections to the DH and traditional humanities communities. As measures of this positive spirit and connections, they are extending their collaboration into associated research areas as well as contemplating another large-scale research project.

This research will make several contributions to the knowledge base about the nature of collaboration within the DH community of practice. First, this research contributes to efforts to make work patterns and relationships more explicit and understand those factors that tend to predispose them to success, and perhaps, more importantly, to avoid those which may lead to problematic interactions. Already, lessons from INKE are informing other projects' collaborations (Nowviskie, 2011; The Praxis Program at the Scholars' Lab, nd). Second, INKE's experience demonstrates that these types of team research projects require skills not typically taught in graduate school, including project management and collaboration within a targeted and integrative research environment, which differs from that of curiosity-based one. This reinforces the call to enlarge graduate training beyond purely disciplinary to these larger collaborative skills to ensure that students are prepared for both academic and alternative academic posts (Berman, 2011; Carr, 2012; Leon, 2011; Nowviskie, 2010; Powell, Bouchard, Dalgleish, Keenan, McLeod, and Thomson, 2013; L. Siemens, 2013; Spiro, 2010).

Introduction

One of the key problems in historical political research is that many relevant research questions can only be answered by means of a prolonged and painstaking analysis of large archival series. Questions like: "How did the relationship between the government, the parliament and the political elites change over time?", "What role did political traditions and rituals play?", and "In what ways did the information economy influence the political process?", still require scholars to systematically work through vast bodies of archival material. Only a few scholars, who appeared not to be intimidated by such a daunting task, have come up with long-term analyses of political patterns. This paper proposes a new, digital approach to avoid these time-consuming activities and to open up major archival series for automated text analysis, by applying various tools for text recognition and automated structuring, as well as by using reference data and re-using metadata.

The case study selected to demonstrate the potential of this approach is the opening up of the Resolutions of the Dutch States-General from 1576 to 1795. This archival series of the central assembly of the seven Provinces forming the Dutch Republic is an excellent example of the type of source suitable to answer the above mentioned research questions. Editing the Resolutions has been a task of the Huygens Institute for the History of the Netherlands and its predecessors since 1915 (Japikse and Rijperman, 1915-1970, Van Deursen et al., 1971-1994).[1] This task is hindered, though, by the vast size of the resolutions, which approximately consists of 200,000 pages. The classic edition process, not even aimed at providing a full transcription of the resolutions but only abstracts, reached the year 1625 in 1994. After that, a project was carried out to edit the resolutions from 1626 to 1630 only in digital form, with the help of xml-coding (Nijenhuis, 2006; Nijenhuis et al., 2007). This project ended in 2007 and was not pursued further, because it was clear that this method also was too time and money consuming.

In 2015 we started a totally different approach as an alternative to editing this vast collection of documents. Our goal is to make this important collection accessible, searchable, and analyzable for historical research by applying various advanced digital humanities tools. We will do this by using the metadata of the already printed edited Resolutions, and by enriching and linking the data to other relevant research data. The advantage of this approach is that the Resolutions will be made accessible for researchers in a far quicker way in comparison to the classic way of editing. Also, this approach is to provide insights which will be useful for comparable projects dealing with important archival series in the future, and may provide an alternative to full scale editing of large historical sources in the digital era.

Reusing metadata

On the basis of experience with digital editing, we know that performing a small scale experiment is the best way of establishing best practices and avoiding huge costs. Therefore, we have chosen to apply a multilevel approach with several pilot projects, using various tools which may be applicable for exploring the content of some 200,000 pages of resolutions for historical research. These projects depart from the principle of using what is already there. This means, in practice, that we will construct a framework consisting of the metadata added by the previous editors, like indexes; mark-ups of names, places and institutions; and classification of subjects, as well as contemporary indexes and marginal subject-notes in the resolutions. This framework will serve as a reference to make the resolutions corpus accessible.

Automated Handwritten Text Recognition

Secondly, we experiment with tools for Handwritten Text Recognition (HTR). The software developed by researchers from the Universitat Politècnica de València, which is integrated in the *Transkribus* platform, offers the most valuable results (Sanchez et al., 2013).[2] For the HTR-experiment we manually transcribed 40 pages of handwritten resolutions. Of these pages, 30 were used for training and 10 for testing. The resulting Word Error Rate for this experiment was 40%. We realize that using an only partly correct transcription does not deliver the results one can expect from a traditional edition. The automated transcriptions generated by the HTR-tool should be seen as an alternative that enables researchers to search the text. Of course with a Word Error Rate of 40% this will not deliver perfect results. The HTR may be improved by expanding the training set and by the use of reference data, which is discussed below. In case our approach will be financed for the whole series of resolutions, we intend to use crowdsourcing to improve the HTR results on the handwritten resolutions via the *Transkribus* platform. As has been demonstrated by the developers from Valencia, manual correction of incorrect transcriptions of the HTR-software leads to a recalculation diminishing the mistakes the software made in the rest of the text. This will speed up the work towards an accurate transcription for the whole series. Nevertheless, with the limited number of people able to read 17th-century Dutch handwriting taken into account, we cannot expect crowdsourcing to provide us with a perfect transcription of the whole series of resolutions within a few years.

Automated annotation

Finally, we investigated the use of tools for enriching the resolutions with annotations that will improve exploring the digitized material. For this purpose we used contemporary printed resolutions, of which a series exists from 1703 to 1796. We selected a set of 100 pages from the year 1725, containing 366 resolutions. The text of the resolutions was transcribed and marked up manually using TEI. The printed material consists of blocks of text that can be categorized as follows: "session", consisting of the date of the meeting, the name of the chairman, and the attendees representing each of the seven provinces; "resumption", the summary of the previous meeting; "resolution", the body of the resolutions themselves; and "insertion", mostly incoming letters. We used a standard machine learning approach. The text blocks were marked up with their type manually. Part of the material was used for training the automated categorizer, the other part for testing. The categorizer was trained using as features fixed expressions the successive clerks of the States-General used in their account of the meetings. The comparison of the results with the manual categorization turned out to be promising. We were able to categorize the different types of text blocks with a 98,6% precision.

The next step was to extract information from the text blocks. Building on software of the *Stanford Natural Language Processing Group* we developed a rule-based tool for recognizing dates with a 99,1% precision. The dates in the "session" text blocks could be identified easily, for they have a fixed structure; this allows us to annotate each resolution with its date. Software for identifying more complex dates in the text blocks (for example "the resolution taken yesterday") is yet to be written; it will be used to annotate resolutions with references to other resolutions.

Furthermore, we developed a tool using a Naïve Bayes Classifier for categorizing the attendance list. The manuscript and printed resolutions list the attendants according to the province they represented; the provinces were mentioned in a fixed order. However, at some meetings a province was not represented. With the tool we are able to identify the provinces the attendants as well as the chairman represented in these cases also.

Finally, we took some steps in interpreting the content of the resolutions. Again using fixed phrases and a Naïve Bayes Classifier, it turns out to be possible to recognize in most cases whether or not a decision was taken in a resolution (96,9% precision) and whether the States-General asked a person or a body for advice (99,3%). The results for analyzing to whom the States-General asked advice; and whether and to whom they asked for a report, are yet inconclusive because of the limited amount of training material.

Apart from improving the results for this last mentioned analysis, our future work will be dedicated to several issues. Firstly, applying Named Entity Recognition to the resolutions in combination with the use of reference data. The Huygens ING owns and hosts several relevant data collections, for instance the *Biography Portal of the Netherlands*[3] and the *Compendium of Office-Holders and Civil Servants 1428-1861*[4]with which we will be able to identify persons and institutions mentioned in the resolutions. Secondly, we aim at improving the OCR for the printed resolutions, for the benefit of the automated annotation. Thirdly, we will investigate whether the tools for automated structuring can be applied also to the automated transcription of the handwritten resolutions.

Introduction

This paper addresses how text-mining, machine-learning and information retrieval algorithms from the field of artificial intelligence can be used to analyze Art-Research archives and conduct (art-) historical research. To gain quick insight into the archive, two aspects are focused on: relations between groups of people using community detection, and global content changes over time using topic modeling. For such archives pre-tagged ground-truth collections are generally not available, and the archives are often too large, geographically distributed, and not always available in digital formats to build such a ground-truth at reasonable costs. To develop and test the validity and relevance of existing tools, close collaboration was established between the AI researchers, museum staff, and researchers in CREATE, a digital humanities project that investigates the development of cultural industries in Amsterdam over the course of the last five centuries.

Data

The research draws on two datasets. The principal dataset is the digitized archive of the Stedelijk Museum Amsterdam, a renowned international museum dedicated to modern and contemporary art and design. The archive of the Stedelijk Museum Amsterdam contains documents from the period 1930-1980. The corpus is a static collection of approximately 160.000 text documents that were digitized using OCR. The second dataset is drawn from Delpher, developed by (Koninklijke Bibliotheek Nederland, 2015). Delpher provides a collection of digitized newspapers, books and magazines that is available for research. A selection of newspapers was made that is used as an additional dataset for this project. Only articles from 1930-1980 that resulted from the query ”Stedelijk Museum” AND ”Amsterdam” were used, forming a set of 18.290 articles.

Methodology

The following methodology uses two approaches to obtain a quick and detailed overview of the content of a digitized archive that contains unstructured information. The first one focuses on the relations between named entities and aims at finding communities in the relation network. The second approach uses time based topic-modeling to get an overview of content changes over time. Finally, a name extraction method is presented that is able to handle multiple causes of name variations.

Relation networks and community detection

In its most basic form, a relation between two named entities can be said to exist when they occur together in the same document. The strength of a relation can be characterized by the number of documents in which both named entities occur. When all the co-occurrences are found, a relation network can be constructed.

In addition, sentiment analysis can be done to further characterize a relation. A sentiment score is assigned to each document, indicating the sentiment content of the document. No distinction is made between positive and negative sentiment polarity. The hypothesis is that relations between individuals with a high sentiment are more interesting than relations with a low sentiment. This is because sentiments around trigger-events are often higher than around common-day events. A lexicon based approach is used with lists of language specific sentiment words. The sentiment score of a document is then given by the sigmoid of the count of the sentiment words in the document, normalized by the number of words in the document.

Finally, community detection algorithms can be applied to the relation network. These types of algorithms aim at finding clusters of groups of entities that have dense connections between members of the clusters and sparse connections with members of other clusters (Fortunato, 2010). The relation weight measure that is used to calculate the communities, is taken as the product of the strength of the relation, i.e. the number of documents where both entities occur in, and the average sentiment score of the documents of a relation. It was found that combining these two measures, resulted in more meaningful communities.

Time based Topic Modeling

In the next approach, topic modeling algorithms are applied to analyze the information content and their evolution over time. Topic modeling tries to discover the underlying thematic structure in a collection of documents. Non-Negative Matrix Factorization (NMF) is being used as a tool for topic modeling (Arora et al., 2012). NMF is an unsupervised method where a matrix is approximated by two low rank non-negative matrices. The extracted semantic feature vectors have only non-negative values and are sparse so they are easily interpretable. Furthermore, NMF is shown to generate more consistent results over multiple runs (Choo et al., 2013), compared to other tools used for topic modeling such as LDA (Blei et al., 2003).

The approach suggested in (Vaca et al., 2014) uses a time-based collective matrix factorization based on NMF and is used in this project. It extends NMF by introducing a topic transition matrix that allows to track topics as they emerge, evolve and fade over time.

Name Extraction

The following method was used to extract named entities from a collection of documents in order to build the relation network. It handles different causes of name variations such as OCR induced errors commonly found in digitized document collections, spelling mistakes, name abbreviations and first and last name combinations.

The method makes use of lists of name variations. Starting from a set of names extracted from a name database, such as RKDArtists and (RKD, 2015), the document collection is searched for possible name variations. These variations are found by searching for the last name using a fuzzy search. The similarity between the group of tokens around the found last name, and the original name is then calculated as a similarity score. The similarity score calculation is based on the idea described in (Song and Chen, 2007), which uses a n-gram set matching technique. The lists of name variations can then be evaluated manually or a threshold on the similarity score can be used to identify name variations that correspond to the original name. The method using a threshold of 0.9 on the similarity score was tested on 50 randomly chosen names. The average precision was found to be 81 percent.

Results

A relation network was constructed for the document collection of the archive of the Stedelijk Museum Amsterdam. Only artists with the graphic artist qualification in the RKDArtists and database were used. The methods were implemented using available open source software libraries such as the Apache Lucene text search engine library (The Apache Software Foundation, 2015) and the Gephi platform (Bastian et al., 2009). The standard community detection feature in Gephi was used, which is based on the Louvain method (Blondel et al., 2008). The result is shown in Figure 1. The color of the relation between the nodes indicates the average sentiment score of the relation, starting from blue (neutral) to red (high sentiment content). Communities such as group exhibitions, art movements or a group of artists closely related to the museum director, could be identified with the help of a museum expert.

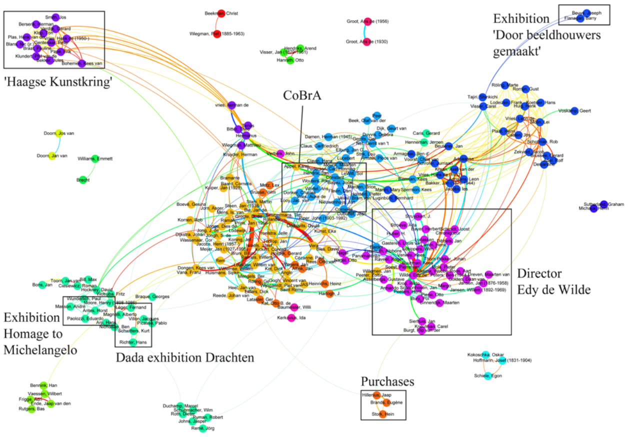

Figure 1: Found communities for graphic artists in the archive of the Stedelijk Museum

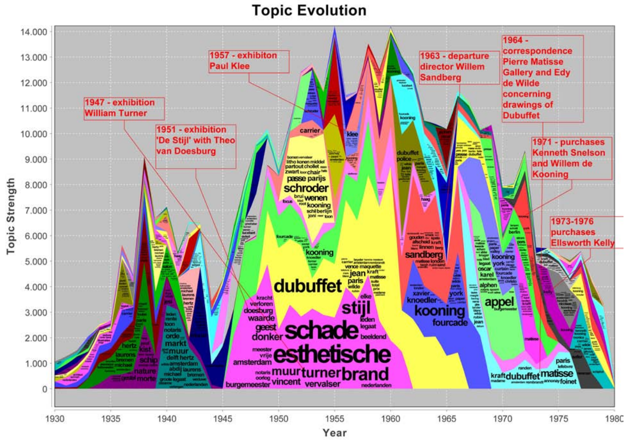

Figure 2: Time based topic modeling for the archive of the Stedelijk Museum Amsterdam

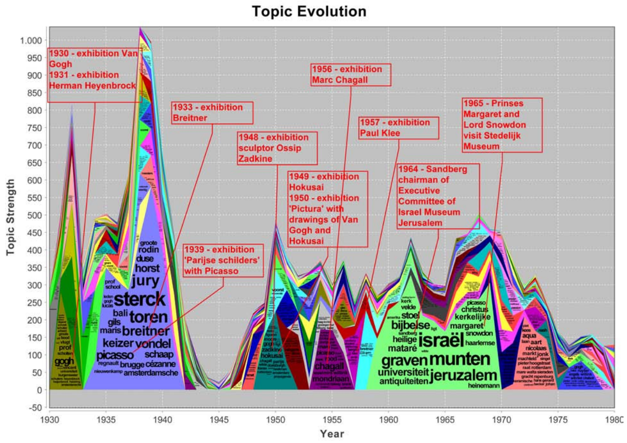

Figure 3: Time based topic modeling for Delpher newspaper articles

The time based topic modeling algorithm suggested in (Vaca et al., 2014) was implemented in MATLAB and Java. The algorithm was applied to both the archive of the Stedelijk Museum Amsterdam and newspaper articles from the Delpher database. The results are visualized over time in the form of stacked topic rivers (Wei et al., 2010), shown in Figure 2 and Figure 3. Several exhibitions and events could be identified and are annotated on the chart.

Conclusion

This paper discusses two approaches to gain insight into a digitized archive. Relation networks of persons with community detection are considered, relying on a robust name extraction method. Furthermore, the evolution of content over time can be explored using time based topic modeling.

For the humanities researchers in this project, the main aim was to asses the research potential of computational analysis of digitized art archives in general, and the Stedelijk Museum in particular. Two types of preliminary research questions were developed to do so. The first type had to do with identifying patterns of change and continuity, across time and place. These include for instance tracing the position of the Stedelijk Museum as an intermediary in Dutch design industries, or the development of the Stedelijk Museum as an increasingly international player. The second type of question is less concerned with general historical patterns, and more with specific art-historical research questions, regarding for instance (networks of) particular artists, artworks or exhibitions. But before we could start asking such questions to digitized art-historical archives, the quality and accessibility of the texts needed to be established. Secondly, specific methods needed to be explored and adapted in order to clean, identify, retrieve, extract, and structure the texts. The first results presented in this paper demonstrate that even though they may not be clean at the first try or capture all historical nuance, they do help archives to open up and show unexpected relationships and patterns, to answer specific questions, and to get connected with other relevant sources, such RKDartists and Delpher. The community detection in relation with sentiment mining, the topic modeling and name extraction method developed in this project therefore provide a solid basis for the next step in assessing the research potential of art-historical archives: developing in-depth case studies, again in close collaboration with art-historians and historians, allowing the archive to speak up in unprecedented ways, offering access to hidden story lines that subvert and augment prevailing historical narratives.

Comparing Digital Scholarly Editions

Citing and comparing texts

Explicit and tacit assumptions of traditional text criticism have been questioned for decades,[1] but the creation of digital scholarly editions has provoked discussion ranging from practical questions of method, to theoretical debate about what constitutes the nature of an edition in an electronic environment.[2] In this paper, we address questions of what it means to compare two scholarly editions, and demonstrate applications of our approach to compare manuscripts of the *Iliad*.

One characteristic of a scholarly edition in any medium is that it makes a text canonically citable. Canonical citation is an essential prerequisite: in order to compare more meaningful units than streams of characters, we must be able to identify and align passages in different versions of a text. We use the technology-independent CTS URN notation[3] to identify books and lines of the *Iliad*. CTS URNs could be applied to any citation scheme, but logical schemes (such as those typically used to cite biblical passage by chapter and verse, or legal document by numbered section and subsection) are superior to arbitrary schemes based on physical artifacts (such as citing Plato by Stephanus page, or referring to the physical page of a specific edition of the works of Jane Austen) since they ensure that our comparison is organized in chunks of texts meaningful for scholarly analysis.

A model for text comparison

Traditional Homeric scholarship offers a useful model for comparing aligned citable texts. Homerists use the terms "vertical difference" and "horizontal difference" to describe two kinds of variety: "vertical difference" refers to entire lines that are present in one text but absent in the other, or that occur in a different sequence in the two texts. "Horizontal difference" refers to lexical differences within a single line. We can generalize the two dimensions of this approach, and understand our comparison of texts as determining the structural and lexical variation between texts.

Structural differences are simply differences in citation structure. For texts cited by CTS URNs, then, we can reduce the determination of structural differences to a comparison of ordered lists of each document's CTS URNs.

Lexical differences are differences in the readings within a single citation unit (line of the *Iliad*, subsection of a legal text, etc.) The crucial question is: what produces a "reading"? Simply comparing streams of characters, or assuming that a stream of characters can be parsed into tokens based on some criterion such as splitting word tokens by white space or punctuation is dangerously underconceptualized. Instead, we recognize that any analysis that tokenizes a citable unit of text for a specified purpose produces an ordered list of tokens that we can compare in order to determine lexical differences between two texts. The lexical type of the token will depend on the goal of the comparison. As we subsequently illustrate, for example, we could analyze literal textual tokens, orthographically normalized tokens, or even morphologically or metrically analyzed tokens.

Implementing the model

When we determine structural ("vertical") variation by comparing ordered lists of URNs and lexical ("horizontal") variation by comparing ordered lists of tokens for each citable unit of text, we are performing exactly the same operation: comparison of ordered lists. This is one of the most studied and best understood problems in computer science, and a typical exercise in first-year programming courses. We have implemented the standard algorithm for Longest Common Subsequence (or LCS)[4] in a library freely available in source code or binary .jar for JVM languages. In addition to solving the LCS, the library determines what items appear in one list but not the other, and what items appear in both lists but in a different order.

Applying the model to the *Iliad*

We illustrate the possibilities of this approach by repeatedly comparing incompletely published manuscripts of the Iliad, focusing especially on *Iliad* 8 in two manuscripts, in the Biblioteca Marciana in Venice and in the Escorial monastery near Madrid. All of our comparisons find the same structural differences. (The run of lines from *Iliad* 8.466-8.468 is present in some manuscripts, for example, but absent from others.) The lexical comparisons, on the other hand, vary depending on the features we analyze.

We begin with a simple tokenization of the literal diplomatic text split on white space. Inventorying the tokens in each manuscript is essentially the collation phase of a traditional edition, but when we fully account for differences in punctuation, accent, abbreviation and spelling, the vast quantities of differences between manuscripts informs us about aspects of Byzantine orthographic practice that are normally suppressed in critical editions.

We next tokenize the same text to a normalized orthography eliminating punctuation, and adapting both accents and spelling to modern conventions. This comparison most closely approaches what we find in a typical critical edition (except that its listings of tokens present, absent or relocated in different manuscripts is comprehensive, rather than selective). Viewed from this perspective with orthographic differences removed, we find much greater agreement in the text of the Venice and Escorial manuscripts, although we still find passages like 8.137 where the reins of Nestor's chariot are either "shining" (σιγαλόεντα) or "red-purple" (φοινικόεντα).

This comparison also reports differences in passages like *Iliad* 9.3, where a few manuscripts have βεβλήατο against the majority with βεβολήατο. The "differences" are actually equivalent forms of the same verb (an epic pluperfect of βάλλω). Depending on our interests, we might prefer to view these two literal variants as identical. We next tokenize the text not to representations of the specific form found in the text, but instead to the lexical entity ("dictionary form") from which the word derives. In this tokenization, the same lexical entity is given for each of the two variant forms, and the lines are, by this reading, equivalent.

Since the formulaic variation illustrated by different readings for the same passage is metrically conditioned, we might also want to tokenize the text to metrical units. Like the preceding tokenizing to an abstract lexical entity, this is often considered beyond the scope of a critical edition, but we do not need to make any procedural distinction in our digital comparison. Reading the same line 9.3 metrically, for example, we next tokenize the dactylic hexameter into six metrical feet. In the majority manuscripts with βεβολήατο, we "read" the text with a dactyl in the third foot,

—∪ ∪ —— — ∪ ∪ — ∪ ∪ — ∪ ∪ —×

while in the minority manuscripts with βεβλήατο we read a spondee

— ∪ ∪ —— —— — ∪ ∪ — ∪ ∪ —×

Each of these comparisons captures a distinct feature of the text. In every case, the analyses are keyed to the CTS URN of the text they analyze, so we can readily combine and compare the results of distinct analyses. In the Iliadic examples, we could equally easily identify passages that are metrically identical with either different vocabulary items or different forms of the same vocabulary item; or, as in 9.3, metrically distinct passages with identical vocabulary in different forms.

Rethinking digital editions

We recognize, as others have before, that many assumptions in the traditional practice of critical editing are self-contradictory and unnecessary in a digital environment. Digital editors are not constrained to eliminate the evidence of manuscripts judged not valuable (*eliminatio codicum descriptorum*); they do not have to select only significant variants (*selectio*) based on the evaluation of a limited set of crucial passages (*examinatio locorum criticorum*); they do not have to present material supporting their editorial choices in a critical apparatus that is flawed both by its circular logic of selectively publishing evidence and by its notational deficiency (a deficiency that has been clearly recognized only when the apparatus is computationally processed).[5] One of the most significant consequences of working with scholarly editions in a digital environment is the potential to automate systematic and comprehensive comparisons of various classes of features across a set of full diplomatic editions.

The comparisons of Iliadic manuscripts presented here further show that the analysis underlying a traditional critical edition is functionally no different than any other kind of analytical comparison: critical editing is one approach to analyzing a comparable set of texts. Our model of textual comparison compels us to specify unambiguously the process that generates our sequence of lexical tokens. This permits us to apply completely generic tools for comparing ordered lists, and to construct increasingly complex cascades of aligned analyses.

Notes

[1] As early as 1934, Pasquali already pointed out that the necessary assumption of the "Lachmannian method" that each copy derives from a single archetype is demonstrably wrong in many instances (Pasquali, 1934).

[2] See for example the collection of essays edited by Sutherland and Deegan (Sutherland and Deegan, 2009), or the recent broad survey assembled by Pierazzo (Pierazzo, 2015).

[3] On CTS URNs, see http://cite-architecture.github.io/ctsurn/.

[4] https://en.wikipedia.org/wiki/Longest_common_subsequence_problem

[5] An important but largely unrecognized implication of Federico Boschetti's work parsing a critical apparatus of Aeschylus is that more than 10% of the entries in the critical apparatuis were not clearly enough expressed to be correctly mapped on to the section of the main text they annotate. This was not due to lack of diligence by the editors: rather, it reflects the notational ambiguity of the traditional apparatus. (Boschetti, 2007)

Evaluating GitHub as a Platform of Knowledge for the Humanities

Lisa Spiro
lisamspiro@gmail.com
Rice University, United States of America

Among the most popular platforms for digital humanities development projects is GitHub.[1] GitHub provides web-based hosting for coding and other collaborative projects, building on the Git version control system. Founded in 2008, GitHub now hosts approximately 31 million repositories and 12 million users, making it " the largest online storage space of collaborative works that exists in the world" (GitHub, 2016; Orsini, 2013). Using GitHub, developers can fork (copy) a public repository to their own account, change the code, and submit a pull request to share the modifications with the repository owner, who can then "merge" the code with the original. GitHub also enables users to create profiles, "follow" others, "star" projects and "watch" them evolve, serving as a social network for developers (Brown, 2014).

Digital humanities (DH) researchers are drawn by GitHub's support for version control and collaboration, as well as by its free hosting for publicly available projects. A range of digital humanities projects use GitHub, including: Software

- Writing projects
- Taxonomies and community documentation
- Websites
- Datasets
- Course materials
- Syllabi
- Research notes

What digital humanities researchers are adopting GitHub, and why? What are the benefits and risks of employing GitHub for digital humanities work?

Academia's growing reliance on GitHub requires careful consideration. As a for-profit company, GitHub does not necessarily operate with the interests of academics at heart. Yet it provides services that would be difficult for scholars to secure themselves, and it enables collaboration. To develop an informed view of GitHub and similar services, we need to establish clear criteria for evaluating platforms. In choosing a platform for a web project, Quinn Dombrowski recommends considering functionality, familiarity, community, support and cost (Dombrowski, 2013). We would add support for openness and sustainability as core criteria for digital humanities platforms.

Through an initial case study of GitHub, we will examine these criteria for evaluating DH platforms:

- **Functionality:** GitHub offers several features that make it attractive to researchers, particularly open science advocates. Karthik Ram suggests that Git (and by extension GitHub) supports open science by providing decentralized version control; attributing changes to authors; supporting distributed backup of data; enabling projects to branch in new directions; collecting feedback through issue trackers; and facilitating reuse through forking (Ram, 2013). Likewise, Konrad Lawson touts the power of GitHub in facilitating "collaboration without collaboration" (easily modifying someone else's code through forking, and contributing that code back through a pull request) and detailed credit for contributions (Lawson, 2013c; Lawson, 2013a). While GitHub can be used for a range of texts, from syllabi to code, it's not necessarily well suited for all uses. For example, Mark Sample notes the significant labor and potentially low rewards in putting syllabi into GitHub (Sample, 2012a). Lawson observes that using GitHub for writing projects requires overcoming a fairly steep learning curve, using plain text (or a converter), creating short documents, and dealing with limited support for non-textual files (Lawson, 2013d).
- **Familiarity/ease of use:** As Lincoln Mullen points out, GitHub's learning curve poses a barrier to entry for some potential collaborators (Mullen, 2012). Indeed, participants discussing how to make it easier for women to contribute to *Programming Historian* identified the publication's reliance on GitHub as an obstacle (Crymble et al, 2015). To what extent do the challenges of using GitHub limit its adoption in the humanities?
- **Community:** As more digital humanists adopt GitHub, it becomes even more attractive, since you are more likely to find collaborators and to gain recognition for your work. Yet the wide adoption of GitHub may reduce diversity and increase dependency on a commercial platform. Not everyone wants to participate in this community. Lawson points to several social and cultural obstacles to GitHub enabling richer academic collaboration, including reluctance to embrace "forking" as means of building on another's work; fears of plagiarism; concerns that the original voice of the author will be lost; anxiety that transparency will reveal one's scholarly flaws; and worry that ideas will be stolen or misused (Lawson, 2013b).
- **Support:** With such a large community, new users can turn to a number of resources to learn how to use GitHub. Some university IT groups offer limited support for GitHub, but in general users are left to secure their own support.
- **Cost/business model:** GitHub uses a "Freemium" business model in which it hosts public repositories for free and charges companies for private repositories (Brown, 2014). It also offers up to five free private repositories to academic researchers and twenty to research groups. While free holds appeal, should the digital humanities community be concerned about becoming dependent on a platform developed by a for-profit company? As Sample warns, "History suggests that relying too much on a commercial service with interests that do not neces-

sarily align with our own is no way to sustain the work of the humanities"(Sample, 2012b). GitHub has attracted $350 million in venture capital and is now valued at about $2 billion, so it faces pressure to generate a profit (Gage, 2015). Klint Finley argues that GitHub's business interests may work against its open source mission, pointing to SourceForge as an example of an open source software site that went astray (Finley, 2015). When SourceForge was acquired, it began to display junky third-party ads that misled people into downloading malicious software, prompting projects such as GIMP and VLC to leave. While GitHub is not funded through ad revenue, its business model could change under pressure from investors.

- **Support for openness:** Compared to some web platforms that claim user-produced content as their own, GitHub articulates an open approach to intellectual property: "Your profile and materials uploaded remain yours"(GitHub, 2015). But should we be concerned about clauses reserving the right to remove content and requiring users to defend and indemnify GitHub against suits alleging that their content violates the law? Does GitHub's model of providing free public repositories lead some users to share work that they otherwise would keep private?
- **Sustainability:** GitHub is not meant to be a preservation repository, and it is easy to delete a public repository (Bergman, 2012). However, Git's distributed, decentralized approach to versioning provides protection against data loss, since everyone who contributes to a GitHub project has a local copy of the code (Finley, 2015).

In addition to these criteria, we will also consider the significance of factors such as accessibility and multilingualism.

In performing this research, we are first identifying digital humanities users by 1) searching for publicly available GitHub accounts associated with presenters at the last three Digital Humanities conferences and 2) searching for GitHub accounts associated with Digital Humanities centers listed on CenterNet. To understand patterns of collaboration and code reuse, we will analyze publicly available statistics for selected users such as number of commits, branches, releases and contributors, as well as networks connecting users. We will survey GitHub DH users to understand how and why they use GitHub, its strengths, and its weaknesses. We will also conduct interviews with selected GitHub users. Where possible, we will use GitHub to share ongoing work about this project.[2] By analyzing public GitHub statistics and gathering insights and information from users, we will illustrate how GitHub is being used in the digital humanities community and develop principles for evaluating platforms.

This is an extension of our previous work in which a longitudinal (1989-2014) co-citation analysis of literature in Digital Humanities was (DH) conducted to explore the degree of interdisciplinarity in DH. The selection of the literature was based on a combination of keyword search with Scopus and articles published in the key journals in the field (i.e. journals published by members of ADHO). A dual trend of gradual increases in both topical diversity and network cohesion, two hallmarks of interdisciplinarity (Porter et.al., 2007; Rafols and Meyer 2010), were found in the co-citation network. For example, as shown in Figure 1, the average path length remained steady relative to the gradual increase of the network diameter, which suggests continuing growth of the literature and its gradual consolidation (the sharp rise at the tail being the artifact of citation window). On the other hand, the growing diversity was demonstrated by the steady increase of distinct author-assigned keywords over time.

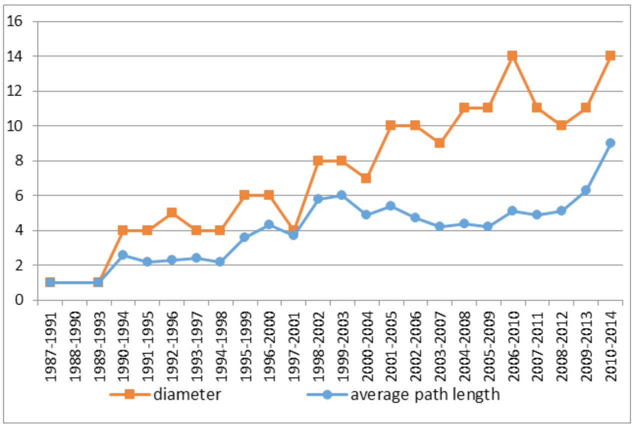

Figure 1. Growing of co-citation network and average path length

In this article, the results of further analyses were reported that aimed to, firstly, further explore of the issue of disciplinary cohesion using co-authorship and bibliographic coupling networks; and secondly, to identify cohesive subgroups or specialties in the DH literature.

Disciplinary cohesion of DH

Based on the assumption that the knowledge integration process in research communities depends heavily on the topology of the underlying social network, Moody used the structure of collaborative (i.e. co-authorship) network to represent the integration of knowledge in Sociology over time (Moody, 2004). The concept of "structure cohesion" or "connectivity" in network analysis was used to measure the degree of social cohesion in Sociology, which is defined as "the extent to which a network will remain connected when nodes are removed from the network (Moody and White, 2003)." Moody (2004) discussed three types of network structures: star production, small world, and structurally cohesive and surmised on the corresponding collaborative practices each represents. Moody (2004) believe that a cohesive collaboration network signals the presence of "permeable theoretical boundaries and generic methods" that allows scholars specialized in particular theoretical, empirical or theoretical skills to collaborate freely. He added that, if enough scholars engage in this kind of cross-fertilization, mixing across multiple areas, there will be few clear divisions presented in the collaborative network (Moody, 2004). Similarly, Carolan (2008) used network structure of articles published by a leading journal in Education to examine how well the heterogeneous set of ideas and practices were integrated within the discipline.

As shown in Figure 2, contrary to the co-citation network, the DH co-authorship network is very sparse and highly fragmented. The percentage of the nodes in the main component hovered only below 20% even after discounting the isolates, which is extremely low compared to other disciplines or research areas (See Table 1). Notice the contrast is especially striking with sciences, medicine, and IT. The low percentage of nodes in main component (Figure 2), coupled with extremely high clustering coefficient and modularity (Figure 3), indicated most collaboration took place at the local level, lacking global "shortcuts" found in the small-world model to hold the network together (See Figure 4).

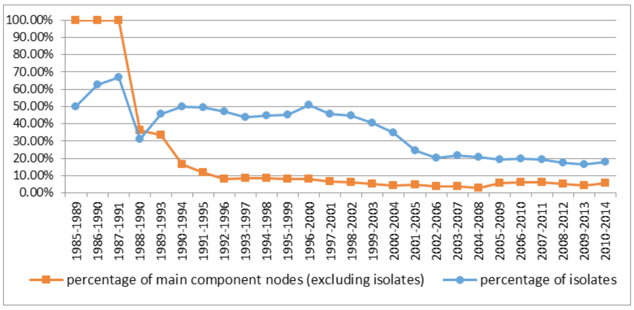

Figure 2. Percentage of nodes in the main component in the co-authorship network

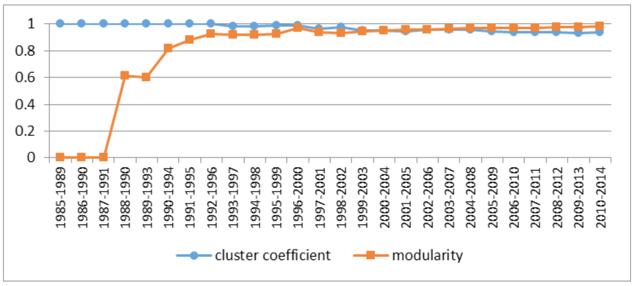

Figure 3. Trends of clustering coefficient and modularity in co-authorship

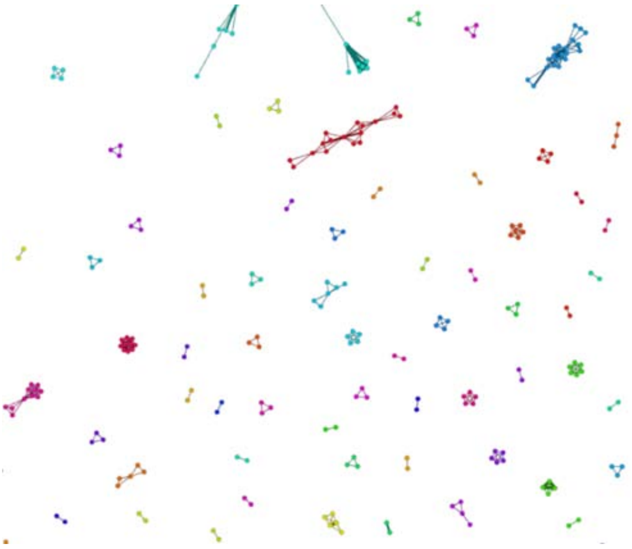

Figure 4. Part of the co-authorship network

A closer examination of the co-authorship network shows that, beyond the two largest components, there were relatively few international collaborations (See Figure 5). The largest component was composed of scholars mainly from the U.S. (28.53), Canada (27.12%), U.K. (26.84%), and Germany (10.45%); the second largest component was composed of scholars from the U.S. (39.71%), the Netherlands (30.88%), and Japan (5.88%); and the third component was composed of all Italian scholars.

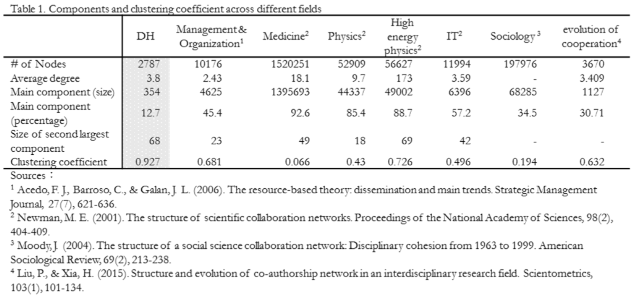

Table 1. Components and clustering coefficient across different fields

	DH	Management & Organization[1]	Medicine[2]	Physics[2]	High energy physics[2]	IT[2]	Sociology[3]	evolution of cooperation[4]
# of Nodes	2787	10176	1520251	52909	56627	11994	197976	3670
Average degree	3.8	2.43	18.1	9.7	173	3.59	-	3.409
Main component (size)	354	4625	1395693	44337	49002	6396	68285	1127
Main component (percentage)	12.7	45.4	92.6	85.4	88.7	57.2	34.5	30.71
Size of second largest component	68	23	49	18	69	42	-	-
Clustering coefficient	0.927	0.681	0.066	0.43	0.726	0.496	0.194	0.632

The identification of specialties in DH

Modularity maximization graph partition was applied to both the co-citation and bibliographic coupling networks to identify subgroups or specialties in DH. Both co-citation and bibliographic coupling have been widely used to establish similarity or linkages between documents in bibliometrics (See, for example, Yan and Ding, 2012; Boyack and Klavans, 2010).

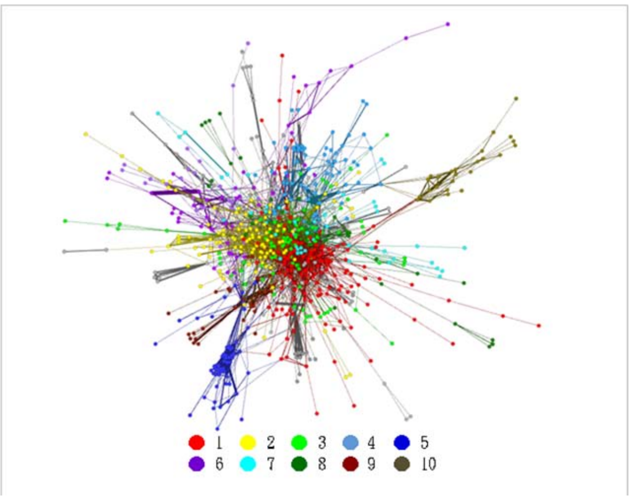

Figure 6. Modularity analysis of co-citation network

The co-citation network was construed by using Google Scholar's citation tracing function. The citations received by every article in our target set were first identified and downloaded then pair-wise matching was performed to identify shared citations. The bibliographic coupling was generated by pair-wise comparison of cited references retrieved from Scopus. A threshold of shared 3 citations in the reference lists was set to dichotomize the network. Figure 5 and 6 show the results of the modularity-based partition resulted from co-citation and bibliographic coupling networks, respectively. Due to the lack of global cohesion, only the giant component in either network was analyzed.

We are currently in the process of identifying the research topics represented by the clusters in either network, which will be done by examining the author-assigned keywords and authors appearing in each cluster. The labeling of the clusters by each's prominent authors has been shown to be an effective way of visualizing a field (e.g. White and McCain, 1998). Interviews with experts who have broad knowledge in the field of DH will be done in order to help us interpret the meaning of the clusters. Efforts will also be made to explore the reasons behind the lack of cohesion in the DH co-authorship network.

Computers on Law and Order

Jeff Thompson
mail@jeffreythompson.org
Stevens Institute of Technology, United States of America

Detailed accounts have been written of mainframes and cloud computing, social media and online commerce, but there are few books about the more humble aspects of technological culture. Screensavers, bubble-jet printers, computer desks, and other physical technologies are thrown in the trash or overwritten with new versions; the way we talk about computers, the "Web," and the ways technology shapes culture has changed considerably since the birth of the PC. This paper examines how we can find anthropological details about our relationship with technology through popular media, specifically the television program *Law and Order*.

In 2012, I was commissioned by the new media arts organization Rhizome to create a project recording every computer on *Law and Order*. After watching all 319 hours of the show (or the equivalent of about two straight months watching 40-hours a week) and extracting approximately 11,000 screenshots of computers and related technologies, it is clear that *Law and Order* forms a unique database of images and speech, and one that reflects the fascinations, fears, and biases of its time. *Law and Order's* long run and its "ripped from the headlines" content makes it a useful lens with which to look at a period of great political and economic change in the United States. In particular, the show coincides with a major cultural shift: the rise and eventual ubiquity of computers and networked technologies over a crucial 20-year period in technological history.

Using my *Computers on Law and Order* project as a case study, this paper focuses on how these kind of details that can be unearthed from popular media, and that in fact such sources may be the only way to recover the most mundane details. Through a series of categorized screenshots and quotations, I examine several pathways through the archive of the show: the physical infrastructure of computers from shared desktop terminals to smartphones, the development of software interfaces from often-faked text-only input to interactive graphical user interfaces, and peripherals such as mice and printers.

Introducing *thresholds*

handwritten sticky notes, highlighted document pages, and grainy photographs rub against one another, forming dense and shifting thickets. the blank spaces between once-distinct districts become cluttered and close. geographically distant realms ache to converge. the bookcase furiously semaphores toward the far corner of the room. thin lines of colored paper arrive to splay across sections. the wall bursts at every seam.

Whether it be real or virtual, every project has its own "wall": the irrepressibly interdisciplinary network that inspires and propels the work. Populating this capharnaum are the ideas, images, sentences, scenes, and characters that "stick to us," to use Lara Farina's evocative phrase (Farina, 2014). They are the "encounters" that Deleuze describes as the impetus toward work, the things that "strike" us, as Benjamin puts it, like a hammer to unknown inner chords (Deleuze, 1988; Benjamin, 1999). This affective principle of collection (what strikes you) means that the wall is an intensely personal artifact. Its unique architecture springs from a thinker's nomadic wanderings through and amidst a cultural and aesthetic landscape, whose dimensions are stretched beyond traditional disciplinary boundaries to include anything that clings to us, whether it be Werner Heisenberg's letters or an episode of *Breaking Bad*.

Although instrumental to every humanities project, the wall has a brutally short lifespan. The writer strives to reassert control over its borders and boundaries by whittling down its undisciplined excesses; indeed, training to be a scholar is in large part learning to compress and contain the wall's licentious sprawl. We shorten our focus to a single period, place, or author; excise those fragments that fall outside the increasingly narrow range of our "expertise"; and briskly sever any loose ends that refuse to be tied. These regulatory measures help align our work with the temporal, geographic, and aesthetic boundaries of our disciplinary arbiters: the journals and university presses that publish our work, the departments that hire and tenure us. In an increasingly tight academic marketplace, where the qualified scholars, articles, and projects far outnumber the available positions, deviation from the standard model can seem like risky business indeed.

Even as entrenched structures dictate compression and containment in scholarly writing, the open networks of the web have enabled a publication model based on public sharing and collaboration, spurring a turn to process across the humanities. It has become normal for scholars of all fields to share their incipient, in-progress research on blogs and wikis, and look to the comments sections for peer review. On a larger scale, these moves toward a collaborative process of knowledge-making are visible in the editing policies of Wikipedia; in Femtechnet's Distributed Open Content Course (DOCC), an open repository for course materials; and in new open access imprints like the Dead Letter Office of Punctum Books, which publishes abandoned scholarly projects (to name just a few examples among many). This turn to process has put pressure on the gatekeeping mechanisms described above, as many scholars yearn for a less rigid publishing model that foments the networked creativity of the wall.

Advocating for the transformative effect of a process-oriented model of digital publication, this short paper asks: how can digital humanities not only embrace process rhetorically, but in fact accrete tangible value to the more piecemeal, contingent aspects of knowledge creation? How can we make it the wall's scholarly sprawl "count" within systems that still rely on the trimmed and trussed-up products of research? How can we not only laud conceptually but help to build materially critical practices that eschew disciplinary (and disciplining) boundaries in favor of openings and traversals?

After a brief survey of existing digital journals and other publishing initiatives, including *Hyperrhiz*, Scalar, and Electric Press, we turn to our own incipient venture, titled *thresholds*. *thresholds* is a web-based digital publishing platform for creative scholarship, stitched together from existing digital humanities tools. By sketching the primary design features of *thresholds* – both their theoretical motivations and technical solutions, described in brief below – this short paper argues for a capacious digital publishing model that negotiates, without dissolving, the shifting edges between reading and writing, process and product, the fragment and the collective.

Design Features

The primary design feature of *thresholds* is the split screen. On the webpage's virtual verso are short critical essays that exceed disciplinary boundaries, whether it be in content, style, or approach. We solicit work that a traditional academic journal may deem unfinished, unseemly, or otherwise unbound, but which discovers precisely in its unboundedness new and oblique critical perspectives. Along with her essay, the author submits the textual, visual, and audible fragments that provoked and surreptitiously steered her work. These are published on the right side of the screen and scroll in tandem with the corresponding essay. These scraps are not explicitly harnessed to the work's main body, but instead lie beside it to create provocative juxtapositions; it is left to the reader to forge lines of connection between recto and verso.

Reinforcing its commitment to process and material form, *thresholds* further provides a digital toolkit for readerly making. These tools assign names and haptic functions to those critical traversals that a reader makes through and against a text. As the author's fragments scroll up the right-hand side of the screen, the reader can anchor a piece, holding it in place for future reference, or join one scrap to another to generate new patterns and co-movements. She can also import new material, either by copying text over from the essay on the verso or by composing additional fragments that leak new texts, artists, or ideas into the system. At the end of any given reading session, then, the reader will have generated her own "wall," plucking, amassing, and recomposing the author's fragments to create her own annotative assemblage.

At any time, the reader can capture and conserve the "constellation" that she has produced—that is, the current arrangement of the fragments that she has chosen to lock and join together. Although every user has access to the same firmament of texts that cycle through *thresholds*, each constellation will be singular; their unique spatial architecture will attest to the creative and critical value in visualizing the relations between fragments and texts, readers and authors, and readers and texts. Readers who choose to publically share their work will be able to see how their own creation fits into a galaxy of all other users' constellations, mapping their own choices against that of a collective readership. By enabling the reader to place herself in relation to both the author's text *and* all other readers of the site, *thresholds* models criticism as an intimate yet communal activity that inheres in the delicate links we build in the spaces between each other, as much as between the texts themselves.

To ensure that this intervention is not only conceptually provocative but also formally useful, *thresholds* endows each fragment with a flexible markup language. Readers can download their constellations, receiving a file listing all texts, objects, and art cited therein. This file can then be imported into citation software or shared with others. This underlying information architecture, not immediately present to visitors but baked into the structure of the site, plugs the swirl of scraps that make up any given constellation into the existing citational infrastructure of the humanities. In so doing, it allows *thresholds* to negotiate the gap between that which is in-progress and incomplete within our reading practices—the stray underline, the forgotten marginal note—and more formalized and prescriptive methods for incorporating others' work into our own. There is a place, *thresholds* implicitly argues, for the fragmentary in our collecting and collective practices; for the wall's sprawl within the more regimented systems that order our work.

Adding Semantics To Comics Using A Crowdsourcing Approach

Mihnea Tufis
mihnea.tufis@gmail.com
Pierre and Marie Curie University, Paris 6 (UPMC), France

Introduction

With over 85 million print units sold in 2014 for the top 300 comic book titles only, the comics industry is reaching a new high for the first time since 2007 (before the economical crisis). And this doesn't include the increasingly popular graphic novels or the increasingly more accessible digital comics. The resurgence of comics and the establishment of the graphic novel as a literary genre prompted Humanities scholars to turn their attention on comics as a medium. In this paper, we address the difficulty of creating a digitized corpus by using a crowdsourced approach for annotating comic books. The resulting XML-based encodings could assist not only researchers, but publishers and collection curators equally.

Motivation

Our approach should provide Digital Humanities (DH) scholars with a (currently missing) structured, annotated corpus; this should enable or speed up research related to the comics and sequential art theory: identifying the rhythm of the narration based on the shape, size or number of panels and its relation to the depicted action, investigations about the style of comics authors, historical periods, cultural movements etc.

Curators and collectors (professional or amateur) of physical or online comics collections would be provided with a structured content which could be more easily integrated within their collections or databases. This may assist them into enlarging public or private databases of characters or comics series and enable the creation of artefacts such as comic books dictionaries, search indices and dictionaries of onomatopoeia. A certain number of projects are already in place and could greatly benefit from the creation of comic books annotations. We mention here the Grand Comics Database[1] (an online database of printed comics), Comic Book Database[2], Digital Comics Museum[3] (a collection of scanned public domain comics from the Golden Age) or the Catalogue of the *Cité Internationale de la Bande Dessinée et de l'Image*[4] from Angoulême.

From a publishing perspective, current standard specifications related to digital comics, such as EPUB's Region Based Navigation (Conboy et al., 2014) and Metadata Structural Vocabulary for Comics (Ichikawa et al., 2014) are taking care exclusively of the presentation layer (i.e. rendering a publication on a screen device). But the artistic nature of comics and the great potential digital comics have already showcased allow us to go beyond simple content presentation. We believe that the data we are collecting will allow publishers and digital comics authors to create better, enhanced content and in the end a superior reading experience.

Crowdsourcing Annotations for Comics

Participants to our crowdsourcing experiment (Azavea, 2014; Sharma, 2010) are digital comics readers. Previous research has identified expertise sharing, belonging to a community and helping with a research project as strong motivating factors for crowdsourcing participants (Dunn et al., 2012). In addition, our industrial partner will incentivize participants with product vouchers for their platform[5].

The tasks we propose are organized around a set of questions regarding a series of comics-related topics (Eisner, 1985; Ichikawa et al., 2014) on which computer algorithms are not performing well enough: complex page layouts, identification of narration elements (characters, places, events, objects), stylistic elements (balloon shapes, onomatopoeia, movement lines).

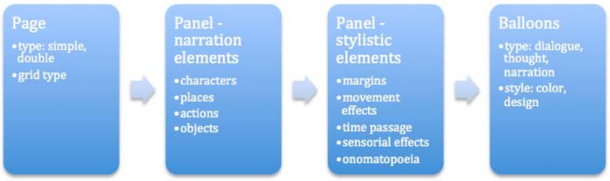

Figure 1. The 4 key annotation themes

We aggregate the answers (Feng et al., 2014; Snow et al., 2008) taking into account the reliability of an annotator in a given context (task difficulty, user experience with the task, type of question) and the agreement between the annotators (Nowak et al., 2010). A quality score is thus generated for each annotation, with the best of them being selected as solutions.

We subsequently are able to generate the ComicsML encodings (Walsh, 2012). This XML derived format is particularly useful since it's based on the already widespread Text Encoding Initiative (TEI), allowing for declarations of page structure and composition, panels, characters, text (in all the varieties hosted by the comics medium: different types of balloons, diegetic text, onomatopoeia), events and even panel-to-panel transitions.

Page structure

The annotators are presented with a simple interface (Fig. 2) in which they will have to make a choice between a set of suggested grid layouts. These layouts are the output of applying the automatic frame extraction algorithm developed by (Rigaud et al., 2011). Alternatively, for complex page layouts, they will be asked to draw the page layout themselves.

Character identification

At this step, we ask the "crowd" to simply enumerate all the characters they can identify in the current page. Characters are identified by reading their names in the text, recognising them from experience or simply giving a general statement about the character (e.g., " *masked man*" may be referring to *Batman*). Using state of the art symbolic learning algorithms we fusion generic and specific information (e.g. if *Batman* and "*masked man*" both have high quality scores in the same context, they will both denote the same concept and will be considered as valid annotations).

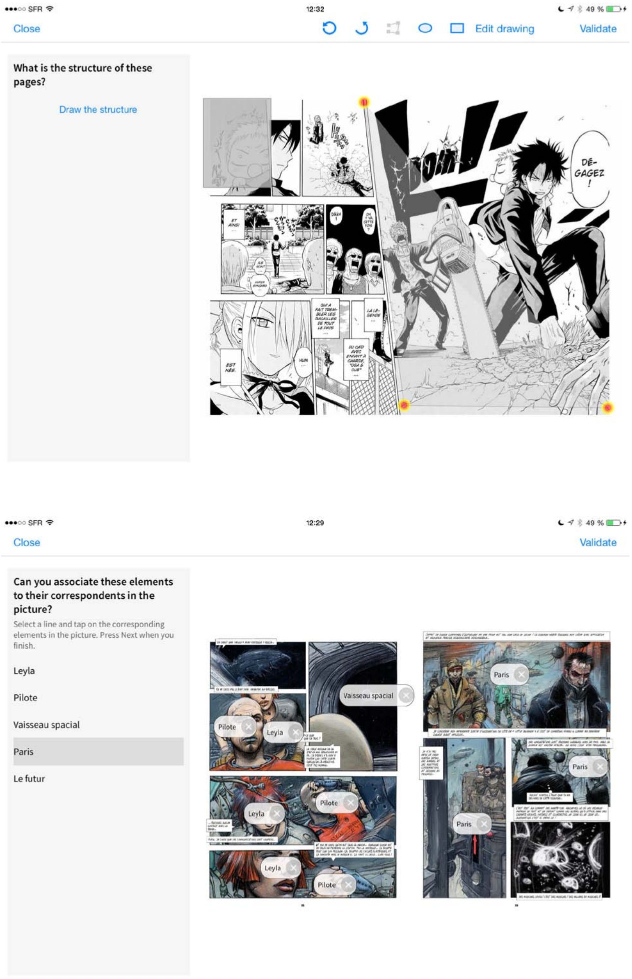
Places identification

We ask the annotators to simply enumerate all the places they can recognise on the current page. We are particularly looking for named places (e.g., *Gotham City, NY, planet Mars*), but will also ask the annotator to mark any generic place that he might consider important for the scenes in the page (e.g., “ *the interior of a bank*“ [in case of a robbery], “*inside a space ship*” [in case of a battle in space]). These are exactly the kind of very specific annotation tasks for which state of the art image recognition algorithms are expected to fail.

Events identification

This is yet another highly specific recognition task. Annotators are asked to describe the most important events occurring in the page. The solutions generated at this step, together with the annotations obtained in the previous steps will be used to further build the ComicsML encoding of the page.

Comics scholar Scott McCloud stresses the role of elipsis (“the blood in the gutters“ – the space between two panels) as an artistic mean for authors to engage their readers, and describes a typology of these transition spaces (McCloud, 1993). ComicsML allows us to declare such transitions through the #ana attribute of the cbml:panel element, giving us the possibility to investigate their use and their distribution across different cultural spaces (France/Belgium, Japan/Korea, USA).



What is the structure of these pages?

Can you associate these elements to their correspondents in the picture?

Select a line and tap on the corresponding elements in the picture. Press Next when you finish.

Figure 2. Annotation interface (drawing page structure-left, narration elements-right)

Non-visual cues

Comics are a special medium, making use of the visual to depict all other non-visual senses, with the help of different drawing “tricks”, such as:

- Smoke coming out of a cigarette may engage the reader’s smelling sense
- Onomatopoeia form a particular language of their own; comics and especially manga authors have proven great creativity when it comes to expressing different sounds via stylised text (e.g., “ *POW!*” – punch, “ *BAM!*” – gunshot)
- Horizontal lines around a car suggest the car is moving at high speed, while around a ball, they express the ball’s movement.

Researchers could study, for instance, the drawing style of an author and his use of non-visual cues, and go as far as creating onomatopoeia dictionaries for comics (to our knowledge, such dictionaries already exist for manga, but not for American nor European comics).

At the end of this stage, we should be able to generate a reasonably complete ComicsML encoding of the current page (see Fig. 3).

```
<cbml:panel
    n="2"
    characters="#pilot #leyla"
    ana="#subject-to-subject"
    xml:id="case_002"
    xmlns:cbml="http://www.cbml.org/ns/1.0">
        <cbml:balloon xml:id="boule_002" type="speech" who="#pilot">
            You should reconsider. Look above!
        </cbml:balloon>
        <cbml:balloon type="speech" who="#leyla">
            What is this thing?
        </cbml:balloon>
</cbml:panel>
```

Figure 3. A fragment of the ComicsML encoding for the page presented above

Conclusions

We have presented the outline of our crowdsourced annotation system for comics, as well as details of how we have designed our tasks, having in mind three main aspects: the limits of current digital comic book formats, the specifications behind the ComicsML metadata schema and theoretical principles of comics as a medium (Eisner, 1985). Last, we have presented the way in which the collected results are merged into the final ComicsML encoding and have briefly discussed some potential applications.

Mapping Multilingual Responses To Famine And Dearth In The Early Modern Landscapes Of India And Britain

Charlotte Tupman
c.tupman2@exeter.ac.uk
University of Exeter, United Kingdom

Richard Holding
r.j.holding@exeter.ac.uk
University of Exeter, United Kingdom

Hannah Petrie
h.petrie@exeter.ac.uk
University of Exeter, United Kingdom

Gary Stringer
g.b.stringer@exeter.ac.uk
University of Exeter, United Kingdom

Famine, as John Walter writes, was "…a recurring reality and ever-present fear" in the early modern period (Walter, 2015). The AHRC-funded project *Famine and Dearth in India and Britain, 1550-1800: Connected Cultural Histories of Food Security* (http://humanities.exeter.ac.uk/english/research/projects/famine/) examines the practices, discourses and literary modes through which societies in early modern India and Britain articulated their concerns about the availability and distribution of food (Mukherjee, 2014). A collaboration between the University of Exeter and Jadavpur University, Calcutta, the project draws upon a large body of texts written in languages including English, Latin, Persian, Bengali and Hindi for evidence about cultural responses to landscapes of famine and dearth. Its aim is to produce a digital resource that includes encoded extracts from the source materials and maps that reflect the variety and scope of identified responses to the landscapes encountered in the sources.

The application of digital methods to large corpora of thematic texts presents both opportunities and challenges, which will be examined in this work-in-progress paper. The dataset is highly diverse, not only in terms of the languages in which these texts are written but also in the types of documents that form our body of evidence. The source materials include chronicle histories, gazetteers, official correspondence, legislation, pamphlets, periodicals, plays, poetry, surveys and prose (fiction and non-fiction), and the project will publish excerpts from each of these categories. Our markup priorities (beyond the basic structure of the document) lie in how to encode the many themes surrounding famine and dearth that are present in our texts, which we need to extract in order to address the research questions of the project. We can use natural language processing tools to help us identify names and places, for instance (at least for some of the languages), but the range of terms used in these texts to describe the features of the landscape, the people, and the food situation are extremely varied. Inevitably there are also subtleties in the ways in which particular concepts are represented in the various languages of our source materials, as well as added complications such as variant spellings. The project uses the open source software GATE (General Architecture for Text Engineering, http://gate.ac.uk/) to identify names and places in the texts written in English, and we would like to apply a similar process to the texts written in other languages. It is likely that we will create some of the gazetteers from scratch, in which case we would aim to make these available as part of the project's outputs.

One of the most interesting challenges is in how to map the resulting data meaningfully. Exploring responses to landscapes of scarcity is a key research question of the project, and descriptions of such responses feature very heavily in some of our texts, particularly in the travel writings (see McRae, 2009 for a discussion of some of themes in travel writing of this period). The works of Peter Mundy, for instance, are full of rich descriptions of the places he visited, including very personal observations of the circumstances in which he found himself (Carnac Temple, 1914; Pritchard, 2011). We are particularly keen to place our work in the context of some of the projects that have taken place during the last decade on mapping emotional responses to landscapes at other periods and in different geographical areas. While many of the recent projects on emotional cartography use wearable technologies to measure and record responses to the landscape, such as Christian Nold's 2006 Greenwich Emotion Map (an art project combining annotations with measurements of skin responses at different stages of a walk through the Greenwich area of London: http://www.emotionmap.net/background.htm), we see potential in learning from, and building upon, their approaches to visualising the resulting data (Nold, 2009). Projects such as Kurt Jensen's representation of Sterne's *A Sentimental Journey*, built using Neatline (http://neatline.org/), have also suggested possible directions for representing some of the travel writings (http://enec3120.neatline-uva.org/neatline/show/a-sentimental-journey), and our recent workshop on food security has helped to clarify the relevant user requirements (http://foodsecurity.exeter.ac.uk/). However the question of how to integrate such a wide variety of sources and languages into useful and meaningful maps remains one of the most interesting and challenging aspects of the project. As such, it will be a key focus of our paper, and we anticipate that presenting the results of our experiments with this data could be helpful for other projects that are grappling with similar issues, potentially in very different subject areas.

A lesson in applied minimalism: adopting the TEI processing model

Magdalena Turska
tuurma@gmail.com
University of Oxford, United Kingdom

James Cummings
james.cummings@it.ox.ac.uk
University of Oxford, United Kingdom

The Guidelines of the Text Encoding Initiative Consortium (TEI) have been used throughout numerous disciplines producing huge numbers of TEI collections. These digital texts are most often transformed for display as websites and camera-ready copies. TEI Simple (Rahtz et al, 2014) project was the first one to propose more prescriptive approach providing the baseline rules of processing TEI into various publication formats, while offering the possibility of building customized processing models within the same infrastructure. For the first time in history of TEI there exists a sound recommendation for default processing scheme, which significantly lowers the barriers for entry-level TEI users and enables better integration with editing and publication tools. The TEI Simple project was a Mellon-funded collaboration between the TEI Consortium, Northwestern University, the University of Nebraska at Lincoln, and the University of Oxford.

The new (on track for acceptance by early 2016) TEI method for documenting processing models gives editors and TEI customisers a method for high level recording of processing intentions in a machine-processable but implementation agnostic manner. Nevertheless, the processing model is a new proposal and needs to be extensively tested before announcing it a success. As the TEI Technical Council works to integrate the TEI processing model extensions created by the TEI Simple project, we endeavour to employ it on real world projects, both of which have been running for a significant number of years and have already produced vast collections of material: historical documents of the US Department of State, Office of Historian (http://history.state.gov/) and the corpus of Ioannes Dantiscus' correspondence (http://dantiscus.al.uw.edu.pl/). The Office of the Historian publishes a large collection of archival documents of state, especially those appartaining to foreign relations. The Dantiscus project spans over ten thousand original sources from the early sixteenth century including correspondence, poetry, and diplomatic documents. This makes it a good test case for implementation of the TEI Processing Model because it is far beyond the scope of the original TEI Simple sample collections. Having the material previously published with custom-built XQuery/XSLT packages means that we are in a position to compare the results of using an approach based on the processing model with the previous one in terms of the quality and consistency of final presentation but also in more quantitative ways like the size of necessary code base, development time and ease of the long-term maintenance.

The first challenge is, obviously, rephrasing the transformations previously formulated in XQuery/XSLT using ODD meta-language extensions proposed by TEI Simple project. Preliminary results are very encouraging even though, as expected, it became necessary to extend the behaviours library to accommodate some specific needs. From the developer's perspective it is immediately clear that using the TEI processing model brings substantial advantages in development time and results in much leaner and cleaner code to maintain. For the Office of Historian project figures suggest code reduction by at least two-thirds in size. Numbers are even more impressive realizing that the resulting ODD file is not only smaller, but much less dense, consisting mostly of formulaic <model> expressions that make it easier to read, understand and maintain, even by less skilled developers.

To a lesser extent, but it is still interesting to see if, thanks to the additional layer of abstraction that processing model brings to the table, the editors can become more independent from developers in tweaking the processing rules. This heavily depends on the personal predilections of the editor, but again, in cases where editors are already deeply involved in the decisions about encoding on the level of XML markup and do have some fluency in XPath and/or CSS our results show that it is perfectly reasonable to expect them to tailor the existing high-level processing models to fit their specific needs in a majority of cases. We will also investigate the effect of incorporating the Processing Model into eXist-db native database and application framework (Meier et al, 2016) environment in terms of easening the learning curve, for the non-technical users in particular.

The processing model at the time of writing this paper proposal is not a mature technology yet, in the sense that it still lacks the critical mass of its practitioners as well as formal acceptance by the TEI Technical Council (although this will have been integrated into the TEI infrastructure by the time of DH2016). This presentation aims to present both challenges and open questions as well as already demonstrated advantages of applying this technology. It will draw on the evidence from early adopters available by the time of DH2016. It is not only the quantitative measures of improvements in technical implementations that will be reported on, but the variation in methodologies employed by the test projects and others.

Exploring Networks Of Confidentiality And Secrecy In Early Modern Transconfessional Correspondences

Ingeborg van Vugt
ingeborgvanvugt@hotmail.com
Scuola Normale Superiore di Pisa, Italy

With this contribution, I would like to discuss how multi-layered visualizations of epistolary networks can contribute to a better understanding of the circulation of illegal literature and confidential ideas between Catholic Tuscany and the Calvinist Dutch Republic. It questions how intellectual exchanges between these two regions maintained a balance between, on the one hand, the necessity to distribute (prohibited) books and to express controversial ideas and, on the other, social control and the need to avoid the objections of powerful political and religious institutions and individuals. This comparative analysis allows for a sharper focus on the differences and similarities on how intellectuals capitalized on opportunities in the social and religious structures to which they were connected. Indeed, they had to deal with the many tensions between the oppressive catholic environment of the court of Cosimo III and the Dutch Republic, already well known for its relative tolerance and freedom of printing (e.g. Touber, 2014).

These personal and societal conflicts forced scholars and booksellers to take strategic measures of secrecy and confidentiality, which in turn depended on what Mauelshagen (2003) also called "networks of trust". If we pose the question how epistolary networks evolved, understanding changing relationships between people, one might provide insights into aspects of confidentiality. For instance, as relationships grew friendlier, correspondence grew in confidence and trust, while on the other hand one did not correspond with adversaries (Heuvel, et al. 2014). Other examples include studies of Lux and Cook (1998), who claimed that the success of the Dutch Republic depended on what Granovetter (1973) also called "weak ties" instead of central hubs. This implies the importance of intermediaries between communities for the faster distribution of ideas: if you have a particularly close friend from another community, you are more likely to introduce him to your other close friends whom you know that will trust you (Barabási, 2009: 55).

If we wish to verify these statements and to understand how intellectuals were able to overcome these confessional and social barriers, the analysis of multi-layered networks of correspondences provides a very interesting addition to archival research. Or in other words, the combination of methods for network analysis for distant reading of large sets of letters with close reading devoted to detect the role of secrecy and confidentiality in epistolary exchanges strengthens historical research. This means that qualitative analysis will uncover how social relations are represented and constructed, sometimes reinforced and sometimes transformed, which is enriched by traditional hermeneutic methods to focus on specific religious and personal features that have influenced those dynamics.

It is important to consider that full data integration, in particular when dealing with early modern letters, is impossible for reasons of incompleteness, complexity and uncertainty in data. Therefore the focus should not be on analytical and statistical methods of network representations alone, but on approaches that allows us to handle, inquire and interpret these complex historical data. We do not need just networks as static representations, but also networks as interactive interfaces (Heuvel, et al. 2016). To this end, the software tool Nodegoat is used to bring together, explore and contextualise these epistolary exchanges. Nodegoat, differently from network visual-analytical tools such as Gephi, is built around data entry, management and curation processes (http://mnn.nodegoat.net/viewer). It enables us to explore and to combine historical networks in various configurations, involving a diverse set of actors. This means that not only persons (scholars and booksellers) constitute relationships but also textual objects, like books with their dedicatees and introduction letters. For instance, the overlay of networks highlights those artefacts that played an important role in the establishment of contacts. If we look at their intersection with their function in the network, new opportunities may rise about how to link book dedications to strategies adopted by scholars. The importance of textual objects as participants in networks has also been stressed by Latour (2005). From the correspondence of the Florentine librarian Antonio Magliabechi, for example, it turned out that the Dutch microbiologist Antoni van Leeuwenhoek (1632–1723) chose to dedicate his work the *Arcana Naturae Detecta* to Magliabechi. By using this strategy, Leeuwenhoek was able to benefit from Magliabechi's extensive network for the distribution of his work in Italy. Overlaying different networks sheds light on the role of the *Arcana* in the network of Magliabechi (fig. 1 and 2). For instance, the image illustrates those correspondences in which Magliabechi mentioned the publication of Leeuwenhoek, showing in this way the diffusion of his publication over time.

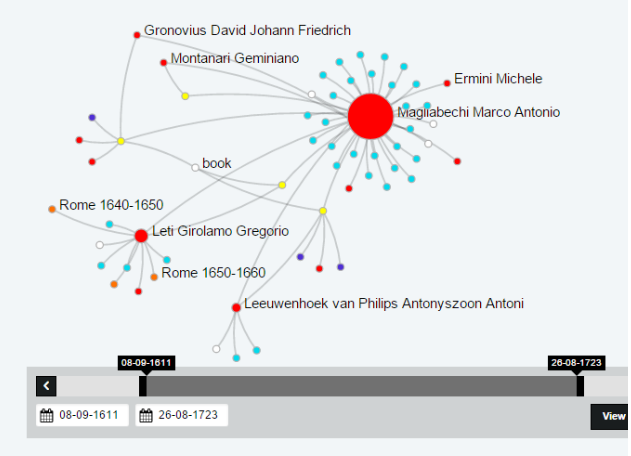

Fig. 1 A visualization of networks around the *Arcana Naturae Detecta* of Leeuwenhoek (the right yellow node) and Magliabechi. Magliabechi, at the centre of this visualisation, is surrounded by other dedicatees (represented in red), their accompanying books (yellow) and the letters in which the *Arcana* is mentioned (light blue). Hovering over the nodes and ties opens an overview with the different connections, and specifies the nature of the relationships (see fig. 2)

Moreover, the analysis of relationships between people can provide insight between direct and indirect transfer of confidentiality via intermediaries. In the Mapping Notes and Nodes in Networks project (Álvarez and Heuvel, 2014) it appeared that the overlay of more networks shed light on the evolution of co-citation networks and introduction networks. As correspondents entered networks of epistolary exchange, they did so not in some ideal egalitarian society, where anyone could join simply by writing a letter, but in a world regulated by social norms and rules of etiquette. In short, letters of introduction were often necessary to be admitted into an epistolary network. Following the evolution of introduction letters alongside a citation network and determine whether a shift takes place in the number of intermediates between correspondents (revealing shrinking degrees of separation), could reveal the importance of introductions in the establishment of epistolary networks.

Fig. 2 Overview of the *Arcana Naturae Detecta*, linked to the Short Title Catalogue of the National Library of the Netherlands (KB)

Furthermore, Nodegoat is used to bring and contextualise epistolary networks by means of data integration from various data resources such as the Short Title Catalogue Netherlands (STCN) and archival research from archives in the Netherlands and in Italy. The STCN has been queried in order to disambiguate objects and to enhance the interoperability of my data. For example, information on books in epistolary networks can be linked directly to the STCN, which allows me to map the unstructured data in the letters (as titles are often mentioned incomplete) to structured data.

Using Big Cultural Data To Understand Diversity And Reciprocity In The Global Flow Of Contemporary Cinema

This paper explores the relationships between countries in the exchange of movies and measures the reciprocal nature of these relationships. This investigation represents an innovative way to explore international exchanges of digital cultural content based on global cinema screenings analysed at the national level. Rather than focus on the market dominance of particular cinemas (e.g. the US or Indian cinemas) we examine the relative strength of two-way relationships in order to understand cultural reciprocity in the film industry. The dynamics of shared cultural exchange are explored in terms of the volume of transactions between ‘cinema nations’ expressed in the form of dyadic networks.

The paper is based on the premise that films can be understood as cultural goods that are distributed both between 'territories' or markets and across the globe according to industrially unique spatial patterns and temporal flows. Seeing film diffusion in this way invites us to explore the industrial aspects of movement and location but it also invites reflection on our use of these large datasets. For example, understanding the dynamics of global film exhibition and distribution demands an appreciation of scale and velocity in both the film industry and in a data-driven approach to its study. Data-driven approaches to Cinema Studies are at best an emergent aspect of the discipline (Verhoeven). This paper makes a significant contribution to the development of Cinema Studies by extending a trans-disciplinary, digital humanities approach to critically understanding the dimensions of a global creative industry at scale.

Digitisation and globalisation are full of contradictions in terms of how they impact diversity of screen culture represented by film. On one hand digitisation has facilitated an explosion in the number of films being made and that can be distributed and viewed online. This has had the effect of increasing the diversity of films available to audiences with digital access over the web. On the other hand however, only a relatively small proportion of films produced are released widely into cinemas. This paper seeks to provide insight into diversity at cinema locations that extends beyond the obvious dominance of Hollywood blockbusters. We are interested in drawing attention to equitable reciprocal exchange relationships that exist between nations, even where these may be small in scale, as evidence of alternative practices in the promotion of diversity at the cinema. This enables us to explore relational geographies using dyads in an approach similar to that of Taylor, Hoyler, Pain and Vincigurrra (2013) in their investigation of the connectivity between cities in the services sector. We use dyadic analysis to explore an equitable exchange in film that extends beyond the unilateral to ensure cultural exchange between two nations is assessed as a two-way flow where cultural content from both sides to the dyadic relationships are valued and accounted for.

The data used in this paper is drawn from the Kinomatics Global Showtime dataset (Kinomatics, 2015) which comprises over 330 million individual records of film screenings from across 31,500 venues covering 47 countries, including the US, India, most of Western Europe, Japan, Brazil and Australia for the years 2013 – mid-2015 (see Arrowsmith et al). For this analysis, the kinomatics data is analysed using a variety of methods that draw from a range of disciplinary perspectives including the digital humanities and economics as well as geospatial and computational sciences. Our key tool is Principal Components Analysis that explores dyadic relationships as part of Social Network Analysis (see: Wasserman and Faust, 1999). We apply this approach to 'nations' as they are defined by the kinomatics (cinema screening data aggregated at the national level) and imdb (film production aggregated at the national level) datasources. Further to this, in a selection of countries, we employ a Herfindahl-Hirschman Index (HHI) to consider case study analysis of cultural diversity based on cinema screen count data. We use spatio-temporal visualisations as a way to represent the results and propose insights into the relational geographies of film flow and exchange that are found to exist.

Using dyads to explore international exchanges between nations we are able to consider diversity in relation to films screened at the cinema in terms of the two key dimensions stemming from globalised relations between nations, namely in terms of intensive and extensive international exchanges. The intensive dimension aids understanding of the most important national dyads that dominate cinema screenings that can be seen as the core centres of the globalised market for film, while the extensive dimension is focused upon the multitude of links between nations in a broader globalised market for film screened at the cinema. The analysis of dyadic relationships enables us to move beyond the assumption that the flow of cinema is simply unilateral. Instead we are concerned with the relative strength of exchanges in which a strong reciprocal dyadic relationship is one that has an equal exchange between two nodes, in this case, countries.

In considering diversity using the HHI we focus on the screening of new release features within the case studies of Australia, France and the Republic of Korea in order to analyse the relationship between cinema venue location (capital cities versus regional), venue type (in terms of the number of screens) and film programming allocations between domestic, US and other imported feature films. We find that as an increasing number of films are being released, non-US derived films are struggling in a tight contest for screen time.

"Digital" in practice: survey of Russian historians' research practices

Andrei Volodin
volodin@hist.msu.ru
Moscow State University, Russian Federation

Realm of Digital history

"Digital history" became a professional realm, because new ways to store, process, and study information entered the everyday historical research practices in Russia (Rosenzweig, 2010). Obviously, the "digitization" introduces new approach to the craft of the historian, when digitization became the indispensable stage of many studies (Volodin, 2015). Interdisciplinary framework of "digital history" is often placed in the context of a broader movement of the "digital humanities" (Schreibman et al., 2004; Schreibman et al., 2016). However, it should be emphasized that historical research has lots of specific features, and "digital turn" makes a significant impact on the research practices (Weller, 2013).

Historical research is a kind of reconstruction of the past on the basis of the extant monuments and documents, "remains" and "legends". This reconstruction is based on three pillars: heuristics, criticism and interpretation. These basic practices today meet the challenges of the "digital age". It's important to mention that the "digital turn" in the profession of historical research was one of the four main themes of the International Congress of Historical Sciences in 2015. It seems that time has come to investigate the specificity of research practices and digital tools for professional historians.

Survey of "digital" in practice

The research is based on questionnaires and interviews of historians in Russia in 2015 and 2016 (178 respondents). In questionnaires and interviews I tried to ask not only "geeks" among historians, but also "pure" historians whom "digital turn" also touched (cf.: DARIAH Survey, 2015; Schreibman and Hanlon, 2010; Trinkle, 1999). First questions ask respondents to name main "digital practices" that they consider important. Such start helps to create "folksonomy" of practices and tools that historians define for themselves as "digital" (e.g. it's not obvious whether text-editing is considered as digital practice, or email as research tool?). Then I started to ask questions about different fields of digital practices as we hypothetically classified in several groups: access, digitization, editing, mark-up, visualization, modeling/simulation, and others. Each group (or type of practice) includes different techniques and tools. We define techniques as more general term to call research procedure, when tools are linked to particular software or platform.

History in the "digital turn"

The instancy of the research is associated with a new stage in the development of information and digital technologies in history. "Digitizing" is not just a technical procedure now, but it becomes a preparation for further computerized analysis of historical sources, using different tools for visualization and analysis of historical information.

The "digital turn" in history requires a monographic study as well as a full systematization of historians' research practices. We don't know any systematic attempt to generalize the results achieved by "digital history". This research project is designed to systematize the research practices (both visualization and analysis of historical data). This study tries to "catch" the development of contemporary digital practices, and we hope to make classification that will summarize achievement in the field of "digital history". Summarizing the answers, it's possible to draw several valid observations: one insight and three dichotomies.

Insight: Digital is "Invisible"

It looks that a prediction which was vividly pronounced in "A New Companion to the Digital Humanities" that "a decade or two from now, the modifier "digital" will have come to seem pleonastic when applied to the humanities" is much closer. Most of answers were concerned with some concrete experience of usage of digital tools, mentioning that they are so "natural" or "spontaneous". The time has come when historians are really in the majority of cases are so-called "digital natives" (even if not in age, but at heart).

The usual remark on state-of-art in historical digital practices was that so-called new ICT (Information and communications technology) became usual, familiar, and mostly routine ICT. The increase of computing power broadens digital practices form tables and databases to full-text search in enormous online collections, and then to visualizations from GIS to 3D (cf.: Gregory, 2014).

Heuristics dichotomy: Analog versus Digital

Digital in Russian literally means numeric (like chiffre or numerique in French, or Zíffern in German) without any link to fingers, but strongly connected to quantitative research and computing. That's why for main historians "digital history" strongly refers to quantitative history or cliometrics. History as one of "traditionally print-based disciplines" (Hayles, 2012, 1) is deeply connected to studies of analog primary sources. This dichotomy has two implications: on the one hand, historians usually see no principle differences between analog original and digital copy, but, on the other hands, they mainly prefer to study analog archives, because it shows their professional skills of access to rare documents.

Criticism dichotomy: Capta versus Data

The “digitization” became the usual and common practice of collecting information. But it's important to mention that for many respondents digitization is almost the same practice as “writing out” or “making notes”, not planning the future possibilities of processing this “capta”.

Distinction between “capta” and “data” in digital history became indicative. If capta is “taken” actively while data is assumed to be a “given” (Drucker, 2011), in digital history capta explains the “catch” of the researcher in terms of his/her sampling of primary sources as well as a critical attitude to the choice of the sources.

Interpretation dichotomy: Close versus Distant

The distinction between “close reading” and “distant reading” came to digital history from computer linguistics (Moretti). This dichotomy explains the conscious choice between brains or processors in solving different research problems. And main present question (or prospect) is that to what extent main practices of history can be robotized? This vision of the future is usually mixed with vague hope that at least interpretation will remain in the researches’ hands and heads. It also brings up an issue of possibilities of digital infrastructure for analytical level.

The aim of the lasting research of digital practices is to create a list of solutions and techniques developed in real research practice, and thus to disseminate such solutions among historians and researchers of the past. The classifier of digital methods and tools will help to choose the most appropriate solution for particular research aims.

Akademie der Wissenschaften und der Literatur | Mainz, Germany

Launched in 2013, the project *The School of Salamanca. A Digital Collection of Sources and a Dictionary of its Juridical-political Language* is establishing a collection of more than a hundred sources from Iberian theologians and jurists of the 16th and 17th century. These texts deal with political and juridical topics and the collection of sources is supplemented by a dictionary that comprises, next to biographical information on the authors of the sources, the development of central terms and ideas of the Western history of political and legal ideas, as it is reflected in the source texts.

Both parts, the sources and the dictionary, will be published under Open Access conditions. In the beginning of 2016, the project’s web application will be launched online with the first batch of sources and dictionary entries as TEI-XML texts plus corresponding facsimile images. At the moment, we are running a proof-of-concept mechanism and some experiments, which at the time of release will be constituting a Linked Open Data interface to our data along with a SPARQL-Endpoint.

At the beginning of the presentation the project’s rationale and web application will be introduced shortly. But the focus of the presentation will be on giving insights in the workflow, the decision making process and the implementation of the LOD mechanisms, that have been realized:

1. The first aspect accentuated in the presentation is the modelling of the information contained in our TEI-XML data within a Linked-Data-environment: Which TEI elements or attributes are assigned to which objects and predicates of which ontology? How are these assignments processed in order to offer the data as semantic data? Problems that we are dealing with are the questions of how to record the temporal dimension of much biographical information (see Ramos, 2009; Mynarz, 2013), and how to cope with alternative values like e.g. conflicting data about the date of birth of a person? Do considerations such as these affect our main objectives, e.g. the TEI-scheme or the collection of data?

Here is what has been settled up to now: We will offer semantic data about the sources and about the authors of the collection. The ontologies we use are mainly the foaf-, bio-, relationship-, and SPAR-ontologies (see, among others, Peroni, 2014). The TEI-data will be transformed into RDF by the xtriples webservice (Schrade, 2015).

2. The second highlighted aspect concerns the very networking of the data itself and its utilization in the project's infrastructure. This concerns technical issues, such as the questions of which services and resources should be – directly or indirectly – provided in order to offer our data for external reuse? It concerns issues of academic strategies such as negotiations with favored partner projects and data providers over the data they expose and the interfaces they provide. But it also concerns scholarly questions, such as eventual opportunities to handle new research questions, or to handle questions in new ways, opened up by the integration of our data with the data of other LOD-providers. In which form could or should such expanded possibilities be provided on the publicly accessible website? What stance are we taking on rights management and quality insurance of federated queries/data?

Again, here is the current status: We have mechanisms for the resolution of resource URIs, for content negotiation and for dumping the complete triple store as well as a SPARQL endpoint in place. We are elaborating federated queries responding to specific, concrete research questions. And we are still in the process of evaluating the Linked Data Fragments (Verborgh, 2014) mechanism. We are in contact with several projects the data of which would nicely complement our own (Schmutz, 2008; Sytsma, 2010; Bullón, 2012; Mrozik, 2016). And we are probing possibilities of offering a configurable interface to (federated) querying to our users and of rendering network information visually in our web application. Except most likely for the last point (due to time constraints), the talk will present the state of affairs we will have achieved in summer 2016.

The presentation will thus point out conceptions and their implementations of linking TEI resources into the semantic web, difficulties encountered and needs still left open by scholarly research questions.

Preserving Ireland's Digital Cultural Identity towards 2116

Digital Repository of Ireland

1 Introduction

The Digital Repository of Ireland (DRI) is a national Trusted Digital Repository for Ireland's social and cultural data, accredited by the Data Seal of Approval. The repository links together and preserves historical and contemporary data held by Irish institutions, providing a central internet access point and interactive multimedia tools. In June 2015, the Digital Repository of Ireland was publicly launched at the *Digital Preservation for the Arts, Social Sciences and Humanities* (DPASSH) conference. At this conference, three organisations were presented with the DRI 'Decade of Centenaries Digital Preservation Award', the culmination of a six month project aiming to provide support and training to owners of digital collections relating to the Irish decade of centenaries commemorations. This paper will discuss the implementation of this Irish Research Council-funded project which allowed staff from the DRI to engage with collection owners and provide digital preservation and digitisation services and training. In this paper we outline the aims of the project, the methods by which we engaged with relevant collection owners, and how our findings have helped to determine the status of digital preservation in Irish heritage organisations.

2 Background

In June 2015, the first DPASSH conference was hosted in Dublin by the DRI, to highlight the technical, cultural, and social problems, challenges, and opportunities of long-term digital preservation in the arts, social sciences and humanities. The conference theme, 'Shaping our Legacy: Safeguarding the Social and Cultural Record', was developed to reflect concerns within the community that digital cultural heritage is at risk of destruction. The conference's call described the destruction of the Irish Public Records Office (IPRO) in 1922 during the Battle of Dublin. As the Irish Civil War broke out, a priceless archive containing a thousand years of Irish history was destroyed.

The destruction of the IPRO was used as an analogy to highlight the vulnerability and fragility our digital cultural heritage in the long-term. The challenge, however, is that "long-term", in this context, comes nowhere near the thousand years of history housed in the purpose-built store of the IPRO; as Jeff Rothenberg (1999) states, 'digital information lasts forever—or five years, whichever comes first.'[1]

It is within this context that we sought expressions of interest from custodians of heritage material relating to the Decade of Centenaries (DC) who wished to digitally preserve their holdings. Funded by the Irish Research Council's New Foundations Award, we aimed to assess the scale of vulnerable digitised collections related to the DC in Ireland, to provide support in digitally preserving those collections, and to create a centralised access point to encourage their wide dissemination. Importantly, we wanted to raise awareness of the issues related to digital preservation and provide resources, best practice advice and guidance to all applicants. We also planned to have an impact on the community beyond the span of the funded project, providing equipment and training to continue to support the digital preservation of Irish cultural heritage.

3 Methodology

Our call for expressions of interest was announced in December 2014 and was circulated by the DRI community. The call sought collections that were partially or fully digitised and described, and which contributed to the national narrative on the period 1912-22. The winners were offered resources to ensure the digital preservation of their collections, including staff time from professional archivists and librarians, digitisation services, metadata creation, and the ingestion of content into the DRI for long term preservation.

Interested collection owners were invited to submit a detailed application form, providing information on the types of digital assets in their collection, the volume, current storage provisions, and its connection to the DC.

Eight proposals were received, and through the collection assessment and selection phase, three were chosen: the Irish Capuchin Provincial Archives (The Capuchins and the Irish Revolution),[1] the Dublin City Archives (Dublin City Electoral Lists, 1915),[2] and the National Irish Visual Arts Library (Michael Healy Collection).[3]

Our assessment procedure enhanced our understanding of the types of relevant digital assets held nationally, and gave us insight into the challenges faced by collection owners in ensuring that their content is digitally preserved.

The second phase of implementation included a scoping exercise and requirements analysis for each collection, the creation of a project plan and allocation of resources. Requirements gathering was conducted through interviews with collection owners, undertaken by the DRI's Requirements Manager and a Digital Archivist or Librarian in all cases. Work plans were created with tasks including digitisation, metadata creation and standardisation, ingest preparation and collection creation, review and publication. We worked closely with each collection owner to ensure that the processes and workflows we created could be repeated, and that these were reflected in our existing guidelines.

Following the completion of the work plans, a digital preservation workshop was held at the Royal Irish Academy to ensure that collection owners were trained in the procedures required to prepare their content for ingestion into the DRI Repository - all applicants to the original call were invited.

4 Findings

From the initial submissions to the call for expressions of interest, it was clear that there is a need in the community, not only for preservation services, support and advice, but also for digitisation support. Digitisation services were requested by nearly all of the applicants, and in some cases digital preservation was not included in the application. It appears that Irish archives lack resources (i.e. staff time and equipment) for digitising their collections. While perhaps not surprising, the technical infrastructure required to provide robust digital preservation was also not available to any of the participants. This confirms the need for shared infrastructures, or indeed shared strategies on preservation, on a national level.

Regarding the three selected collections, it was found that while metadata standards had been applied, they were in some cases customised according to the needs of the collection owner. Furthermore, although ISAD(G) compliant descriptions had been used by two collection owners, these could not be exported from the cataloguing software as EAD-XML, and needed to be manually marked up using an XML editor. These limitations create a barrier to metadata exchange and indicate that some archives are not planning for interoperability with other collections and/or repositories. While this was indicated in our 2012 report, Digital Archiving in Ireland, this project highlighted the practical difficulties involved in overcoming these barriers to interoperability.[2]

The DRI guidelines and workflows were tested by the process of preparing content for preservation in the Repository and found to be comprehensive and robust. However, the underlying knowledge in the community regarding standardised metadata creation and the principles of digital preservation was not well developed. The preservation workshop held at the RIA was booked to capacity with a waiting list, and training in basic digital preservation and metadata preparation was identified as a requirement for our stakeholder community.

5 Conclusion

The award has allowed the DRI to engage with a number of new stakeholder organisations who had not previously undertaken any digital preservation processes for their collections. Through the award, and the subsequent preservation workshop, the team worked with seven organisations who had not previously deposited content with the Repository. As well as providing training to allow participants to deposit with DRI, advice was also provided on smaller scale, in-house preservation practice which participants could bring back to their organisations.

The DRI believe that digital heritage is at risk of destruction and loss if action is not taken. Digital decay is the gradual decay of digital content. The solution is digital preservation – active ongoing data management. Long-term digital preservation is concerned with providing sustained access to digital objects and content and requires that institutions are cognisant of the processes and procedures required to ensure the form, as well as functionality, of digital objects.

DRI actively engaged with our designated community and have sought participation throughout our phases of development - from our requirements analysis phase, through to user acceptance testing and content population. Therefore, while the DC call provided an opportunity to preserve and publish content it also provided a platform from which to engage with an important national programme of events, communicate with a wider audience and test our user guidelines and documentation. Crucially, it also emphasised the fact that long-term preservation is a socio-technical problem - the solution requires not just digital infrastructures but advocacy, industry and societal engagement, and cooperation with content owners.

In addition to the practical aspect of this work we wanted to highlight the need for the national programme of commemorations to be cognisant that digital collections or projects created now, should be considered as historical artefacts for future historians. That is, our current digital commemorations should be preserved for future use and analysis. Commemorative events (both online and offline) are performative acts of nationalism and are an integral part of how we understand both our current and future selves. Current national projects should consider how they are preserving Ireland's digital cultural identity for 2116.

Acknowledgements

We acknowledge the support of the Irish Research Council's New Foundations Programme.

Faceting and Mining Network Graphs

Claude Willan
cwillan@princeton.edu
Princeton, United States of America

The network graph is one of the best-known and overdetermined of all data visualizations. And it suffers, more than most such modes, from the problem of fetishization. When non-specialists see network graphs, which are information-heavy, aesthetically appealing, cognitively suggestive, and yet curiously hard to read, their first reactions are often along the lines of "Oh wow!", "Cool!", or "Neat!". The corollary to admiration, for members of the academy, however, is often distrust.

The problem is two-fold. Critical thinkers are justly skeptical of enthusiasm, since enthusiasm can foreclose critical engagement. But the network graph's prominence as a mode of data visualization, as featured in new outlets like the New York Times, or in prominent projects like Mapping the Republic of Letters or Six Degrees of Francis Bacon , makes it uniquely vulnerable to the hermeneutic of suspicion (see Elijah Meeks, "The Digital Humanities as Lightning Rod"). If the digital humanities are still distrusted in some more conservative corners of the academy — such as mine, eighteenth century english literary manuscript studies — then network graphs, because they have become synecdochic for digital humanities writ large, are doubly distrusted.

This short paper addresses three states of addressing this skepticism head-on, embedding network graph literacy in the context of a larger disciplinary argument. Those three stages correspond to three key perspectives practitioners of network analysis can assume when wanting to persuade skeptics of the probative value of network graphs, to show how condign those graphs are to traditional "analogue" analysis, and to build a persuasive argument within your own field.

Those three perspectives are: targeted data gathering; graph design, and argument design.

Much of my own work centers on networks of distribution of Jacobite manuscript poetry from 1688 — 1750. Once I knew that I would be using network graphs to illustrate the richness of the social and material facts I had uncovered, I started enriching my dataset with an eye to encoding metadata to reveal those richnesses as precisely as possible. Those metadata categories include size of manuscript, number of copies of each poem in circulation, names of manuscript collectors, languages contained in each manuscript, dates of manuscript, and so on. I entered this metadata on each future node in my two sets of network graphs (one of individual poems, one of manuscripts).

Graph design, the next stage, was just as important. Having settled on a layout in Gephi that I felt reliably showed relations among objects in a way that I knew I could explain simply (such as proximity as a function of similarity; distance as an index of relative dis-similarity) I then worked to combat the visual fetish character of the network graph by partitioning the nodes multiple times while keeping them within the same layout. This meant that one my audience had had time to accustom themselves to the layout, successive graphs with differing color schemes, node sizes, and edge weights would show them the facets, the richness, of the dataset. By showing the same graph layout faceted in multiple different ways, my audience could comprehend the layout as a function of multiple and overlapping functions.

Argument design, the last stage, is a way of making the procession of network graphs an intuitive progression of visual arguments that draws the audience into, and educates them about, the rhetoric of the network graph precisely by showing its malleability and, in some ways, its very partiality. By showing the protean capacities of the network graph, by showing the extent to which each network graph is itself a reading, skeptics more at home with paleography and stemmatology are able to grasp quite intuitively the resource that is faceted network graph: a flexible and powerful tool to show the richness and interrelatedness of large datasets based on archival discoveries very like their own.

This short paper will include slides of my own faceted network graphs to show how we can use this form of argumentation as a kind of nested pedagogy.

I enclose here a collection of faceted and mined network graphs made for a colleague's project on Modernist journals. These bimodal graphs show the interrelation of different contributors to various roughly contemporary journals. By showing the same layout several times, but using node color, node size, edge weight and color, we are able to see:

- which nodes are journalists and which are journals;
- nodes clustered with a granularity of 1.0 (fewest communities of the largest size);
- nodes clustered with a granularity of 0.23 (many smaller communities);
- which journalists contributed the most (edge weight), which journals had the most contributors (node redness and size), and
- which journalists contributed to the most journals (by node size).

These five network graphs taken together not only supply a much richer picture of the system of writing and publication than a single graph would; by showing the range of information that can be displayed on that graph with a series of simple adjustments, the reader is shown how the graph is a product not of vulgar scientism but of intentional humanism.

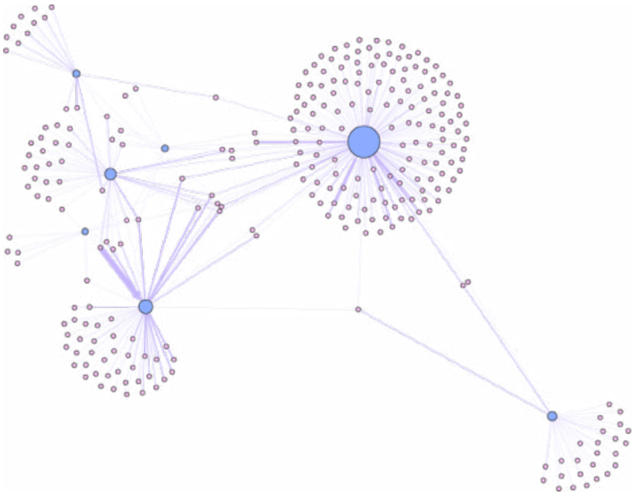

Illustration 1: Lilac nodes are journalists; blue are journals

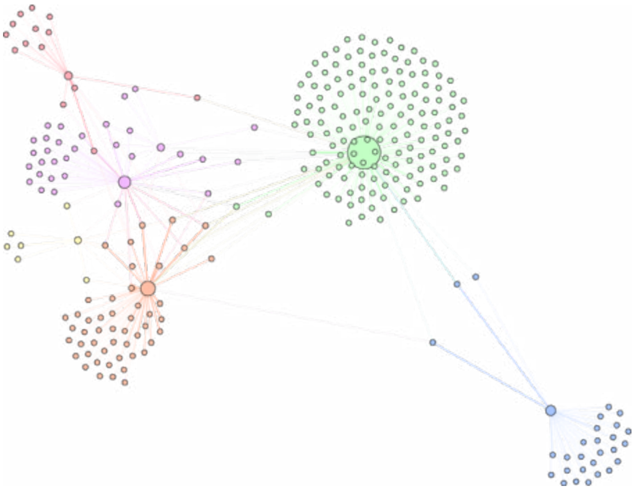

Illustration 2: Modularity at granularity 1.0; the fewest communities of the largest size.

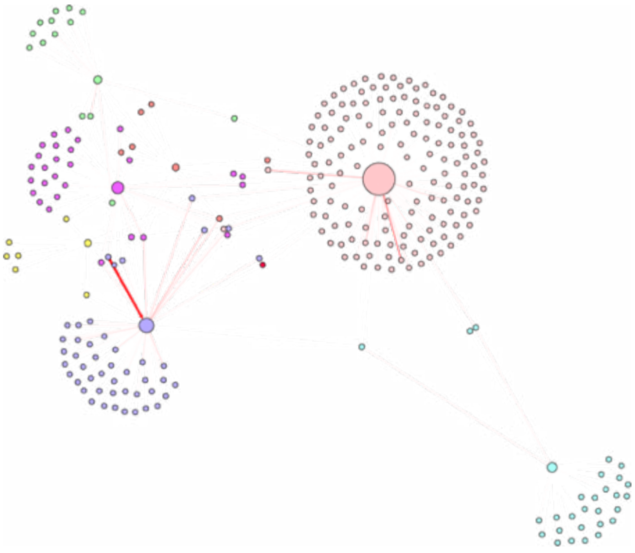

Illustration 3: Modularity class 0.23; more communities of a smaller size.

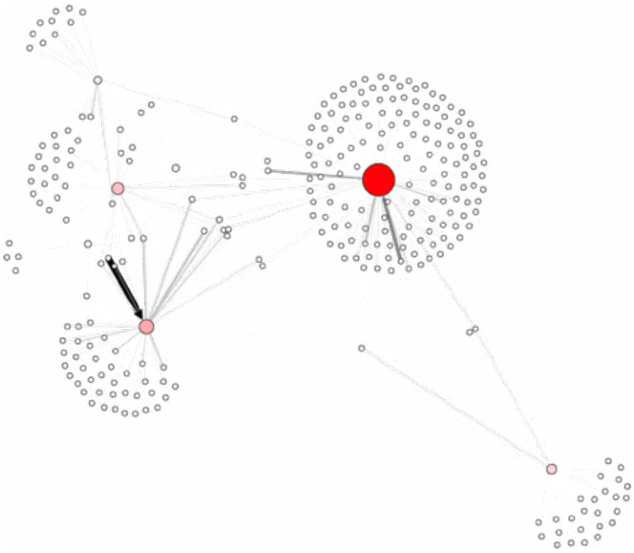

Illustration 4: Edge weight shows number of of contributions by a journalist; node redness and size indicates number of contributors.

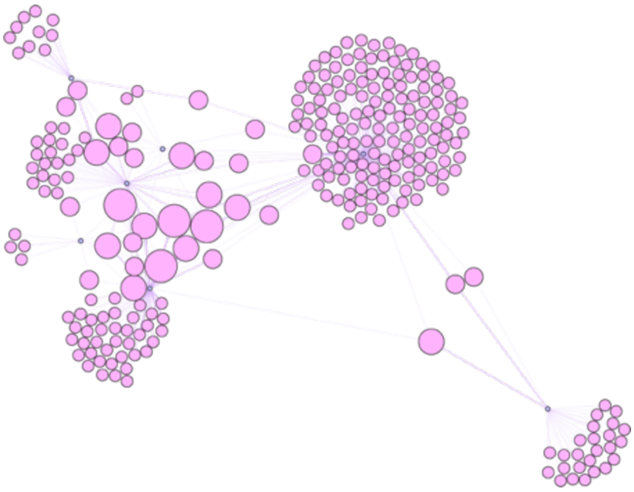

Illustration 5: Node size indicates number of journals to which a journalist contributed.

Tackling Terms In Furetiere's 'Dictionnaire Universel'

Geoffrey Clive Williams
williams@univ-ubs.fr
Université Grenoble Alpes, France

First published posthumously in 1690, Furetière's *Dictionnaire Universel* had aroused controversy well before its publication. Nevertheless, it was quickly followed by an enlarged and corrected version edited by the protestant scholar Henri Basnage de Beauval. It is this extended version of 1701, with its broad coverage of terminological language that is our subject.

The Furetière project seeks to render the entire 1701 dictionary available as an open access digital resource in an XML-TEI compliant format. Given the size of the task, and the current total lack of finding with little hope in the short term, the first stage will be an attempt to map and describe terminological coverage by reference to a small number of themes, namely architectural, legal and maritime terminology. This paper will demonstrate the mapping procedure being carried out using the Atlas Ti Computer-Assisted Qualitative Data Analysis Software (CAQDAS) and the building of a model for the TEI encoding.

Historical background

Furetière was both a member of the French Academy and participant in the dictionary building team, hence the uproar at his publishing what was seen as a rival dictionary. This explains why a Catholic priest should end up being published by the protestant publisher in the Netherlands, Arnaud Leers. The dictionary was a success, but still needed much revising. This was carried out by the French émigré and scholar, Henri Basnage de Beauval. Despite being the most complete edition, only one attempt at digitising was ever made (Wionet and Tutin, 2001). Our aim is to encode the Basnage dictionary but with cross references to the edition of 1690 and the publication of Corneille (1694) so as to see how the terminological entries evolved and to what extent complementary information can be found in the Corneille dictionary (Williams, Forthcoming).

Using CAQDAS

One important task for the Digital Humanities community will be to bring or adapt existing tools to disciplines that are often less digitally aware. Thus, in using a CAQDAS tool to explore the three dictionaries, we aim not only to use a very powerful tool to allow pre-digitising analysis and mapping of data, but also to bring this technology into the sphere of literary analysis.

CAQDAS were essentially created to meet the needs of sociologists carrying out rigorous qualitative analyses on data from multiple supports. Literary specialists also carry out qualitative analyses, but often tend to use highlighters to work on printouts of PDFs. By using a CAQDAS to work through a document as big and as complex as the Furetière's dictionary, we aim to show how an electronic highlighter that allows coding and network analyses can be used in humanities research, and particularly in our own.

There are a number of commercial CAQDAS on the market, and only one open-source tool. Although open-source tools are important to the community, we have adopted Atlas Ti as being a very powerful tool that is evolving rapidly with new functions.

The 1701 Basnage edition is over 4000 pages of very tight text. Text quality is poor which precludes use of OCR. Whilst it is structured, we are in a period of great experimentation in dictionary compilation leading to a complex meta and microstructure. The only way forward is to read the text. Using Atlas Ti, we skim the pages so as to locate and code entries designated as terms, to find the different introductory formulae, as well as spotting potential search formulae for unmarked terms, and to list the domains and crafts to which they belong. The coding system allows us to carry out a bottom-up conceptualisation of the dictionary with the quotations allowing us to create a headword list that links directly to the entries in the PDF file. Knowing the terminological domains covered by the dictionary is interesting in itself, but it also gives further keys for reaching unmarked terms. Networks allow us to reorganise domains and crafts into groups, such as legal terminology – represented by several domain names-and maritime terminology, which is often closely linked to language of fortification, architecture and law. Atlas Ti allow to output data in a machine-readable format so that the headword list could be transformed as an organised lexicon for use in the XML encoding process.

XML TEI

Use of Atlas Ti as an electronic highlighter with all its coding and management functions does permit a full qualitative analysis of the data. However, it is still not possible to share the data itself. Digitising the entire dictionary is a mammoth task that is only feasible using crowd sourcing over a long period of time. Marking up only thematically designated terminological domains allows us to create and test a model for the data as well as making available machine readable data rapidly. The dictionary is unique in having definitions accompanied by lengthy examples and citations thus providing both technical and phraseological information that will only be retrievable using in-depth mark-up. Whereas Wionet and Tutin (op.cit) marked up one letter, our plan is to attempt to follow the terminology through the entire dictionary.

The first stage consists of marking up terms from a small number of highly productive thematic fields isolated using the CAQDAS analysis. The first field to be explored in depth is related to maritime activities as designated by 'terme de marine' (maritime term) so as to open a collaboration with French historians so as to compare an élite vision of naval terminology as compared by the situation in a major naval port, that of Lorient which founded in 1666 by the Compagnie des Indes, and then became a major naval base from 1703.

Our aim is to illustrate the decisions taken and how these affect output through visualisation, but also analysis using linguistic analysis tools as TXM and a database system as BaseX. Once more advanced, the data will be put online using a query interface. At the moment, we are sharing code on GitHub under the name Basnage.

Mark-up is being carried out using Oxygen so as to mark-up using the TEI guidelines and use XQuery to ensure consistency. Entries can be extremely complex, as will be illustrated by reference to the verb *Abatre*. This means that the TEI guidelines do not always adapt easily to what is found in the text. However, we are endeavouring not to customise the guidelines so as to retain full compatibility with other dictionaries and allow easier linking with source texts.

The dictionary tends to group words orthographically so that there is a main headword in large capitals, which also carried the grammatical information, but then a series of subentries that generally have the headword in small capitals. These subentries may include the specialised terminological usage. To complicate affairs, polysemy is illustrated within an entry with short comments and examples. To handle this, we are using <superEntry> to group the whole, and then <entry> for what might be considered as subentries. <Sense> is used to cover polysemy within a given entry. The main entry for ABATRE has three main senses illustrated by a series of synonyms, with each sense accompanied by numerous examples, and occasionally a citation with bibliographic reference. The examples frequently contain collocations that activate a particular synonym, it would be useful to mark-up and illustrate this. Similarly, citations generally only give a link to a person, often via an abbreviated name, as in MEN for Ménage or ABL for M. d'Ablancourt. These are generally listed at the beginning of the dictionary, but it is not always the case and sometimes the abbreviations are inconsistent. Sometimes, even if a text is not named, it is possible to link to a source document. Given that Basnage was a prolific letter writer at the centre of network of European scholars, and the author of the *Histoire des Ouvrages des Savants*, and important task will be to cross link to this valuable source of information.

Collocation mark-up means that we can link dictionary analysis to words in a wider context as fund in Frantext or, when a text has already been digitising by using a language analytical tool as TXM. Mark-up also aims to make an onomosiological analysis possible using BaseX rather than simply presenting the data in a linear semasiological format.

Conclusion

This is a mammoth mark-up task which we believe is rendered easier by mixing tools so as to permit on-going analysis whilst gradually digitising the whole into XML compliant TEI. This strategy means that other scholars can use data without having to wait for the entire digitalisation process to be completed. In so doing, we seek to explore data whilst collaborating in the dissemination and improvement of digital tools and also a contribution to the art of digital mark-up of early dictionaries.

Digitale Tools und Methoden für die geisteswissenschaftliche Forschung praxisnah erklärt: Ein neues Format im Test.

Tanja Wissik
tanja.wissik@oeaw.ac.at
Austrian Academy of Sciences, Austria

Claudia Resch
claudia.resch@oeaw.ac.at
Austrian Academy of Sciences, Austria

Aufgrund der technischen Entwicklungen in den letzten Jahrzehnten sind GeisteswissenschaftlerInnen in ihrem Forschungsalltag vor neue Herausforderungen gestellt. Während es für den wissenschaftlichen Nachwuchs in Österreich eine Reihe von curricularen Angeboten sowie Summer Schools im Bereich der Digitalen Geisteswissenschaften gibt[1], sind erfahrene Forschende meist auf sich gestellt, wenn es darum geht, sich forschungsrelevante ICT-Kompetenzen für individuelle Fragestellungen anzueignen: Gemäß der von DARIAH[2] initiierten Umfrage (Schneider / Scholger in Druck) im Jahr 2014/2015 gaben mehr als 50 Prozent der befragten Forschenden in Österreich an, dass Weiterbildungsangebote zum Thema DH-Methoden und Werkzeuge und wie diese ihre eigene Forschung verbessern könnten und tendenziell wichtig oder sehr wichtig für ihre Arbeit wären.

Das Austrian Centre of Digital Humanities (ACDH) an der Österreichischen Akademie der Wissenschaften sieht es als eine seiner Aufgaben, DH-Inhalte und -kompetenzen zu vermitteln und die Forschenden dabei zu unterstützen, das Potenzial digitaler Methoden und Werkzeuge für ihre konkreten Forschungsprojekte zu nützen. Aus diesem Grund werden am ACDH unterschiedliche Formate der Wissensweitergabe erprobt und evaluiert. In unserem Kurzvortrag stellen wir eines dieser Formate, die ACDH Tool Gallery[3], als Fallstudie vor und berichten über deren Konzeption und Etablierung als außeruniversitäres Weiterbildungsangebot.

Anders als in herkömmlichen Vortragsreihen, in denen praktischen Aspekten weniger Bedeutung zugemessen wird, stellt die ACDH Tool Gallery das Experimentieren mit eigenen Daten in den Mittelpunkt. Das Konzept der ACDH Tool Gallery besteht darin, zwei Gruppen von Expertinnen und Experten zusammenzubringen: einerseits jene, die sich mit der Entwicklung von Tools beschäftigen und diese bereitstellen, und andererseits jene, die in ihrer geisteswissenschaftlichen Fachdisziplin ausgewiesen sind, und diese Tools in Zukunft verwenden möchten. Bei der Auswahl der Kurzreferate am Vormittag wird diesem Konzept insofern Rechnung getragen, als dass sowohl IT-ExpertInnen als auch GeisteswissenschaftlerInnen, die diese Tools bereits für ihre Forschung einsetzen, als Vortragende eingeladen werden. Die eintägigen Veranstaltungen sind jeweils einem Themenkomplex gewidmet: Die Tools, die am Vormittag in Einführungsvorträgen und Präsentationen vorgestellt werden, können nachmittags von den TeilnehmerInnen erprobt werden, indem diese Schritt für Schritt von der Installation bis zur Anwendung begleitet werden. Idealerweise hat jeder der TeilnehmerInnen ein eigenes, individuelles Set an Daten am Laptop vorbereitet, an dem die Tools getestet werden. Mit der Teilnahme an der Veranstaltung kann eine Kursbestätigung erworben werden.

Die ACDH Tool Gallery versteht sich als Angebot für EinsteigerInnen im Bereich der Digital Humanities und vermittelt einen Überblick sowohl zu bewährten als auch zu neuesten Tools, die zur Verfügung gestellt werden. Im Vordergrund steht der Austausch zwischen AnbieterInnen und potentiellen AnwenderInnen: Gemeinsam kann eine Einschätzung darüber erfolgen, ob und inwieweit ein jeweiliges Tool zur Beantwortung individueller Forschungsanliegen geeignet ist. Ausreichend Zeit zur (spontanen) Diskussion ist die Voraussetzung zum Gelingen dieses innovativen Formats.

Die Zielgruppe sind ForscherInnen aller geisteswissenschaftlichen Disziplinen sowie zum Teil MitarbeiterInnen von wissenschaftlichen Einrichtungen wie Bibliotheken und Archiven. Die ACDH Tool Gallery ist ein unentgeltliches Angebot, das sich nicht nur an ForscherInnen der Österreichischen Akademie der Wissenschaften richtet, sondern allen Interessierten offensteht. Damit dieses Format gelingt, braucht es intensive Vorbereitung auf allen Seiten: 1. liegt es an den TeilnehmerInnen zu überlegen, an welchen Daten sie das jeweilige Tool zu testen beabsichtigen; 2. leisten die Tool ExpertInnenen Vorarbeit, indem sie einen Zugang zu ihren Tools schaffen; und 3. gibt das ACDH die konzeptionellen und organisatorischen Rahmenbedingungen für dieses Format vor. Da es sich um ein neues Angebot handelt, wird die ACDH Tool Gallery intensiv über die ACDH-Website, die dha-Website, die ÖAW-Website, diverse Mailinglisten und Social Media (Facebook and Twitter) beworben.

Die ACDH Tool Gallery wird dreimal im Jahr angeboten und hat bislang bereits zu den Themen "Automated Recognition and Transcription of Handwritten Documents", "Basic Text Enrichment - TreeTagger for DH-Application" und "Semantic Web Tools" stattgefunden. In einem Bewertungsbogen wurden die TeilnehmerInnen jeweils nach der Veranstaltung befragt, wie sie dieses neue Format einschätzen, mit welchem Vorwissen sie daran teilgenommen haben, was sich verbessern ließe und welche weiteren Tools relevant für ihre Forschungen wären, um künftig im Rahmen der Tool Gallery vorgestellt zu werden. Im Fragebogen wurden außerdem anonyme personenbezogene Daten (z.B. Alter, Geschlecht, Beruf, Herkunftsinstitution) erfasst.

Die Ergebnisse dieser Fallstudie werden im Kurzvortrag präsentiert. Vor dem Hintergrund dieser Erfahrungen möchten die Autorinnen diskutieren, was daraus abgeleitet werden kann und Empfehlungen geben, wie ein attraktives, außeruniversitäres Weiterbildungsangebot, das den disziplinären Anforderungen[4] unterschiedlicher Forschenden gerecht wird, gestaltet werden könnte.

The Formation of Australia's Economic History Community, 1950–1970: A Multidimensional Network Analysis

Claire Wright
clairew@uow.edu.au
University of Wollongong, Australia

This paper adopts a social-deterministic view of intellectual history in order to link changes in social and professional interactions to the intellectual character of a community. The formation of Australia's economic history community between 1950 and 1970 is used to illuminate the link between these social and intellectual forces. The economic history field globally has experienced a number of changes over the twentieth century, and although some of these aspects are understood for the larger communities in the US and the UK (see Hudson, 2001; Lyons et al., 2008 for recent examples), Australia's economic history field remains neglected. Social connections within the community were driven by contextual factors such as the post-WWII expansion of higher education, the growing emphasis on research output and the development of domestic PhD programs. These connections then developed in a multi-dimensional way throughout the 1950s and 1960s, with co-location and collaborative relationships emerging simultaneously between individuals. It is found that the increased density and multiplexity of ties in the community contributed to the development of a distinctive intellectual approach.

This project combines the quantitative analysis of social and intellectual relationships between members of the field with the qualitative analysis of published works of economic history in this period. Though there is a long tradition of emphasising the importance of social interactions for the development of ideas (Kuhn, [1962] 1970; Mulkay et al., 1975; Whitley, 1984), there have been only limited attempts to visualise social relationships in intellectual history (for some examples, see Harvard University, 2015; Shakeosphere, 2015; Six Degrees of Francis Bacon, 2015), and even fewer attempts to relate changes in the social structure to changes in the intellectual character of the group.

Methodology

This project links the social and knowledge networks for this community. The social network has been visualised through co-location and collaboration networks. The knowledge network has been visualised through citation analysis and is discussed further through the qualitative analysis of texts. The collaboration and citation analyses are based on a selection of key texts of Australian economic history for the period 1950 to 1970. Texts have been selected from prior wide reading of the subject, with further guidance from secondary analyses that focus on the literary aspects of the field. This has determined the key ideas, approaches and debates for this community, which has informed the selection of texts.

Based on these texts, collaboration for this community has been recorded in three ways: co-authorship, contributions to edited works, and sub-authorship (acknowledgments). These networks are bonded-tie and valued, based on the number of separate texts that each pair of individuals collaborated on. Collaboration in this context represents ongoing, two-way interaction and the trading of theoretical insights and ideas (Laudel, 2002; Wang et al., 2014). Co-location has been used to map geographic proximity between two individuals, assuming that if they worked within the same university or faculty, they were more likely to have contact than those who were geographically disparate (Jaffe et al., 1993; Ponds et al., 2007). This network is also bonded-tie and valued: if two people were both employed by the same university for 2 years, their relationship is given a score of 2, and so on.

From the raw collaboration and co-location data, a network of key actors in the community has been determined to allow the combination of the different social networks. All authors of key texts and key collaborative works are included. Otherwise actors are included if they were involved in more than one type of social interaction in this community, for example if an individual was appointed to one of the key universities in this period, as well as involved in the sub-authorship network. From this, each social network map has been weighted based on the strength of that particular relationship. Co-location has been weighted by 0.5, because although geographic proximity may induce interaction between scholars, there is no guarantee. Sub-authorship and contributions to edited works are weighted by 2, and co-authorship is weighted by 4.

The knowledge network has been partially analysed through citations, as these represent the ideas that are shared between different authors and the place of a text in the wider context of the field (Leydesdorff and Amsterdamska, 1990; Newman, 2010; Siler, 2013). The citation network for this project has been coded manually, as texts are generally non-digitised books and articles – features that make the use of the Social Sciences Citation Index (SSCI) inappropriate here. This network is directed, indicating the one-way transfer of ideas, and is valued for the number of times in each text that the citation is made.

Supplementing the quantitative analysis of social and intellectual relationships is a qualitative component. The key texts in this community, as identified above, have been analysed using Lloyd's (1995) framework, which classifies works of economic history based upon the author's assumptions about how the economy operates (ontology) and the author's methodology for gaining knowledge about the economy (epistemology). By analysing both qualitative and quantitative aspects, this methodology is able to link social and intellectual interactions with the ideas that emerge in the author's texts.

Preliminary results

The data has been visualised with *NetDraw*. Although the community had some mobility between different locations, the co-location map shows that interactions were primarily between those in the same city. This includes those appointed to the Australian National University (ANU) (located in Canberra, and visualised as the large cluster on the right in figure 1), the University of Melbourne and Monash University (both located in Melbourne, and visualised as the cluster at the bottom of figure 1), or the University of Sydney and the University of New South Wales (both located in Sydney, and visualised as the cluster on the left of figure 1).

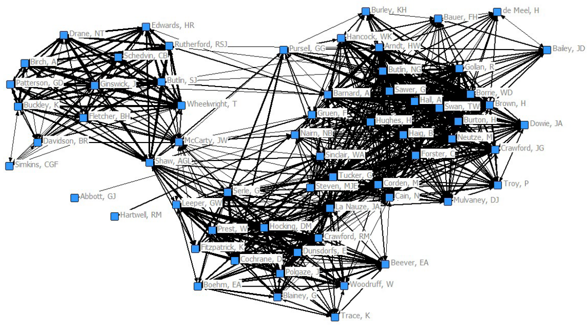

Figure 1: Co-location, 1950–1970

Collaboration was less geographically determined, though there was still greater interaction between those working at the same site. All co-authors were those who also had co-location ties (see figure 2). Contributors to edited works were also generally those that were geographically proximate to the editors in this period (see figure 3). Sub-authorship was the least geographically determined social network, responsible for most of the interactions between those in different cities (see figure 4). Having said that, the sub-authorship network was still clustered around the main institutions, with the ANU group experiencing the greatest frequency of sub-authorship in this period. Figure 5 shows that when each of these measures are combined, social interactions between members of the community in this period broadly followed co-location trends.

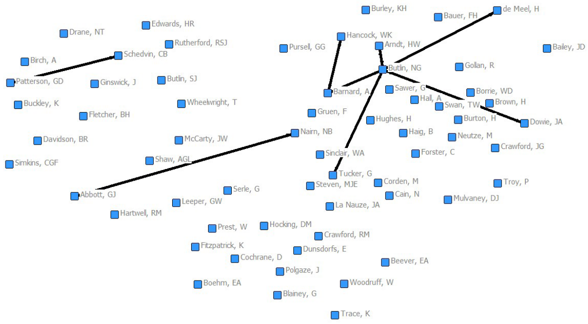

Figure 2: Co-authorship, 1950–1970

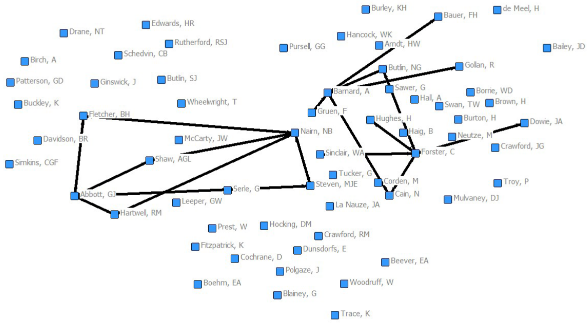

Figure 3: Contributors to edited works, 1950-1970

Figure 6 shows the citation network for this community, with authors of those texts included in the citation analysis highlighted. There was a broad tendency for those that had strong interactions in the social network to have similar citation patterns. A good example of this is NG Butlin, WA Sinclair, N Cain and AR Hall, located together towards the centre of figure 6. In the social network, these individuals were part of the large ANU cluster, with co-location and collaboration interactions throughout this period. There is evidence to support the counterfactual as well: that a lack of social interactions with the core of the community led to distinctive citation patterns. BR Davidson and E Dunsdorfs are good examples here, located on the fringes of figure 6 below, and also with limited interaction in the social networks above. However, this is a loose relationship, with non-social factors such as choice of research topic and approach to the subject also converging citation patterns.

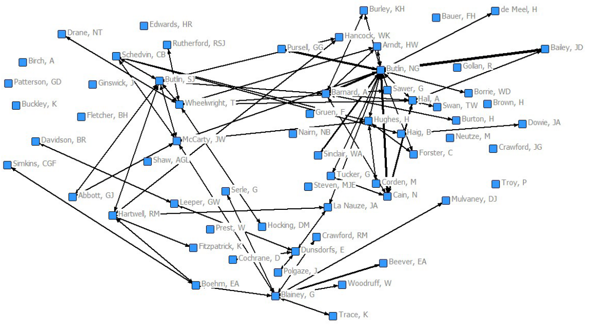

Figure 4: Sub-authorship, 1950–1970

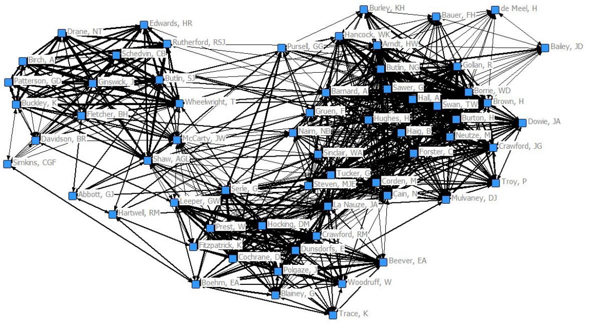

Figure 5: Multiple measures, 1950–1970

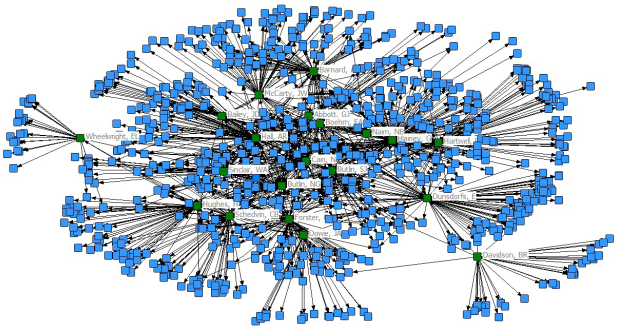

Figure 6: Citations, 1950-1970

The networks above show that there was a range of social and intellectual interactions in Australia's economic history field between 1950 and 1970, particularly structured around key institutions and prominent figures. This was accompanied by the development of a distinctive intellectual approach for the community. The orthodox approach to economic history in this period focussed on national income accounting, domestic determinants of growth, urbanisation, and the treatment of economic agents in an abstract and aggregate way. Core proponents of this approach had multidimensional interactions in the social network, mostly centred on NG Butlin and his colleagues at the ANU. A number of alternative approaches existed in smaller 'pockets' in the community, which were also structured by social interactions.

By combining the quantitative analysis of various social and intellectual relationships with the qualitative analysis of texts and ideas, this project links the social network and the knowledge network for Australia's economic history community. Not only does this provide a pioneering attempt to combine SNA with the more traditional methods for intellectual history, it analyses the Australian economic history field in a dynamic and multi-dimensional way. Key results suggest an association between social interactions and the citation patterns adopted by members of the community in this period. Key social and intellectual relationships between members of the field also led to the development of a distinctive intellectual approach for this interdisciplinary field.

A Management of Personal Name with Alternate Name and its Searching for Japanese Historical Study

Taizo Yamada
t_yamada@hi.u-tokyo.ac.jp
The University of Tokyo, Japan

Satoshi Inoue
inoue@hi.u-tokyo.ac.jp
The University of Tokyo, Japan

1. Introduction

The basis of historical study or historical understanding consists of collecting historical materials (mainly literature materials such as old documents, old diaries, …), precise reading of the materials, and source criticism. In order to perform them, an identification of a personal name is one of important methods or works, and the researchers of history cannot avoid it. The personal name identification is not simple issue, because there is a diversity in the name representations in the materials. The main representing patterns of the diversity are the follows:

a) Written real or original name
b) Written first name only
c) Written nickname, epithet, or alias
d) Written omitted name
e) Written role name
f) Written using different characters
g) Described Kao (which is a stylized signature or a mark.)

Examples of the representations of "伊集院忠棟 (Ijuin Tadamune)", who is a senior statesman of "島津家 (Shimazu family)" and the relatives of the family and is in the 15th century in Japan, there are "伊集院" (which is his family name), "忠棟" (which is his first name), "幸侃" (which is a nick name, is often appeared in the old documents), "伊右衛門大夫" (which is a nick name), "伊右", "右衛門", "伊大夫" (which are his nick names called by familiar persons), "忠金" (which is his original name). Here is a difficult problem that the various represented names should be identified. In the above example, if you understand the various alternate names can be identified with "伊集院忠棟", the problem is not hard. However, in practice, there are no persons (including researchers of the history) who know and understand all historical persons. For the solution of the problem, we consider that the results of personal name identifications which can be performed by researchers of history should be managed. Furthermore, in the search against historical materials, if the results can be available, the performance of the search can be surely improved compared to simply full-text search.

In the paper we introduce a management method of personal names and the alternate names of the persons and a search method using the managed names. In (Ho, 2015) and (Bol et al., 2015), personal names can be extracted and tagged automated against target documents based on China Biographical Database (CBCB; http://isites.harvard.edu/icb/icb.do?keyword=k16229) as a biographical dictionary. Unfortunately, there are no exhaustive the encyclopedias or dictionaries for the names of Japanese historical persons. Moreover, methods introduced in (Ho, 2015) and (Bol et al., 2015) can be performed better if you can treat a document which is a secondary source like a "地方志 (difangzhi)" in which almost personal names indicates its real name. Most of documents which we treated in the work is primary source and hardly have real names of the person.

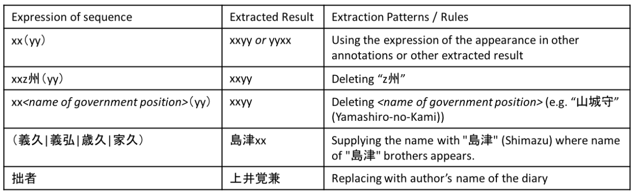
2. Extraction of personal names and alternate names

At first, in order to collecting personal names, we used "上井覚兼日記 (Uwaikakken nikki)" which is a diary of Japanese medieval period (from 1574 until 1586) written by "上井覚兼 (Uwai kakken)" who is a senior statesman of "島津家" of Japan. For the historical study in Kyushu (which is a local area of Japan) or "島津家" in medieval period, the diary is one of important historical materials and Japanese national treasure. The text of the diary has been stored in "The Full-text Database of the Old Japanese Diaries" which has been published by Historiographical Institute, The University of Tokyo. In the text the number of characters is about 1.4 million (for 1777 days; note that there are days which he was not written in the diary). The format of the text is very simply, because the text is just plain text and does not have tags such as XML, TEI. The sample is as follows:

…一、此朝、入来院（重豊）殿太刀を、東郷（重尚）殿次に拳可有之由被申候、御老中よりハ、東郷·祁答院· 入来之事ハ同家にて候間、東郷之次に者根占殿（禰寝重長）太刀を可被召成之由、…

This is a part of the text in the diary of “天正2年8月 1 日” (which indicates A.D. 1574-08-17)”. There are three persons (“入来院 (Irikiin)”, “東郷(Togo)”, “根占 (Nejime)”) in the part. If an alternate name against written name could be solved, the alternate name was added using parenthesis.

The representation can be understood by human (who can read and understand the sentence), but machine can not be solved if the machine doesn’t know or understand the pattern. Due to machine usable, we extracted a written name, an alternate name of the name and the date and we managed the result as a set. As shown in the example, a real name or well-known name is hardly written in the Japanese historical materials, and alternate name added by researcher what indicates real name in most cases. The added name can be used for personal name identification, because this is controlled by the researchers who added the alternate names, and the notation is consistent if the same person. We performed the identification method and could obtain a name pair of 520 sets. In the process of the method, a method of a personal name extraction was needed. We could extract personal names using Machine Leaning method (which consists of an appearance patterns of the names and SVM (Support Vector Machine)). Figure 1 shows examples of the appearance pattern, which an expression of a sequence, an extraction pattern and an extracted result. We used SVM to judge whether the extracted results indicate personal name or not. The SVM results were fed back to the appearance patterns, and we performed the extraction based on appearance patterns and judgment with SVN again. The feedback was preformed several time in the work.



Expression of sequence	Extracted Result	Extraction Patterns / Rules
xx（yy）	xxyy *or* yyxx	Using the expression of the appearance in other annotations or other extracted result
xxz州（yy）	xxyy	Deleting “z州”
xx<*name of government position*>（yy）	xxyy	Deleting <*name of government position*> (e.g. “山城守” (Yamashiro-no-Kami))
（義久|義弘|歳久|家久）	島津xx	Supplying the name with "島津" (Shimazu) where name of "島津" brothers appears.
拙者	上井覚兼	Replacing with author’s name of the diary

Figure 1 Name extraction patterns

We prototyped text search system which supports alternate names using the above constructed personal pairs rather than simple text matching. In the search, for example you queries “忠棟”, then you can obtain the results including “忠棟” as a string, “伊集院忠棟” which is controlled name (well-known name or real name), and alternate names such as “幸侃”, “伊右衛門大夫”, “伊右”, “右衛門”, “伊大夫”, “忠金” (which are mentioned above).

3. Conclusion

Personal name extraction method which we introduced above is useful only target document is “上井覚兼日記 (Uwaikakken nikki)”. In order to extract more generalization, preparing a pattern suitable to each historical material is necessary. We constructed a database which can be stored the personal name pairs. Currently we also have been collecting personal names from other texts and databases, and storing it in the database. The data in the database indicates the results as an identification of personal name. The data can assist to identify personal names in a material which reading comprehension has been not yet done. We expect that the method can be useful to progress of the study of Japanese history.

Computation-Aided Analysis on Film Credits

Li Yang
yangll@lafayette.edu
Lafayette College, United States of America

xwj@tacc.utexas.edu
Texas Advanced Computing Center, University of Texas at Austin, United States of America

Introduction

This project is centrally concerned with using digital computation to analyze historical and comparative data of film credits in order to study the evolution of film production. Our hypothesis is that the elements of film production, as credited by the film itself, have a direct correlation with the historical and cultural background of film production. We want to identify the specific connection with each query, hence contributing to the understanding of the culture of film production in general.

In the introduction to *The Production of Culture and the Cultures of Production*, Paul du Gay points out that culture and economy are mutually constitutive in the present day. Not only are most of popular cultural products manufactured by organized industries, but the production activities themselves also manifest cultural values (Gay, 1997). Our project is theoretically oriented toward the latter, the cultures of production. Although relatively less studied than the production of culture led by the theories of the Culture Industry (Horkheimer & Adorno, 1997), significant scholarship has been conducted to discern the cultural patterns of the film and television productions, such as John Thornton Caldwell's book, *Production Culture: Industrial Reflexivity and Critical Practice in Film and Television* (Caldwell, 2008). The primary data Caldwell and other researchers used are trade publications, interviews, and field observations. Sharing the same theoretical inclination of Caldwell, our research breaks the methodological new ground by analyzing the most conspicuous records of film production—the credits shown on film itself.

Influenced by fiction publication and theater programs in earlier years, film crediting convention has evolved throughout the history of cinema. Today, it is typical for an American film to open with a title sequence and end with a longer rolling credit crawl. The end credits for big production blockbusters are relatively lengthy, featuring both above-the-line categories such as director, producer, and cast, and below-the line categories such as production assistants, camera operators, electricians, special effects specialists, sound editors, etc. As records of film production, film credits contain a plethora of vital information, disclosing not only involved labor (personnel), and corporations (financiers, production companies, and distribution companies), but also procedures (e.g. special effects units and location shootings), and technologies (e.g. Panavision cameras and Chapman camera cranes).

The scholarly attention to film credits has steadily increased in recent years. Many focus on the credits' aesthetic and philosophical values (de Mourgues, 1993; Moinereau, 2009; Tylski, 2009). Some use film credits as an evidence to study the Hollywood star system and labor hierarchy (Clark, 1995; Chisholm, 2000; Carman, 2008). Will Straw's article "Letter of Introduction: Film Credits and Cityscapes" represents a significant contribution by linking the design of the title credit sequence to the socio-historical condition of film viewing – the development of city life after World War II (Straw, 2010). Two recent dissertations also offer interesting insights (Allison, 2001; Crawford, 2013). Allison's research is statistical in nature but only confined to opening title sequences. Crawford's dissertation presents multiple perspectives (aesthetic, legal, and industrial), convincingly justifying the importance of film credits.

This project focuses on actually accessing and analyzing film credits to generate insights into the evolution of film production. More specifically, we propose to employ large-scale computation to perform comparative analysis on film credits. Digital computation is necessary to carry the study of film credits to another level since physically examining the credits even for one film is a daunting task. The final crawl of *Dark Knight* (2008), for example, runs for 7.5 minutes and contains hundreds of names and entities. The listed order and naming of some categories also differ from film to film. Besides increasing efficiency by substituting for human labor, digital computation also invites a large quantity of research subjects. These methods will potentially discover patterns across an extended period of time as well as across national and genre boundaries. We are confident that the potential of film credits as written records will be fully tapped with the aid of digital computation, and our research project will represent a major contribution to film studies.

Our project is mapped into two stages. For the first stage, we will pull available digital records of American films on the Internet to perform some statistical analysis. The second stage will see the expansion of selected works from American films to Chinese films. The Chinese film industry is chosen because of its dramatic development trajectory in the last 30 years. The industry was resuscitated in the 1980s from its near death in the Cultural Revolution (1966–1976) (zero output for three years), and only found itself slipping into financial crises throughout the 1990s in its attempt to balance political and commercial imperatives. Just when the industry was on the brink of collapse at the dawn of the new millennium, it picked itself up with full-scale capitalization while still maintaining substantial degree of governmental control. Charting an extraordinary growth curve to the present day, the Chinese film market has become the second largest in the world since 2012, and is on track to overtake the United States in 2017 or 2018 if the current growing pattern sustains. Tracing the information listed as credits over time and comparing to that of Hollywood will demonstrate the trajectory of both local changes and external influences in the development of Chinese commercial cinema. Because the digital records of Chinese film credits are not as readily available as their American counterparts, we will employ video-capture as well as optical character recognition technology to establish source data sets.

Preliminary Findings

In this conference paper we will present some of our preliminary findings from the first stage. We have developed a software tool to aggregate and analyze records from International Movie Database (IMDB) for analysis. The application is implemented in Java and can parse IMDB records, extract named entities, conduct statistical and association analysis. One of our queries is the number of people listed under major credit categories as documented by the IMDB. We selected 20,690 titles since 1900 with at least one director and at least 10 cast members (actors and actresses). The average number of crew for each film over years is shown in Table-1. For 1900 to 2010, the film statistics are aggregated every 10 years. For example, "1900 to 1910" refers to films released between Jan. 01, 1900 and Jan. 01, 1910. Figure 1 shows the growth of cinematographer, composer, costume-designer, director, editor, miscellaneous workers, producer, production-designer, and writer categories. And Figure 2 shows growth in the number of actors and actresses.

	ACTOR	ACTRESS	CINEMATOGRAPHER	COMPOSER	COSTUMER	DIRECTOR	EDITOR	MISC	PRODUCER	PRODUCTION	WRITER	Movie count
1900 to 1910	9.57	6.57	0.57	0.29	0.00	2.14	0.00	0.14	1.14	0.14	2.00	7

Table 1 Average number of crew per film from 1900 to 2015

From Figure 1, we can see the dramatic increase in the number of credited producers and miscellaneous workers (below-the-line film crew) over time. After years of steady increase, the number of producers took off around 1975, the same year that saw the release of modern blockbuster prototype *Jaws*. Our findings put a direct link between the spreading of the blockbuster business model and the number of producers on board. The miscellaneous worker category displays an even steeper rise. Interestingly, the time of dramatic increase coincides with that of producers – around 1975, but its down size in the early 1990s has no parallels. This graph pinpoints key historical moments for further investigation in the area of union activities, film labor division and representation. Finally from Figure 2 we can see that the gap between male and female cast has remained steady over a century. The biggest gap, however, does not appear in recent years when superhero films reign at the box office – probably thanks to an increased awareness of gender equality – but in the period of 1925 to 1945. Our findings invite further scrutiny into the pre-Paramount Decree (1948) years to study gender dynamics in Hollywood. From this perspective, the conventionally-defined golden age of Hollywood studio era (1927–1960) (Bordwell et al., 1985) may not be as seamlessly continuous as once conceived.

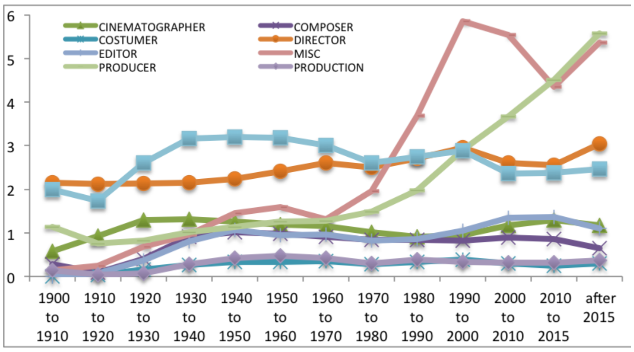

Figure 1 Average number of crews excluding actors and actress per film

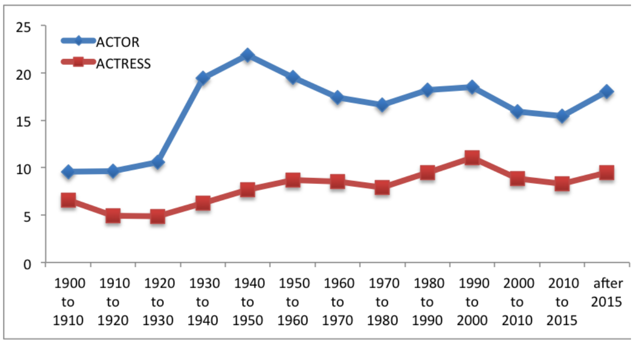

Figure 2 Average number of actors and actress per film

Summary

In summary, these preliminary findings illustrate the mechanism of using computation to analyze the credits of a large number of films across historical periods. The inquiries described above all fall into the category of the "personnel." There are three other categories for future considerations: companies, procedures, and technologies. We believe that the computation-aided study of film credits will detect patterns or gaps, which will serve as important clues and evidences to analyze the cultural dynamics of film production.

From Language Revolution to Revolutionary Language

Ching-Syang Jack Yue

Wen-Huei Cheng
wenhuei_cheng@yahoo.com.tw
National Chengchi University, Taiwan, Republic of China

In his insightful book *The Language of the Third Reich*, Jewish linguist Victor Klemperer pointed out, "One tends to understand Schiller's distich on a 'cultivated language which writes and thinks for you' in purely aesthetic and, as it were, harmless terms [...] But language does not simply write and think for me, it also increasingly dictates my feelings and governs my entire spiritual being the more unquestioningly and unconsciously I abandon myself to it." Thus he observed and detailed the language change during and after the rise of Hitler and Nazism, kept an invaluable record for study of the impact of language on the mind.

Klemperer was by no means the only scholar who was alert to the influence of language. In Chinese context, when May Fourth intellectuals followed the flow of turning the classical Chinese into something more colloquial in late Qing period and advocated a new literature/cultural movement, which was at its heart a language revolution, the idea under the action was that one cannot separate the language habits from the operation of mind. They started the vernacular movement in magazines like *the New Youth*, and hoped by modernizing language, they would empower the mind of the nation, modernize the culture, and eventually really modernize China, a task that 1911 revolution apparently did not fully succeed. The language revolution in early Republic was closely studied by many scholars. Our team also contributed by bringing in digital humanity methods, finding effective ways to tell the classical Chinese from modern Chinese by computer. It was when we analyzed the data of *The New Youth Magazine* that we noticed something rarely discussed by modern scholars: the language changed significantly in Volume 8 of the magazine, published on the eve of the rise of Chinese Communist Party.

According to our study, by the end of Volume 7 (published in 1920), modern vernacular Chinese had almost completely replaced classical Chinese as the main written language. However, the language of Volume 8 seems to be a new breed, deeply influenced by the translation of Soviet language and full of political jargons. It seems that right after success of language revolution, *The New Youth Magazine* immediately change the language again and promote a new kind of "revolutionary language" to advocate the Communism before the Chinese Communist Party was founded. Was there someone like Klemperer to observe the language change before the political turmoil? It called for further study. What we are doing here is to analyze the language turn in the late period of *The New Youth Magazine*. For comparison, we draw in two other materials. First, the editorials of *United Daily News* from 1951 to 1960, inherited the May Forth legacy and published in Taiwan before Taiwanese Modernist movement in 60s and Indigenized movement in 80s changing the written language violently. Second, the essays from the Chinese Communist Party's *People's Daily* from 1971 to 1989, published in mainland China before the Chinese economic reform.

There are two types of data: one is structured data (with a high degree of organization) and the other is unstructured data. Most of the textual data are unstructured and quantifying them often requires certain knowledge about the application domain. We need to create a relational structure for the textual data before plugging classification methods. In particular, we use the notion of Exploratory Data Analysis (or EDA, proposed by famous statistician J.W. Tukey in 1977) to evaluate potential variables which can differentiate the language styles of Volume 7 and Volumes 8~11 in *New Youth Magazine*. According to our previous study of writing style for Volumes 1~7, we found that the number of words, the number of different words (or vocabularies) and their distribution, in addition to function words in classical and modern Chinese, can be used to distinguish Chinese writing styles. We also include species diversity indices, such as Simpson index and entropy (or Shannon index).

Since there are more than 30 variables, we also consider data reduction methods, such as principle component analysis, to include fewer variables. Then, we apply classification methods (logistic regression) to judge the style of an article is close to Volume 7 or Volumes 8~11. Also, to avoid over parameterization (i.e., using too many unnecessary variables), we use cross validation to check whether the model is stable. The regression model is first built based on training data and then applied to the testing data. The fitting accuracies of training data and testing data are recorded separately, and these two numbers of accuracy should be close if the model is stable. For every simulation run, we randomly separate the training data and testing data into proportions of 90% and 10%, respectively. Based on 100 simulation runs, the regression model is fairly stable since it has very similar fitting accuracy (and small standard errors) for training and testing data.

Next step, we apply the constructed regression model to the articles from two newspapers, *United Daily News* and *People's Daily*. Both newspapers have about 500 articles and Table 1 shows their classification results. The *United Daily News* is published in Taiwan and the Soviet Union should have little influence on this newspapers. As expected, only 10% articles are classified to the group of "Revolutionary Language." On the other hand, more than 50% of articles from *People's Daily* are classified to "Revolutionary Language." This matches to our anticipation, since the articles from *People's Daily* are published in 1971~1989, in which period China had close link with the Soviet Union.

No. of Article	**Classified to "Revolutionary Language"**	**No. of Article**	**Proportion**
United Daily News	550	57	10.36%
People's Daily	534	308	58.68%

Table 1. Classifications of *United Daily News* and *People's Daily*

Similar to the cross-validation for the articles from the *New Youth magazine*, we can fit the regression model to the articles from two newspapers year by year. Figure 1 shows the yearly classification results. It seems that the results of *United Daily News* are fairly stable and the yearly results lie around the average (red dotted line). The fitting results of *People's Daily* somehow show an inconsistence pattern. The average proportion of "Revolutionary Language" is 76.3% for the articles in 1971~1977 and is 39.2% in 1978~1989 (the overall average is the red dotted line).

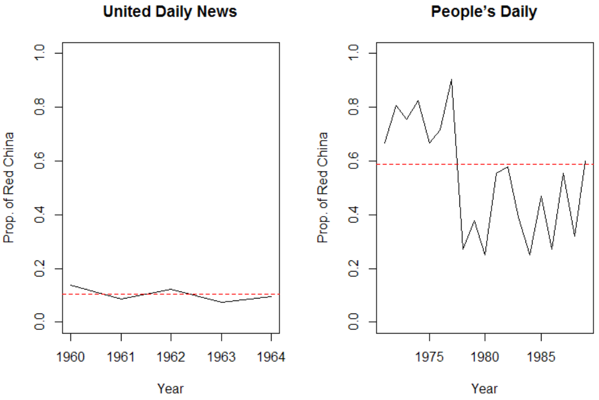

Figure 1. Yearly Classifications of *United Daily News* and *People's Daily*

The yearly classification results of *People's Daily* are interesting and very encouraging. The first stage of China's reform and opening is between 1978~1989, under the formal leader Deng Xiaoping. China started to open to the outside world gradually since 1978, and it also triggers the economic blooming of China at the end of 20th century. Figure 1 suggests a similar story. The proportion of "Revolutionary Language" (under the influence of Soviet Union) articles is larger before 1978 and has a radical change ever since 1978 until 1989, coincide with the years of reform and opening in modern China.

2015 marks the 100th anniversary of The *New Youth Magazine*. By employing the digital humanity methods and focusing on the language change of the latest few volumes that so far rarely discussed by scholars, we hope to make some new contribution to the study of both The *New Youth Magazine* and the writing style of modern Chinese language. Our study shows that the styles of articles from *United Daily News* are close to that of Volume 7 in *New Youth Magazine*, while those from *People's Daily* have about equal probability for being classified to Volume 7 or to Volumes 8~11. This implies that the Chinese writing styles of Taiwan and mainland China are different and the writing style of mainland China is likely to be influenced by the Soviet language.

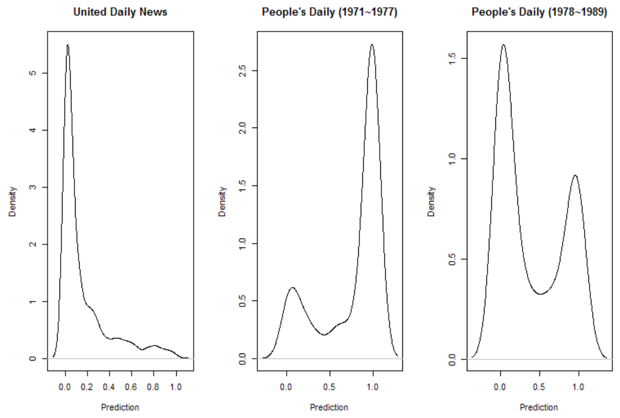

Figure 2. Predicted Results of *United Daily News* and *People's Daily*

Also, the change of "Revolutionary Language" in 1978 seems to indicate a new possible writing style. Judging from the proportion of "Revolutionary Language," those of 1978~1989 lie between "Revolutionary Language" and *United Daily News,* and it seems that the writing style of China turned into a new direction in 1978~1989 (namely, Reform China). Figure 2 shows the predicted results (after kernel smoothing) of all articles, with a value near 1 indicating style closer to "Revolutionary Language" and vice versa. If we treat *United Daily News* and 1971~1977 *People's Daily* as two extremes, then 1978~1989 *People's Daily* is somewhat in between (or a mixture of) these two extremes. It would be interesting to explore the writing style in China since 1978. For example, we can further compare the writing styles of China according to the following three periods, 1978~1989 (first stage), 1989~2002 (economic blooming), and 2002~today (modern China).

Content Based Social Network Analysis of Reşat Nuri Güntekin's Letters

Sumeyye Akca
sumeyyesakca@gmail.com
Hacettepe University, Turkey

Muge Akbulut
mugeakbulut@gmail.com
Yıldırım Beyazıt University, Turkey

Reşat Nuri Güntekin is one of the most important authors in Turkish literature, who gave a direction to the Turkish literature with his many novels and essays. He also conducted significant bureaucratic tasks in the early years of the Turkish Republic. He left substantive materials which have historical and literary value, considering his lifetime. The letters he wrote to his wife give us important information about this period. In addition, these letters are also of capital significance in terms of their evincing the historical events and social life of early period of Turkish Republic through the eyes of an author and statesman. The letters also constitute alternative historical as well as official information resources.

The letters began to be written to his wife, Hadiye in 1927. Although 62 letters were written with their dates affixed, there are 22 letters without dates. The letters were written in Ottoman Turkish. They were transcribed into the Latin characters and published. In order to discover the relationships between events and people in the text, we visualize the letters by using social network analysis and content analysis methods.

Social network analysis method is used to visualize the connections between communities whose existing connections are not easy to be perceived and modelled, through describing the network structures. Social network analyses are important in terms of visualizing the complexity in a simpler way. The fact that the letters Reşat Nuri Güntekin sent to his wife were from different cities and about important people of the period makes them suitable for a social network analysis. With the social networks obtained from the archive of letters, the closeness between the historical figures and the indirect effects to each other can be detected and the historical inferences can be made by examining these connections.

Content analysis method is the process of summarizing the content of the written information and the messages contained in them. This method has been used frequently in social sciences and typically preferred for the analysis of written texts such as books, letters, newspapers etc.

Primarily the descriptive statistics about the content of the letters are presented and then the findings from the content analysis on the messages are revealed. In this paper, the big picture and the details are explained through social network analysis method and the connections and relationships which are indirect, are made apparent.

Relationship between people and the citations etc. are mostly suggested clearly in social network analysis studies. However the relationship between the people in the mentioned letters is not clear. Therefore it is determined in the study based on the proximity and frequency of the names in the text. Proximity-based method is based on the names similar to each other in the letters. Within the scope of the study, CiteSpace software was used for visualization.

Engaging Students in Digital Literary Analysis: GALGO (Golden Age Literature Glossary Online), a Social Semiotic Platform

Nuria Alonso Garcia
nalonsog@providence.edu
Providence College, United States of America

Alison Caplan
acaplan@providence.edu
Providence College, United States of America

This poster showcases a digital teaching application that approaches the study of language and literary texts from a social semiotic perspective and represents an innovative pedagogical model for world language and literature classes. The Golden Age Literature Glossary Online, known by the acronym *GALGO*, consists of an online glossary of select keywords, from canonical texts of Golden Age Spanish literature, whose multiple connotations illuminate important linguistic and social concepts of the 16th and 17th centuries. *GALGO* incorporates British cultural historian Raymond Williams' methodology in his *Keywords: A Vocabulary of Culture and Society*: namely, identifying problem-laden words or "keywords," charting their distinct usages across texts, and reflecting critically on clusters of associated words. Implicit in William's keyword analysis is a social semiotic theory of language that takes as its starting point the observation that meanings "are created by the social system and are exchanged by the members in the form of text" (Halliday, 1978, p.141) and find in literary texts their fullest creative expression (Lotman, 1990). Contextualizing poetic language in its particular space-time, therefore, reveals the linguistic codes derived from the culture in which the work has been produced.

GALGO seeks to instantiate the theoretical construction that embeds the semantic configurations of a literary text simultaneously in the cultural environment, the linguistic system, and the social system. The computer is an ideal semiotic machine to expose these multiple interwoven strands of meaning at once. Applying the structure of M.A.K. Halliday's theoretical model in *Language as social semiotic*, *GALGO*'s interpretive apparatus allows the user to identify the *field of discourse* or social function of each instance of a specific keyword and determine its distributional profile[1](DP) with respect to underlying semantic relationships. The platform is capable of presenting a list of clusters, word groupings based on semiotic affinity, along with their fuller contexts in the works. Simultaneously, within the cluster analysis, *GALGO* also prompts an interpretation of the *tenor of discourse*, highlighting sociological variables connected to class status, gender role and racial category that refine the text's meaning from an interpersonal perspective.

We envision the architecture of the platform to not only be suitable for our corpus of 16th and 17th century Spanish works, but rather potentially abstracted in such a way that any set of words could be glossed from any collection of works. *GALGO* offers students the opportunity to explore a wide variety of views and re-combinations of words and definitions in order to engage more effectively with primary sources that are written in a language, discipline, or time period that is "foreign" to an undergraduate. In this, its third prototype, *GALGO* suggests untapped potential for computer-assisted textual analysis and would now benefit from additional critical feedback offered by the larger digital humanities community.

Participants will have the chance to engage with the platform during the poster session and share their feedback and experiences with the authors:

- How user-friendly is GALGO' s interface?
- How successful is GALGO in performing its intended tasks (cultural semiotic analysis, sociolinguistic research, student engagement in reading)?
- How can GALGO be improved?
- How do others engage students with new media methods?
- How suitable is GALGO for texts from other disciplines?

Starting Point

The project objective of **D**igitizing **E**arly **F**arming **C**ultures (DEFC) is the standardization and integration of research data from sites and finds from the Neolithic and Copper Age (7000–3000 BC) located in Greece and Western Anatolia. These datasets are based on digital and analog resources of research projects of the research group Anatolian Aegean Prehistoric Phenomena (AAPP) at the Institute for Oriental and European Archaeology (OREA) of the Austrian Academy of Sciences.

Greece and Western Anatolia are two neighbouring and archaeologically closely related regions. They are, however, usually studied in isolation from each other and have therefore developed different terminologies and chronologies. Direct results of this de facto separation are not only huge amounts of fragmented research data but also several different models and standards for ordering and describing more or less the same kind of data. To pose and answer archaeological research questions concerning the whole territory, the information must be harmonized.

The aim of the DEFC project is now to harmonize the existing data, to digitize analog resources and make metadata available to facilitate access and reuse this data. To achieve those goals an archaeological data management system is needed.

Data model and Application

The particular requirements to the data model are to reflect the high granularity of the archaeological data structure which correlates on different levels to the excavation process workflow, geographical location, chronological periodization and at the same time to keep the complex relationships between the data objects. After an evaluation of already existing solutions for managing (archaeological) data (e.g. Microsoft Access, Arches Project) it turned out that those were not comprehensive enough for modeling and capturing the very heterogeneous datasets the DEFC project is confronted with. Therefore the development of a more customizable application to collect, standardize, analyze and visualize archaeological data was necessary.

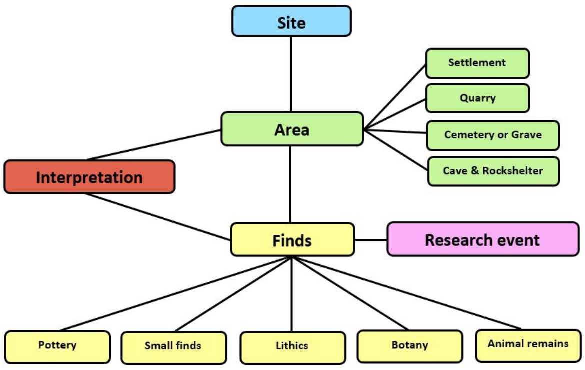

Figure 1. Simplified data model

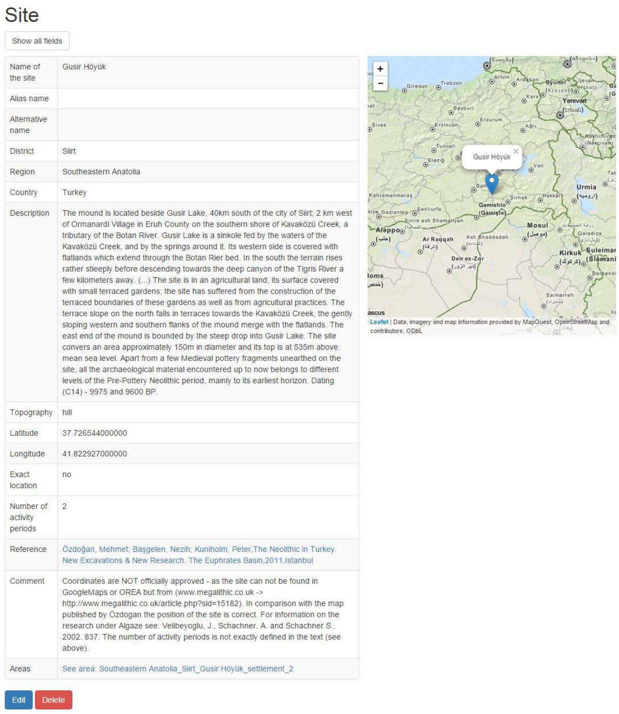
To meet the needs of researchers a clear conceptual data model based on archaeological objects relationships has been defined with the following main model classes:

- Site (location where research took place/observations were made)
- Research Event (project and type of archaeological research that was carried out)
- Area (particular part of the site, defined by its geolocation, period, as well as its type)
- Finds (artefacts, animal and plant remains found)
- Interpretation (archaeologist's interpretation of areas/finds etc.)

Each of those classes is defined through several properties, most of them linked to a carefully curated set of controlled vocabulary.The DEFC-App is based on the Python web framework Django. As one of the application's design principles is to keep things as simple as possible, the application tries to leverage Django´s built-in generic functionality as far as possible. The application's web interface is based on Bootstrap. Client-side scripting, which is needed for a better user guidance and enabling a more responsive data querying and presentation, is implemented with JavaScript, jQuery, Tablesorter and Leaflet.



Site

Name of the site	Gusir Höyük
Alias name	
Alternative name	
District	Siirt
Region	Southeastern Anatolia
Country	Turkey
Description	The mound is located beside Gusir Lake, 40km south of the city of Siirt; 2 km west of Ormanardi Village in Eruh County on the southern shore of Kavaközü Creek, a tributary of the Botan River. Gusir Lake is a sinkole fed by the waters of the Kavaközü Creek, and by the springs around it. Its western side is covered with flatlands which extend through the Botan Rier bed. In the south the terrain rises rather stieeply before descending towards the deep canyon of the Tigris River a few kilometers away. (...) The site is in an agricultural land, its surface covered with small terraced gardens; the site has suffered from the construction of the terraced boundaries of these gardens as well as from agricultural practices. The terrace slope on the north falls in terraces towards the Kavaközü Creek, the gently sloping western and southern flanks of the mound merge with the flatlands. The east end of the mound is bounded by the steep drop into Gusir Lake. The site convers an area approximately 150m in diameter and its top is at 535m above mean sea level. Apart from a few Medieval pottery fragments unearthed on the site, all the archaeological material encountered up to now belongs to different levels of the Pre-Pottery Neolithic period, mainly to its earliest horizon. Dating (C14) - 9975 and 9600 BP.

Figure 4. Referencing Geonames

Development and Upcoming tasks

The project aims to integrate open access resources by using Web APIs and Linked Data practices. At the time being Geonames referencing is implemented for the archaeological locations and provided via a user interface. Hence the fetched Geonames IDs are stored within the database to later be linked to the Pelagios project.

The bibliographic data formerly stored in proprietary formats MS-Access and AskSam was imported to a Zotero library and linked to the DEFC-Database so that every reference record in DEFC redirects to a Zotero library record, where the entire bibliography can also be explored.

To make the published data available 'open access' for further reuse in research, a REST-API (Django REST framework) was implemented along with the web user interface for querying and exporting data.

The outlook of the project is to turn the data into Linked Open Data and make it available via a SPARQL endpoint. Moreover, the thesaurus consisting of hierarchically structured archaeological data units (respectively the aforementioned controlled vocabulary) has been partially mapped to the CIDOC CRM ontology and will later be mapped to the SKOS schema. This will, overall, enhance the quality of the RDF data in the future.

Conclusion

The development of the DEFC-App and its underlying data model could be understood as a very common use case in the broad field of digital humanities as it involves a tight cooperation between archaeologists, data analysts and developers.

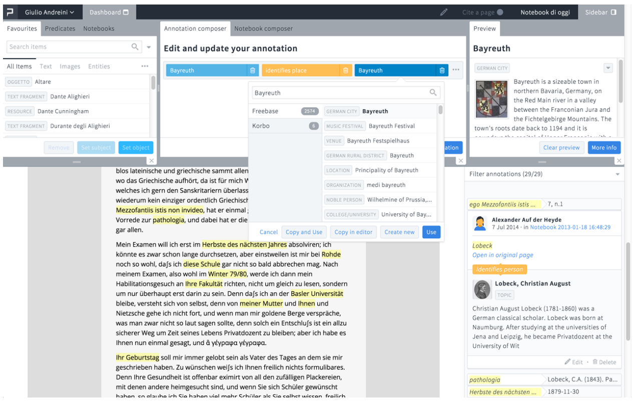
Students and researchers are used to study on books and printed articles, underlining and taking notes on the text itself in the meantime.

Pundit (http://thepund.it/) allows to perform the same actions on any web page, being it an online magazine, a blog or a digital library. In fact, Pundit (Morbidoni et al., 2015) is an open source suite of applications that allows users to build semantic annotations with different levels of expressivity on web pages, collaborating in the meantime with others. The knowledge base created by annotations can be reused inside the Pundit applications or by external third party projects.

Pundit implements a client-server architecture and is made up of several components which interact with each other, but, if needed, are able to work independently:

- **Pundit Annotator**: a simple and lightweight annotator tool that allows to highlight and comment text in web pages with ease. This tool is intended for general users, students and journalists.
- **Pundit Annotator Pro**: an advanced tool for web annotation that allows to create semantic annotations (built by one or more triples) using text fragments, web pages, Cultural Heritage Objects or Linked Data entities. This tool is intended for scholars and researchers.
- **Pundit Annotations Manager**: the Annotation Manager is a web application that allows users to review and manage their annotations as well as to export them in different formats.
- **Pundit Server**: it is where all annotations are stored in a graph format. The data model of annotations is an extension of the Web Annotation Data Model standard (http://www.w3.org/TR/2014/WD-annotation-model-20141211/), defined by the Web Annotation Working Group of W3C.



Bayreuth is a sizeable town in northern Bavaria, Germany, on the Red Main river in a valley between the Franconian Jura and the Fichtelgebirge Mountains. The town's roots date back to 1194 and it is

gar allen.

Mein Examen will ich erst im Herbste des nächsten Jahres absolviren; ich könnte es zwar schon lange durchsetzen, aber einstweilen ist mir bei Rohde noch so wohl, daſs ich diese Schule gar nicht so bald abbrechen mag. Nach meinem Examen, also wohl im Winter 79/80, werde ich dann mein Habilitationsgesuch an Ihre Fakultät richten, nicht um gleich zu lesen, sondern um nur überhaupt erst darin zu sein. Denn daſs ich an der Basler Universität bleibe, versteht sich von selbst, denn von meiner Mutter und Ihnen und Nietzsche gehe ich nicht fort, und wenn man mir goldene Berge verspräche, was man zwar nicht so laut sagen sollte, denn solch ein Entschluſs ist ein allzu sicherer Weg um Zeit seines Lebens Privatdozent zu bleiben; aber ich habe es Ihnen nun einmal gesagt, und ἃ γέγραφα γέγραφα.

Ihr Geburtstag soll mir immer gelobt sein als Vater des Tages an dem sie mir geschrieben haben. Zu wünschen weiſs ich Ihnen freilich nichts formulibares. Denn Ihre Gesundheit ist offenbar eximirt von all den zufälligen Plackereien, mit denen andere heimgesucht sind, und wenn Sie sich Schüler gewünscht

Christian August Lobeck (1781-1860) was a German classical scholar. Lobeck was born at Naumburg. After studying at the universities of Jena and Leipzig, he became Privatdozent at the University of Wit

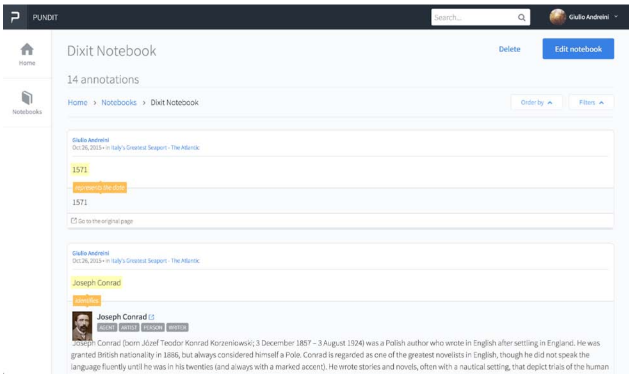
Pundit Annotator Pro used in the project The European correspondence to Jacob Burckhardt

By using Pundit, users contribute to create a new knowledge layer on top of web pages, thus enriching the web of data.

Thanks to the possibility of sharing public annotations, adding comments to or evaluating existing annotations, Pundit can be portrayed as a collaborative platform, allowing the users to cooperate and share their results with workgroups, thus enabling revisions and a form of peer reviewing. Saved annotations are collected in notebooks that can be made public or private.

Users are able to visualize and manage their annotations in the so-called 'Annotations Manager'. Besides browsing their notebooks and performing advanced research, there users can export their collected data in various standard formats. In this way, is possible to save copies of collected data, to be potentially exported in different systems, compliant with the Web Annotation standard.

The Annotation Server implements a set of REST APIs, which allow to expose public resources through content negotiation. The knowledge base can be integrated in third party projects such as Digital Libraries[1] and be used to build advanced research systems or advanced semantic data visualizations.



Joseph Conrad (born Józef Teodor Konrad Korzeniowski; 3 December 1857 – 3 August 1924) was a Polish author who wrote in English after settling in England. He was granted British nationality in 1886, but always considered himself a Pole. Conrad is regarded as one of the greatest novelists in English, though he did not speak the language fluently until he was in his twenties (and always with a marked accent). He wrote stories and novels, often with a nautical setting, that depict trials of the human

The Pundit Annotations Manager is the application where users can manage their annotations

In these last years the software underwent continuous refactoring with the objective to make it more and more modular and adaptable in several contexts. Besides the graphical interface flexibility, with its pro and light modes, the client allows the use of custom vocabularies and ontologies.

Pundit can be customized for tailor made projects where requirements lie outside its standard features. Starting from open source code new features not present in the original version are developed.

The first version of Pundit was developed from 2010 within the EU Semlib project (http://cordis.europa.eu/result/rcn/57391_en.html). Then in 2012 the development continued in the context of the EU DM2E project (http://dm2e.eu/). In 2014 the StoM project (http://www.stom-project.eu) started with the aim of bringing Pundit in the market as a software-as-a-service platform. Specific features of Pundit are also under development within EU Europeana Sounds (http://www.europeanasounds.eu/) project.

Pundit is used for semantic annotations in research projects such as the ERC AdG LOOKINGATWORDS (http://cordis.europa.eu/project/rcn/102545_en.html) and ERC AdG EUROCORR (http://www.burckhardtsource.org) funded projects. In both applications it is used by teams of researchers to semantically enrich the corpus of text of their digital library.

Playing With Cultural Heritage Through Digital Gaming: The New Narrative of the ARK4 Project

Alexandra Angeletaki
alexandra.angeletaki@ub.ntnu.no
Norwegian University of Science and Technology (NTNU)

Agiatis Benardou
a.benardou@dcu.gr
Digital Curation Unit, Athena Research Centre, Greece

Nephelie Chatzidiakou
n.chatzidiakou@dcu.gr
Digital Curation Unit, Athena Research Centre, Greece

Eliza Papaki
a.papaki@dcu.gr
Digital Curation Unit, Athena Research Centre, Greece

In this poster we illustrate the impact of digital technology applications in the field of the contemporary museum and cultural heritage practice using data from workshops held at the 3D laboratory in Trondheim, Norway as well as in the Digital Curation Unit, ATHENA R.C. in Athens, Greece.

Significant transformations have taken place in the field of digital heritage due to the large extent of digitization of cultural heritage collections, the development of gaming and the application of more interactive use of cultural information on the Web. Going digital in the cultural heritage sector has created another space of interaction for users who seem to be increasingly involved in this digital landscape. Apart from that, digital applications have wore different disguises employed in different kinds of devices used effectively in the GLAM sector. Whether this wide adoption of technology suggests the wider engagement of the public with cultural heritage awaits interpretations.

Does a digital visit realize itself differently in an immersive cultural landscape where the person visiting a site or an exhibition is active in seeking knowledge? Does this innovation really transforms the relation between user and cultural object? These are some of the main questions the project ARK4 has been dealing with since 2014. Experimenting with content, appearance and user design, our aim was to create a new virtual space of dialogue between the person asking the question and the organisation holding the answer and to explore different methods of technology in disseminating knowledge from the past to a young audience. To this purpose, we have experimented with different kinds of content from botany to archaeology and with different types of technology applications, from digital games on touch screens to online questionnaires. By following user centric methods, this varied interplay of content, digital applications and audience has presented interesting findings in terms of user satisfaction, evaluation of the content and the digital means.

As the project enters its second phase, it also aims to create engagement and educational activities in the immediate community in order to engage school-children, university students and local enterprises in the seek of knowledge of the past. Each individual can be allowed in the frame of our project to deliver their own experiential perception on the story/game he/she chooses to interact with according to their own individualized level of pre-understanding and motivation. That is the visitor`s background, nationality and identity may influence and vary the outcome of the experience to be expected. Thus the visit becomes a complex process of interpretation and our inquiry might add a new dimension to the debate of creating a dialogue between European shared memory institutions and the individual visitor which can then manifest itself in experiencing diversity. Using the interaction between the participants and the objects as an observation field one allows the outcome to be varied and justified by the visitors' personal intention. Our poster will present findings of three workshops organized in collaboration with museums and schools in Norway and Greece between 2014 and 2015. In our study we analyze data on how school children interact, work and learn in the context of educational workshops, through observation, discussions, and direct surveys, interviews of the students, system log-files and performance tests. Focusing on archaeological context, the project ARK4 in its new phase will further explore user interactivity with digital technologies and gaming. The broader impact of the study contributes to the discussions on issues pertaining to educational activities from the users' perspective.

ITAF: Rewiring the Italian 'Nation' of the Army of Flanders (1567-1714)

Maurizio Arfaioli
m.arfaioli@gmail.com
The Medici Archive Project, Italy

Established in 1568 to crush a rebellion triggered by religious strife, which through the years turned into a conflict of empires, the Spanish Army of Flanders rose to the challenge, becoming Europe's largest standing army since Roman times. An army in which troops from all corners of the Spanish empire (and beyond) were called to serve, from Portugal to the Balkans, from Scotland to Sicily. Between 1568 and 1713 – when the Treaty of Münster put an end to the existence of the Spanish Netherlands – more than forty infantry regiments, dozens of companies of light cavalry, several thousands of gentlemen adventurers, sailors, artillerymen, administrators, ecclesiastics and architects from all corners of Spanish Italy 'passed to Flanders' (as the saying went) to help restore the authority of their king. And that without mentioning the numerous unaccounted-for women and children that followed them.

In the course of a century and a half of almost uninterrupted conflicts, the Italian military 'nation' of the Army of Flanders existed as a protean, complex and extended network, created through a largely unplanned and spontaneous process of social and cultural sedimentation by wave after wave of soldiers and officers that spent an important part of their active lives in the Low Countries. Still, owing the heavy historiographical stigma that accompanied for a long time the memory of 'Spanish Italy', the Italian military 'nation' in the Army of Flanders has gradually slipped into oblivion, and is nowadays largely forgotten.

ITAF (Italian Troops of the Army of Flanders), is an application tailored to 'rewire' the tangled web of military and social hierarchies which sustained the life of the Italian military 'nation' in the Low Countries through the effective integration of data extracted from a variety of archival and bibliographic sources. I intend to present at DH Krakow 2016 the trial version of this application/database, with which I am conducting a pilot study on the history of the longest-lived Italian infantry *terzo* (the Italianization of the Spanish word *tercio*) of the Army of Flanders – a unit that served the Spanish monarchy in the Low Countries from 1597 to 1713. The final version of this application is meant to be applied to the study of the entire Italian 'nation', and, with a few adaptations, its use could be extended to that of each of the other 'nations' (Spanish, Walloon, British, German etc.) of the Army of Flanders – or to the Army as a whole. **ITAF** is developed open source and relies on a NoSQL Database for data management.

Documenting Material Culture: 3D Laser Scanning, Photogrammetry and Archaeological Ceramics from Lincoln Pottery Works

Effie F. Athanassopoulos
efa@unl.edu
University of Nebraska-Lincoln, United States of America

Aaron Pattee
acpattee30@gmail.com
University of Nebraska-Lincoln, United States of America

This poster explores the application of laser scanning and photogrammetric recording methods to archaeological ceramics excavated from a former pottery factory in Lincoln, Nebraska, USA. As 3D modeling methods continue to become more user-friendly and affordable, they offer an attractive alternative for artifact documentation, analysis and sharing of data, compared to the traditional methods of photography and profile drawings. Several studies have utilized 3D scanning for accurate data acquisition, including 2D profiling, and the calculation of attributes that are harder to measure by traditional means, e.g. volume, surface area, and symmetry. Furthermore, the 3D models can become part of digital publications and form the basis for the creation of new digital resources.

Here we are presenting 3D models created with two different methods: laser scanning and photogrammetry. We used a Next Engine 3D laser scanner, a portable scanner, suitable for small to medium-sized artifacts. The scanner generates 3D point clouds and also records texture. The texture is not high resolution, so it is not as sharp as high quality digital photographs. Multiple views are needed to create a complete model. The model requires editing (trimming, aligning, fusing) and, depending on the complexity of the object, it can take from one to two hours for a complete edited model. The 3D models created with the laser scanner are very accurate; they include any surface lines, indentations, breaks, imperfections, etc. We also use photogrammetry in order to improve upon texture and to compare the accuracy of the photogrammetric models with the 3D laser scanner models. All photographs are taken with a Nikon D3300 DSLR camera. Agisoft Photoscan Pro is used for the alignment, dense cloud, mesh, and texture for each model. Additional trimming and modifications are completed with CloudCompare (an open source 3D point cloud processing software). The combination of both methods allows for precise replication and creation of high resolution models. It also facilitates multiple types of analysis.

The case study is the Lincoln Pottery Works (LPW), in Lincoln, NE, USA, which operated from 1880 until around 1903. The inventory of the LPW centered on utilitarian, domestic wares. It produced crocks, jugs, bowls, jars, lids, flower pots, planters, architectural terra cotta and other types of ceramics. Ceramic technology developed rapidly during this period to include semi-mechanized means of forming pots, known as “jigging” or “jollying,” which allowed for mass production of vessels. LPW also exhibits the latest innovations in nineteenth-century kiln design in the form of downdraft kilns. When the LPW was founded, Lincoln was a prosperous and rapidly growing city with a population of c. 13,000 in 1880 which had increased to 55,000 in 1890 (Bleed and Schoen, 1990: 34). After the factory closed, most of the property became part of a housing development. The site was excavated by Peter Bleed in 1986-1987, and the results were published in 1993. The LPW collections are currently in the Nebraska State Historical Society.

This is a pilot project and a work in progress. The digital recording of representative types of LPW ceramics through 3D interactive models is the first step in the creation of an online exhibit and digital resource. Currently, we are documenting the most common types of ceramics produced by LPW. The LPW collection is extremely large. For example, the estimated number of bowls is 5,633 vessels and represent 38.45% of the assemblage. Thus, our goal is to document a representative sample of the collection, we do not plan to document the collection fully. Once the pilot phase is completed, we will make the 3D models, along with other content, available on a website (in collaboration with the Nebraska State Historical Society).

The digitization project will facilitate different kinds of analysis that build on the original publication of the results; for example, the distribution of LPW products in other Midwestern states (the records of the business have not been preserved), socioeconomic aspects, food ways, a gendered perspective, etc. The first step, however, is to create a digital resource that will draw attention to this collection and engage other researchers and the public. By utilizing the latest technology to create and present accurate models of LPW representative products, we hope to bring wider attention to this important assemblage, which is an integral part of the history of nineteenth century Nebraska and the industrial archaeology of the Great Plains region.

Extraction and Visualization of Toponyms in Diachronic Text Corpora

Adrien Barbaresi
adrien.barbaresi@oeaw.ac.at
Austrian Academy of Sciences, Austria; Berlin-Brandenburg Academy of Sciences, Germany

Hanno Biber
hanno.biber@oeaw.ac.at
Austrian Academy of Sciences, Austria

Introduction

This paper focuses on the extraction of German and Austrian place names in historical texts. It is part of a cooperation between the Berlin-Brandenburg and the Austrian Academies of Sciences. The latter is the holder of the text basis for this investigation, the digitized version of the satirical literary magazine "Die Fackel" ("The Torch"). It has been originally published and almost entirely written by the satirist and language critic Karl Kraus in Vienna from 1899 until 1936, and contains a considerable variety of toponyms (Biber, 2001).

Gazetteers and lists

Toponym resolution often relies on named-entity recognition and artificial intelligence (Leidner and Lieberman, 2011). However, knowledge-based methods using fine-grained data – for example from Wikipedia – have already been used with encouraging results (Hu et al., 2014).During the 20th century there have been significant political changes in Central Europe that have severely affected toponyms, so that geographical databases lack coverage and detail. Consequently, the database we develop follows from a combination of approaches: gazetteers are curated in a supervised way to account for historical differences,and current geographical information is used as a fallback.

First, a cascade of filtersis used: (1) current and historical states (e.g. Austria-Hungary); (2) regions, important subparts of states, and regional landscapes (e.g. Swabia); (3) populated places; (4) geographical features (e.g. valleys). Wikipedia's API is used to navigate in categories and to retrieve coordinates, which are completed by hand for states and regions.Second, current information is also compiled from the Geonames database[1]: data for European countries are retrieved and preprocessed(variants and place types).

In order to exclude common and proper nouns, the German version of the Wiktionary serves as a reference[2], and registers of frequent surnamesand family names, as well as well-known persons (especially writers) are built using Wikipedia and Wikidata.

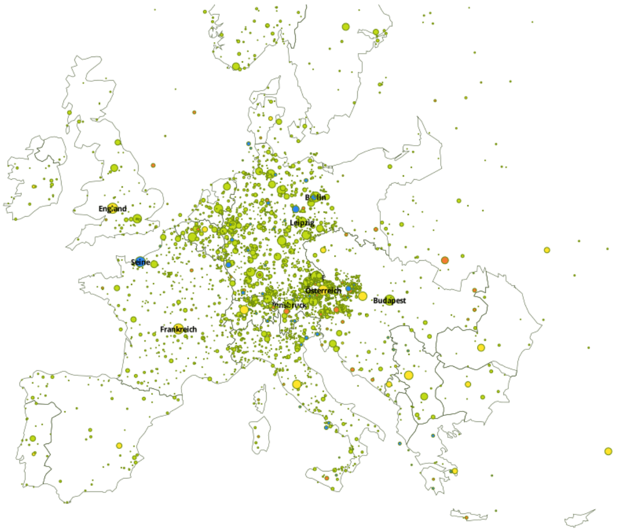
Extraction

The texts were digitized, manually corrected as well as manually annotated with respect to the names of persons and institutions, so that most proper nouns which are not place names can be excluded from the study.

The tokenized files of works to be analyzed (Jurish and Würzner, 2013) are filtered and matched with the databaseby finite-state automatons: toponyms are extracted using a sliding window (for multi-word names up to three components). Disambiguation being a critical component (Leetaru, 2012), an algorithm similar to Pouliquen et al. (2006), who demonstrated that an acceptable precision can be reached that way,guesses the most probable entry based on distanceto Vienna (Sinnott, 1984), contextual information(closest-country, last names resolved), and importance (place type, population count).

Visualization

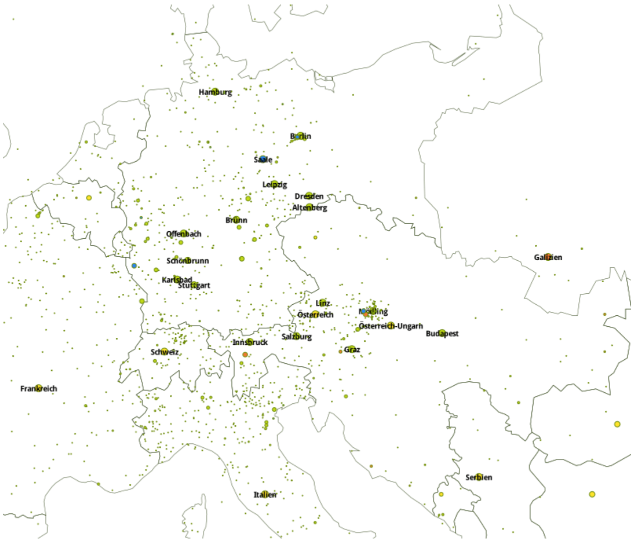
The results are projected on a map of Europe with boundaries of 1914[3] using TileMill[4]. They are customized with CartoCSS: multiple trial-and-error iterations are performed concerning both data quality and graphical output. The two experimental maps belowground on the same data, they result from different settings.



Map 1– Experiment on European scale with boundaries of 1914 (yellow: sovereign territories; orange: regions; green: populated places; blue: geographical features)

Discussion

Potential conceptual caveats include previous times as well as fictitious places, especially names which can refer to mythological and actual places of Ancient Greece or Rome. Practical caveats are for instance false localizations due to disambiguation errors (e.g. Brünn/Brno on map 2). We plan to bypass the disambiguation for a hand-picked list of places. As big datais an entanglement of implicit theoretical assumptions (Crawford et al., 2014), the difference between a mere data collection project and a digital humanities study resides precisely in the number and diversity of filters used. The code and listings produced for this study are available online.[5] We plan to integrate corpora of greater variety and scope and to include more specific metadata in order to design versatile visualizations.



Map 2– Central Europe, experiment with a restrictive filtering

Conclusion

A map is a discrimination, a marking of difference (Wulfman, 2014): our maps highlight the linguistic and cultural ties of Kraus and his contemporaries with Bohemia and Northern Italy, where there are more numerous toponyms to be found than in Hungary.Beyond that, "Die Fackel" is (at least) a European phenomenon; Kraus' vision of Europe is more inclined towards cultural centers (Prague, Munich, Paris, Berlin).

It is our hope that visualization studies based upon mixed methods contribute to a greater awareness of the potential of digital heritage as well as literary studies in the digital age. Although the maps seem immediately interpretable, they are not an objective result but a construct (Juvan, 2015), the result of a filtering. The "human" interventions on the map as well as the technical competence to do so replace this study in the hermeneutic circle of the philological tradition.

amaeda@media.ritsumei.ac.jp
College of Information Science and Engineering, Ritsumeikan University, Japan

In this paper, we demonstrate a named entity extraction method for digitized ancient Mongolian documents by using features of traditional Mongolian script. In the field of humanities, getting knowledge by analyzing various historical documents is an important task. There are increasing demands from Mongolian humanities researchers to perform text analysis at massive scale with prompt and accurate results. A few ancient Mongolian historical manuscripts including 1) the "Qad-un ündüsün-ü quriyangγui altan tobči neretü sudur (The Altan Tobchi or the Golden Summary: Short history of the Origins of the Khans)" a.k.a "Little" Altan Tobchi, and 2) the "Asaraġci neretü-yin teüke or Asragch nėrtiin tüükh (The Story of Asragch)", which were written in traditional Mongolian script have been converted to digital texts and made publicly available through the traditional Mongolian script digital library (TMSDL) (Batjargal et al., 2013). Figure 1 shows a page of the "Little" Altan Tobchi in the TMSDL. The demands from Mongolian humanities researchers, as well as the lessons learned from the TMSDL have encouraged us to conduct further research in developing a new method for extracting named entities from ancient Mongolian historical documents. However, there has been little research on text mining or named entity extraction for Mongolian language and none of the research has considered text mining on ancient Mongolian historical documents due to the lack of research in those areas. Thus, we want to propose a named entity extraction method for ancient historical documents in traditional Mongolian script by employing machine learning techniques for aiming to reduce the labor-intensive analysis on historical text.

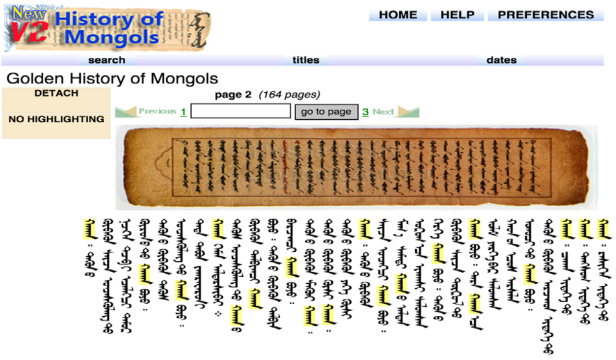

Figure 1. Screenshot of the TMSDL

In the proposed approach, an ancient Mongolian corpus gets tokenized, each token gets annotated and gold standard annotations are prepared for inputting into computer system for learning. The proposed method learns the extraction rules of personal names and place names from annotated training corpora, and then extracts named entities from ancient Mongolian texts by employing machine learning techniques (Batjargal et al., 2015).

We use the IOB2 (Ramshaw and Marcus, 1995) format for tagging tokens. Because of some unique features of traditional Mongolian script, we also use "Start/End" (SE) chunk tag set (Asahara and Matsumoto, 2003). "S" tag is attached to the first character of each word including the named entities and "E" tag to the last character. Thus, each token will include the 1) IOB2 tag and 2) SE tag.

We also consider the following features of traditional Mongolian script for differentiating personal names and place names.

- **Information of the preceding** and **following tokens:** Features are extracted by looking the context of the current, preceding, and succeeding tokens. If the preceding token is generational or dynastic information, an inherited or life-time title of nobility, or a traditional descriptive phrase, it could indicate the current token is a personal name.
- **Suffix:** Many living being and humankind proper names take only certain plural suffixes such as ᠨᠠᠷ (nar/ner) and possessive suffixes (Chinggaltai, 1963). Some suffixes are visually separated from the stem of a word or other suffixes, but any attached suffixes are considered to be an integral part of the word.
- **Beginning of a sentence:** Subjects or personal names often appear at the beginning of a sentence.
- **End of a token:** Words with a final vowel letter 'a' or 'e' are separated visually from the preceding consonant by a narrow gap. However, the 'a' or 'e' is an integral part of the word stem.

For evaluation, we calculated precision, recall, and F-measure by the 5-fold cross-validation. To prepare the gold standard annotations, we annotated all the personal names and place names in the "Little" Altan Tobchi using the manually compiled personal and place names' indices obtained from the "Qad-un ündüsün quriyangγui altan tobči –Textological Study" (Choimaa, 2002). For the experimental corpus, we utilized digitized text of chronological manuscripts "Little" Altan Tobchi. We utilized the LIBLINEAR with the L2-regularized L2-loss support vector classification (dual) solver (Rong-En Fan et al., 2008).

We will further improve the proposed method by considering more features by conducting various experiments with different combinations of features for checking whether the particular feature set will improve the preliminary results of 0.70 of precision, 0.57 of recall and 0.63 of F-measure or not.

Interoperability: a new horizon for data sharing in Humanities and Social Sciences. The input of three digital services developed by Huma-Num

In the field of Humanities and Social Sciences, the production of digital or scanned data has increased considerably in recent years. These data, which are usually very expensive to produce, are often lost at the end of the project. They are therefore rarely reused, due to a lack of financial, human and technical resources of the communities that produced them.

The TGIR Huma-Num, whose mission is to facilitate the digital turn in Humanities and Social Sciences research, offers services dedicated to the production and reuse of data. These services aim at avoiding loss and facilitating the re-use of scientific data. To do this, Huma-Num supports research teams throughout their digital projects to allow the sharing, reuse and preservation of data thanks to a chain of devices focused on interoperability.

The aim is to foster the exchange and dissemination of metadata, but also of data itself via standardized tools and lasting, open formats. These tools developed by Huma-Num are all based on Semantic Web technologies, mainly for their auto-descriptive features and for the enrichment opportunities they enable. Other interoperability technologies complement them, such as the OAI-PMH. Interoperability is used internally to allow Huma-Num services to communicate with one another and externally to let users plug their tools into Huma-Num services.

Another important point is to make the storage of data independent of the device used to disseminate the data.

This poster will present three services designed and developed by Huma-Num to process, store and display research data while preparing them for re-use and long-term preservation.

These services embrace the research data life cycle and are designed to meet the needs arising therefrom:

- SHARE data and metadata, using interoperable technologies, with NAKALA. Another feature is the possibility to make DATA CITEABLE with PIDs;
- SHOW and DISPLAY the data with NAKALONA, using the CMS Omeka allowing customised editorialization of data stored in Nakala (e.g. virtual exhibitions) benefiting from the features of this CMS such as its search engine and extended OAI-PMH feeds which facilitate interoperability;
- TAG and PUSH data through ISIDORE, enriching and interconnecting them to ensure better visibility.

These three complementary services thus constitute a coherent chain of research data tools. While they interact smoothly with each other, they are also open to external tools using the same technologies. In fact each tool, considered individually, is not ground-breaking, but we consider that the combination of these tools is the key to address needs and to prepare the long term preservation of scientific data.

The scientific objective is to promote data sharing so that other researchers, communities, or disciplines, can reuse them, including from an interdisciplinary perspective and in different ways. A map, for example, may become a scientific object that reflects both the point of view of a geographer and that of a historian. More generally, the principles and methods of the Semantic Web (RDF, SPARQL, SKOS, OWL) on which these services rely enable data to be documented or re-documented for various uses without confining them to inaccessible silos.

The second objective is to prevent the loss of data by preparing their long-term preservation. Documenting the use of appropriate formats, which are the basis of data interoperability, greatly facilitates the archiving process.

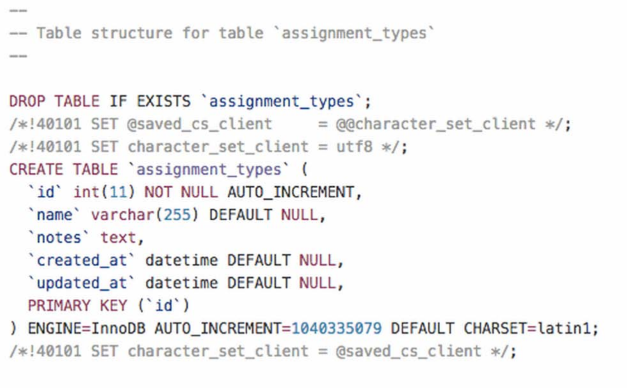
Through these services, the TGIR Huma-Num is developing solutions based on digital technologies and, in particular, those of the Semantic Web, to meet the needs of researchers and scientific communities, and make new research in the field of Humanities and Social Sciences possible.

Seeing the Argument: Visualize Your Database with DAVILA

Jean Ann Bauer
jabauer@princeton.edu
Princeton University, United States of America

Data modeling is a subject of study within digital humanities (Flanders and Jannidis, 2015) with special emphasis on the creative, scholarly, and normative aspects of data modeling in database design (Verhoeven, 2014; Bauer, 2015). By imagining our sources as data, and then abstracting th ose data to the point where quantitative methods gain purchase but still retain their original context, digital humanists are reimagining what it means to study the human record. While the study of data modeling is crucial to digital humanities, it is complicated by database schema conventions. Whether expressed in technical diagrams or computer code, database schemas initially present as confusing to anyone not trained to read them. Yet, schemas contain crucial information about how humanities data are translated to the computer, creating affordances for querying, browsing, and display – making direct access to schemas valuable to researchers, users, and peer reviewers.

DAVILA is an open source relational database schema annotation and visualization tool created to help bridge this gap. While there are other database schema visualization tools (ex. MySQL Workbench, DbVisualizer, and DbSchema) available, DAVILA was specificallydesigned tofunction within digital humanities project teams and to document digital humanities projects for the non-technical audiences that use and review them. Drawing onthe scholarly practice of annotation as well as the principles of Information Design (Tufte, 2006a; Tufte, 1997; Tufte, 2006b; Tufte, 2006c) and Computational Information Design (Fry, 2004), DAVILA creates a modified Entity-Relationship diagram (see (Ramsay, 2004) for a more detailed description of E-R diagrams) that can be used by both technical and content experts.



```
--
-- Table structure for table `assignment_types`
--

DROP TABLE IF EXISTS `assignment_types`;
/*!40101 SET @saved_cs_client     = @@character_set_client */;
/*!40101 SET character_set_client = utf8 */;
CREATE TABLE `assignment_types` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `name` varchar(255) DEFAULT NULL,
  `notes` text,
  `created_at` datetime DEFAULT NULL,
  `updated_at` datetime DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB AUTO_INCREMENT=1040335079 DEFAULT CHARSET=latin1;
/*!40101 SET character_set_client = @saved_cs_client */;
```

Figure 1: A sample database schema, in this case the output from a mysqldump file for Project Quincy (http://projectquincy.org)

DAVILA takes two files as inputs: a database schema and an optional plain text customization file. Examples of both files are included with the software. When a schema is processed without a customization file DAVILA will create a blue box for each entity, and connect the entities based on their relationships (if specified in the schema). So, if a user is given someone else's database without documentation, she can use DAVILA to create a technical diagram from the schema. The user can then explore the entities in the interface and get a better sense of a new system. The customization file can be completed in an iterative process until the entire system has been documented.

The customization file is the heart of DAVILA, and what separates it from other database schema visualization software packages. The plain text file allows scholars to annotate the resulting diagram. These annotations begin with basic project metadata, crucial to data curation (Flanders and Muñoz, 2014): project name, URL, developer names, and the copyright license applied to the diagrams. The customization file allows users to group entities into modules, color code those modules, indicate which entity is central to each module, and provide annotation text for every entity in the database. The annotated text is particularly crucial, describing in a sentence or two the essence of a particular entity and its relationship to the larger database. The color coding and positioning bring order to the diagram, but the annotation gives non-technical team members or peer reviewers a way into the schema.

Once DAVILA is running, users can click and drag the entities into different positions, expand an individual module for more information, or hide the non-central entities in a module to focus on another part of your schema, all in a fun, force-directed environment courtesy of the toxiclibs physics library. Pressing the space bar saves a snapshot of the window as a timestamped, vector-scaled pdf. As a visualization tool, DAVILA has limited use for a team that combines sighted and blind (or colorblind) team members. For such groups, the customization file may provide a more fruitful locus of collaboration than the visual output.

Generated with DAVILA

Figure 3: Example of the "Locations Module" in Project Quincy laid out in DAVILA. Note that the other modules are still in the visualization, but have been minimized. Also note that primary keys are highlighted, relationships have directionality, and datatypes are specified for each attribute.

DAVILA is written in Processing, a Java-based artistic scripting language originally created by Ben Fry and Casey Reas, and released under GPLv3. Special attention was paid to documenting DAVILA itself. Each file in the program starts with at least one paragraph, in English, describing what the following code does and how to modify it as needed. This supplements the extensive inline commenting of the code, which can double as a tutorial for >Processing. Finally, there is a detailed README file which walks new users through installing Processing and using DAVILA with their own database schemas.

DAVILA-generated schemas are used to teach database design and were included in a database inflected doctoral dissertation in history (Bauer, 2015). To generate your own diagram visit.

First We Feel Then We Fall – Multimedia Adaptation of Joyce's Finnegans Wake

Katarzyna Maria Bazarnik
k.bazarnik@uj.edu.pl
Jagiellonian University, Poland

Jakub Wróblewski
jakub.a.wroblewski@gmail.com
Academy of Fine Arts in Warsaw, Poland

Finnegans Wake is the last, most mysterious book by the Irish writer James Joyce. Usually described as a novel, it is a fascinating text written primarily in English (more strictly Hiberno-English), but the words are often fused with any of several dozen languages (McHugh, 1991). This dream-like narrative features a Dublin pub owner Humphrey Chimpden Earwicker, his wife Anna Livia Plurabelle, their twin sons Shem and Shaun and their daughter Issy. They travel through space and time to discover the truth about a scandalous incident in Phoenix Park in which HCE was implicated and to deliver a letter written by ALP in his defense. Drawn into a whirlpool of the past, they metamorphose into historical and legendary figures, a hill, a river, a cloud, a tree and a stone (Campbell and Robinson, 1944/1959; Bishop, 1986). The story of HCE's fall overlaps with the story of a drunken bricklayer Tim Finnegan who fell off a ladder but was resurrected when whisky splashed on his face during a fight at his wake. This fuses with the original Fall, with sexual falls of politicians and celebrities, with Napoleon and Wellington on the battlefield of Waterloo, with Tristan and Iseult's romance, a hen discovering an ancient manuscript in a rubbish heap, and more. Full of sexual innuendoes, historical, literary, autobiographical allusions and hilarious wordplays, multiple plots of *Finnegans Wake* develop in non-linear ways and can be followed like a maze, or a hypertext (Hart, 1962; Hayman, 1978; Loska, 1999 and 2000; Armand, 2003; Bazarnik, 2011).

In *The Middle Ages of James Joyce. The Aesthetics of Chaosmos* Umberto Eco offers a diagram that visualizes hypertextual complexity of the Wakean language (Eco, 1989). It shows how MEANDERTALE and MEANDERTHALLTALE, two of innumerable puns making up the textual labyrinth of *Finnegans Wake*, can be unpacked into separate words. The image represents a network connecting major components: *meander*, German *Tal*, *tale*, and *Neandertal*, which combine to suggest a cluster of meanings. This Wakean pun nudges us about how to read the book: as a "tall tale" wandering waywardly, looping backward and flashing forward, into the pre-historic past, and the origins of the human species. And as a watercourse – of course, 'the Meander' is a river which (giving us the word) meanders. Working on the logic of associations, it hints at different interpretative paths, visualised by the wavy lines of the diagram.

In our project – *First We Feel Then We Fall* – we aspire to offer a similar, dynamic, visual translation of hypertextuality and simultaneity of *Finnegans Wake* (Joyce, 1939/2002). Inspired by Eco's diagram, our project is based on a comparable analysis of narrative streams in Joyce's text. Having analysed the Wakean imagery, euphonies, rhythms and polyphonic contexts, we have selected four narrative strands, or "plots," which are translated into an up-to-date audiovisual form of an interactive Internet app. Thus networks of linguistic, historical, symbolic, and mathematical meanings entailed in Wakean puns are transposed into a dynamic audio-visual structure that the audience can co-shape in the process of interactive viewing. The viewer can switch at will between four simultaneous streams of film clips accompanied by sound (and optional captions with the *FW* text). The interactive and immersive nature of *First We Feel Then We Fall* will go beyond previous cinematic adaptations of Joyce's novel. It is the advance of digital technologies that has enabled us to approach complexity of *Finnegans Wake* in this novel way.

The application devised for this project is a multichannel, interactive video app. It will enable the viewers to experience Joyce's text in an audiovisual format consisting of simultaneously running streams, and thanks to this, offer them a portmanteaux-like audio-visual experience. The app will also contain an option suggesting a narrative path modelled on selections made by previous viewers. It will be available on the Internet browsers and mobile devices (Wróblewski, 2015). The software used includes: Final Cut for editing; Adobe After Effects and Processing for animation, and DaVinci Resolve for colour grading. Video capture was made with Canon 5D Mark III, Sony A7SII, Sony FX7e, Phantom HD Gold, and Found Footage, whereas the website was developed with Python, Django, JavaScript, HTML 5, and CSS3.

In our presentation we will briefly describe the rationale for our multimedia adaptation of *Finnegans Wake*, and let the audience experience it in an individual, interactive viewing on an available mobile device and/or a computer.

Boutique Big Data: Reintegrating Close and Distant Reading of 19th-Century Newspapers

M. H. Beals
m.h.beals@lboro.ac.uk
Loughborough University, United Kingdom

From their earliest incarnations in the seventeenth-century, through their Georgian expansion into provincial and colonial markets and culminating in their late-Victorian transformation into New Journalism, British newspapers have relied upon scissors-and-paste journalism to meet consumer demands for the latest political intelligence and diverting content. Although this practice, wherein one newspaper extracted or wholly duplicated content from another, is well known to scholars of the periodical press, in-depth analysis of the process is hindered by the lack of formal records relating to the reprinting process. Although anecdotes abound, attributions were rarely and inconsistently given and, with no legal requirement to recompense the original author, formal records of where material was obtained were unnecessary. Even if they had existed, the number of titles that relied upon reprinted material makes systematic analysis impossible; for many periodicals, only a few issues, let alone business records, survive. However, mass digitisation of these periodicals, in both photographic and machine-readable form, offers historians a new opportunity to rediscover the mechanics of nineteenth-century reprinting. By undertaking multimodal and multi-scalar analyses of digitised periodicals, we can begin to reconstruct the precise journeys these texts took from their first appearance to their multiple ends.

Before the advent of the telegraph, individual texts were disseminated manually, through postal and private correspondence routes, over sea and land. This allowed for the relatively slow spread of texts across communication networks, as well their adaptation, truncation and expansion various stages. In a manner similar to modern internet memes, blogs and online news content, texts underwent evolutionary changes with each reprinting. These could be minute, such as the correction of spelling errors or the application of house style, or significant, through selective reordering and truncation to alter the overall meaning of the text. While identifying meme families, or collections of related texts, can help us understand what made particularly texts popular, or viral, it is only by tracing the specific trajectories and pathways of these texts that the causes and consequences of evolutionary changes can be understood.

Doing so requires us to approach these texts on multiple scales. First, by mining extremely large corpora, derived from several independent collections, we are able to identify a statistically sufficient portion of the historical network. Then, by carefully analysing the chronology and discrepancies between these reprints, hypotheses regarding institutional and industry standards can be posited and tested against the wider corpus. These efforts can be further buttressed by utilising manual transcriptions found in the personal archives of researchers using historical newspapers, such as the Scissors and Paste Database (www.scissorsandpaste.net). These transcriptions, far more accurate than the majority of datasets derived from optical character recognition, greatly improve the mining of the corpora, yielding a more complete initial network to analyse, as well as offset the skewing effect of the 'offline penumbra'.

This poster will explore the possibilities of large-scale reprint identification within and across digitised collections using a combination of Lou Bloomfield's *Copyfind* and project-specific code to identify matches between individual articles or full pages of texts in both manual (perfect) and OCR (messy) transcriptions. Exemplar collections include the British Library's 19th-Century Newspapers digital collection and planned expansions into the digital collections of the National Library of Wales (Welsh Newspaper Online) and of Australia (Trove). The poster will also demonstrate the means by which reprint branching can be mapped using chronology and character clustering and the relative precision of manual and computer-aided techniques. Finally, it will explore the nature of multi-scalar analysis and how we might best reintegrate 'boutique' periodical research, such as the author's *Scissors and Paste Database*, into large-scale text-mining projects.

While there has been a significant investment in the development of digital tools that can be used in the humanities, information about their use is frequently located in disciplinary silos, with little transfer of knowledge about the features of specific tools that make them valuable for research across the humanities. This poster shows the collaboration between two initiatives, the NeDiMAH Methods Ontology (NeMO) and the EuropeanaTech FLOSS Inventory Task Force. The aim was to carry out research in order to align the FLOSS Inventory against the Activity Types in NeMO, the Ontology of Digital Methods for the Humanities developed by the Digital Curation Unit (DCU), IMIS-ATHENA R.C with the ESF Network for Digital Methods in the Arts and Humanities (NeDiMAH).

The FLOSS Inventory is an effort undertaken by the Netherlands Institute for Sound and Vision and EuropeanaTech to raise awareness of, share access to, and improve the overall status of Open Source software available for cultural heritage developers internationally. The Inventory contains over 200 well-documented, active and relevant OS tools and is actively updated and maintained.

NeMO provides a conceptual framework for representing scholarly practice in the Humanities. This is the main output of NeDiMAH, a Network that ran from 2011- 15 and brought into collaboration 16 countries to document the practice of Digital Humanities across Europe in a series of Methodological Working Groups. Building on earlier expertise in digital taxonomies for the digital humanities, NeDiMAH facilitated a research project carried out by DCU, building upon earlier work on scholarly activity modeling in projects including DARIAH, EHRI and Europeana Cloud. NeMO is a formal ontology which enables the representation and codification of scholarly work by providing a controlled vocabulary of interrelated concepts. NeMO offers a flexible tagging system through a taxonomy of Activity Types, structured in five hierarchies that correspond roughly to scholarly primitives (Unsworth, 2000), and incorporates existing taxonomies and related work such as TadiRAH, Oxford ICT, and DH Commons.

The research teams working on FLOSS and NeMO collaborated to map each tool in the FLOSS inventory against NeMO Activity Types. According to the structure established by NeMO, scholarly research practices are divided into five core Activity Types within a scholarly research lifecycle: acquiring, communicating, conceiving, processing and seeking, which encompass narrower terms accounting for further detail and specialization. This study allows the integration of the information about tools gathered by FLOSS into a uniform conceptual framework for expressing knowledge about scholarly work. By doing so, it also validates the ability of the NeMO ontology to act as a sound framework for the conceptual representation of digital tools and services in one important area of the humanities. This mapping enables the categorisation of available tools according to the function they serve, and could permit researchers in the Humanities - even those without a technical background - to consult an authoritative list of tools covering their needs according to the type of activity they wish to undertake. Availability and the role that each tool can play in the research practice may increase its overall use by the community. The representation of the FLOSS Inventory using NeMO adds value to digital research, and the visualization of categorization ratios it provides facilitates an important debate about software development trends, probing the question whether development is weighted towards software tools that address researchers' needs, a major topic of research in Research Infrastructures across Europe and beyond.

Summary: This poster presents work on documenting user needs in the Humanities and Social Sciences as illustrated through Case Studies in the context of the Europeana Cloud “Unlocking Europe's Research via the Cloud” project. Conducted as part of a wider methodological effort including desk research, expert fora and a web survey, methodology and findings of actual use of innovative digital tools and services will be visually represented. This work will form the basis of the Europeana Research Case Studies which will seek to gather and process an evidence-based record of the information practices, needs and scholarly methods in the respective communities.

This poster reports on collaborative, cross-European work conducted during 2013-2015 in the context of the Europeana Cloud “Unlocking Europe's Research via the Cloud” project, and touches upon planned activities in the context of Europeana Research in 2016. Europeana Research is an initiative which aims to create stronger links between the cultural heritage sector and academia. More particularly, it aims to ensure that open, high-quality data from the cultural sector is available for reuse by the digital humanities community.

One of the main objectives of Europeana Cloud was the enhancement of the understanding of digital tools, research processes and scholarly content used in the Humanities and Social Sciences, thus informing the development of tools and aggregation of content in Europeana for research purposes. To this end, and in order to contribute towards the development of the new platform of Europeana Research, Case Studies were developed as part of a wider methodological effort which included desk research, expert fora and web survey for reaching user requirements.

The purpose of this poster is to visually represent the methodology followed and results reached in documenting actual use of innovative digital tools and services in the Humanities and Social Sciences research communities illustrated in three main Case Studies in the disciplines of Education, Art History and Sociology, and further complemented by satellite cases.

The Case Studies were initially selected based on the disciplines and tools that might best make use of current Europeana content. By defining “innovative” as “either performing functions that were previously unavailable, or performing already available functions in a qualitatively different way”, three tools were identified as best fitting this criteria (Transana, HyperImage, NodeXL) enriched by two “satellite” tools more frequently used in the respective research disciplines (NVivo, Voyant).

These were further approached following a threefold methodology of semi-structured interviews, empirical observation of the tools and background research. The results were then discussed both from the perspective of the discipline area, and through the lens of the scholarly primitives (Unsworth 2000, Palmer et al 2009), to determine their use with Europeana content. The poster will also highlight the importance of accessibility of data for research infrastructures and research groups and need to focus on high quality metadata and content both for Europeana Research and the wider GLAM sector, and will illustrate how digital tools are not themselves a guarantee of good research, as researchers do not necessarily use the same digital tool throughout the research process; rather they use one tool per step (one tool = one research primitive).

This poster will also present future work planned to be undertaken in the context of Europeana Research in 2016. Based on Europeana Cloud, a series of new Case Studies will be developed and expanded towards different research communities. The Europeana Research Case Studies will be undertaken in collaboration with existing European research initiatives, and will seek to gather and process an evidence-based record of the information practices, needs and scholarly methods of arts and humanities and social sciences researchers within the broad Europeana ecosystem and particularly in relation to Europeana content. The Case Studies will employ a mixed methods approach combining various ways of gathering empirical evidence on the information needs and scholarly methods employed in digitally-enabled arts and humanities and social sciences research across Europe and beyond.

symogih.org, a project in constant evolution

The collaborative platform for historical research developed as part of the *symogih.org* project has reached a mature stage[1]. With an active SPARQL endpoint, the system is now interoperable and interconnected[2]. It is housing 16 ongoing projects, including several on a European scale (France, Germany, Switzerland, Belgium); there are about 50 active users and it contains nearly 1.700.000 data rows. The research projects include, for example, the Siprojuris project[3], a prosopographic data publishing site interconnected with IdRef, the authority data repository of the French higher education libraries' catalogue[4]; the Historical Atlas of Political Territories[5], a project that is mapping the evolution of world political borders; Society Religion Science (SRS)[6], an experimental digital intellectual history website providing documents encoded in XML following the recommendations of the *Text Encoding Initiative* (TEI) and annotated using the *symogih.org* ontology[7].

The institution hosting the project is the *Laboratoire de recherche historique Rhône-Alpes*[8]. Its human and material resources being limited, to avoid a growth crisis and with a view to building an international community of users, the evolution of two principle aspects of the architecture of the *symogih.org* project needs to be reconsidered and planned for from today: these are,its interface with other information systems, in particular with those put in place by heritage institutions; and the management of a growing community of users.

The purpose of our DH 2016 Conference poster is to share our prospects with other DH projects and to present a proposal for the evolution of the platform and operational information, for both the technological and project management domains, and to call for an international collaboration which could function as a consortium.

Towards a distributed and multi-instantiated database

A possible technological answer to the challenge of the increasing number of projects hosted by the *symogih.org* platform, i.e. to provide the expected information centralization without creating a bottleneck and low performance, is to evolve its architecture by distributing the data between a primary node and several secondary nodes of a clustered database.

The primary node would contain all of the shared repositories (object authority records and instances of the collaborative ontology), as well as general-interest data. The secondary nodes, hosted in various research institutions, would contain the information produced by the local projects. To allow the collaborative management of a shared, good-quality ontology to be maintained, avoiding redundant and messy data, a user of any secondary node shoud be able to access all the data, whether it is held in their database instance or not, via a table held in the primary node, which would hold the keys of all the existing knowledge units and their location in the distributed system.

The whole information system will be interoperable with reference ontologies like CIDOC-CRM or FRBRoo and interlinked with authority files repositories (ISNI, VIAF, BNF, etc.). In addition, a growing portion of the information will be directly accessible in RDF format through a SPARQL endpoint, allowing the data to be queried at the same time as those from other linked data warehouses. The data will be available under a Creative Commons 4.0 international licence.

Establishing an international community of users

This distributed platform management entails the creation of an international organized community of users in the form of a consortium. This community will need to be built around a governance committee, responsible for ensuring a collaborative approach at all levels, from managing the definitions of ontology instances through to data capture. The primary node could be managed, as at present, by the *Pôle histoire numérique* (Digital History Department) of the LARHRA, founding institution of the *symogih.org* project; but it could be hosted in the data centre of an institutional structure such as, in France, the TGIR HumaNum[9].

The other nodes would be managed by teams made up of researchers and IT technicians, ensuring not only management of the respective databases and software development for the whole project, but also running local scientific projects and training users in data modelling and capture, working closely with the governance committee. The evolution towards the participation of projects using different languages will imply the implementation of a multilingual version of the information system, both at the level of the interface and for drafting instances of the collaborative ontology.

By offering access to a collaboratively designed ontology and a robust technological solution, intended for an increasingly wide community of users, the *symogih.org* project will contribute to the evolution of practices in the domain of data production and data curation in historical research.

Crosslingual Textual Emigration Analysis

Andre Blessing
andre.blessing@ims.uni-stuttgart.de
University of Stuttgart, Germany

Jonas Kuhn
jonas.kuhn@ims.uni-stuttgart.de
University of Stuttgart, Germany

The presented work describes the adaptation of a Natural Language Processing (NLP) based biographical data exploration system to a new language. We argue that such a transfer step has many characteristic properties of a typical challenge in the Digital Humanities (DH): Resources and tools of different origin and with different accuracy are combined for their use in a multidisciplinary context. Hence, we view the project context as an interesting test-bed for a few methodological considerations.

In previous work, we developed a web-based application called Textual Emigration Analysis (TEA) (Blessing and Kuhn, 2014). The system consists of two components. The import component automatically extracts emigration paths from a German Wikipedia data set. The user interface component provides several views (interactive map, aggregated tables and underlying textual content) on the extracted data. The whole application was originally designed for German Wikipedia articles and the applied NLP pipeline is based on webservices of the CLARIN-D infrastructure (Mahlow et al., 2014). Later, other German sources of biographical data were included by adapting the import component (ÖBL: Austrian Biographical Dictionary 1815-1950, and NDB: the New German Biography).

One often requested feature was the adaptation of the system to other languages. In DH research it is important to investigate different sources. As a consequence, textual data may include different languages. In particular, biographical analysis systems benefit if sources of different languages can be analysed. However, the development of such language-sensitive systems still lacks sufficient support. Therefore, the used methods should not require any knowledge of the new target language during development phase. In this work we present the adaptation process for French.

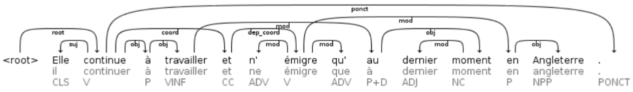

Figure 1: Parsed French sentence which describes an emigration path.Wikipedia and Wikidata are important resources for the development of language technology tools which also holds for cross-lingual approaches. Wikidata enables a clean mapping between the different language editions of Wikipedia. Following the idea of cross-lingual distant supervision (Blessing 2012), our method consists of three steps. First, we use the results of our TEA tool to find biographical articles that include mentions of emigration paths. Subsequently, Wikidata is used to map those articles to their corresponding French articles, if they exist. Finally, we use anchor points in the text to find comparable sentences.

In most cases, emigration sentences contain geospatial and time expressions (e.g., "He emigrated in 1941 to Switzerland."), which can be used to find comparable sentences in the target language. We exploit the hyperlink structure of Wikipedia to recognize geospatial expressions and HeidelTime (Strötgen, 2013) to identify time expressions. The locations can be mapped through Wikidata into the target language and the atomic date representation of HeidelTime enables a simple identification of all matching sentences in the target sentence.

Detecting Musical Paratext at Scale

Mark Edward Boettcher
mark.e.boettcher@dartmouth.edu
Dartmouth College, United States of America

John Wallace
john.m.wallace@dartmouth.edu
Dartmouth College, United States of America

Summary

In this work we will detail the open source tools, custom code and processing steps that were used to support textual analysis for a Digital Humanities (DH) project. Additionally, a more general genre classification tool will be described which was developed to support a machine learning model. Extensions of this work will be proposed that may allow these tools to identify types of text.

Background

The Multimedia in the Long 18th Century (Wallace et al., 2015) project is an attempt to automate the process of detecting and quantifying music references in French and English manuscripts written in the 'Long 18th Century', a period ranging from 1685 to 1815. Hundreds of thousands of volumes have been scanned to digital image format and are readily available from a number of online sources. The process of automatically analyzing these images and identifying music rendered in standard music notation is relatively trivial. However, the vast majority of music in the corpus is represented as text, often with various keywords or key phrases, i.e. 'sing the following to the tune of…'. Most people can recognize the difference between poetry, lyrics and prose almost immediately. We assimilate and analyze a large number of clues and usually reach the correct conclusion without conscious effort. This is not the case with the current state of the art in computer technology. While many separate pieces of the solution already exist, gaps still exist. To achieve our goals, it was decided that it would be necessary to leverage the existing work of others while adding a few innovations of our own.

Methods

We have developed a number of batch-processing tools to retrieve the relevant scanned PDF files from online sources and split them into individual images, each representing one page. We use the open source ImageMagick image processing tools to clean up the images. These are then fed to a customized version of the Tesseract OCR engine. Tesseract performs the optical character recognition (OCR) to convert the source images to HOCR files containing bounding box, plain text and recognition confidence levels for each individual paragraph, line and word. This is used to produce PDF files that duplicate the page layout of the original image and contain searchable text that is typically >90% accurate. We have developed an in-house tool to create training data for the machine learning (ML) algorithms used later on. The tool has a user interface that displays both the original image and the formatted PDF side by side. This tool allows the user to choose a category such as: lyrics, poetry, key word, key phrase, etc. The user is able to select regions of the page encompassing anywhere from a single word to the entire page. This generates a very fine-grained database, accurate to within a single word. This database is subsequently used to train the ML engine and to perform validation of the automated classification algorithms. Similar solutions typically have the users classify sections by operating on the page after it has been processed by the OCR engine. This can lead to misclassifications when the OCR results have numerous misspellings or imprecise page layout formatting. We have the user perform the manual classification on the original page images. This provides precise control and future proofing against improvements in OCR techniques. We employ a multi-pronged, multi-pass approach in order to differentiate music lyrics from other types of verse or prose. We perform detailed shape analysis to identify sections of text that 'look' like some form of verse. Symmetry, right and left indentation, relative length of alternating lines and other shape factors are examined. We look at letter casing based on the OCR-processed version. As a result we achieve 90-100% correct identification of structured verse for almost every volume with a relatively small number of false positives. Once we have identified sections of verses, we used a number of empirically determined factors such as relative word frequency, occurrence of n-grams, proximity of keywords/key phrases and comparison to databases of known song lyrics.

Future Development

We are continuing to fine-tune our model, especially in our ability to handle poorly scanned or otherwise nonconforming documents. All software and techniques that we have developed will be made publicly available so that we can share the results of our efforts and with the hope that others will feel free to contribute. Beyond music detection, we see a number of potential applications in the Digital Humanities. The training set region selection can be used just as easily to select features in cuneiform script or Norse runes.

Bibliography

Collaborative Annotation and Exploration of Literary Works in Learning Contexts

Andrea Bolioli
andrea.bolioli@celi.it
CELI, Italy

Riccardo Tasso
tasso@celi.it
CELI, Italy

In this poster we present the web application "CBook" (or "Crunched Book"), i.e. a DH tool for collaborative reading, annotation and exploration of literary works. The web app can be found here: https://cbook.it/ . It was used in learning contexts during the research projects *Librare* (in high schools) and *Pinocchio: la comunità dei balocchi* (in middle schools). Other teachers are using it in complete autonomy in their classrooms.

Students and teachers can annotate portions of text, explore novel's settings through interactive maps, add and share images and other contents related to a literary work, search for terms into the text (e.g. in the quoted speeches of a particular character), explore connections between characters in their social networks.

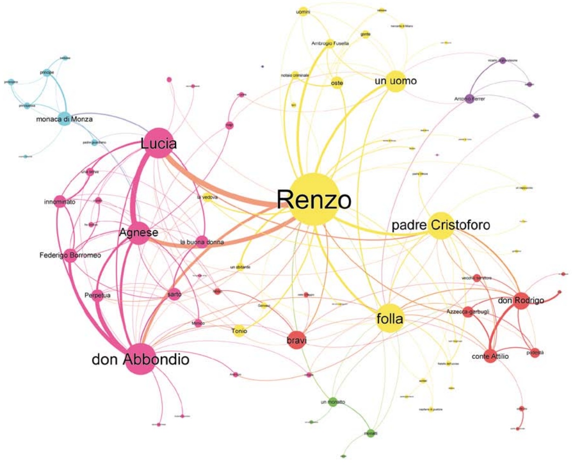
The CBook is used by italian students and their teachers, as an innovative digital tool for reading and studying literature, in primary and secondary schools. The list of schools involved in *Librare* project, for example, can be found here:

Some Italian and English classics are already present in the web app, the full work or a portion: *I promessi sposi* (complete), *Le avventure di Pinocchio* (complete), *Decameron* (3 novels), *Odissea* (book VI, italian translation), *Romeo and Juliet* (complete), *The Wonderful Wizard of Oz* (chapters 15). Other works requested by teachers (e.g. Dante's *Purgatorio*), will be added to the web app in the next months.

We can say that CBook is, in some sense, a collaborative anthology (or an Anthology 2.0), i.e. a collection of literary works selected by the users that are reading, annotating and exploring the works, using some DH tools and methodologies (collaborative annotation, interactive maps, SNA of characters, text mining, etc).

The web app was designed and tested in collaboration with high school teachers, students and DH scholars. It is used on tablets, PCs, interactive whiteboards, and smartphones (with less functionalities).

An important feature of CBook is interoperability between models and tools for TEI XML annotation and models and tools for semantic annotation. A significant difference between the CBook and other annotation tools is its emphasis on user-centered design (for students and teachers).



The annotation system of CBook is based on Annotator (http://annotatorjs.org/) , "an opensource JavaScript library to easily add annotation functionality to any webpage", following annotation standards for digital documents developed by the W3C Web Annotation Working Group. The User Interface is written in HTML5, CSS and Javascript. The texts were annotated in XML, using a simplified version of TEI. On the server side, we use a graph Database and Java.

The actions of cbook's users (sign in, sign out, comment) can be monitored in a public dashboard accessible here: http:/sensori.librare.org/librare/. In this dashboard you can see the events concerning both cbooks (digital) and paper books that users were working on in this project.

The first version of "The digital lab of crunched books" was the Second Runner Up of Digital Humanities Awards 2014 in the Best DH Tool or Suite of Tools section (3 march 2015): http://dhawards.org/dhawards2014/results/

Introduction

The idea that narrative literature comprises two distinct types of speech – that of the narrator and that of characters – dates as far back as Plato's *Republic*. The philosopher distinguished **diegesis** (narrative, narration), when the author speaks for himself, from **mimesis** (imitation, enactment), when the author puts words in the mouths of his or her fictional actors.

Modern narratology places high emphasis on the concepts of **point of view** (POV) and **POV structure** of a text (Schmid, 2003), which are often expressed through specific combinations of author's and character's speech. Authors may switch between the POV's by employing character-specific lexica and the use of temporal and spatial references that indicate certain POV (Uspensky, 1983).

Leo Tolstoy was one of the writers known for **conscious** usage of such means to differentiate between the character POV's. He was a firm proponent of the idea that each character has to speak his/her **own** language if the book was to be convincing. Critics confirm that Tolstoy's characters do have their personal styles of conversation.

In this paper we made an attempt to provide quantitative grounds for these claims. For that purpose we extracted all speech activity instances from *War and Peace*, attributed them to the speaker characters and used the data to train a classifier. Our hypothesis was that if Tolstoy's characters actually possessed these unique speech features, the classifier would be able to predict the speaker with some tolerable accuracy.

Data

Instances of direct speech were extracted from the text with help of ABBYY Compreno (Starostin et al., 2014). For more details on the extraction procedure see (Bonch-Osmolovskaya A., Skorinkin D., 2015). The total number of extracted speech instances was 6853, of which 4476 had their speakers identified.

Apart from the speaker, a number of additional attributes were extracted for each instance: text of the speech, text of the author's introduction ('she cried', 'he said with a laugh'), normalized speech predicate ('to say', 'to cry', 'to whisper', 'to burst out'), the number of question and exclamatory phrases within one speech, the number of words in the speech and the number of punctuation marks.

Before we carried out the experiment we attempted to analyze the data and detect potentially informative features. It appeared that certain characters (Natasha Rostov, Nikolai Rostov) tend to speak in short intermittent bursts and exclaim a lot, so they were expected to have higher average punctuation marks per word ratio and bigger shares of exclamatory speech. To confirm this intuition we gathered some aggregated statistics (see Fig. 1).

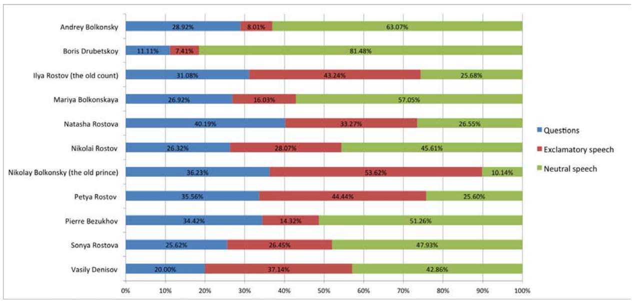

Fig. 1 Shares of exclamatory and question sentences in the speech of the main characters

Exclamatory and question phrases together make up the 'emotional part' of a character's speech. Its share (Fig. 2) seems to correlate with age extremities. Prince Nikolay Bolkonsky is probably the oldest of the main characters, and as his age gets the better of him in the course of the novel, he turns more and more emotional and impulsive; Petya Rostov, on the other hand, is an exuberant and emotional boy, the youngest of the Rostov family.

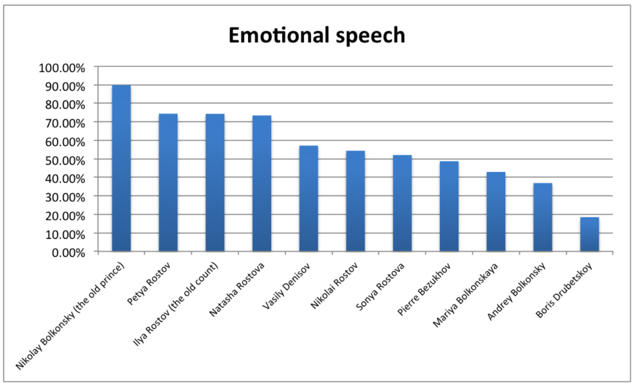

Fig. 2 Characters with the highest share of 'emotional speech' (exclamatory and question sentences combined)

Fig. 3 reflects character's overall punctuation marks per word ratios. Seems like the 'burst speech' pattern is hereditary within the Rostov family:

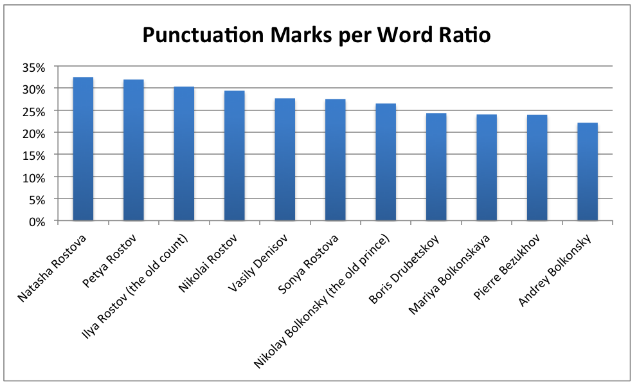

Fig. 3 Punctuation marks per word ratio in the direct speech text

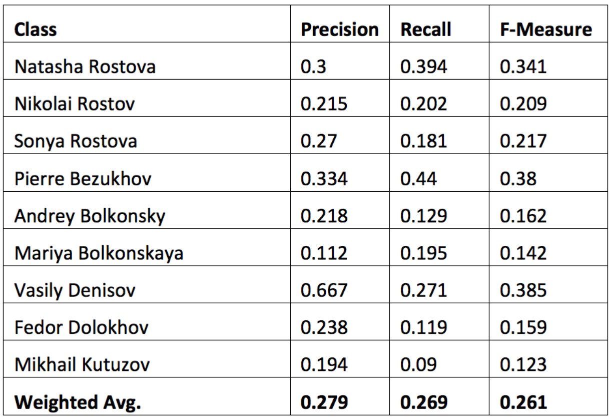
Machine learning experiment

Next step was to try and use some of these features to train a classifier. We used several standard algorithms, of which Random Forest demonstrated the best results. At the first stage we created a baseline by training the classifier solely on the lemma and word form frequencies of speech. Table 1 shows the results we obtained.



Class	Precision	Recall	F-Measure
Natasha Rostova	0.3	0.394	0.341
Nikolai Rostov	0.215	0.202	0.209
Sonya Rostova	0.27	0.181	0.217
Pierre Bezukhov	0.334	0.44	0.38
Andrey Bolkonsky	0.218	0.129	0.162
Mariya Bolkonskaya	0.112	0.195	0.142

Weighted Avg.	**0.279**	**0.269**	**0.261**

Table 2 Results for classifier trained with additional features

Results & discussion

Our first attempts to automatically classify speaker in Tolstoy's text did not prove successful. The best F-measure we were able to obtain so far does not exceed 0.385 for an individual character. However, we were able to show that some formal features, such as punctuation marks per word ratio or the number of exclamatory/question sentences, might improve classification quality. This assumption can be confirmed by the figures in the Data section, where the aggregated values of features correspond with certain character traits that are apparent to the human reader.

Mobile Makerspaces: Te(a)chnology, Design and Digital Humanities

Christina Boyles
christina-boyles@uiowa.edu
University of Iowa, United States of America

Lindsay Kistler Mattock
lindsay-mattock@uiowa.edu
University of Iowa, United States of America

This project explores the development of a mobile makerspace for graduate and undergraduate DH scholars at the University of Iowa and Grinnell College. Blending the approaches of makerspaces like the DHMakerBus <http://dhmakerbus.com> and University of Victoria's Maker Lab <http://maker.uvic.ca/>, this DH makerspace will investigate the use of a suite of tools designed to support the development digital literacy and technological proficiency for students across the DH curriculum. By combining the mobility of the DHMakerBus with the experimental computing of the University of Victoria's Maker Lab, we will produce a new method of digital humanities pedagogy that welcomes the participation of primary and secondary students and educators, local citizens, and digital humanities practitioners.

Designed to support experiential learning - learning through making - in undergraduate and graduate classrooms, across campus, and across Iowa, the makerspace focuses on the computer processes that go into making rather than the products produced by them. As such, it emphasizes the process of making itself, whether successful, failed, or flawed.

In *Debates in the Digital Humanities* Alexander Reid suggest that most graduate students have had little exposure to digital technology during their undergraduate education, "enter[ing] his or her graduate education as a novice in regards to the digital" (357). It is likely, therefore, that his assessment applies to our broader community of Eastern Iowa. To address the our users' lack technological expertise, we are scaffolding projects for learners—starting with littlebits, moving to RaspberryPi, and ending with Aruduino. These tools were selected for the pilot study for their mobility, accessibility, and affordability. Each of these factors makes it easy to implement and replicate the makerspace in unconventional venues—secondary schools, adult education classes, and community events. Additionally, these tools gradually increase participants' comfort and literacy with digital tools.

Te(a)chnology

This mobile DH makerspace utilizes three "gateway" technologies selected for their robust design, sophisticated abilities, and ease of use, and portability:

1. *littleBits* - a digital building kit based on the logic of Lego that allow students and makers to build digital tools and explore the internal logic of computers <http://littlebits.cc>

2. *Raspberry Pi* - a small, but powerful computer, about the size of a credit card with a GUI interface and Python encoding that integrates touchscreens and digital cameras <https://www.raspberrypi.org>

3. *Arduino Kit for littleBits* - build on the capabilities of the littleBits library by adding the Arduino computer, teaching students how to expand their coding skills by working with Java-based programming <http://littlebits.cc/kits/arduino-coding-kit>

Together these three technologies scaffold to develop users' confidence in coding, building, project management, and digital literacy. This particular suite of tools is easily transportable to classrooms and campuses, or may be shipped to students participating in online sections of workshops and seminars. Furthermore, the mobility of the makerspace allows for collaborations with non-traditional and non-academic communities including secondary students, adult education seminars, community partners, and interested citizens. Participants will come away from workshops utilizing this mobile makerspace with increased knowledge of computer processes, an awareness of design thinking, and the confidence to collaborate on a variety of projects with diverse teams.

Methodology

This poster will report on the results of a pilot study of the mobile DH makerspace. Participants in the pilot study included undergraduate and graduate students and faculty completing design challenges and product tests. Working with a convenience sample of graduate and undergraduate students, the makerspace was tested in two modes: (1) students working together in the same space and (2) students working across a distance, collaborating virtually through videoconferencing and other digital collaboration tools.

We assessed the increased digital literacy and confidence of participants through a series of surveys, visualization exercises, focus group interviews, and participant observation. The results of this pilot study will inform the development of individual course units and workshops for courses within the DH Curriculum at the University of Iowa and Grinnell College, in addition to workshops for faculty and staff across both campuses and outreach efforts to reach the off-campus community.

Conclusions

This mobile makerspace affords opportunities for makers to build confidence creating and experimenting with digital tools while allowing students to build digital literacy skills and address other key aspects of DH education, including: working in interdisciplinary teams, applying digital practices, managing projects, and explaining technology (Rockwell and Sinclair 182-183). Ultimately, we argue that this model can be emulated in other educational settings as a new model for DH pedagogy that is more accessible and more collaborative than traditional makerspaces.

A special thanks to Miriam Posner for generously agreeing to review this abstract and provide feedback and suggestions.

Newspaper archives as a linguistic corpus

This research investigates methods to study linguistic evolution using a corpus of scanned newspapers. We use a corpus of 4 million press articles covering about 200 years of archives, thus documenting indirectly the evolution of written language. The corpus is made out of digitized facsimiles of *Le Journal de Genève* (1826–1997) and *La Gazette de Lausanne* (1804–1997). For each journal, the daily scanned issues were algorithmically transcribed using an OCR system. The whole archive represents more than 20 TB of scanned data and contains about two billion words, putting it beyond the capabilities of most usual analysis techniques for regular desktop computers.

The corpus can be easily divided into subsets corresponding to the year of publication. However, the number of pages and their content fluctuates greatly depending on the year, ranging from 280'000 in the early 19th century to about 18 million in the later years of the 20th century. Figure 1 shows the relative size of each subset in terms of number of words for *Le Journal de Genève* (JDG) and *La Gazette de Lausanne* (GDL).

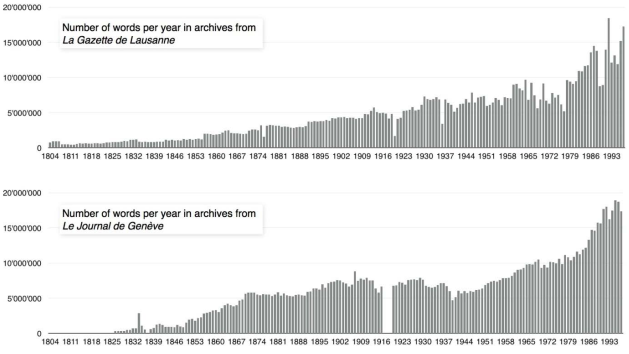

Figure 1: corpus size versus years for GDL (top) and JDG (bottom).

Considering the lack of data for *Le Journal de Genève* for the years 1837, 1917, 1918 and 1919, we left those out in all further graphs and analytics. In addition, some years had to be removed because the scanning quality was too poor (1834, 1835, 1859 and 1860 for JDG and 1808 for GDL).

Lexical kernels: Definition and basic measures

A straightforward approach to the problem consists in computing a textual distance between subsets of the corpora. One could, for instance, easily compute the so-called Jaccard distance (Jaccard 1901, Jaccard 1912) between two consecutive vocabularies. In the same way, other distances could also be tried, such as those given by Kullback and Leibler (1951), Kullback (1987), Chi-squared distance (Sakoda, 1981), and Cosine similarity (Singhal, 2001).

However, the uneven distribution of the corpus subsets (Figure 1) causes methodological difficulties for interpreting these distances. An increase in the lexicon size causes an indirect increase in the linguistic drift as measured by the Jaccard formula (Sternitzke and Bergmann, 2009). Under such conditions, it is difficult to untangle the effects of the unevenness of the distribution of subsets of the corpus from the actual appearance and disappearance of words.

These difficulties of interpretation motivate the exploration of another, possibly sounder approach to the same problem. Let us define a *lexical kernel* $K_{x,\, y,\, C}$ as the sequential subset of unique words common to a given period starting in year *x* and finishing in year *y* of a corpus *C*.

$K_{1804,1998›GDL}$ is, for instance, the subset of all words present in the yearly corpus of *La Gazette de Lausanne*. It contains 5242 unique words that have been used for about 200 years. The kernel $K_{1826,1998,JDG}$ contains 7486 unique words, covering a period of about 170 years. As the covered period is smaller, the kernel is naturally larger.

The exact contents of both $K_{1804,1998,GDL}$ and $K_{1826,1998,JDG}$ are provided in the appendix. It is interesting to note that 4465 words are in common between the two kernels.

Figure 2 shows the statistical distribution of word-typologies for both kernels.

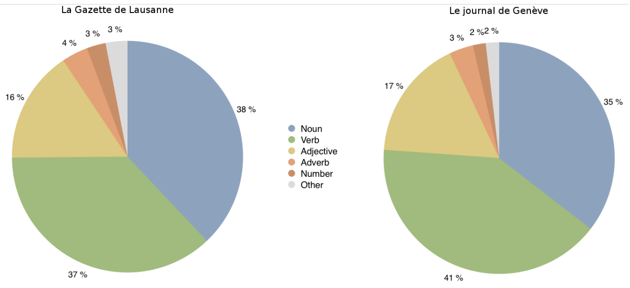

Figure 2: Distribution in terms of typologies of words contained in the kernel of $K_{1798,1998,\mathrm{GDL}}$ (left) and $K_{1826,1998,\mathrm{JDG}}$ (right).

Word resilience

Extending the notion of a kernel, it is rather easy to study the resilience of a given word. Let R_d be the union of all words contained in a kernel corresponding to a duration of $y - x \geq d$ years. For instance, $R100$ contains all the words that maintain themselves in the corpus for at least 100 years. R subsets are organized as concentric sets:

$$R_1 \subset R_2 \subset \dots \subset R_i \subset R_i + 1$$

The relative proportion of each subset sheds light on both the stability and dynamics of language change. Figure 3 shows the distribution of word resilience for both journals.

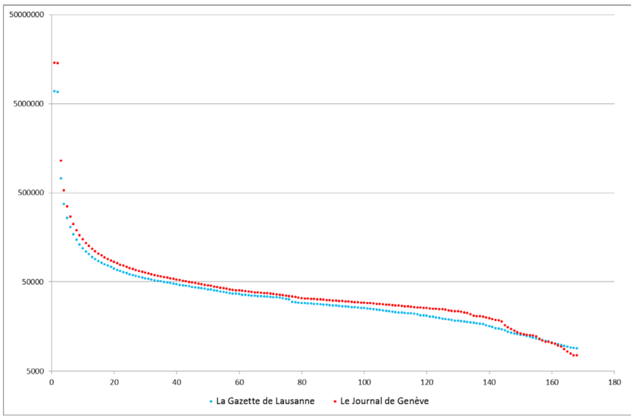

Figure 3: Size of R_d versus the number of maintained years d (logarithmic scale) showing the word resilience distribution for JDG (green) and GDL (blue).

The GDL resilience curve is normalized (on the same years range as JDG) in order to make the two curves comparable. This representation of R_d shows a similar global word resilience trend for both JDG and GDL. However, we notice that the two curves intersect when considering the longest durations.

Discussion

Large databases of scanned newspapers open new avenues for studying linguistic evolution. However, these studies should be conducted with sound methodologies in order to avoid misinterpretation of artifacts. Common pitfalls include misinterpreting results linked to the size variation of the subsets or overgeneralizing results obtained on one particular newspaper corpus to general linguistic evolution.

In this paper, we have introduced the notion of a kernel as a possible approach to study linguistic changes under the lens of linguistic stability. Focusing on stable words and their relative distribution is likely to make interpretations more robust.

Results were computed on two independent corpora. It is striking to see that most of the results obtained are extremely similar for both. The kernels composition in terms of grammatical word typologies is very similar. Results in terms of word resilience are also similar. This suggests that our methods are indeed measuring general linguistic phenomena beyond the specificity of the corpora chosen for this study. However, this still needs to be confirmed with subsequent studies involving other corpora, such as non-journalistic texts and texts in other languages.

Beyond Shot Lengths – Using Language Data and Color Information as Additional Parameters for Quantitative Movie Analysis

Introduction: Quantitative movie analysis

Film studies make use of both, qualitative as well as quantitative methods (Korte, 2004). While there is a large variety of qualitative approaches to analyze movies (cf. e.g. Monaco, 2009; Sikov, 2010), most quantitative attempts seem to be focused on the analysis of the length and frequency of a film's shots, which are understood to be the "single definable elements which can be nominated and described" (Salt, 2006: 14). After Barry Salt's[1] seminal article "Statistical Style Analysis of Motion Pictures" appeared in 1974, numerous other quantitative studies were to follow[2]. "Cinemetrics" (Tsivian, 2009) has been suggested as a term to describe these quantitative, shot-based approaches for analyzing movies. Cinemetrics is also the name of a large online database that contains information about shot lengths and frequencies for several thousand films[3].

Studies that take into account quantifiable parameters other than shots are, however, rather rare. Among the few examples are Hoyt et al. (2014), who describe a tool that can be used to visualize relations between the characters of a film. Another example can be found in Ewerth et al. (2009), who present a toolkit that allows researchers to automatically detect shots and camera motion, superimposed text, faces and audio signals. While the latter example is rather focused on the automatic annotation of quantitative features, other projects, such as Lev Manovich's (2013) „Visualizing Vertov", focus on the presentation and visualization of quantitative parameters.

In this paper, we suggest to enhance the existing, shot-focused approaches to quantitative movie analysis, by considering additional parameters, such as language (cf. Forchini, 2012) and color use (cf. Flückinger, 2011). We present a prototype that can be used to automatically extract and analyze these parameters from movies and that makes the results accessible in an interactive visualization.

A prototype for the analysis of language and color use in movies

Language use as well as the use of colors in movies have long been known in the area of qualitative film studies. We argue, that these parameters are equally suited for a quantitative approach and present an experimental prototype that can be used to quantify the language and color used in different movies. Much like Clement et al. (2008), who discuss the drawbacks and opportunities of computer-based methods in the field of literary studies, we believe that digital, quantitative movie analysis tools can be helpful in "offering provocations, surfacing evidence, suggesting patterns and structures, or adumbrating trends". As the prototype allows researchers to investigate potential correlations between color usage and corresponding language in a movie, it can be used to examine questions such as the following:

- Are there characteristic patterns in color or language use for movies from different eras, genres, or directors (e.g. dark colors and words such as "kill" or "blood" in horror movies)?
- Are there characteristic color patterns within a film that correlate with the occurrence of certain characters or objects (e.g. bright colors whenever the hero is speaking)?
- Are there characteristic color patterns within a film that correlate with the sentiment of the language (e.g. dark colors for language with negative sentiment)?

Obtaining language and color data

Machine-readable instances of movie language can be obtained fairly easy in the form of subtitle files, which are freely available via sites such as OpenSubtitles[4]; for a precompiled corpus of subtitles also cf. Tiedemann (2012). The standard file structure of such subtitles contains a timestamp as well as a transcription of the actual dialog fragments.

Information about color usage can be extracted directly from the movie itself, by cutting the digital movie into single frames and by calculating the most frequent colors for each frame (color histograms).

Analyzer component

Our prototype comprises an analyzer and a viewer component. The analyzer can be used to extract single frames from a movie by using the open source tool FFmpeg[5]. We used a K-means Cluster algorithm (Wu, 2012) to group together similar RGB values in each frame, as the actual variation of distinct RGB values is too high to allow for any kind of meaningful, quantitative interpretation. The analyzer also processes the subtitle file of a movie and uses Python NLTK[6] to perform basic POS tagging, as we are mainly interested in how nouns correlate with certain colors. We used the Python library TextBlob[7] to perform a simple sentiment analysis for each of the adjectives, tagging them with a polarity score between -1 (negative) and +1 (positive). After the analysis, each frame is saved as a JPG file; all quantitative data is stored in a JSON file.

Viewer component

The viewer component uses this data to generate an interactive HTML page that can be viewed in any recent web browser. A popular visualization of the most frequent colors that occur in a movie can be found in the MovieBarcodes[8] project. In a MovieBarcode, each frame of a movie is skewed to be only one pixel wide; all frames are then lined up in a row that looks very much like a colored barcode. On the overview page of our tool, all movies that have been analyzed before are rendered in a MovieBarcode visualization, together with information of the four most frequent colors in the movie (cf. Fig. 1). This view can be used to compare various movies with each other from a more distant perspective.

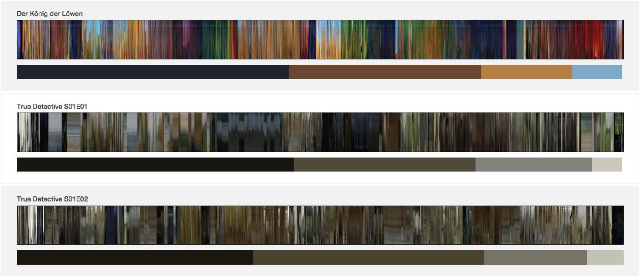

Figure 1: Overview of analyzed films in a MovieBarcode visualization ("The Lion King", top; "True Detective, season 1, episode 1", middle; "True Detective, season 1, episode 2", bottom).

By clicking on one of the MovieBarcodes, the tool zooms into the respective movie and renders different kinds of information in a more detailed view (cf. Fig. 2).

Below the MovieBarcode appears a sentiment graph that aggregates a score between -1 and +1 for each dialog. In the bottom row, the most frequent nouns are displayed. All different types of information are also aligned to the time axis of the movie. The visualization is fully interactive, i.e. by hovering over one of the frames in the MovieBarcode, or a node in the sentiment graph or the noun distribution, the corresponding frame and subtitle appear as an overlay. The complete movie can also be navigated back and forth by means of the arrow keys.

Conclusion and future directions

We believe the real strength of a quantitative approach that makes use of language and color information lies in a mix of "distant watching" (cf. Howanitz, 2015) and close watching, i.e. characteristic language-color patterns identified in specific movies can be used as a query to search other movies for similar patterns. Our next steps will therefore go into the direction of an information system that allows researchers to search and compare a collection of movies according to language and color characteristics.

From Ashes to Ashé: Digital Disaster Archives as Memorials

Patricia Lynn Carlton
carltonpatricia@knights.ucf.edu
University of Central Florida, United States of America

The rapid proliferations of digital archives that develop in response to, and often in the immediate aftermath of, globalized, catastrophic events are not only repositories for historical documentation and collective memories, but are also spaces where rituals of mourning and formations of subject identity can be critically examined. This poster presents close and distanced readings of the mission statements and selected verbal and visual elements of four disaster archives/memorials: The September 11 Documentary Project; The National September 11 Memorial Museum; Our Marathon: The Boston Bombing Digital Archive and WBUR Oral History Project; and UC QuakeStudies.

Optimally, the disaster memorial archive aggregates and displays artifacts of mourning, recovery, and a diversity of shared memories while simultaneously facilitating a sense of public agency and participation in the community's collective wellbeing. As evidenced by the expansion of local cultural heritage archives and crowdsourced collection development, collections of local, private memories co-exist with other documents of official or journalistic origins. Archivists Joan Schwartz and Terry Cook are among many who discuss the paradigm shifts in the archive profession that have been initiated by postmodern ideas and facilitated by the affordances of digitization (Schwartz and Cook, 2002). Contemporary archives reach into the local constituencies and beyond in the increasingly global and interdisciplinary network of digital archives (McKemmish and Gilliland, 2004: 84).

Notwithstanding the stated missions of disaster archives to provide an open-source archive that facilitates the participation by all constituents and interested public, the archival affinity for historical truth and broad representation of its public can sometimes work against public mourning and recovery. As one of my research questions, I explore whether the archival affinity for historical truth and broad representation of its public can co-exist with public mourning and recovery. Modern archives were traditionally associated with progressive and positivist concepts of history whereas memory was associated with unstable sensory triggers and artifices (including rhetorical applications). Postmodern influences and recordings of 20th and 21st century witnesses to and survivors of war crimes and other atrocities have influenced the policies and heuristics used by archivists and historians to critically assess and incorporate individual and collective memories of previously marginalized populations in the archive.

Although skepticism towards the evidentiary value of collective memory has abated, the tasks of balancing memories with official accounts are, nevertheless, complicated. The eventual selection, classification, and creation of policies for access and long-term preservation are negotiable products—an outcome of the balance of power between the public and the archive, and also between the digital media and technical platforms. From my research that triangulates data from my critical analysis of the purpose and functionality of disaster archives, and field studies, I coded themes and abstracted dimensions of private and public mourning, formations of subject identity (such as witness, victim, first responder, or "other"), and evidence of ethics and personal judgment used to create archival policies and collections. The refinements of these dimensions and data visualizations are represented in the poster.

Beyond the discovery of relationships between these dimensions and attaining insight into, if not a solution to, whether the historical and memorializing functions can seamlessly merge in the disaster archive, this poster also rationalizes the interdisciplinary methods of ethnographic and social science research as applied to humanities issues and, conversely, assumes a humanities perspective in critiquing the technical infrastructures of the reviewed disaster archive/memorials. The digital disaster archive promotes the active outreach and mobilization of local communities and establishes models for building resilience to the globalized man-made and naturally caused disasters.

The aesthetics of the archive—the database structure and narratives told within—is also an ethical decision. Sharon Daniel (2007: 150) describes these collaborative spaces (archives, in general) as "dialogic spaces in which the acts of writing, imaging, storytelling, and political statement are a collective production, a process rooted in social interaction and dialogue that produces a narrative without authorial consistency." The narratives emerging from the disaster archive/memorials convey an urgency to rebuild and perhaps, redefine the rituals of mourning and civic responsibility to others. It is the intent of this poster to illustrate the narrative arc of my research, highlighting the areas of interest for digital humanists, including the construction of an ethical and aesthetic database, and to illuminate patterns of online memorialization in disaster archives.

Poetry in Prose: automatic identification of verses in brazilian literature

In 1946, the brazilian poet Guilherme de Almeida published a study on the structured patterns of verses that he discovered in the prose of 'Os Sertões' ('Rebellion in the Backlands') by Euclides da Cunha (1902). According to Almeida's work, there is, in the Euclidean prose, apparently more often at the end of the paragraphs, versification structures of various rhythmic patterns. In 1996, another study on the same literary work was published by Augusto de Campos validated Almeida's discovery and revealed several others versified patterns in Euclidean prose. Dodecasyllables and Alexandrines are among the most used metric patterns, in varied combinations and positions. The diversity of patterns found, disregarding "the strict metrification" and admitting "more rhythmic freedom" (Campos, 1996), creates surprising zones of tension, "areas spread with poetry in significant portions of poetry in his prose" (Campos, 1996).

The process of separating and nesting of poetry syllables, the scansion process, is usually applied to text structures categorically defined as poetry, allowing mapping of poetry metric characteristics present in the author's writing. Performed by a person, the same analysis carried out by Almeida and Campos require, depending on the size of the piece, hours, days or even months of work.

Our work proposes the use of computational techniques to perform the process of automated scansion and analysis of Euclides da Cunha's prose, revealing its verse structures, thus reducing time for the task, providing a new tool for prose analysis and opening a new research agenda. These verse structures, distributed along the text, are found using computational methods based on scansion rules for Portuguese language. As the location of these structures are not previously given, any sentence is treated as a potential candidate for a verse, moreover segments of the sentences can also be considered.

In order to identify metric verses in the text, our system performs four major steps: extraction of sentences, separation of syllables, scansion, and overlay of verses in the original text. From a digital copy of the book, sentences are extracted according to punctuation mark present in literary piece. In Portuguese, the rhythm or musicality of a verse follows the alternance of strong (tonic) syllables and weak (atonic) syllables, so along with syllable boundaries, the position of the tonic syllable is also identified for every word. Therefore, every word in each sentence undergoes syllable separation following grammatical rules, applying the software developed by Neto et al (2015), defining initial syllable boundaries. Besides the positions of tonic syllables are also identified, determining rhythmic features.

To identify verses, the final process of scansion is performed, considering intravocabular (syneresis and diaeresis) and intervocabular (elision and crasis) phonological changes. These changes may alter initial syllable count, for example with the omission of one or more sounds, merging two syllables in a single one. As a final output, the verses identified are overlaid on the original document, along with verse classification, metric count, syllable separations and tonic syllables position, replacing the original sentence, allowing analysis by the user in context.

Initial experiments with the proposed system were performed for the book ‘Os Sertões’ by Euclides da Cunha, aiming to reproduce in a computer lab the work performed by Guilherme de Almeida in the 40s and Augusto de Campos in the 90s. As an example of the results, in page 67, the system identified previously twenty-four candidates verses. Of these, we have, "O sertanejo é, antes de tudo, um forte", one segment of text that starts the third chapter, identified by our system as a dodecasyllable "O / ser/ta/ne+/jo é+,/ an+/tes/ de/ tu+/do/ um/ for+/te", where ‘+’ identifies a tonic syllable, and, starting the third paragraph, "É o homem permanentemente fatigado.", a autonomous paragraph which was also identified by our system as a dodecasyllable, “É+ / o ho+/mem / per/ma/nen/te/men+/te / fa/ti/ga+/do.”. Both verses were indicated by Augusto de Campos in his work. Overall, among dodecasyllables and decasyllables, considering only whole sentences as a possible verse, our system was able to identify 273 verses, many of them already manually identified by Almeida or Campos. Nevertheless, previous works on the annotation of verses in the book ‘Os Sertões’ were not comprehensive annotations, so it is not possible to have full statistics on accuracy. Nevertheless, our system has exactly identified 52% of Augusto de Campos’s annotated verses, and the other 48% of the verses were identified with a difference of one unit in syllable count, due to differences in elision.

Various approaches have been proposed to publish XML/TEI scholarly editions or XML/EAD finding aids on line, but no standard XML software with a ready to use web application has yet emerged. As a possible next step after the XML mark-up of an edition or of an inventory, online publications are still a difficult issue for many projects in Digital humanities. Among available frameworks (like eXist or baseX) there is no ready to use web application to easily expose XML scholarly corpora as Linked Open Data (LOD).

Initiated by the Digital humanities network of ENS Lyon (Atelier des Humanités Numériques de l'ENS de Lyon), SynopsX is a lightweight framework which goal is to easily publish and expose XML scholarly corpora. It's a full XQuery web application built with the native XML database BaseX. Involving different partners from various institutions the project is developed as a free and open source software under GNU, and is hosted on GitHub (https://github.com/synopsx). Three principles have guided the conception of the software: collaboration, mutualization and genericization. Thus, we decided to put together all the publication problems and needs we could encounter in our very various Digital Humanities corpora (disciplines, approaches, institutions) to specify the needs of a generic web application.

SynopsX has been conceived as a scalable and easily customizable solution for XML publication of XML files (TEI, EAD, OAI, etc.). The software brings a templating system for various renderings of XML resources according to predefined or customized mappings from XML data to various output formats. SynopsX use the BaseX implementation of Adam Retter's proposed specifications for RESTXQ. Because it allows full control on the URL scheme to build real REST applications, it could be used to expose XML corpora as Linked Open Data.

This poster will present the needs of LOD for XML corpora publication. It will explain the different strategies that could be used and how we're planning to use a RESTXQ controller with views and models to propose a tool that allows the contents exposition as LOD through a restful API.

Enhancing Close Reading

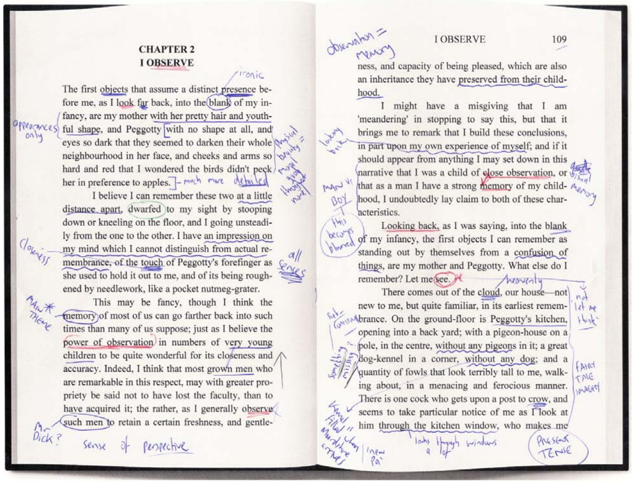
Motivation

In last years, the advancements in computer science brought a global change in the way information is stored, retrieved and analyzed. The digital humanities also benefit from these developments, and now, a vast amount of texts is available in digital form. This information explosion generates interesting research questions for humanities scholars who are capable of deriving new insights from this knowledge bank. In order to support humanities scholars, many visualization techniques – summarized in a survey (Jänicke et al., 2015b) – were developed to aid exploring large texts collections. Most of these techniques are interactive and belong to the category of distant reading (Moretti, 2005). The authors of the mentioned survey observe that less work has been done to improve the close reading capabilities of humanities scholars even though they are often focused on close reading text passages.

Close reading is the careful interpretation of the text, where the scholar iteratively reads the text in order to explore its meaning, inherent topics and occurring relationships (Boyles, 2013). Traditionally, close reading is done on paper. Several ideas and thoughts are made persistent by annotations written at the margins alongside the text (see Figure 1). But as the margin space is limited, not all observations can be put around the text. So, annotations may become cluttered and confusing for the reader, especially, when obsolete ideas are struck through. Despite its disadvantages, annotating on paper is still quite popular as it benefits the scholars to record observations about the hypothesis and all these changes reappear in front of the scholar's eyes as soon as he re-reads the text passage. We observed that the way of annotating in close reading resembles the idea of mind maps (Buzan et al., 1993) that are based on a central concept and thoughts are represented around it using lines and text. In the close reading scenario, the text can be considered as the central concept and annotations represent thoughts.

An important task of computer science is to enhance the original workflows of researchers with computational methods. As most humanities scholars are well trained in close reading and nowadays often work with digital texts, it is necessary to enhance their capabilities for digital close reading. We propose an enhanced close reading design inspired by mind-maps that not only mimics the traditional way of annotating a text on paper, but also helps humanities scholars to perform live visual analyses. Furthermore, we use extendible margins to provide enough space for all thoughts of the scholar.



CHAPTER 2
I OBSERVE

The first objects that assume a distinct presence before me, as I look far back, into the blank of my infancy, are my mother with her pretty hair and youthful shape, and Peggotty with no shape at all, and eyes so dark that they seemed to darken their whole neighbourhood in her face, and cheeks and arms so hard and red that I wondered the birds didn't peck her in preference to apples.

I believe I can remember these two at a little distance apart, dwarfed to my sight by stooping down or kneeling on the floor, and I going unsteadily from the one to the other. I have an impression on my mind which I cannot distinguish from actual remembrance, of the touch of Peggotty's forefinger as she used to hold it out to me, and of its being roughened by needlework, like a pocket nutmeg-grater.

This may be fancy, though I think the memory of most of us can go farther back into such times than many of us suppose; just as I believe the power of observation in numbers of very young children to be quite wonderful for its closeness and accuracy. Indeed, I think that most grown men who are remarkable in this respect, may with greater propriety be said not to have lost the faculty, than to have acquired it; the rather, as I generally observe such men to retain a certain freshness, and gentle-

ness, and capacity of being pleased, which are also an inheritance they have preserved from their childhood.

I might have a misgiving that I am 'meandering' in stopping to say this, but that it brings me to remark that I build these conclusions, in part upon my own experience of myself; and if it should appear from anything I may set down in this narrative that I was a child of close observation, or that as a man I have a strong memory of my childhood, I undoubtedly lay claim to both of these characteristics.

Looking back, as I was saying, into the blank of my infancy, the first objects I can remember as standing out by themselves from a confusion of things, are my mother and Peggotty. What else do I remember? Let me see.

There comes out of the cloud, our house—not new to me, but quite familiar, in its earliest remembrance. On the ground-floor is Peggotty's kitchen, opening into a back yard; with a pigeon-house on a pole, in the centre, without any pigeons in it; a great dog-kennel in a corner, without any dog; and a quantity of fowls that look terribly tall to me, walking about, in a menacing and ferocious manner. There is one cock who gets upon a post to crow, and seems to take particular notice of me as I look at him through the kitchen window, who makes me

Related Work

Nancy Boyles (Boyles, 2013) defines close reading, which has become a fundamental method in literary criticism in the 20th century (Hawthorn, 2000), as follows: "Essentially, close reading means reading to uncover layers of meaning that lead to deep comprehension." Annotating the text in close reading is a strong method for scholars to facilitate the understanding of a text passage. Figure 1 shows the result of a traditional close reading approach. In this example, various annotation methods were used by the scholar to annotate various features of a text passage in Charles Dickens' „David Copperfield".

The availability of digital texts has further awaken the interest of humanities scholars in collaboratively close reading the same texts. There are several annotation tools for such a purpose, such as eMargin (Kehoe et al., 2013), Hypothes.is (Bonn et al., 2014) and NB (Zyto et al., 2012). These tools are beneficial for collaborative research and classroom environments as they provide an excellent paradigm to share thoughts, as well as find collective answers. To avoid clutter, these tools work with popup windows that are only shown on demand. In Figure 2, the eMargin system is shown where colors are used to highlight different text features, and a popup window on demand, lists the comments of collaborating scholars.

Digital Ink Annotations systems (Schilit, 1998, Bargeron et al., 2003, Agrawala et al., 2005, Yoon et al., 2013) also support annotating text, but their use is only limited to pen-based computing devices such as tablets. The systems are designed to work well on smaller screens, and the adaption to larger screens is not appropriately implemented.

I OBSERVE

John Thomas said:

All early chapter titles cast David in passive role: 'I am Born', 'I Observe', 'I have a Change', 'I fall into Disgrace', 'I am sent away from Home'. This changes after he is forced to leave home: 'I enlarge my Circle of Acquaintance'.

Peter Hughes said:

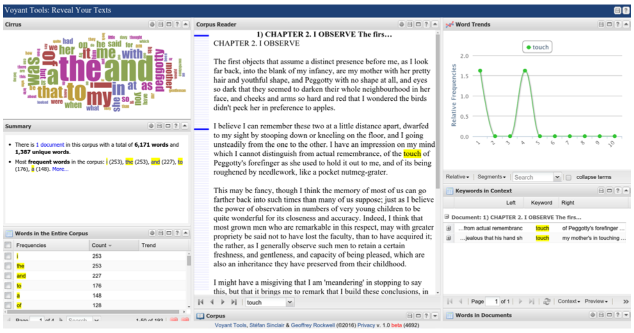
'I Observe' is not quite passive but I agree that David begins to play a more active role after he is forced to leave home.

Sarah Young said:

Observation and memory are closely linked throughout this chapter and throughout the novel.

Figure 2: eMargin annotation tool[2]

Close reading tasks can also be assisted via distant reading tools. For example, parallel coordinates, a heatmap and a dot plot are used to analyze the variance of a selected text passage from different German translations of Shakespeare's Othello (Geng et al., 2013). Heat maps are appropriate visualizations to illustrate the distribution of specific phrases or annotations in a corpus (Muralidharan, 2011, Alex et al., 2015). Voyant Tools allow the user to perform basic text mining functions with selected word statistics shown in linked views (Sinclair et al., 2012). The Voyant Tools interface in Figure 3 shows statistics about Chapter 2 of Oscar Wilde's "David Copperfield". Goffin's idea to enhance close reading is the integration of small visualizations (e.g., maps or bar charts) besides the words of a text (Goffin et al., 2014).



- There is 1 document in this corpus with a total of 6,171 words and 1,387 unique words.

Enhanced Close Reading Design

In contrast to the tools mentioned above, we combine traditional annotation tasks with distant reading analyses to enhance the close reading capabilities of the scholar. We suggest a design inspired by mind mapping (an example mind map is shown in Figure 4a), a methodology that allows a researcher to work on a central concept, and thoughts and features about that concept are placed around it using figures, lines etc. In a mind map, the associations spread out from a central concept in a free-flowing, yet organized and coherent manner (Budd, 2004) - thus forming a mental map of the central concept. We observe that like in the case of mind maps, fixed annotations around the central text in a traditional close reading process facilitate forming a mental map of the thoughts about the text of interest, and help the scholar to draw conclusions when seeing the whole picture.

Figure 4a: An example mind map[3]

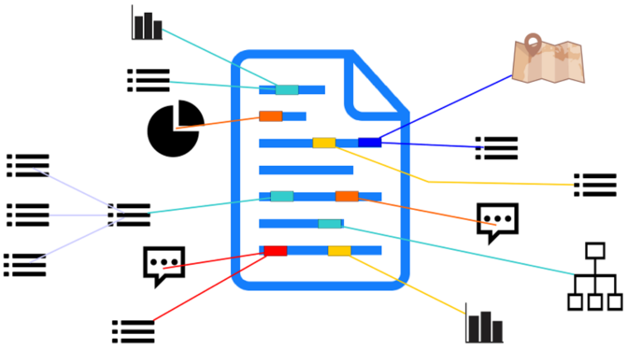

Figure 4b: Mind-map inspired close reading

Figure 4b illustrates the idea of a mind map inspired interface with multiple types of annotations supporting the scholar in the close reading process. Textual annotations known from the traditional close reading are also necessary in the digital process. In addition, images, videos and charts can facilitate text interpretation and the generation of valuable hypotheses about the text. To support dynamic, multifarious views on a certain text passage or a term of interest, we designed our interface the way that the literary scholar can apply a multitude of visual analyses and generate distant reading visualizations that are placed as annotations alongside the text. This combines the traditional close reading paradigm with elaborated text visualization techniques valuable for exploration purposes. An important feature of our proposed interface design is to support the scholar to „stay in the flow" (Bederson, 2004), so that the central focus remains on the text, which can be analyzed without interrupting the scholar. The major advantage of our design over existing tools that assist close reading tasks is interface versatility. For example, Voyant Tools (see Figure 3) provide a predefined set of visualizations based on text statistics. On the other hand, our design allows the scholar to choose an appropriate text visualization as an annotation alongside the text, which is based on a user-defined query on the text.. Therefore, the scholar can apply different text visualizations for different passages of the text to support a variety of close reading tasks.

An example of the design discussed above is shown in Figure 5. The example from Figure 1 is annotated using different kinds of annotations. Like in other digital tools, certain topics of the text are annotated using colors. In addition, the character(s) Peggotty is marked and a panel shows thumbnail images based on a Google Images search. Also the relative word frequency chart of the term "Peggotty" in Chapter 2 is shown on the bottom left. Furthermore, on the left area, a TagPie (Jänicke et al., 2015a) showing the co-occurrences of both the terms memory and observation helps to investigate the hypothesis of the literary scholar about the similar meaning of both topics. The example depicts how the scholar can use different annotation tools as well as different distant reading tools to enrich the close reading experience.

Future Work and Conclusions

We held discussion with the collaborating humanities scholars about the design as well as the usability of the proposed interface. The scholars remarked that such an interface will help removing fears of using digital humanities tools and that they intend to use the tool as it mimics their existing workflows. They also mentioned that such a tool could help users getting a better big picture of the text, and that it enhances the close reading capabilities of the scholar. Another important point is the capability in supporting teaching activities. They mentioned that various types of annotations (text, pictures, charts) are also used in teaching material, but it is not easy to share these with students. Such a tool could support this process as it generates persistent annotations to be analyzed and discussed collaboratively in courses.

We observe that the scholar's initial reactions after seeing the prototype of the tool, which is still in development, are convincing and encouraging. We think that rigid modeling syntax is inappropriate for annotation. Our final interface will allow the scholar to make annotation styles versatile. At the digital humanities conference, we will demonstrate our prototype and discuss future prospects within the community. An additional user study will compare the viability of our proposed, mind map inspired annotation technique to existing approaches.

Acknowledgements

We thank our colleagues from the humanities department, Judith Blumenstein in particular, who provided insights and expertise that greatly assisted this research.

This poster will present the rationale behind as well as the work in progress of an international collaborative project funded by the Volkswagen Foundation (scheme *"Original – isn't it?"* New Options for the Humanities and Cultural Studies, Funding Line 2 Constellations), 2016-2017. The project aims to link scholarly modelling as a formal and informal reasoning strategy across disciplinary boundaries, and to bridge between modelling in research and teaching.

In Digital Humanities (DH), modelling is a creative process of reasoning in which meaning is made and negotiated through the creation and manipulation of external representations. Through the lenses of critical humanities traditions and interdisciplinary takes on making and using models, the project *Modelling between digital and humanities: thinking in practice* builds on the novelty of DH research in making explicit and integrating existing diverse models of cultural phenomena (e.g. texts; events) with the aim to:

- explore possibilities for a new interdisciplinary language of modelling;
- analyse modelling in scholarship as a process of signification;
- develop connections between modelling as research and learning strategies.

By modelling we intend the creative process by which researchers create and manipulate external representations ("imaginary concreta," Godfrey-Smith, 2009: 108) to make sense of the conceptual objects and phenomena they study. In order to integrate diverse theoretical frameworks around modelling (McCarty, 2005, 2009; Mahr, 2009; Frigg and Hartmann, 2012; Morgan, 2012; Kralemann and Lattmann, 2013; Flanders and Jannidis, 2015) with a practical dimension, the project makes use of DH as an interdisciplinary departure to study modelling as anchored both to computer science and to the humanities.

Research focus

Our working hypothesis is that in DH research, implicit and explicit models of cultural phenomena are integrated into external metamodels, e.g. graphical representations, which often embed natural language and are informal. These metamodels are iteratively translated towards computable implementations via a variety of more or less formal models: models for.

Two case studies are used to reflect on modelling in practical terms:

- Textuality, standing for the complexity of cultural objects and activities addressed by a plethora of subject-specific approaches. Sahle (2013) proposes a metamodel to chart and relate single models of textuality from several disciplines. The metamodel acts both as a **model of**the phenomenon of textuality and as a **model for** working with texts to inform the development of text technologies, digitisation practices, and rules for transcription and annotation.
- Events. While textuality mediates the world we live in, events are central to an epistemological perception and description of the processes shaping this world. Many disciplines contribute to theoretical reflections on and practical applications of the modelling of events (see, e.g., Le Boeuf et. al., 2015). The project aims at combining contributions from philosophy, literary studies, history, linguistics, and computer science with cultural heritage documentation and the news industry in the transition from **models of** events as things to perceive and talk about to **models for** event detection and description.

The analysis of modelling practices in the areas outlined above will aim at gaining new insights in the epistemology of modelling:

- How are theory and practice blended in these modelling efforts?
- What role do formal and informal metamodels play in translating models of cultural phenomena into implementations?
- What shared terminology can help us gaining an integrative and non-reductive understanding of digital modelling?
- Can we define the methods of digital modelling informed by such an integrative and non-reductive approach?

Societal resonance

The rationale of the project places the practice of DH within a broad understanding of how humans think through things. Models are ubiquitous in our contemporary society as powerful tools to schematise the complexities of our universe, from genes to climate, from the economy to the stars. By linking DH practices to the craft of computer science as well as to the critical humanities tradition, this project tackles issues at the centre of the construction and deconstruction of (digital) models. It also advocates for a critical DH research offering the instruments to unpack the rhetoric of digital and data models, so as to contribute to a pedagogy of the digital age and to act at the core of a new cultural literacy.

Outcomes

Over 18 months, the project aims at producing: 1) an open access book about modelling, and 2) An international workshop devoted to selected controversies around the theorisation and practice of modelling (e.g. fictions vs. non-fiction; theory vs. data), which will give important input to the book. A consulting group will be set up to discuss draft chapters and ongoing work.

Since its foundation, the Homer Multitext project has been creating digital diplomatic editions of manuscripts of the *Iliad*, editions which record every intentional mark on the manuscript, in order to create a resource to explore larger Homeric questions. Our poster presents one aspect of Homer Multitext research. The authors' original research involves analyzing the Venetus A to look for multiforms, that is, substitutions for Homeric text that fit both metrically and contextually. The Venetus A, a tenth-century manuscript currently housed in Venice, is the oldest complete manuscript of the *Iliad* existing today. In addition to the intact poem, the Venetus A includes an abundance of scholia, scholarly notes which comment on the poem. It is in these scholia that we find the evidence for multiforms. Our use of the term "multiform" intentionally follows Albert Lord's of the *Iliad* as an orally composed and transmitted poem: "the word multiform is more accurate than variant, because it does not give preference or precedence to any one word or set of words to express an idea; instead it acknowledges that the idea may exist in several forms." (Lord, 2000). Ultimately, in looking for multiforms, we found a definitive correlation between the appearance of multiforms in the scholia and the reference to one of three Homeric textual editors, all of whom served as the head of the library at Alexandria at various times from the third to second centuries BCE. While it has been previously hypothesized that the work of these three Alexandrian editors, preserved in the Iliadic scholia, is responsible for the current standard canon of available multiforms, the research represents our first steps in using statistics to better understand the transition from an oral tradition to today's critical print editions.

The first task in our research was to analyze how many multiforms existed in a select portion of the *Iliad*. Books 18 and 19 of the *Iliad* served as our sample, and we accessed the manuscript through openly-licensed digital photography. From these photographs we created digital diplomatic editions of the poem and its corresponding scholia using an XML editor and following TEI guidelines. Within our editions we used the TEI element "quote" to identify every instance of text reuse found in the scholia, and then generated a separate table in which we classified the types of text reuse. Our classification was modelled on work by Monica Berti who defines "text reuse" as "the meaningful reiteration of text, usually beyond the simple repetition of common language" https://wiki.digitalclassicist.org/Text_Reuse). By assigning distinct URNs to the different types of text reuse in the table and not in our XML mark-up, we applied a unique approach that kept our external analysis separate from our digital edition.

We automatically generated a table displaying the occurrence of multiforms in relation to references to Alexandrian editors in preparation for a chi-square test for independence.

This table shows 34 instances of overlap, in which one of the scholars was named with a multiform. For the chi-square test, we compared these two sets of data, beginning with the null hypothesis that they were independent. Then, having set a significance level of 0.01, we obtained a p-value of $1.2 *10^{-42}$. This p-value shows that the probability of randomly obtaining the results we did is negligibly low. Thus, we were able to reject our null hypothesis and conclude that there is a correlation between the occurrence of a multiform and references to one of the Alexandrian grammarians.

Given the correlation between Alexandrian editors and multiforms attested to in the Venetus A, we conclude that the Alexandrian editors were responsible for setting the canon of multiforms which has been transmitted in this manuscript, and from there to the modern world. In respect to further avenues of research, the strength of this correlation remains to be tested. Additionally, we have not yet attempted text reuse analysis with the majority of the Venetus A; drastically increasing the sample size will likely yield more insights into the nature of the poem's transmission and production. The ability to statistically support this conclusion exemplifies the great promise statistical, analytical methods hold for the field of Homeric studies, as well as wider areas in other fields of the humanities.

Editing in a text-image-sound form: the eTalks

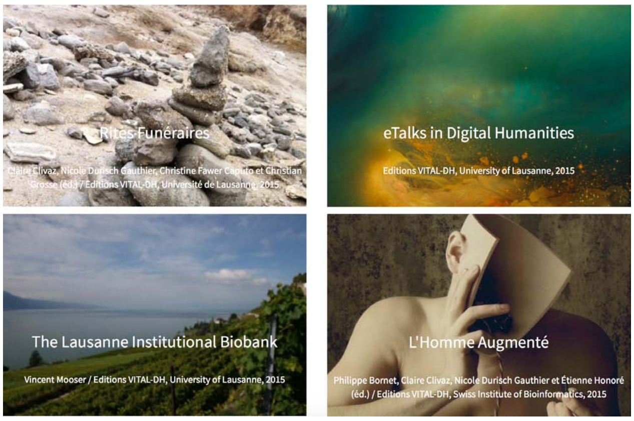
An interdisciplinary team of researchers has built a new multimedia editorial tool: the eTalks (Clivaz 2014; Clivaz et al., 2015a; Clivaz et al., 2015b; EADH projects, 2016), based primarily on speeches of scholars. Simple videos or MP3 recordings of lectures may prove insufficient to many researchers since they are unquotable in detail and they do not offer the possibility of being combined with text, images, hyperlinks, and references. Until now, no tool has been available for creating a carefully edited product that includes text-image-sound, all entirely quotable in details: yet, this is what we have achieved with the eTalks [http://etalk.vital-it.ch/mooser/mode-demploi-en/].

In creating the eTalks, we were motivated by the fact that academic publications and pedagogy have been deeply reconfigured by the emergence of a new kind of knowledge produced by the synergy between text, image and sound. As Tanya Clement points out, diverse Digital Humanities (DH) pedagogies, such as new media studies and game studies, can be characterized by looking at multiliteracies "that are engaged within undergraduate humanities curricula through general skills, principles and habits of mind that allow students to progress within and engage society in the twenty-first century" (Clement 2012). Academic publications in Humanities are slower than pedagogy in terms of the testing of multimodal literacies. However, different tools are now able to present slides joined to videos of scholarly talks, such as Slideshot and Dashboarding [http://slideshot.epfl.ch/play/cops_binney; http://www.infoq.com/presentations/dashboard-data-analysis?utm_source=infoq&utm_medium=related_content_link&utm_campaign=relatedContent_presen], but they cannot be quoted in detail. Scalar, a very impressive multimodal tool, proposes to "create interpretive pathways through the materials"[http://scalar.usc.edu/about/], privileging users' points of view. The eTalks claim to rely on the scholar's oral talk as a leading way among multimodal materials while giving the users the possibility of reconsidering the auctorial point of view by directly accessing all the quoted sources.



Rites Funéraires

eTalks in Digital Humanities
Editions VITAL-DH, University of Lausanne, 2015
The Lausanne Institutional Biobank
Vincent Mooser / Editions VITAL-DH, University of Lausanne, 2015
L'Homme Augmenté
Philippe Bornet, Claire Clivaz, Nicole Durisch Gauthier et Étienne Honoré (éd.) / Editions VITAL-DH, Swiss Institute of Bioinformatics, 2015

The eTalks application implements an easy-to-use editor interface, designed for the use of researchers themselves, allowing for the creation and editing of original enhanced talks. This permits the linking together of images, sounds and textual materials by means of hyperlinks, thereby enriching the content with relevant information. The result of the editing is displayed through a viewer interface, allowing one to experiment with the entire eTalk or to actively navigate, scroll and search inside its content. After recording the speech of the scholar, the Audacity software allows for the splitting of the speech into pieces of 2-3 sentences. Each piece of speech can be associated with its written version, a slide, images, or hyperlinks and so forth. Each piece is also quotable with a specific URL: a new kind of reference. Thus, the final release of eTalks allows for the complete 'citability' of its contents: each and every portion of the researchers' talks can be precisely referred to and therefore cited, just like any traditional, paper-based scientific publication but with all the potential for plural literacies.

The core of the eTalk engine was developed in JavaScript and the code is now available as open source on Github as a free application for further development. The eTalks are currently being further developed and disseminated by an interdisciplinary team of researchers in Digital Humanities and bioinformatics at the Swiss Institute of Bioinformatics (Lausanne). Four series of eTalks have thus far been published as openly accessible: twelve on funerary rituals, nine on the enhanced Human, two on the institutional biobank of Lausanne, and one in Digital Humanities [http://etalk.vital-it.ch]. The eTalks are now in development by institutional and research collaborations, notably the Pedagogical High School of Lausanne (HEPVaud) and the ERASMUS+ #dariahTeach project, whose purpose is to offer a webportal by 2017 that will include digital teaching modules [www.dariah.eu/teach].

We will present eTalks' main features in our poster, and in particular the question of copyrights: to be able to quote several images, the team had to learn the basic rules of the relevant Swiss laws, and how Wikipedia commons work in Switzerland; furthermore we plan to develop European test-cases. We have also learned to negotiate with the authors and to convince them to rather use open access material. In difficult cases, we consult specialized people. Such obstacles had to be navigated and new skills acquired by our team as new, necessary knowledge. We will secure the interoperability of our data, and progressively introduce videos, and purl references.

Discursive Constructions Of Culture: A Semantic Model For Historical Travel Guides.

Ulrike Czeitschner
Ulrike.Czeitschner@oeaw.ac.at
Austrian Academy of Sciences, Austria

Context

The *Baedeker Corpus*, a digital collection of early German travel guides that is currently being developed in the *travel!digital* project[1], brings together a valuable but rarely investigated part of cultural heritage in an up-to-date and sustainable digital form. A combination of source oriented approaches and Semantic Web formats (Meroño-Peñuela et al, 2014) allows for enhanced access to both the TEI-based digital edition and the rich domain-specific knowledge. As complex inter-texts (Wierlacher, 1997; Koshar, 2000) and significant discourse-historical artefacts (Maingueneau, 2014) travel guides represent codified and authorized versions of local culture and history (Pritchard et al, 2005). Reflecting dominant discourses, (re)producing and (re)constructing them, the genre plays a central role in shaping the tourist experience and directing the tourist gaze (Thurlow et al, 2007; Urry, 1990). Giving insight into various readings of history, tradition and culture, the new language resource is meant to foster cross-disciplinary research in cultural representation and identity constructing discourses.

The *Baedeker Corpus* comprises *all* first editions of German travel guides on non-European countries which were brought out by the Baedeker publishing house before World War I. It contains more than 1.5 million running words and covers various regions, offering a balanced picture of different cultural areas.[2] Along with the basic layers of linguistic annotation, controlled vocabularies and content contextualization by *Linked Open Data* resources will assist in exploring cultural narratives from the turn of the 19th century.

bdk:ConceptScheme(s)

Focusing on *people* and *monuments,* two essential components of the guidebook genre and of cultural discourse itself, the extensive lexical inventory is represented by means of the *Simple Knowledge Organization System SKOS*. Besides personal names, people are addressed in a variety of different forms in the guidebooks. References to classes are frequently used in making generalizations about groups and individuals as well (cf. Schmidt-Brücken, 2015). Each of these generic expressions is represented by a *bdk:Descriptor*, which is defined as a subclass of *skos:Concept*. Individual terms are encoded as *skosxl:prefLabel(s)* and *skosxl:altLabel(s)*. Variants and translations are designated on term-level by the properties *hasVariant/isVariantOf* and *hasTranslation/isTranslationOf*. Modelled in this way, the vocabulary identified in the guidebooks forms the basis of the concept scheme. Seven categories indicated by *skos:topConceptOf* improve structuring of the bdk:ConceptSchemeGroups:

1. Collective terms: *population, tribes, natives;* **2.** ethnic/national communities: *Englishmen, Wedda;* **3.** geographical concepts: *Europeans, Orientals;* **4.** names of languages and scripts, language affiliation: *Arabic, Cyrillic;* **5.** professions, including political, religious, economic roles, and styles of living: *merchants, government officials, priests, peasants, nomads;* **6.** religious communities: *brotherhood, pilgrims; Buddhists, Sikhs;* and **7.** social classes: *castes, workers.* Concepts and labels include both nouns and adjectives, indicating associations among them by means of the property *skos:related*. Figure 1 lists definitions of *skos:topConcept(s)* and shows selected examples of concepts and labels.

	Ägypter @de ↕ ägyptisch @de	*hasTranslation* *hasVariant* *isTranslationOf* *hasVariant* *hasVariant*	*isVariantOf* *isVariantOf* *isVariantOf*
	Orientale @de ↕ orientalisch @de		
		hasTranslation *isTranslationOf*	

Figure 1: bdk:ConceptSchemeGroups.

The picture is similarly varied for monuments and notable sights. Since assessments and classifications of cultural heritage objects are integral parts of cultural representation, they are included in a separate concept scheme. The bdk:ConceptSchemeMonuments is organized by skos:topConcept(s) which indicate topical spheres the objects belong to, ranging from architecture and artworks, to accommodations, landscapes, and breath-taking views.

Prospects

By the end of the project, a web application based on the *corpus_shell* framework[3] will make the digital texts available along with their facsimiles, exposing them via FCS/

SRU protocol[4] that is part of the CLARIN infrastructure. This online edition will offer querying capabilities inside of both the text and the linguistic annotation layers. It will provide indexes of word classes, lemmas and the semantic entities defined by the SKOS-vocabularies presented in this abstract. Transforming names of *people/s* and *monuments* in the texts into links to the LOD cloud[5], the vocabularies will connect occurrences in the *Baedeker Corpus* to other online resources, providing enhanced access to the corpus and additional information via the guidebooks' main actors. The presented data model aims at supporting fine-grained examinations of semantic components that have a lasting influence on cultural perceptions of "Other" and "Self". It is expected that semantic technologies do have the potential to reveal much about a discourse that goes far beyond travel literature.

Introduction

The *Lokalbericht* project (2013-2016)[1] aims to deliver a scholarly digital edition of Swiss author Hermann Burger's first novel *Lokalbericht*. Accompanied by a reading edition in print (fall 2016), the digital edition will include all extant precursory stages of the novel as well as Burger's final revision of the text, written between 1970 and 1972 (Wieland et al., 2012). The project relies on document oriented encoding, as supported by the TEI guidelines since P5 v. 2.0 (cf. Burnard et al., 2012), in order to aptly capture the materiality and the genetic dimension of the work.

Macrogenetic Challenges

Whereas the recommendations of other textgenetic edition projects as well as the tradition of genetic editions in print were very helpful for the encoding of local, microgenetic phenomenons (i.e. intradocumental) and their presentation to the reader, much less information was available on how to document interdocumental textgenetic relations in a structured manner. In order to better understand the challenges and needs of what we dubbed macrogenetic editing, a workshop was convened in Bern in 2014.[2] As Hans Walter Gabler concluded, 'a digital genetic edition will only tap its full potential by capturing and visualizing "macrogenetic" aspects' (Gabler, 2014).

Incited by the outcomes of the workshop we investigated ways that offer immediate insight into Burger's way of writing – the novel was crafted as a mosaic consisting of numerous tesserae that were worked over repeatedly. This writing technique results in an f *avant texte* consisting of many segmented and related texts, of which at times more than a dozen copies are extant. Taking a bird's eye view of the corpus, the reader should get a clear understanding of the writing process and be able to follow the development of specific segments or chapters and their integration into the final typescript, before swooping down to the text level to discover the textgenetic minutiae.

A Visual Approach to Macrogenetic Relationships

In printed and early digital genetic editions, macrogenetic relations are often visualized as a stemma. Such stemmata leave much to be desired – they often abstract on a high level (e.g. witnesses or versions of a text) as opposed to smaller textual entities such as paragraphs or sentences, require considerable intellectual and manual effort, and remain comparatively static, perhaps linking to representations of related documents, but lacking in precision. Yet their genealogical tree structure serves still as a powerful basis to represent editorial changes.

Taking the underlying idea to represent temporal development on the vertical axis and introducing finer levels of granularity in a stemma tree on one hand threatens to lead to over-complexity and problems of positioning. Resorting to force directed plotting as it is often used to display and investigate graph data on the other hand does not satisfy the sequentiality inherent in written text. For the manageable amount of typescript pages and drafts of the novel at hand, we found that a prearranged layout that entails a temporal dimension (y-axis) and material evidence of the texts (x-axis) works best (cf. figure 1).[3] Genetic relations between the typescript pages, the smallest units of display,[4] are highlighted on mouse actions. Interacting with this visualization, the user of the digital edition can trace the development of the early and final drafts of the novel.

Accessing Data through Visual Navigation

Good textgenetic visualizations should not be mere by-products of digital editions, but closely tie in with the structure of the digital edition, i.e. serve as a subsidiary navigation to its contents. By way of two panels that yield lists of related typescript pages the user can access detail views in the main interface of the edition (single or synoptical views) directly from the visualization. Vice versa, the visualization initially highlights the current selection of the main interface in order to provide specific views of the *dossier génétique*.

Outlook

While the *analytical approach* based on genetic paths defined by the editors (on sheet level) should provide the most valuable knowledge about the production of the novel, it would be desirable to complement the visualization by an *explorative mode* based on relations encoded on more granular levels.[5] A visualization of this kind would be less useful to pursue particular authorial changes, but it would help to identify patterns that deserve closer attention and facilitate the isolation and display of the least interpretation-ridden relations and consequently better suit a reader-centered concept of a digital edition.

The wish for visualizations that abstract from the detailed genesis of a text to a more approachable overview is shared by a number of genetic edition projects.[6] After all, imparting his or her knowledge and insight to the readership lies at the core of a scholarly editor's role. We hope to contribute to the debate by sharing our approach to this problem at DH 2016 and finally by launching the digital *Lokalbericht* edition in October 2016.

Notes

[1] Cf. the preliminary project website at http://lokalbericht.unibe.ch.

[2] Cf. http://lokalbericht.unibe.ch/hermann_burger/workshops.html

[3] The actual technical implementation makes use of the D3.js JavaScript library (cf. http://d3js.org) for manipulating documents based on data, but similar outcomes might be realized using other tools.

[4] More complex genetic corpora and different choices of granularity would however require more sophisticated zooming and panning mechanisms or ways of three-dimensional stacking and it remains to be seen whether the chosen approach would serve them well.

[5] The development of an explorative visualization of the entire *Lokalbericht* corpus as initially planned will presumably only be implemented for selected texts due to limited resources.

The success of the digital humanities as a field of research has led to two pressing needs at the interface of computer science and the humanities. First, sustainable software development projects are needed that are focused on humanities research problems. Second, graduate and undergraduate training models are required that address the interdisciplinary nature of digital and computational humanities research (Ramsay, 2012; Reid, 2012). From the application and development of new algorithms to mine texts (e.g. Murdock et al., 2015) to the development of multi-institutional software systems (e.g. Neuroth et al., 2011), many digital humanities projects can only be implemented with the help of computer scientists and software engineers.

We believe that the future success of applying digital and computational approaches to research questions in the humanities depends on forging links between computer science and the humanities. However, the digital humanities need to involve more than adding a computer scientist to a humanities project. Many digital humanities programs include computer science courses in their degree and certificate programs, but this is not yet the norm. Specifically in the history and philosophy of science, many programs do not impart the skills necessary to take advantage of the new modes of research. Likewise, computer scientists typically receive little training in the humanities, making it difficult to foster meaningful and productive collaborations with humanities scholars.

Our poster describes the Digital Innovation Group (DigInG) in the Center for Biology and Society at Arizona State University (ASU). DigInG's primary objective is the development of computational solutions for questions in the digital humanities with a focus on digital history and philosophy of science. Our group trains students from the computer science department together with students from the humanities. We develop user-oriented innovative tools, methods, and infrastructures, and foster an understanding for each other's fields by teaching a skill set that enables students to communicate more effectively.

As part of DigInG, we developed a course that puts computer science students in a room with humanities students to work together on digital humanities projects. In addition, we offer the opportunity to work on the software development projects in our lab as student workers. We emphasize software engineering best practices and cross-disciplinary interaction. For example, in the beginning of the semester the class develops a course website, which requires them to learn how to use Git and GitHub. Students from the humanities learn the basics of programming. Computer science students acquire a mindset that better prepares them for working on digital humanities projects and learn how to better communicate with those outside their field. We discuss topics such as the importance of authority control, metadata, or resource discovery. In our experience, the students gain a lot from participating in our class as for many of them it is the first time that they work with students from a very different field of study. For instance, one humanities student noted that "learning to formulate questions in ways that computer scientists and software developers can understand" was one of the most valuable outcomes for them.

Not only does DigInG play an important role in developing software for humanities research, it also creates an environment for hands-on training for graduate and undergraduate students in computer science and the humanities. We hope that our poster will contribute to broadening the discussion about how digital and computational humanities programs are organized. We believe that software development and training in the digital humanities do not need to be separate endeavors.

The Attribution of the Lazarillo de Tormes. Shedding Some Light into a Centuries Old Problem

Javier de la Rosa Pérez
jdelaro@uwo.ca
The CulturePlex Lab, University of Western Ontario, Canada

Summit work of the Spanish Golden Age and forefather of the so called picaresque novel, The Life of Lazarillo de Tormes and of His Fortunes and Adversities (henceforth: the Lazarillo still remains an anonymous text (Rico, 2011). The 400 years of attributions have left us an enormous, nearly intractable, amount of bibliography that must be reviewed and studied. Paradoxically, scholars, instead of shying away from this mystery, are still adding new proposals to the pool of candidate authors, although some of them use modern and less explored methods (mostly computational) that were not available a decade ago.

Chronologically, the Hieronymite Friar José de Sigüenza was the first to propose a possible author: Friar Juan de Ortega. Father Sigüenza's Historia de la Orden de San Jerónimo gathers his finding of a manuscript of the Lazarillo in the cell of Juan de Ortega. Although a draft was indeed found in the Friar's cell, the circulation of handwritten copies was a common practice during the Spanish Golden Age (Botrel and Salaün, 1974). The claim that Father Ortega was the author is hard to sustain as the draft does not seem to be enough proof. Diego Hurtado de Mendoza was proposed a couple of years later, in 1607. His candidacy as the author of the Lazarillo was proposed by Valerio Andrés Taxandro. Over the years other scholars contributed to the diffusion of Mendoza being the author, and the attribution proved to be extremely popular. For almost three centuries book catalogues all over Europe recorded Hurtado de Mendoza as the author of theLazarillo. In 2010 Mercedes Agulló provided documentary proof to support the authorship, although some dispute the validity of such evidence (Agulló y Cobo, 2011). Other humanists were also proposed. The reformist Juan de Valdés was defended by Morel-Fatio and Manuel J. Asensio, but in view of the lack of solid evidence, this candidacy was abandoned in favor of his brother Alfonso. Rosa Navarro Durán supported Alfonso de Valdés, as she found connections between the works that influenced both Valdés' work and the Lazarillo. The lack of direct comparisons has been strongly criticized.

In the last decade, a couple of names have taken center stage. Juan Luis Vives was proposed and devotedly defended by Francisco Calero. Following the same precepts as for Alfonso de Valdés' candidacy, the fact that all Vives' known works were written in Latin makes the attribution lose some credibility. In 2008, after abandoning the authorship of Francisco Cervantes de Salazar, José Luis Madrigal proposed Juan Arce de Otálora. Using existing corpora such as Google Books and CORDE, Madrigal employed basic computational analysis based on the counting of words in order to find correlations between the style of authors in the corpora and the style of the author of the Lazarillo.

Computational approaches to authorship attribution are usually not considered to be enough proof to state the final truth in the disputed authorship of an anonymous text. However, the use of modern authorship attribution techniques might help to reduce the pool of candidates and contribute with evidence to support a specific possible author. After building the pool of candidates, we collected each candidate's available texts. Half of them lacked modern editions, which we solved building and using our own crowdsourcing OCR reviewing tool. The corpus we created counts a total of 50 works in a 90 year period surrounding the publication of the first known edition of the Lazarillo in 1554. All the major candidates for the authorship of this book were included, as well as some authors who had not been considered previously to add robustness to our analysis. The rules we followed for regularizing the spelling of old Spanish were borrowed from Ocasar's system (Ocasar, 2014). Features from the text were then extracted following the winners of several editions of the authorship attribution competition known as PAN at CLEF, which establishes the state-of-the-art in attribution techniques (Stamatatos et al., 2015). The final set of features were composed by several distributions: functions words, the 300 most common words (BOW), the 3000 most common character 3-grams (CNG), punctuation signs, the 30 most common parts of speech; tf-idf for a maximum of 1000 word bi- and tri-grams, and for a maximum of 1000 character {2,4}-grams; and average sentence length, sentence length variation, and sentence lexical diversity. A combined feature vector with all the abovementioned features was also included.

Once the texts were in digital format, we explored the dataset through distance-based methods, such as Burrows' Delta and its variations (Burrows, 2003), which outperformed any other. For compression-based methods we applied Cilibrasi and Vitanyi's NCD with BZIP2, RAR and PPM (Cilibrasi and Vitanyi, 2005). We tested PCA and Linear Discriminant Analysis with different settings for number of chunks per work, components and features (Burrows and Hassall, 2002). Our final approach was comprised of three steps: first we used unsupervised learning to reduce the pool of candidates. Then, applying supervised learning, we ranked the possible authors. Finally, only six of these candidates were fed into an ensemble algorithm for "unmasking" the most likely author. As for unsupervised learning techniques, we obtained that Ridge, Bernoulli, multinomial, and nearest centroid had the best performance for our total feature vector, BOW, and CNG. In supervised learning the best results were provided by SVM and maximum entropy models, for the same feature sets. This allowed us to reduce the pool of candidates for the unmasking method proposed by Moshe Koppel and Jonathan Schler since it is a computationally expensive method (Koppel and Schler, 2004). The results were consistent for all methods and in line to what we first obtained applying Burrows' Delta. We found that the most likely author seems to be Juan Arce de Otálora, closely followed by Alfonso de Valdés. Unfortunately, although supporting previous hypotheses about the authorship of the Lazarillo and providing with evidence in the case of Valdés, the method also stated that no certain attribution could be made with the given corpus.

Introduction

The development of applications in the field of Digital Humanities (DH) does not adequately take into account domain modelling, software design principles and software engineering methodologies (Bozzi, 2013; D'Iorio, 2015; McCarty, 2008; Terras and Crane, 2010). In fact, many systems developed in the context of DH-related projects have not been conceived to be modular, extensible, and scalable: they only tend to solve specific problems such as data-driven and project-oriented tools (Boschetti and Del Grosso, 2015). In addition, most projects focus on the requirements of humanists (as end users), but leave out the needs of software developers.

This research was motivated by a number of issues emerged from the projects we worked on (Abrate et al., 2014a; Albanesi et al., 2015; Bellandi et al., 2014; Bozzi, 2015; Del Grosso, 2013; Ruimy et al., 2012) and it fits into an ongoing discussion about textual modelling and research infrastructures (Moulin et al., 2011; Pierazzo, 2015;

Schmidt, 2014). In particular, this work aims at providing methodological guidelines for the definition of the core entities of a digital scholarly environment. We chose to adopt an object-oriented approach since it can bring benefits in the definition of efficient and effective digital tools (Boschetti et al., 2014; Del Grosso and Nahli, 2014). To give an analogy, the environment we propose can help developers and scholars as CMS (e.g. Wordpress) can help Web designers and publishers.

The development of the environment follows three criteria: i) adopting an agile process (Ashmore and Runyan, 2014) to define the nature and behavior of the environment through both functional (e.g. user stories) and non-functional requirements (e.g. data model, system architecture) (Cohn, 2004; Collins-Cope et al., 2005); ii) providing well-defined Application Programming Interfaces (APIs) among components (Grill et al., 2012; Tulach, 2008); iii) applying analysis, architectural and design patterns for the sake of abstraction, generalization and flexibility (Ackerman and Gonzalez, 2011; Buschmann et al., 2007; Gamma et al., 1995).

Following the agile methodology, we are developing a modular environment by starting from the design and implementation of a **microkernel** (Buschmann et al., 1996) as the manager of the different components. In addition, the microkernel provides all the operations needed to manipulate the domain basic entities which are described in the section "Domain entities and design patterns".

Related works

Digital humanists have access to several tools for literary studies. TextGrid, for example, provides integrated tools for analyzing texts and gives computer support for digital editing purposes (Hedges et al., 2013). The NINES project offers an environment to support scholars in the creation of long-term digital research materials. It includes three main tools: Collex (Nowviskie, 2007), Juxta, and Ivanhoe. Annotation Studio is a collaborative system to annotate texts and add links to multimedia objects (Paradis et al., 2013). The CULTURA project aims at developing a "corpus agnostic research environment" providing customizable services for a wide range of users (Steiner et al., 2014). The development of an online workspace which helps scholars in the production of critical editions is the main objective of the Workspace for Collaborative Editing framework (Houghton et al., 2014). It uses existing standards and open-source solutions to create an architecture of reusable components. Other platforms worth mentioning are TUSTEP/TXSTEP (Ott, 2000; Ott and Ott, 2014), WebLicht (Hinrichs et al., 2010), Perseids (Almas and Beaulieu, 2013), Muruca/Pundit (Grassi et al., 2013), Textual Communities (Bordalejo and Robinson, 2015), SAWS (Jordanous et al., 2012), Voyant Tools (Sinclair and Rockwell, 2012), Transcribe Bentham (Causer and Terras, 2014) and Alcide (Moretti et al., 2014). However, the aforementioned initiatives allow digital scholars to meet specific needs, but none of them seems to provide, simultaneously, all the following characteristics: i) reusability and extensibility, ii) ease of use and configuration, iii) continuous availability of the services and development over time, iv) a well-grounded software data model.

Domain entities and design patterns

One of the main challenges of the DH community is to provide suitable software models and tools (Ciotti, 2014). To model the literary domain and the relative user requirements, we chose to follow the engineering principles of **object-oriented analysis and design** (Ackerman and Gonzalez, 2011). The digital representation of a textual resource is a challenge as it involves several theoretical and epistemological issues in semiotics, paleography, philology, linguistics, engineering, and computer science (McCarty, 2005; Meister, 2012; Moretti, 2013; Robinson, 2013; Sahle, 2013).

In this work, we define each textual element by means of four properties: i) the **version** allows to select a specific textual element among those available in its history of changes; ii) the **granularity** represents a level of a hierarchical structure (e.g. a page composed of lines); iii) the **position** provides the location of a textual element within the hierarchical representation (e.g. the second page of a book); iv) the **layer** indicates the set of homogeneous information the textual element belongs to (e.g. morphological layer). As pointed outby (Buzzetti, 2002; McGann, 2004; Pierazzo, 2015), the information conveyed by a textual resource is logically organized through multiple layers (also called *dimensions*) of information.

On these four properties we have designed and implemented a set of core entities as the fundamental data types shared among all the components of the environment (Fig. 1)[1]. The **Source** class is in charge of managing the low-level data: it is composed of a **Payload** representing the information conveyed by the textual resource and a **SourceType** which indicates the nature of the Source (e.g. text, image, audio, etc.). Payload objects (as used in networking) have the only purpose of encapsulating the information. The **Locus** and the **PlaceOfInterest** (POI) classes identify, through a *composition pattern*, specific data fragments of the source content, and they are used to establish the boundaries of an **Annotation**. A chunk of text, for example, can be addressed to by a locus having a POI (of type Sequence of Interest) representing its start and end coordinates. Similarly, a region of an image can be identified by a locus having a POI (of type Region of Interest) composed of a sequence of coordinates. The Locus and POI provide a stand-off text annotation technique able to tackle, for example, the overlapping hierarchies problem, which cannot be handled easily with inline markup techniques (Schmidt, 2010). As a matter of fact, it is possible, simultaneously, to manipulate a resource on the basis of its documental and textual structure (Renear et al., 1996; Robinson, 2013) (see the example in the following section). However, since stand-off models are affected by the issue of the indexing updating, a dedicated component must be in charge of automatically maintaining the coherence of the annotations each time the underlying text is edited.

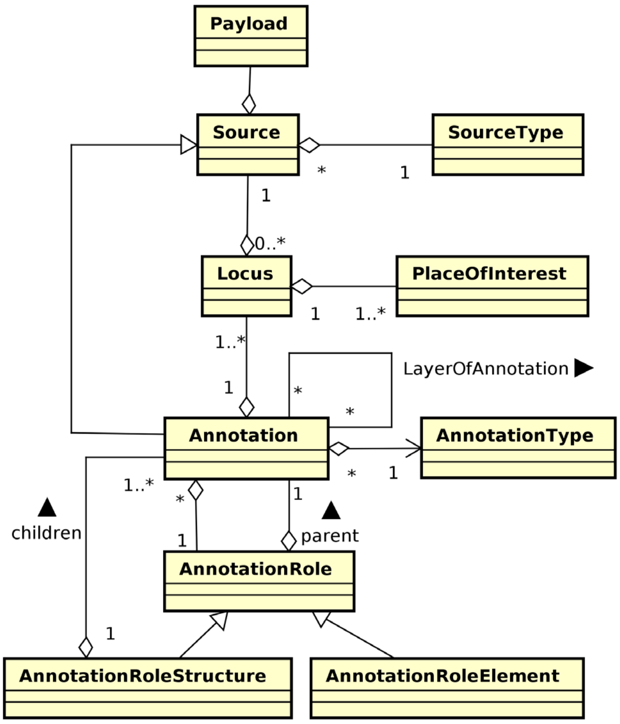

Fig. 1: Class diagram of the domain entities

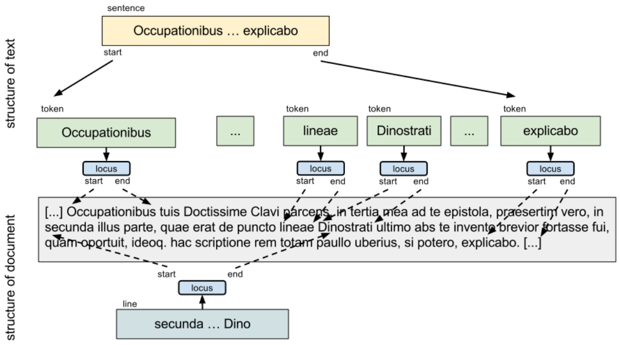
An Annotation represents an information associated to a locus and is defined by an **AnnotationType** (e.g. a token, a lemma, a named entity, etc.). Since the hierarchical structure of the source may evolve over time, the changes to the relative tree must be managed. For example, a tree structure having tokens as leaves could need to be updated with a finer-grained layer of characters (e.g. to assign annotations to specific letters). In this case, the tokens should become intermediate nodes and the characters would become the leaf nodes. Typically, this kind of editing is unpredictable and it often implies heavy adaptations if the software is not flexible enough to manage changes in the underlying text representation schema. Consequently, we decided to exploit the flexibility of the Object Oriented model by adopting the Role Design Pattern (Fowler, 1997) to switch between leaf and intermediate nodes dynamically. This pattern has been implemented by the **AnnotationRole**, **AnnotationRoleElement** and **AnnotationRoleStructure** classes. Moreover, an annotation is a source in itself (see the inheritance relationship between the Annotation and the Source classes in Fig. 1) and, thus, it can be annotated recursively.

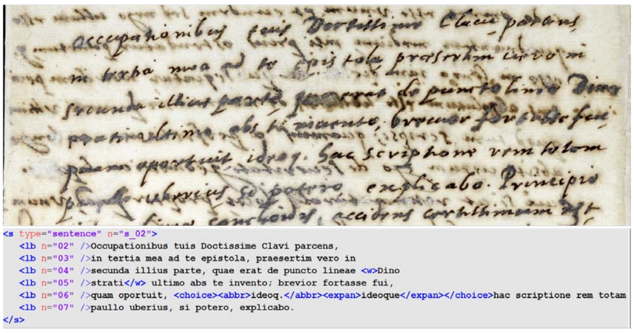
An Example

We here introduce an example showing a representation of a snippet of text with annotations. The chosen text is an excerpt of a letter, written in Latin, belonging to the epistolary corpus of the Clavius on the Web project[2] (Abrate et al., 2014b). Fig. 2 shows a typical way of encoding sentences and lines with a markup language as TEI (Burnard, 2014): the resulting XML hierarchical structure has been broken by the addition of the line anchors (<lb />) mixing up the textual and documental structure of the text. Indeed, to preserve the integrity of the word "Dinostrati" (spanning across lines 4 and 5), it is necessary to encapsulate it with the element <w />.



[...] Occupationibus tuis Doctissime Clavi parcens, in tertia mea ad te epistola, praesertim vero, in secunda illus parte, quae erat de puncto lineae Dinostrati ultimo abs te invento brevior fortasse fui, quam oportuit, ideoq. hac scriptione rem totam paullo uberius, si potero, explicabo. [...]

Fig. 2: A standard way of encoding a text with TEI-XML



```
<s type="sentence" n="s_02">
   <lb n="02" />Occupationibus tuis Doctissime Clavi parcens,
   <lb n="03" />in tertia mea ad te epistola, praesertim vero in
   <lb n="04" />secunda illius parte, quae erat de puncto lineae <w>Dino
   <lb n="05" />strati</w> ultimo abs te invento; brevior fortasse fui,
   <lb n="06" />quam oportuit, <choice><abbr>ideoq.</abbr><expan>ideoque</expan></choice>hac scriptione rem totam
   <lb n="07" />paullo uberius, si potero, explicabo.
</s>
```

Fig. 3: Multi-layered stand-off annotation of text

The model we propose solves this problem with the stand-off annotations: as shown in Fig. 3 the document (made of lines) and the textual structure (made of sentences and words) are logically separated. Lines, sentences and words do not overlap and they are structured in separate hierarchies.

Next Steps

We plan, in future works, to release a first version of a web environment, called *Omega*, built around the core entities that we here described. The environment will allow to load, index, annotate, and query a textual collection. Furthermore, we'll carry on the development of modules for text analysis and textual scholarship with the related APIs.

Although Digital Humanities have been defined from a discipline perspective in many ways, it is surely a field still looking for its own objects, practices and methodologies. Their development in the Spanish-speaking countries is no exception to this process and, even it is complex to trace a unique genealogy to give account for the evolving field in Spain and Latin America (Gonzalez-Blanco, 2013; Spence and Gonzalez-Blanco, 2014; Rio Riande 2014a, 2014b), the emergence of various associations in Mexico (RedDH), Spain (HDH) and Argentina (AAHD) that seek for a constant dialogue (Galina, González-Blanco and Rio Riande, 2015), and academic lab and DH center initiatives such as LINHD (Spain and Argentina), GRINUGR (Spain), Medialab USAL, LABTEC (Argentina), TadeoLab (Colombia), Elabora HD (Mexico), among others, make it clear that research has become increasingly "global, multipolar and networked" (Llewellyn Smith, et al., 2011) and that the academic field is looking for a global outreach and aims to open spaces of shared virtual work. Virtual Research Communities (VRCs) are a consequence of these changes.

Virtual Research Environments (VREs) have become central objects for digital humanist community, as they help global, interdisciplinary and networked research taking of profit of the changes in "data production, curation and (re-)use, by new scientific methods, by changes in technology supply" (Voss and Procter, 2009: 174-90). DH Centers, labs or less formal structures such as associations benefit from many kind of VREs, as they facilitate researchers and users a place to develop, store, share and preserve their work, making it more visible. The focus and implementation of each of these VREs is different, as Carusi and Reimer (2010) show in their comparative analysis, but there are some common guidelines, philosophy and standards that are generally shared (as an example, see the Centernet map and guidelines of TGIR Huma-Num, 2015).

This poster presents the structure and design of the VRE of LINHD, the Digital Innovation Lab at UNED (http://linhd.uned.es), and the first Digital Humanities Center in Spain. This VRE focuses on the possibilities of a collaborative environment for (profane or advanced) Spanish-speakers scholarly digital editors. Taking into account the language barrier that English may suppose for a Spanish-speakers scholar or student and the distance they may encounter with the data and organization of the interface (in terms of computational knowledge) while facing a scholarly digital edition or collection, LINHD's VRE comes as a solution for the VRC interested in scholarly digital work. Moreover, it will make it possible to add an apply tools that contribute to improve Spanish-English applications or tools developed locally, such as *Contawords*, by Iula-UPF http://contawords.iula.upf.edu/executions. Opening such an environment to the Spanish speaking world will make it possible to reach different kinds of communities, whose profile and training in digital humanities differ from the typical users of DH tools and environment. Testing all these tools in this new environment will, for sure, draw interesting project results.

In this sense, our project dialogues and aims to join the landscape of other VREs devoted to digital edition, such as *Textgrid*, *e-laborate*, etc. and, in a further stage, to build a complete virtual environment to collect and classify data, tools and projects, work and publish them and share the results with the research community. After having studied the structure and components of other digital virtual environment, our VRE has been designed on a humanist-user centered perspective, in which interface design, accessibility easiness and familiarity with tools and standards are key factors.

Therefore, the key of our VRE is the combination of different open-source software that will enable users to complete the whole process of developing a digital editorial project. The environment is, up-to-now, divided into three parts: 1) A repository of data to (projects, tools, etc.) with permanent identifiers in which the information will be indexed through a semantic structured ontology of metadata and controlled vocabularies (such as *Isidore* and *Huni*, but using *LINDAT* software by *Clarin. eu*). 2) A working space based on the possibilities of *eXistDB* to work on text encoding together with *Tei-Scribe*, a tool developed at LINHD to tag texts in an intuitive way, storing and querying, plus some publishing tools (pre-defined stylesheets and some other open-source projects, such as *Sade*, *Versioning machine*, etc.). 3) A collaborative cloud workspace which integrates a wiki, a file archiving system and a publishing space for each team.

Sustainability and long-term preservation are issues which we contemplate from the beginning, as our group is leading the addition of Spain into Dariah and LINHD is also part of a Clarin-Knowledge center with two powerful NLP groups from U.Pompeu Fabra in Barcelona and IXA in País Vasco. Our project has been conceived according to DH standards and open-source tools and its infrastructure is supported by our university UNED.

Diachronic Semantic Lexicon of Dutch (Diachroon semantisch lexicon van de Nederlandse Taal; DiaMaNT)

Katrien A. C. Depuydt
katrien.depuydt@inl.nl
Instituut voor Nederlandse Lexicologie, Netherlands, The

Dutch language has been described extensively in the comprehensive historical dictionaries of the Institute for Dutch lexicology. These dictionaries (Oudernederlands Woordenboek, Dictionary of Old Dutch, ca. 500-1200; Vroegmiddelnederlands Woordenboek, Dictionary of Early Middle Dutch, 1200-1300 ; Middelnederlandsch Woordenboek; MNW, Dictionary of Middle Dutch, ~1250-550; Woordenboek der Nederlandsche Dictionary of the Dutch Language, 1500-976) cover over 15 centuries of Dutch and are as such a perfect guide to understanding historical language. The dictionaries also provide the core material for the diachronic computational lexicon of Dutch (GiGaNT), that can be used to support search in historical texts by users without (expert) knowledge of historical spelling variation: when searching for *slager* ('butcher') the user also gets the morphological and spelling variants like *slagers, slagher(s), slaeger(s) slaegher(s)* or *slegher(s)*. However, when a user wants to study the history of the butcher's trade, it is not immediately obvious from the way these traditional dictionaries are structured that one has also to look for *vleeschhouwer* or *beenhouwer* or *beenhakker.* And it is only after reading the complete articles that a user learns that *vleeschouwer* can also mean 'executioner', and *slager* 'a person who slays so.', be it though that in the case of *vleeschhouwer* the meaning *'executioner´* is derived from vleeschhouwer 'butcher', while *slager* in contemporary meaning 'butcher' is derived from the meaning *'a person who slays so'.*

In this contribution we describe the first results of our work on the development of a diachronic semantic lexicon of Dutch. The lexicon aims to enhance text accessibility and to foster research in the development of concepts, by interrelating attested word forms and semantic units (concepts), and tracing semantic developments in time. In the lexicon, the diachronic onomasiology, i.e. the change in naming of concepts and the diachronic semasiology, i.e. the change in meaning of words, will be recorded in a way suitable for use by humans and computers. The onomasiological part of the lexicon is meant to enhance recall in text retrieval by providing different verbal expressions of a concept or related concepts (*slager → beenhouwer, beenhakker, vleeshouwer; boer → landman*). The diachronic semasiological component (which charts semantic change), aims to enhance precision by enabling the user to take semantic change into account; the oldest meaning of *appel* for example is 'a fruit' (so *appel* is also used for pears, plums etc.).

We describe the structure of the diachronic semantic lexicon and procedures for the acquisition and aggregation of content. The INL historical dictionaries will be the main source of the lexicon, as these dictionaries describe the Dutch lexicon from the 6th to the 20th century and cover most of the basic vocabulary of this period. Word sense descriptions are illustrated by dated quotations, which constitute a first step towards dating a concept. The temporal distribution of quotations pertaining to different senses gives a first picture of the diachronic development of the sense inventory of a headword. The fact that many words in the historical dictionaries are defined (partly) by synonym definitions and contemporary semantic (near)-equivalents enables us to extract an initial set of semantic relations.

Information from other sources is not disregarded. For contemporary Dutch, several lexical resources cataloguing semantic relationships are available. This includes traditional synonym dictionaries like Brouwers "Het Juiste woord" and more recent initiatives such as Open Dutch Wordnet (Vossen). For some specific domains, thesauri with a diachronic component are in development (eg. the *HISCO* (http://historyofwork.iisg.nl/index.php)).

Besides lexical sources, diachronic corpus material[1] and corpus-based methods are no less essential to the development and verification of the relevance of the lexicon content. This includes: i) corpus based analysis of semantic change at the "type"-level, using distributional methods. Here, the fact that our starting point is defined by the set of quotation dates per word sense provides an interesting perspective. ii) research into the application of token-based distributional methods to the interlinking of historical corpora and lexical resources.

Pierre-Yves Brandt
Pierre-Yves.Brandt@unil.ch
University of Lausanne, Faculty of Theology and Religious Studies: Institute for Social Sciences of Contemporary Religions, Switzerland

Gauntlet was developed for the international SNSF project "Drawings of gods", which is dealing with up to 5'100 drawings collected in different parts of the world (e.g. Japan, Russia, Switzerland, Romania). The data was digitalized and deposited on a publicly available database designed on MySQL for this project (http://ddd.unil.ch). The presentation of this tool will then make use of a specific application on such material.

Subsequent analyses involve interpretation of collected data and metadata (Brandt et al., 2009; Dandarova, 2013) as well as image analysis (Konyushkova et al., submitted). While algorithms and software tools for automated image analysis of photographic pictures are steadily expanding, high-variability and approximate nature of children's drawings make analysis and object detection (e.g. stars, clouds, eyes) rather challenging.

Convinced that the curation (i.e. manual annotation) of our complex objects is the solution both to tackling such a big data problematic and to guiding further automated computational approaches, we built Gauntlet, a web application tool for image annotation. It results from a collaborative and interdisciplinary software development process gathering psychologists, theologians and bioinformatics specialists. The tool is available for Chrome (version 44.0 or higher) and Firefox (version 41.0.2 or higher). It was built on modern and open source web standards for software development such as HTML5/CSS3 and AngularJS. There is no restriction to the use of this tool and it is GNU GPLv>=2. The logic behind follows from web tool development in bioinformatics, aiming to provide platform-independent and barrier-free solutions - which could not be found with existing tools.

Gauntlet's main benefit is to provide our worldwide collaborators with common semantics from a set of attributes (i.e. features) and geometrical tools for annotating the collected drawings. The set is displayed on the interface as a hierarchical list - termed "annotation tree" - of categories and subcategories (e.g. "characters area" branch contains sub-branch attributes: "human", "non-human", "text" and "blank sheet"). The tree is designed and edited via Excel and converted to JSON for web display. Such an implementation grants us flexibility and editing of the annotation tree based on curators' comments (full text comments can be dropped at every level) and the degree of attributes occurrences. The annotation tree first took after McCarty et al.'s personification model (2004) approach, but is currently fashioned in such a way that the role played by annotators' subjectivity should be reduced.

While it allows relatively fast annotations of large samples of drawings, Gauntlet's main purpose is to provide positional coordinates of attributes from smooth and accurate user-image interactions. Such interactions rely on points to target repeated objects of a specific attribute (e.g. accessories or hands) and boxes to mark off the whole spanning area of an attribute (e.g. characters area). Curators can, at any time, export the current status of annotation in CSV format and run comparative statistical analysis on feature frequency, occupancy or positioning. So far, annotations have been carried out by researchers who are affiliated with our project, although crowdsourcing may be used in the future.

In the end, it is expected to help highlight developmental, intercultural and interfaith variations on the material collected for the abovementioned project "Drawings of gods". Moreover, exports from Gauntlet will help complete further explorations into pattern recognition by providing the ground truth.

At this stage the tool is client-based and main features are ready for use. Even though it is stand-alone, it may go through further development to plug into API for operating with any kind of data storage systems (e.g. RDBMS, nosql or rdf-based). Beside this, due to its flexibility such a tool might prove practical for a wider use, targeting the processing of data in various contexts, such as photos of paintings or other art forms.

Overall, the collaborative and interdisciplinary work from which Gauntlet emerged represents a great deal of mutually enriching influences between agents from various fields ready to revise their initial views, thus shedding light on what today's scientific project development should look like.

EVT (Edition Visualization Technology[1]) is a lightweight, open source tool specifically designed to create digital editions from XML-encoded texts, freeing the scholar from the burden of web programming and enabling the final user to browse, explore and study digital editions by means of a user-friendly interface, providing a set of tools (zoom, magnifier and hot-spots for manuscript images, text-image linking and an internal search engine for the edited texts) for research purposes. The starting point of the system is one or more documents in the standard TEI P5 format, which is turned into a web based application – a mix of HTML5, CSS3 and JavaScript – that can be easily shared on the Web. The text can be presented in different levels of edition (e.g. interpretative, diplomatic) and, besides the default visualization layout where text and scans of the original manuscript are linked together and placed side by side, a book reader mode can be activated if double side images are supplied.

Even if it was born in the context of the specific use case the Digital Vercelli Book project, whose first version has been available online for about a year[2], it is able to fit different texts and needs. For example, it is now being used to publish the digital edition of the Codice Pelavicino manuscript[3], a medieval codex preserving charters dating back to the XIII century. Moreover, it has been used by the CVCE[4] (Centre Virtuel de la Connaissance sur l'Europe) as a starting point to create a publication framework for bilingual (French, English) documents of the W.E.U. (Western European Union). As a first consequence of these collaborations, EVT has been enriched with several new features[5]:

- thanks to an appropriate encoding, it is now possible to automatically create a list of all the entity names in the text that can be used both to provide a direct access to the page where a particular entity occurs and to present all the additional information considered relevant for that specific entity;
- an internal search engine allows the user to perform textual searches in a specific edition level for the shown text, and a virtual keyboard holding special characters is available if necessary;
- a generalized method to add critical textual notes has been implemented;
- all the information included in the TEI header, in particular the <msDesc> element, and in the <front> element, can now be shown to the user in a separate formatted panel;
- the user interface is now more flexible thanks to new configuration options, and it can be localized in different languages.

Figure 2: EVT 1.0 - Search results

The continuous development and need to adapt EVT to different types of documents and TEI-encoded texts has shifted the development focus towards creation of a more general tool for the web publication of TEI-based documents, able to cater for multiple use cases. This decision has led to a complete revision of the infrastructure in order to improve flexibility and modularity, to make it easier to implement new features and to adjust the UI layout for different kinds of editions. This is why the development team decided to refactor the whole code of the viewer and base it on AngularJS[6], a Javascript framework which implements the MVC (Model View Controller) pattern to separate presentation, data, and logic component, providing a great modularity of the web application.

Perhaps the most important new feature developed for the next EVT version is the support for critical editions, again encoded according to the TEI XML P5 standard. This new level of edition is based on the current TEI relevant CA module and Guidelines chapter[7] and it supports the Parallel Segmentation method. The current implementation, however, is kept as generic and flexible as possible to make it easier to update it when the TEI module will be rewritten and expanded to become more powerful and suitable to philologists[8]. Among the different tools offered, EVT will provide a straight and quick link from the critical apparatus to the textual context of a specific reading; moreover, it will allow to compare witnesses' texts among each other or with respect to the base text of the edition (or to another specific text); finally, if the digitized images of each manuscript are provided, each variant can be examined in its palaeographic context.

From the point of view of the editor, the new architecture will be as easy to use as the current one: the only technical skill required from the editors will be a general competence in XML editing to configure EVT properly and the care to place each XML-related component of the edition (mainly the schema besides the encoded texts) into the correct area of the directory structure. Moreover, the editor will be able to modify the CSS style sheets to customize all aspects of text visualization, according to his/her needs.

Figure 3: EVT 2.0 - Critical edition. Collation of witnesses

The poster that we would like to present at the DH 2016 will show how far EVT has progressed and matured in terms of features, code robustness and UI innovation especially with regard to critical edition support and handling of manuscript variants.

During the poster session you will be able to try a working demo of the software.

Testing Delta on Chinese Texts

Keli Du
keli.du@stud-mail.uni-wuerzburg.de
Universität Würzburg, Germany

Delta (Burrows, 2002) is a measure, which has already been proven as a reliable method to resolve authorship attribution problems in different languages such as English and German. However, there has been no report about the accuracy of Delta on Chinese texts so far. As such, I set an experiment to test it. The tests cover both modern and classical Chinese because of the grammatical and lexical differences between them.

First I determined whether Delta works on modern Chinese. After that I did tests on classical Chinese. At last, I tested the *Dream of the Red Chamber* (DRC, 红楼梦)[1]. The number of authors of DRC is a classic question of Chinese literary studies. The tool I used in the experiments is "stylo", an R package introduced in the context of stylometry in 2013 (Eder, 2013). Using "stylo" I have done cluster analysis. All texts of one author should stay in one group. Misplaced texts are considered as mistakes. The more mistakes Delta makes, the less Delta is appropriate for Chinese.

Working on Chinese language processing is different compared to languages like English. The greatest challenge lies that we are unable to recognize the boundary of words because there are no spaces between words. There are two possibilities to address this problem: (i) by using a segmenter to split a text into words and select words as the textual feature, or (ii) by selecting character N-grams as the feature. Both solutions were tested here and the results are presented as a comparison.

For my first experiment I gathered 45 modern Chinese texts from 6 authors. I used the Stanford segmenter to split the texts and select both words and characters as features. The results showed that Delta is reliable (Fig. 1). With the 100 most frequent words bigrams Delta correctly identifies 38 of 45 texts. The best results, 43 of 45 texts, occur with the 200 to 700 most frequent character bigrams or most frequent words unigram.

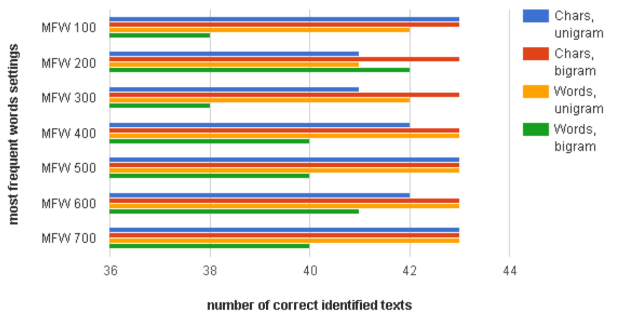

Fig. 1 Delta test results for four sets of features in 45 modern Chinese texts

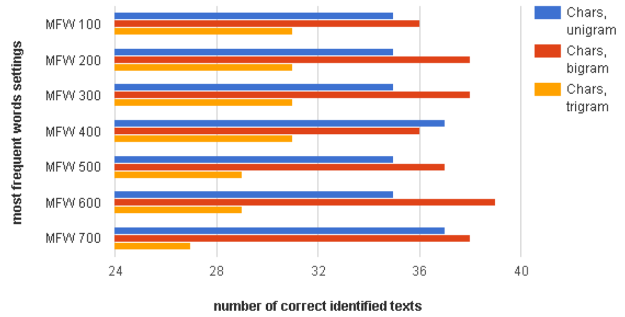

Fig. 2 Delta test results for three sets of features in 40 classical Chinese documents

After the tests on modern Chinese, I proceeded with my second experiment on classical Chinese. I took 4 chapters each randomly from 10 novels from the Ming and Qing Dynasties (16th to 19th century) and built a corpus of 40 documents. One problem was that the Stanford segmenter did not work anymore, because the segmentation standards are not suitable for classical Chinese. Hence the only option was to take characters as feature. The results showed that Delta also works (Fig. 2). While many mistakes occurred with characters trigrams, taking characters bigrams for the tests achieved a high level of accuracy. With 600 most frequent characters 39 of 40 documents were correctly identified.

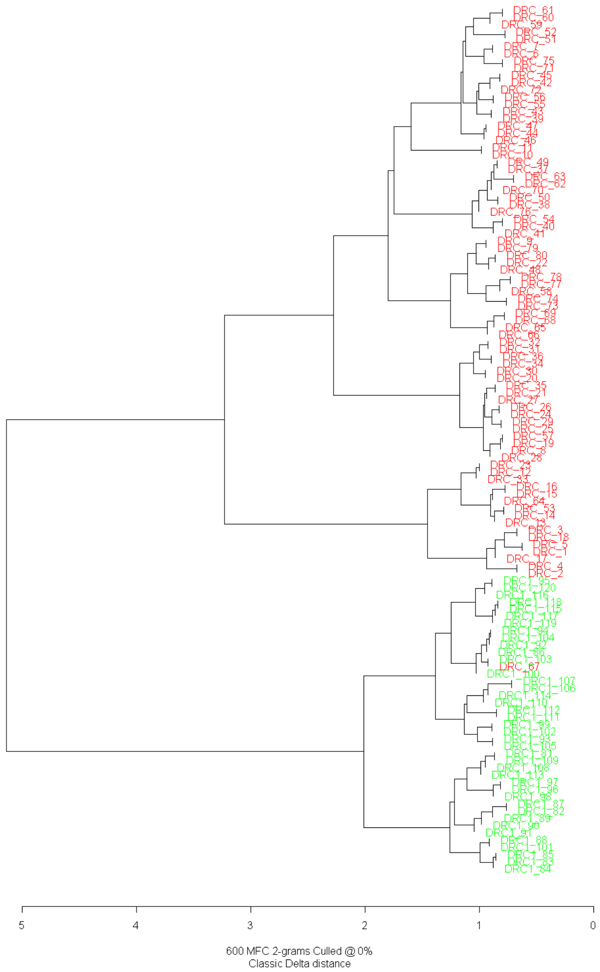

Fig. 3 Delta test results of DRC, (600 MFC, 2-grams)

The first two experiments confirmed Delta as a valid measure for both modern and classical Chinese. In the third experiment Delta was applied to *Dream of Red Chamber* (DRC)[2]. As one of the most famous Chinese classic novels, DRC was written by Cao Xueqin (曹雪芹) during the 18th century. The first version had 80 chapters. However in 1791 Gao E (高鹗) and Cheng Weiyuan (程伟元) published another edition with 120 chapters. They claimed that theirs was the complete version. Since there, there has been a constant debate about the number of authors of DRC. Some scholars think that Cao penned all 120 chapters. Some beg to differ. According to a study by

Hu Shih (胡适) (Hu, 1998), the first 80 chapters of DRC are the original work of Cao and the last 40 chapters are written by Gao. Hu's research is now widely accepted in China. Some modern research approaches also suggest that the first 80 chapters and the last 40 chapters of DRC are written by two different authors. They also find evidence that Chapters 64 and 67 may not be written by Cao (Hu, 2014; Tu, 2013).

My experiment suggested the same conclusion as the other scholars that DRC is written by two different authors (Fig. 3). The texts were divided into two groups. Red texts represent the first 80 and green texts are the rest 40 chapters. Delta also suggests that Chapter 67 is written by the second author.

Knowledge Representation

The research we present is a digital reworking of the categories. This research forms part of a larger work which explores the impact of computational methods on philosophy. Nearly 40-years-ago Aaron Sloman anticipated this *Computer Revolution in Philosophy* (Sloman, 1978). This revolution is as yet not fully under way, we would argue, at least not to the same extent that it is currently transforming the humanities and has already transformed the sciences. Our research adds momentum.

A distinction must be made between the general notion of category in philosophy and the top-level categories of metaphysics. When we refer to the categories of virtue of vice, for instance, it is to the general notion of category to which we refer. When we refer to the ontologies of Aristotle, Kant, Peirce, Whitehead, or whoever, it is to the top-level categories that we refer. Every object/entity there is, without exception, participates in at least one of these top-level categories because these categories indicate universal properties. Properties such as: quality, substance, modality, form, and so on. C. S. Peirce arguably took these investigations to their logical conclusion with his triad of logical terms: firstness, secondness, thirdness. John F. Sowa in *Knowledge Representation* (Sowa, 2000) presents a historical account of this philosophical activity and its connections with software modelling, we regard our research is a continuation of Sowa's investigations.

Saffron (Bordea, 2013) is a domain modelling research tool that uses novel natural language parsing and taxonomic techniques. Specifically, it performs domain adaptive extraction of topical hierarchies. *Saffron* was conceived and is being developed at the Insight Centre for Data Analytics in the National University of Ireland, Galway.

PACT.x (Durity, 2015) is a purpose-built corpus of philosophical texts, these are stored in plain text with their associated metadata and they reflect 2500 years of mainly Western thought, from Plato's *Symposium* to Wittgenstein's *Tractatus*. *PACT.x* was conceived and is being developed at the Digital Arts and Humanities program in University College Cork, Ireland.

We arrive at a digital reworking of the categories in a number of algorithmic steps.

(1) By performing a semantic-based analysis of the *PACT.x* corpus using *Saffron* we obtain result set α, $R\alpha$, which comprises a sequence of terms, $S\alpha$, and related taxonomy, $T\alpha$, of philosophical concepts (Vulcu, 2015) and their corresponding visualisation - Figure 1. Sequence $S\alpha$ is ordered by a weighted combination of frequency and coherence, meaning frequency of occurrence of a word within the corpus coupled with terms that contain a word from the domain model, and terms that appear in the context of a word from the domain model. The structure and relation of the topics in taxonomy $T\alpha$ are drawn from result set $R\alpha$. The directed edges of the graph are constructed using the broader/narrower than relation from WordNet[‡] and the graph is pruned using the ChuLiu/Edmonds algorithm resulting in a directed acyclic graph.

The first 30 terms in sequence α are:

1 Nature	16 Truth
2 Life	17 Matter
3 God	18 Cause
4 Knowledge	19 Mind
5 Law	20 Terms
6 Words	21 Object
7 Principle	22 Character
8 Sense	23 Soul
9 Power	24 Person
10 World	25 Philosophy
11 Time	26 Moral
12 Reason	27 Pleasure
13 Body	28 Experience
14 Idea	29 Government
15 Form	30 Action

(2) We Iterate through each of the terms in result set α in turn and query the open knowledge graph Wikidata[1] to perform further analysis. By tracing the compositional relationship properties (instance-of, subclass-of, part-of) of each term we infer the compositional structure of these concepts and obtain ultimately another sequence, $S\beta$, and related taxonomy, $T\beta$. The list of topics that is sequence $S\beta$ is more or less identical to sequence $S\alpha$ save for disambiguation and completeness. Note that taxonomy $T\beta$ differs from taxonomy $T\alpha$ in that it reflects the mereological structure of Wikidata rather than WordNet.

(3) Taxonomy $T\beta$ is then divided into two parts using a heuristic method: the base taxonomy, $T\gamma$, which comprises the most abstract part, and superstructure which comprises the rest.

Taxonomy $T\gamma$ is the digital reworking of the categories.

Critical Assessment in Context

We compare taxonomy γ with the traditional categories of philosophy to see how the singular vision of individuals (Aristotle, 1938; Kant, 1787, for instance) differs from what may be viewed as a complex adaptive system (WordNet and Wikidata). To clarify, the idea here is to contrast the semi-isolated contemplation of individuals from different eras with the distillation of the organic collective behaviour of billions of wiki edits. In what way does a digitally generated ontology differ from the standard hand-built ones? For a contrasting approach see the recent theoretical work *Foundations of an Ontology of Philosophy* (Grenon and Smith, 2011) with attendant Web Ontology Language applied work *Philosophy Ontology* (Grenon, 2007)

We validate resultset α against authoritative philosophical reference works such as *The Oxford Dictionary of Philosophy* (Blackburn, 2008), *Routledge Encyclopedia of Philosophy* (Craig, 1996), and so on. In this way we are able to understand how a distant reading (to use a term that has almost become a genericized coinage) of topics by machine algorithms compares to professional reference works. Is it possible that topics that philosophers have touched on down through the ages, as highlighted by the machine, haven't gotten the attention they deserve? If so, why? Is it possible that there are topics which are considered important enough to gain a reference entry that have been overlooked by the machine? Again, what could be the reason? Because the topics in resultset α are ordered by frequency we now have a rough quantitative measure of the relative usage of different philosophical concepts which perhaps can be used as a proxy for their relative human significance; reference works obviously arrange entries in alphabetical order having no other metric.

Our research indicates that novel computational methods may be brought to bear on the task of philosophy. It suggests a radically different route than that taken by others, such as that of modelling the formal systems discussed within philosophical works, as exemplified by *The Philosophical Computer* (Grim, Mar, and St. Denis, 1998). It suggests also that we should take a sustained look beyond the more, if we may say, pedestrian use of the computer as an educational and communication tool as discussed, for example, in *Cyberphilosophy* (Moor and Bynum, 2002).

Though some way off from becoming part of the standard philosophical curriculum the investigations we have undertaken indicate further avenues of fruitful research and hint at future novel results once the methods have been refined through third-party experimentation, replication, and feedback.

Notes

[1] https://wordnet.princeton.edu/ "WordNet® is a large lexical database of English. Nouns, verbs, adjectives and adverbs are grouped into sets of cognitive synonyms (synsets), each expressing a distinct concept. Synsets are interlinked by means of conceptual-semantic and lexical relations."

[2] https://www.wikidata.org/wiki/Wikidata:Main_Page "Wikidata is a free linked database that can be read and edited by both humans and machines." "Wikidata acts as central storage for the **structured data** of its Wikimedia sister projects[…]" Wikidata is a triplestore. A triplestore is a database of semantic web triples, each with the form: subject, predicate, object. It is no coincidence, we suggest, that the ultimate store of structured data that has evolved on the web shares the same form as Peirce's triad of logical terms.

"Remapping Leigh Hunt's Circles": Voyant Tools and Hunt's Dramatic Criticism

Michael Eberle-Sinatra
michael.eberle.sinatra@umontreal.ca
Université de Montréal, Canada

Stéfan Sinclair
stefan.sinclair@mcgill.ca
McGill University, Canada

Emmanuel Château
emmanuel.chateau.dutier@umontreal.ca
Université de Montréal, Canada

"Remapping Leigh Hunt's Circles" is an ambitious project that explores Leigh Hunt's central position in the London literary and critical scene of the first half of the nineteenth century, through the lens of digital humanities tools. Hunt is today considered one of the key figures of the Romantic period in England, known for his work as editor, journalist, poet, and facilitator. Numerous articles, essay collections, biographies, and monographs published in the last fifteen years have made this clear. Hunt's contribution to Romantic and Victorian literature was as extensive as it has proven durable, in matters as various as prosodic experimentation and the modernization of the magazine essay. Yet little work (beyond some biographical notes) has been done on the second half of his life, a period that was as productive as the first, and during which Hunt was intimate with many of the finest writers of the time, and continued to contribute to London's literary circles through the ongoing publication of critical essays in periodicals and anthologies. This project aims to redress this imbalance/oversight and reassert Hunt's place in the Romantic and Victorian eras, as well as his continuing significance for understanding the London literary scene between 1805 (publication of his first critical essay) and 1859 (date of his death, with his last article published only a few weeks before).

"Remapping Leigh Hunt's Circles" makes a case for Hunt's position as a key critical voice in London beyond his already established prominence during the *Examiner* years. It does so through a careful analysis of his critical reviews and essays (with a specific focus on his drama criticism to underscore Hunt's ongoing engagement with the public sphere) published during his entire career, which spanned the first half of the nineteenth century. Data mining and textual analysis offer exciting opportunities to bring together different sets of data which, when prepared to the highest standard of text encoding, can yield new and innovative results that encourage reconsideration of preconceived notions regarding the transfer of ideas from one author to another, or one literary genre to another. The results of the research undertaken in "Remapping Leigh Hunt's Circles" will be presented in a collaborative, visual context that reimagines the digital scholarly edition as a transparent workspace in which established primary objects from existing databases can be gathered, organized, correlated, annotated, and augmented by multiple users in a dynamic environment.

All the texts prepared for inclusion in our project are encoded to the Text-Encoding-Initiative (TEI) standards. The mark-up language and quality controls for improving metadata in all the resources provide more accurate search and discovery, allow for the presentation of well-supported content on multiple devices and develop tools for assembling, archiving and indexing research objects and artifacts. Ongoing work on this platform will enable researchers to undertake world-class research by providing the means to link data-sets to published content, encouraging data reanalysis, replication studies, and data re-purposing, all of which improve research quality and efficiency.

Our poster will report on the first year of this project, and the implementation of the latest version of the *Voyant Tools* to examine the dramatic essays written by Hunt between 1805 and 1813 (when he was sentenced to two years in prison for libel against the Prince Regent). We will showcase in particular two aspects of the integration between the Hunt archives and Voyant Tools. First, the ability to identify and visualize named entity connections and their networks across multiple documents (this a refinement of the previous RezoViz tool in Voyant). The Hunt collection presents an ideal corpus for network exploration given the interconnectedness of the people, locations and events that animate the documents. Second, Voyant provides a generic and customizable way of presenting a web-based corpus catalogue with the same kinds of faceted browsing and advanced querying capabilities we have come to expect from library databases and online stores. A further benefit of this functionality is the ability to create dynamic subsets of a corpus to examine more closely (in other words, using a catalogue skin in Voyant to create worksets destined for Voyant's more conventional analytic skin).

The "Remapping Leigh Hunt's Circles" is essentially a project of digital text editing and literary criticism whereas Voyant Tools is essentially a software platform for reading, analyzing and visualizing digital texts. These are separate traditions and separate concerns, but this poster will demonstrate the value of symbiotic development: both projects benefit from the collaboration.

The Digital Émigré: Russian Periodical Studies and DH in the Slavic Fields

Natalia Ermolaev
nataliae@princeton.edu
Princeton University, USA

Philip Gleissner
pg4@princeton.edu
Princeton University, USA

Digital Humanities has seen slow adoption in the Slavic language and literature fields in North American academia. This issue frames our project, the Digital Émigré, a digital resource for exploring Russian émigré periodical literature. Our project has a threefold aim. As periodical studies scholars, we want to enable access to Russian émigré journals for new audiences. As digital humanists, we believe that DH tools and methodologies can facilitate new forms of knowledge about twentieth-century Russian, and more broadly diaspora, literary and cultural history.

Finally, as Slavists, we hope our project will be a hub for discussion about the applicability of DH theory and practice for scholars working with Russian-language material.

At this pilot stage, Digital Émigré is a web-based searchable database of article-level metadata of Russian-language journals published outside of Russia in the twentieth century. Our pilot contains four titles (approximately 100 issues and 1,500 articles): *Novoselye* and *Novyi zhurnal* were published in the 1940s in New York, and *Sintaksis* and *Kontinent*, in the late 1970s and 1980s in Paris. Our pilot site provides insight into literary culture at both the beginning and end of the Cold War, bookending the twentieth-century Russian diaspora experience. Digital Émigré is intended to scale, and will eventually contain additional titles and new functionality.

We will highlight the main scholarly avenues that DH methods allow us investigate, such as mapping networks of co-publication, tracking evolving political, social and cultural concerns of émigrés over the course of the Cold War, demonstrating the increased opportunities for émigré women as editors and contributors, and highlighting the proportion of original vs. re-printed work in émigré publications. This way, our project encourages experimentation that will enrich the study of Slavic periodical culture: accessing journals through their data can challenge narratives that are often framed by retroactive canonization, close reading and focus on individual authors. Digital Émigré thereby bridges philological approaches and sociological questions about intellectual networks and communities of artistic production.

The poster address the project's core technical design: our strategy for data modeling and management and database design. We will also present our plans for next steps, which is to provide full-text access and to federate our titles with other digital periodical collections. For this, we are designing a TEI schema modeled on major periodical studies digital collections - specifically the Blue Mountain Project at Princeton University (http://bluemountain.princeton.edu and the Yellow 90's Online at Ryerson University (http://www.1890s.ca).

We will also discuss the specific challenges of working with Russian language material and Cyrillic script, such as character encoding, transliteration, translation, and tokenizing and stemming. These issues can be barriers to success when working with popular DH tools that are developed primarily for Western scripts and languages, and we will show our solutions for using some well-known tools for: data normalization (OpenRefine), text analysis (Voyant), network analysis (Gephi), visualization (Raw, Palladio), and topic modeling (MALLET).

Digital Émigré is committed not only to the exploration of the intellectual experience of diaspora cultural life. As a digital humanities project, it is itself invested in building intellectual communities around the engagement with this material and its afterlife. It aims to foster contact between scholars working with Russian and other Slavic languages internationally, especially through the discussion of issues of interoperability and creating multilingual digital research environments.

Faraway, So Close!: Reading Adeline Mowbray Closely Using Topic Modelling

Michael Gregory Falk
michaelgfalk@gmail.com
University of Kent, UK, United Kingdom

1. Introduction: The "reading" debate

Digital humanists disagree fervently about the nature of reading, and how computers can change the way we do it. Some advocate "distant reading" as a radically new form of inquiry (Burdick et al., 2012, Jockers, 2013, Moretti, 2013). Others argue that computers can improve and enrich traditional modes of reading (Burrows, 1987, McGann, 2001, Ramsay, 2005, Ramsay, 2011). McCarty subsumes this debate in his third way of "interactive modelling" (2005). Pasanek, meanwhile, offers a whimsical alternative with his "desultory reading" (2015).

The hot polemic of this debate obscures a fundamental point: all these kinds of reading are deeply intertwined, and none should be treated as an exclusive option.

To demonstrate this, I apply a classic *distant* reading technique, topic modelling, to a corpus of texts, in order to assist in my *close* reading of a single novel, Amelia Opie's *Adeline Mowbray* (1804). This is a good novel to test new methods on, because it poses stark interpretive problems. Its heroine is a radical who dies repenting her earlier beliefs: are we supposed to admire or condemn her? For two centuries, readers have disagreed, some finding the novel conservative (Tomalin, 1974; Butler, 1987), others radical (Kelly, 1981; King, 2009)—its original readers were mostly just confused (Cooper, 2001). If digital reading can help us answer this question, then we will learn more about the nature and use of digital reading itself.

2. Methods

2.1. Software. I used the popular MALLET package to perform Latent Dirichlet Allocation on *Adeline Mowbray* and 55 other realist novels from the period 1776-1822 (Mccallum, 2002). Blei and Jockers describe the method comprehensively (Blei, 2012, Jockers, 2014).

2.2. Corpus construction. A comprehensive selection of similar contemporary novels was taken from high-quality online archives.

2.3. Data preparation. Scholars disagree about how texts should be prepared for modelling: should they be chunked by paragraph (Algee-Hewitt et al., 2015), or by *x*-length chunk (Jockers, 2013, Jockers and Mimno, 2013, Jockers, 2014)? *X*-length chunks make it easier to include dialogue in the analysis, so these were preferred. The length was set at 125 words, any longer made close reading of the chunks harder; any shorter made the "topics" incoherent.

2.4. Parameters. I used hyperparameter optimization and Jockers' stopword list; excluded characters' names from the analysis; and set the number of topics at 150, avoiding the problems of incoherent and "chimera" topics identified by Schmidt (2012).

3. Discussion and Results

Applying this technique to the novels in my corpus produced two main kinds of results. First, the model identifies key "topics" in the corpus:

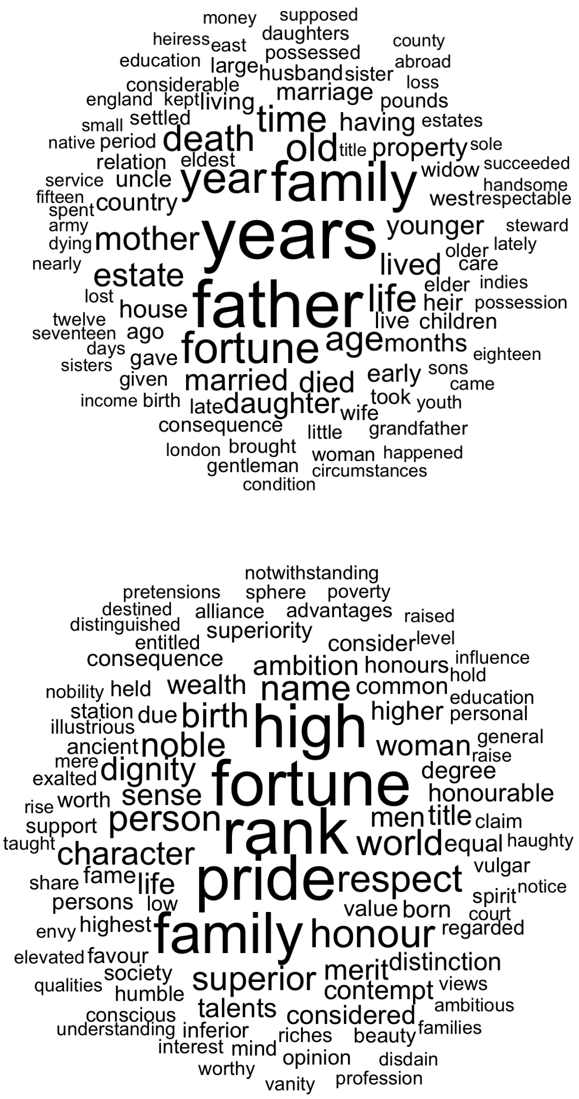

Figure 1. Topics 120 and 24

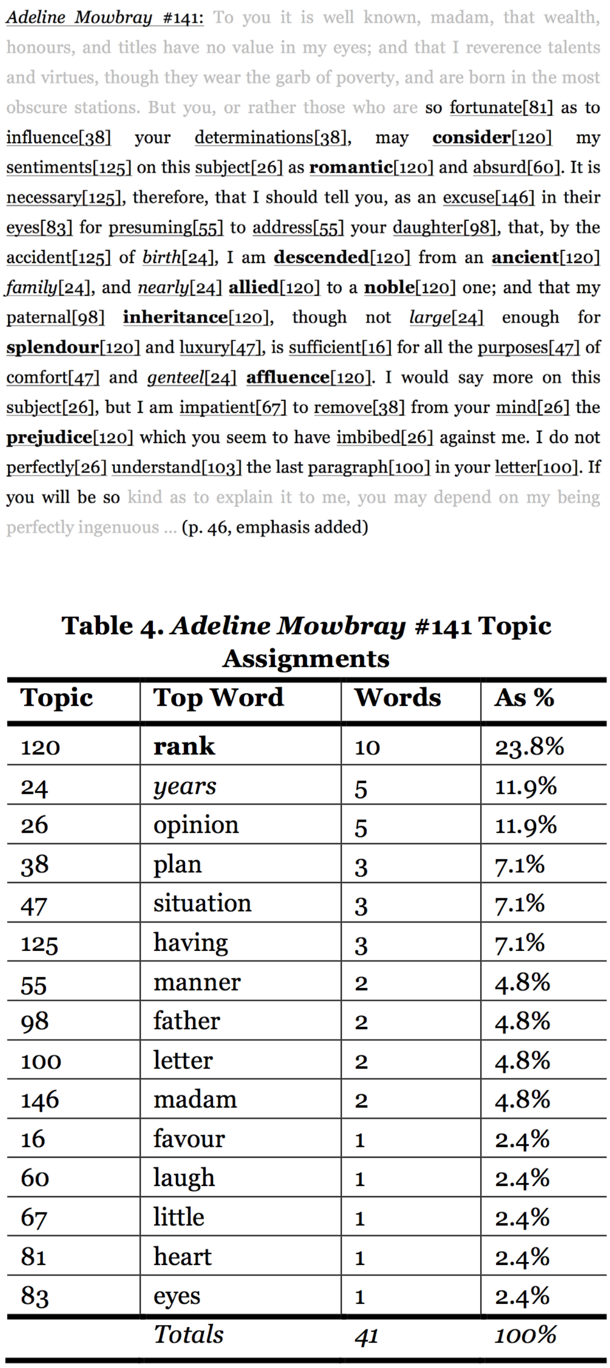
Such topics uncover hidden patterns between words in the corpus: for instance, the prominence of the words "year" and "years" in the discussion of a family's marital history in novels of this period.

Secondly, as Rhody (2012) has shown, topic modelling enables us to visualise the linguistic composition of a passage:



Adeline Mowbray #141: To you it is well known, madam, that wealth, honours, and titles have no value in my eyes; and that I reverence talents and virtues, though they wear the garb of poverty, and are born in the most obscure stations. But you, or rather those who are so fortunate[81] as to influence[38] your determinations[38], may **consider**[120] my sentiments[125] on this subject[26] as **romantic**[120] and absurd[60]. It is necessary[125], therefore, that I should tell you, as an excuse[146] in their eyes[83] for presuming[55] to address[55] your daughter[98], that, by the accident[125] of *birth*[24], I am **descended**[120] from an **ancient**[120] *family*[24], and *nearly*[24] **allied**[120] to a **noble**[120] one; and that my paternal[98] **inheritance**[120], though not *large*[24] enough for **splendour**[120] and luxury[47], is sufficient[16] for all the purposes[47] of comfort[47] and *genteel*[24] **affluence**[120]. I would say more on this subject[26], but I am impatient[67] to remove[38] from your mind[26] the **prejudice**[120] which you seem to have imbibed[26] against me. I do not perfectly[26] understand[103] the last paragraph[100] in your letter[100]. If you will be so kind as to explain it to me, you may depend on my being perfectly ingenuous ... (p. 46, emphasis added)

Table 4. *Adeline Mowbray* #141 Topic Assignments

Topic	Top Word	Words	As %
120	**rank**	10	23.8%
24	*years*	5	11.9%
26	opinion	5	11.9%
38	plan	3	7.1%
47	situation	3	7.1%
125	having	3	7.1%
55	manner	2	4.8%
98	father	2	4.8%
100	letter	2	4.8%
146	madam	2	4.8%
16	favour	1	2.4%
60	laugh	1	2.4%
67	little	1	2.4%
81	heart	1	2.4%
83	eyes	1	2.4%
	Totals	*41*	*100%*

Figure 2. The topic composition of a single fragment

Such visualisation is an invaluable tool of discovery, directing the scholar's eye to significant patterns in a text's language. In this case, the prominence of topics 120 and 24 in the passage turned out to be crucial.

In this passage, Glenmurray uses these topics to persuade Adeline's mother that he is a good suitor. He is a radical who has published philosophical tracts against marriage. If the novel presents him as the ideal suitor for Adeline's hand, we may assume that the novel itself has radical sympathies. As close reading reveals, topics 120 and 24 are often used to describe past or potential suitors, in both this and other novels from the corpus. In *Adeline Mowbray*, the language of these topics is used to describe many characters negatively, and only one positively—Glenmurray. This is compelling new evidence that he is the ideal suitor, and that the novel therefore portrays him and his radicalism sympathetically.

This reading was both "close" and "distant." The reading was "distant" because it involved statistical analysis of 65,000 125-word chunks. But these patterns observed from a distance were used to unravel the complexities of a closely-read text. Close reading reveals strengths and flaws of the distant reading tool: it turns out that LDA assigns words to topics differently each time it is run, and is scuppered by novelists who write idiomatically. Close and distant reading, it seems, are so closely bound together that they are part of a single process. Their messy, unpredictable connections suggest a new kind of readerly ideal for the Digital Humanities: anarchic reading.

The Corpus of Revenge Tragedy (CoRT): Toward Interdisciplining Early Modern Digital Humanities and Genre Analysis

Danielle Marie Farrar
dmfarrar@mail.usf.edu
University of South Florida, United States of America

Discoveries in anatomy and dissection in early modern England and the lively publishing economy of medical texts during this period undoubtedly played a critical role in the popularization of medical and anatomical language in early modern English drama. England's mid-sixteenth century saw the beginnings of the culture of dissection (Sawday 1995), and it was not long until language once exclusive to physicians and anatomists found its way onto the early modern stage and invested the tumultuous worlds of revenge tragedy. Just as the human envelope was peeled away on anatomists' tables, in artists' engravings, and by writers' quills in order to permit autoptic access to what was previously veiled, so can Digital Humanities (DH) techniques and processes of inquiry offer new modes of dissection on dramatic texts. The value of DH to and in early modern dramatic studies rests not only in its capacity to complement existing modes of literary analysis but also in its disruption of reading, interpretive, and knowledge construction practices of early English texts.

Additionally, within the work of genre analysis, DH approaches perform a valuable role in the furthered exploration and understanding of a genre's discursivity and position as a cultural phenomenon rather than just a material object (Steggle 2015). In the continued study of early modern revenge tragedy--a genre that has received relatively little attention in comparison to others--DH can prove invaluable by demonstrating how this genre increasingly participated in discourses of medicine and anatomy across the Elizabethan (1558-1603), Jacobean (1603-1625), and Caroline (1625-1642) periods via mapping the movement of anatomical language from the medical register to a literary and dramatic one. As has been rightly suggested, DH significantly expands the purview of what can be questioned by literary analysis to include not just a consideration of literary texts but also larger modes of cultural production (Wilkens 2015). An examination of how revenge tragedies adopted and exploited the medical register is significant to understanding not only the cultural significance of the revenge tragedy genre but also discovering the early modern conceptions of embodiment and the pervasiveness of the contemporary medical arena in popular culture.

This project thus reports on a hybrid corpus linguistics and geohumanities approach to a genre analysis of early modern revenge tragedy, which serves to widen the scope of inquiry and interpretation in respect to the role of the body and anatomical language in revenge tragedy. As a means to map the increasing frequency of anatomical language and medical vernacular in revenge tragedy, a corpus analysis was conducted using AntConc, a digital tool that enables textual analysis and corpora comparison. I created the Corpus of Revenge Tragedy (CoRT) as an experimental corpus of approximately 40 revenge tragedies to compare against other corpora, including Shakespeare's corpus and other larger corpora, such as the Early Modern English Medical Texts (EMEMT) Corpus, the Corpus of English Dialogues (CED), and the Early English Books Online-Text Creation Partnership (EEBO-TCP) Phase I database of more than 25,000 texts. As a means to focus interpretation, I developed a variety of word lists by collating—through traditional concordance-making methods—an Anatomical Lexicon (AL) of 209 representative material and metaphorical words from revenge tragedies. The AL provides first recorded usages of each word, root language(s), as well as select definitions from the *Oxford English Dictionary* and definitions (when available) from Henry Cockeram's *The English Dictionarie* (1623). In a subset of revenge tragedies, I manually flagged all anatomically inflected words. I then broke the list up into 2 primary categories and 13 secondary categories. Anatomically direct words are words that deal *directly* with anatomy (e.g., *eye*, *brain*, *arm*, etc.). Anatomically indirect words are words that deal *indirectly* with anatomy (e.g., *sconce*, *aspect*, *soul*, etc.). The categories are compositely based on the early modern medical texts of Thomas Vicary, John Banister, Andreas Vesalius via Thomas Geminus, Helkiah Crooke, and Ambroise Paré via Thomas Johnson. As such, data mining is an essential method to this project since this is a method that necessitates and encourages interdisciplinary work (Hagood 2012). Data mining has also helped shaped this project both instructively and interpretively since--as DH typically does--it allows not only new modes of investigation but also produces new systems of knowledge making.

As this diachronic project's interest is grounded in a discussion of how early modernity conceptualized not only the body itself but also understood embodiment (and how those two things manifested in revenge tragedy), this project also looks to geohumanities--a branch of DH--as a means to consider the geography of anatomical language and printing trends in early modern London. Through a lexical mapping of anatomical words in conjunction with a mapping of publication locations that printed revenge tragedy texts, we can gain an understanding of the cultural geography of London in respect to the pervasiveness of the medical register. Through various DH methods, the CoRT and AL complement and enrich existing bodies of knowledge about histories of anatomy and medicine, early modern drama, and early modern theories of embodiment.

3D Scanning for Preservation: Difficulties and Dissemination

Graham Fereday
G.N.Fereday@exeter.ac.uk
University of Exeter, UK, United Kingdom

Michael Mullins
M.K.Mullins@exeter.ac.uk
University of Exeter, UK, United Kingdom

Richard Webb
R.Webb2@exeter.ac.uk
University of Exeter, UK, United Kingdom

Gary Stringer
G.B.Stringer@exeter.ac.uk
University of Exeter, UK, United Kingdom

The use of 3D scanning & visualisation technologies for creation of digital surrogates has begun to gain wider acceptance in the museums and archives sector, largely due to significant advances in technology and price over the last few years. However, the technology is still evolving, and in some situations can struggle to yield accurate results. This poster will look at the pragmatic aspects of scanning for preservation, and will, it is hoped, generate public discussion and sharing of best practice.

We present a number of case studies. Firstly, looking at reflectivity, we show techniques in scanning metallic objects, and non-intrusive ways of reducing and eliminating surface reflection which can introduce unwanted noise and confuse tracking calculations in hand-held scanners.

Secondly, we look at results from a number of objects with significant amounts of very fine surface detail or flexible materials. Various materials such as modern fabrics, leather, thread and wool present particular challenges, and the results of working with these objects will provide the basis of guidance in preparation for undergraduate and postgraduate users of equipment at Exeter, which will be shared publically.

Thirdly, we examine experiments in the use of 3D scanning to evaluate and preserve archaeological finds in situ during excavation, and in particular, we evaluate the accuracy of measurement using hand-held scanners. This has clear advantages if sufficiently reliable, including the taking of otherwise impossible measurement through objects and evaluation through reconstruction of artefact fragments.

Finally, we look at means of disseminating the results of the scanning process, looking at the problems of reducing polygon counts, and the importance of surface texture and overlays in recreating the 'look and feel' of objects. We briefly look at the 'impact' of virtual 3D surrogates against 2D images, in particular referencing a student-engagement project involving the evoking of memory in dementia sufferers, using archival material and 3D visualisations of football memorabilia.

We examine the cross-generational possibilities opened up by engaging groups of students and seniors in the capture process, and suggest further possibilities for triggering memory or emotional responses through the use of detailed and immersive surrogates.

It is highly likely that further case studies will be examined; by June 2016, projects looking at difficult materials such as beeswax and ancient fabric remnants are likely to be under way, and preliminary findings will be included in the poster.

It is hoped that this poster will allow the sharing of ideas and experience both directly at the interactive poster session, and through the linked web objects, where comments can be left and dialogue can continue.

Linguistic DNA is a collaboration by linguists, historians, and digital humanities specialists at the Universities of Sheffield, Glasgow and Sussex. Our aim is to explore the emergence and development of semantic concepts as they are realised in historic textual corpora through a combination of computational processing and data visualisation techniques. This poster outlines the project's goals and methodology, describes the progress made towards those goals, and offers interim results. Prior to the era of big data, semantic research has relied on intuitive selection of concepts worthy for study and has drawn its evidence largely from canonical texts. The advent of large machine-readable textual collections opens the door to new methodologies for research in conceptual history, revolutionising our ability to extract information from such data sets. The Linguistic DNA project explores the use of these techniques for historical semantics, beginning with annotated corpora yet without a predetermined set of concepts to study, the intention being that through text processing and data visualisation, concepts should emerge 'bottom-up' out of collections that extend far beyond the canonical texts.

The main source of data for analysis is the Early English Books Online collection (henceforth EEBO)[1] and Eighteenth Century Collections Online (ECCO).[2] EEBO has been manually transcribed to high accuracy levels by the Text Creation Partnership (TCP) whilst ECCO is partly manually transcribed and partly OCR'd. All are to be annotated with lemma and part of speech information, although our process takes different inputs, and begins with cleaned text. These collections together consist of English-language material printed between the 15th and 18th centuries. Initial stages of investigation involve the development of a software tool or suite of tools to query the data and provide input for visualisation. The success of the visualisations is then evaluated by the project's team of research associates, investigating patterns which emerge, seeking verification of these patterns through returning to the textual source material, and using the resulting insights as input for iterative improvement of the querying and visualisation processes.

In the first year of the project, development of the query software has begun with assessment of the text for potentially challenging features, such as the difficulty posed by pre-standardisation spelling, inconsistent transcription practices, and atypical syntax. Also essential has been identification of the pre-processing required before the texts are analysed, and investigation of existing software packages that might be adapted and extended to meet our research goals. S-Space and BlackLab are examples of tools which might form part of a new pipeline, the components and algorithms of which will be developed by iterative experimentation. The processor will take account of different statistical measures starting with Pointwise Mutual Information, collecting data for a range of proximity windows to assess semantic relevance through distributional semantics techniques. Groups of words with strong patterns of association are output, which are then investigated as candidate concepts. In later stages the project will also use versions of the textual data annotated with sense codes based on the *Historical Thesaurus of English.*[3] This facilitates disambiguation of the senses of homographs, as well as offering another means of assessing relationships between words. To maximise the 'bottom-up' approach to data analysis, the LDNA processor initially indexes and runs queries on every word in the corpus. This avoids presupposing concepts or key terms *a priori*.

Further evaluation will be conducted through the lens of three 'research themes'. Research Theme 1, led by Professor Susan Fitzmaurice at the University of Sheffield, will contextualise the emergence and development of concepts within the historical situations which have instigated and shaped them. Research Theme 2, led by Dr Justyna Robinson at the University of Sussex, will investigate where the boundaries of concepts lie and the families of words which delineate and cross these boundaries. Research theme 3, led by Dr Marc Alexander at the University of Glasgow, will explore moments of rapid change in the lexical items used to instantiate concepts. The research themes begin their work once initial processor development has taken place, and case studies with preliminary findings will be included on the poster. The project runs until 2018.

The Linguistic DNA project is funded by the Arts and Humanities Research Council (project AH/M00614X/1).

Grimm's *Kinder- und Hausmärchen*: Intratextuality and Intertextuality

Described as 'a great monument to European literature' (David and David, 1964; 180), Jacob and Wilhelm Grimm's masterpiece *Kinder- und Hausmärchen* (hereafter KHM) has captured adult and child imagination for 200 years. International cinema, literature and folklore have borrowed and adapted the Brothers' fairy tales in multifarious ways, inspiring themes and characters in numerous cultures and languages. While commonly and erroneously considered the fathers of the genre, the fairy tales were not original to the Brothers. In fact, Jacob and Wilhelm collected and adapted their stories from earlier works, some of them dating back to as far as the seventh century BC, and made numerous changes to their own collection (David and David, 1964, p. 183), producing seven distinct editions between 1812 and 1857. In these four decades of writing and rewriting, the fairy tales changed in number, style and content in accordance with historical, social and literary influences. And yet, how did forty years of revisions not confuse the tradition and transmission amongst followers and readers? Indeed, some fairy tales were changed almost beyond recognition. What makes them so timeless and memorable? What is it that immortalises these tales? An answer to this question can be found in the *motifs* the Brothers borrowed from earlier traditions and disseminated by way of their famous collection.

Motifs, defined by Prince's *Dictionary of Narratology* (2003) as '[...] minimal thematic unit[s]', pervade the Grimm collection and are stable elements interlacing the seven editions of the KHM. The puss with the boots (*Der gestiefelte Kater*) and the concept of the breadcrumb trail (originating in the *Hänsel und Gretel* tale) are both examples of motifs, and they recur not only throughout the Grimm editions, but also over time and space. The occurrence and repetition of motifs within the Grimm collection is a form of *intratextuality*, a term used to describe the internal relations within a text or an author and, in our case, within the KHM editions. But a motif may also appear in other authors across traditions and languages, thus creating *intertextual* relations, relations that the KHM may have with other texts.

Related work and computational opportunities

The breadcrumb trail generated by these motifs in literary history, and internationally spread through the Brothers Grimm, has been extensively studied by folklorists, historians and literary critics. Akin to memes, motifs are a form of information transfer and reuse, which opens up numerous opportunities for computational research in cultural evolution and transmission. Interestingly, however, the study of motifs has not yet fully explored the affordances of digital methods. Many authoritative volumes and ontologies have been published in print, such as the well-known *Enzyklopädie des Märchens*, or the *Estonian Folktales* and the *Catalogue of Portuguese Folktales*, but only a few digital projects or digital editions of these print sources exist. One such digital initiative is the *Aarne-Thompson's Motif-Index*[1], a crucial contribution to the field, often used as a reference system for the production of folktale catalogues.

The situation, however, is different for fairy tales, inasmuch as digital copies of many folktale collections are freely available from Google Books or the Internet Archive,[2] or from online collections, such as the Nederlandse VolksverhalenBank initiative[3] or the Satorbase project[4], fostering intertextual research never before possible.[5] Indeed, we can now leverage hyperlinks and APIs in order to automatically retrieve specific and previously inaccessible information across the web, and to connect existing resources for comparative studies. Moreover, no effort has yet addressed the cross-cultural relations of fairy tales, giving way to opportunities for interdisciplinary, multilingual and big data research.

Our project

The new project[6] described in this paper is one such opportunity, whereby an international and interdisciplinary team of computer scientists and humanists is semi-automatically crawling digitised texts and the web to produce a multilingual motif index that uses the Grimm collection as its base reference.[7] More specifically, we combine knowledge acquired from existing print and digital resources with the deployment of the Google Search[8] and Google Books APIs[9] in order to automatically retrieve as many motifs across the web in as many languages as possible, and hence to explore the intratextual and intertextual relations that characterise the motifs' hosting texts. The end goal is twofold; on the one hand, we provide a comprehensive reference resource for scholars in the field and interested citizens alike and concurrently revise the Aarne-Thompson Index; on the other, by testing state-of-the-art text reuse and retrieval algorithms on a sample of these diverse and large datasets, we are able to refine our methods in order to accommodate further web-scale queries and thus sharpen our understanding of why and how motifs changed.

Methodology

The case studies we are working with to address our research questions are three Brothers Grimm tales: *Snow White*, *Puss in Boots* and *The Fisherman and his Wife*. These were chosen on the basis of their differing degree of popularity in order to better understand how transmission affects popularisation.

Our research starts with digital and clean copies of the Grimm texts, downloaded and catalogued from TextGrid[10] and Wikisource[11]. Next, our international team of researchers and student assistants collects digitally available translations and/or editions of the three tales in multiple languages[12] and manually enters them into a database, where information about the web source, the tales, the language, the work and the author is stored.[13] Once this manually-compiled dataset is complete, we deploy the TRACER suite of text reuse algorithms (Büchler, 2013) to trace additional motifs in other digital libraries or corpora. At the same time, we use the Google Search and the Google Books APIs to search for motifs at a much larger scale, effectively crawling the web.

Impact

Like the KHM, we believe this project appeals to a wide and diverse audience not only because of its subject matter, but also because of its international and interdisciplinary character. Our international group operates at the intersection of Computer Science and the Humanities in the arena that is Digital Humanities. This project is unique insofar as each and every member of the team can contribute a piece of his or her own culture, adding a personal and familiar touch to this joint endeavour. By exploring these different cultures, we aim to establish fruitful collaborations and, in so doing, broaden the boundaries of the Digital Humanities.

Furthermore, we believe that this project fully engages humanists in the digital process of tracing texts through space and time. Following the motif trail back in time allows humanists to investigate lines of transmission of folktales and to potentially uncover additional trails through which other documents or stories travelled. At the same time, it enables the computer scientists in the team to identify any shortcomings in our algorithms and to better understand what to automatically feature when tracing this type of information in a digital ecosystem.

[9] Available at: https://developers.google.com/books/?hl=en (accessed 26 October 2015).

[10] Available at: https://textgridrep.org/browse/-/browse/nxvg_0 (accessed 26 October 2015).

[11] Available at: https://de.wikisource.org/wiki/Kinder-_und_Haus-M%C3%A4rchen_Band_1_%281819%29 (accessed 26 October 2015).

[12] eTRAP is currently a team of twelve people from seven nationalities speaking eleven different languages.

[13] An example may be of use in clarifying the point. Grimm's *Snow White* corresponds to Pushkin's Сказка о Мертвой Царевне и о Семи Богатырях (*The Tale of the Dead Princess and the Seven Knights* in English). The two tales differ in many points, including the title of the tale. In Pushkin the princess is protected by seven *knights* (семь богатырей) whereas in the Grimm tale it is seven *dwarves*. Despite the differences, the motifs of the beautiful princess and of her seven protectors link the two stories. To hyperlink and map these versions and their differences, we use a combination of Thompson identifiers for tales, VIAF identifiers for authors and works, and customised identifiers where existing ones do not apply. This semi-automatic approach allows us to populate our database with both content and metadata, and establish relations between the different versions.

The Southern Netherlands and the Infrastructure of Early Modern Globalisation (1500-1800)

UNAM, Mexico

In the early modern period, books were the most important medium of cultural and scientific exchange. The trade in books and the translation of books were two major aspects in this process. This presentation aims to introduce a research project at the **KU Leuven (Belgium)** that examines the specific contribution of books published in the Southern Netherlands and their role in early modern globalisation. This investigation encompasses four sub-projects, three of which analyse **the importance of books from Southern Netherlands for the cultural life of early modern Spanish America**. These focus on the viceroyalties of New Spain, Peru, New Granada, and Rio de la Plata. The poster introduces the sub-project about the viceroyalty of Peru, thereby outlining the use of digital tools in this research context.

Books from the Southern Netherlands and their role in early modern globalisation (1500-1800)

The fourth sub-project looks at **book translations produced in the Southern Netherlands**. It aims to increase our understanding of the world-system of translations as it existed (and evolved) during the early modern period.

All four sub-projects are unique, in that for the first time, they harness the potential offered by the digitalisation of books and library catalogues allowing us to arrive at more comprehensive conclusions than could be reached in the past.

The two show-cased sub-projects were facilitated by the use of online tools and the effective use of standard software. They are exemplary for new approaches to research questions which could not be posed earlier, because the data was not accessible and/or the amount of resulting detailed information could not be appropriately analysed.

The book trade projects prove the existence of a global network spanning three hundred years, while content analysis based case studies and comparisons made to books by Peruvian authors in the early modern period reveal how publications originating from the Southern Netherlands influenced intellectual elites in the Spanish Colonies. The translation project has documented how translation was used to bolster the image of the Spanish Monarchy and advance the cause of the Counter Reformation.

This presentation gives an **overview of the methodological steps** needed to answer the **research questions** and it presents the **digital tools employed** in these tasks.

The main section provides exemplary representative results based on the evaluation of metadata collected from digital resources such as library catalogues. This data was analysed using standard MS office software.

Initial *results have already been published* in various articles. More comprehensive results are awaiting publication.

A DH-Leavened Musicological Toolbox

Francesca Giannetti
francesca.giannetti@rutgers.edu
Rutgers University

Anna Kijas
kijas@bc.edu
Boston College

In 1996, Don Michael Randel wrote a chapter entitled "The Canons in the Musicology Toolbox," which examined "a common set of techniques that every dissertation and scholarly article employs" a type of "musicological interface" or "toolbox" that addresses the issues of theoretical and methodological consistency across the discipline, and, in theory, reduces the time and effort spent on producing the scholarly output (Randel, 1996:10). Fifteen years after Randel's chapter was published, Zoe Lang reexamined his original concept in a post entitled "Today's Musicological Toolbox," in which she asks that we imagine afresh this concept of the "musicological toolbox" (Lang, 2010). Her argument was that a customized toolbox of both specialized and general tools would be required for producing a diverse range of musicological scholarship. The training of the musicologist should thus include as many of the specialized and generalist tools as possible, with the aim of creating a common ground with scholars of other disciplines, allowing the musicologist to move beyond the boundaries of her academic discipline. In the past twenty years, skills once considered general and essential (music notation) have given ground to areas of specialization like popular music and feminist readings. As in other humanistic disciplines, musicologists consider postcolonial and identity theories, together with the more "native" topics of music analysis and Western "art" repertories.

If we were to reimagine the "musicological toolbox" yet again, how would we do so from a digital humanities and/or information science perspective? What tools should be added to a customizable "musicological toolbox" such that students and faculty become proficient in applying a set of techniques that may eventually become commonplace to all humanistic disciplines? Are there specific misapprehensions to be wary of when appropriating tools created for other academic fields? Can an incubator approach be tolerated to make room for learning and experimentation, without requiring formal, publishable results? Finally, how does one make room for collaboration in a discipline that is still largely driven by individual scholarly endeavor?

As librarians who study and practice both digital humanities and musicology, we use certain tools and methods that we propose be part of a DH musicological toolbox. These include free and open source tools for data capture, cleaning and formatting, geospatial, temporal and network analysis, as well as tools for data enhancement and encoding (i.e. metadata and text/music encoding).

We propose that concepts and methods core to digital humanities, as well information science, should be introduced into the musicological toolbox to expand students' abilities and understanding beyond the boundaries of musicology. These include:

- Digital curation and publishing
- Metadata standards and schemas
- Information architecture (i.e. relational databases, indexing)
- Close reading and content analysis (i.e. encoding (text/music), transcription, analyses)
- Graph theory
- Spatial and temporal analysis
- Exploratory data analysis for framing scholarly arguments

Training students and scholars in all of these concepts or tools may not be feasible, however as it is important for musicologists to be introduced to methods, such as historiography, paleography, or musical analysis, it is also important that they are introduced to the concepts and methods used in digital humanities work, which will allow them to push the boundaries of musicological research and build an understanding around developing scholarship or research projects in a digital mode.

Drawing from our own experiences, first as musicology students, and now as librarians, we will demonstrate how these concepts may be applied to musicological research using our current projects as case studies, *Documenting Teresa Carreño* (Kijas) and an analysis of librettist Felice Romani's *I due Figaro* (Giannetti). In addition, we will demonstrate some of the rewards and challenges of blending the information science, musicology and digital humanities perspectives.

In *Documenting Teresa Carreño*, a project focused on the performance career of Teresa Carreño (1853-1917), a Venezuelan pianist and composer, Kijas curates metadata and content in Omeka to document Carreño's key performances between 1862 and 1917. An understanding of concepts and methods related to metadata standards, musicological research, as well as, digital curation and publishing, are especially relevant to this project. Giannetti's project analyzes Felice Romani's *I due Figaro* alongside its French source play, *Les deux Figaro*. The concepts and methods applicable to her project include close reading, OCR, text transcriptions, network, data and text analysis. These two case studies demonstrate a data-enhanced view of the musicological toolkit in which findings drawn from traditional approaches (archival studies, bibliography, close reading) are challenged and supplemented by digital concepts and methods. Although not without its complement of additional labor and uncertainty, this DH-leavened musicological toolkit compensates by improving one's understanding of sources, enhancing digital literacies, and raising the chances of finding intra- or inter-departmental collaborators.

The Garden: A 3D Adventure Puzzle Game Exploring Bosch's Garden of Earthly Delights

Elizabeth Goins
esggsh@rit.edu
MAGIC Center, Rochester Institute of Technology, United States of America

Christopher Egert
caeics@rit.edu
MAGIC Center, Rochester Institute of Technology, United States of America

Andrew Phelps
amp5315@rit.edu
MAGIC Center, Rochester Institute of Technology, United States of America

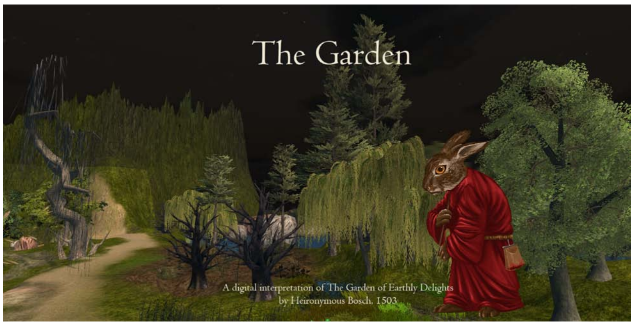
The design of serious, humanities-rich games is a challenging process full of difficult problems. Of particular interest to us is the development of humanities games that might appeal to the general public and compete with commercial games. *The Garden*, is a high level prototype that allows players to explore the world of Hieronymus

Bosch and his painting, *The Garden of Earthly Delights*. *The Garden* prototype focuses on concept, level design and game mechanics and was submitted for review in competitions such as IndieCade. Although the level of polish of the prototype was not high enough for inclusion in mainstream festivals, the concept and game elements were enthusiastically received by the jurors. Our development focus has now shifted to review of the educational content and the development of narrative and characters before the final phase of art asset creation and polish. We are looking for input and feedback from the digital humanities community to improve the educational content and gameplay. Visitors to the demonstration will be able to play the prototype, complete surveys and join in the discussion to help make this a better game for humanities outreach.

To play the game, players take on the role of Godefroy, a tormented denizen of Musician's Hell who is confined by fiery borders within a small patch of the underworld. As Godefroy, the player tries to escape hell by figuring out the secret of each NPC in order to possess them. This is the only way for the player to interact with different areas of hell and win the game.

Mechanics are used to connect the game play to the educational goals of the project. One example is that of engaging the player with history and material culture through the manipulation of identity. As the game location is Musician's Hell, each of the NPCs is drawn from a diverse cast of historic troubadour or trobairitz. General audiences have preconceptions about the Middle Ages and Early Renaissance that are limited, and sometimes incorrect, that they have learned from popular culture. The possession mechanic was developed specifically to engage players with these characters in order to deepen understanding of the culture: musicians could be females or Jews, for example, with rich histories and personal lives. Not only do the players engage in dialogue, but they also must possess each of the characters and take on their identity in order to progress the game. This gives an opportunity to see the world from that NPC's perspective.

The game environment is filled with themes derived from the painting itself. The player is immersed in a world where everything is watched and counted. The object in this interpretation was not to recreate the painting but to interpret it in a way that would resonate with the contemporary players. Players encounter an underworld different from those commonly depicted so that they may connect with Bosch's themes: For example, the importance of being able to see past the superficial, material surface to the spiritual truth of worldly choices and actions. In *The Garden* this is expressed by the environment. Here, Hell is beautiful and invites exploration but poisonous secrets are buried beneath the façade. The player must search for a way out by jumping from soul to soul while avoiding the relentless demon horde run by the bureaucrats of Hell. Along the way, to face the awful overlord Mallebisse, they uncover a story of lust, jealousy and betrayal. Overall, the game puts them in the position of questioning who they really are and what the ultimate objective is in a way, we hope, that parallels Bosch's understanding of choice and salvation.



The Garden
A digital interpretation of The Garden of Earthly Delights
by Heironymous Bosch, 1503

Authorial {X}: A Research and Teaching Platform for Literary Geography

Karl Grossner
karlg@stanford.edu
Stanford University, United States of America

Kenneth Ligda
kenligda@stanford.edu
Stanford University, United States of America

The Authorial {X} project introduces novel means for compiling and mapping references to place within literary works, then exploring and analyzing them from literary, geographical, and biographical perspectives. Its first exemplar locale is London, significantly extending a 2011 project directed by Professor Martin Evans (2011), which mapped the residences of 47 London authors living between the 14th and 20th century. The revamped *Authorial London* project (https://authoriallondon.stanford.edu) delves deeply into hundreds of written works by those same authors, with interactive features permitting the examination of over 1600 place-inflected passages, faceted on dimensions of genre, form, literary community, social standing, and neighborhood.

The *Authorial London* web application has been developed as a re-usable platform, hence, "Authorial {X}.“ Our intent is that researchers and college instructors may readily instantiate a similar site for any place of interest, and engage either a class or research community of interest in gathering data for it: authors, texts, references to places within texts, and the geometry necessary for mapping them. The software code and documentation required for standing up an empty, configurable Authorial {X} instance will be freely available on GitHub.

Scale

The Authorial {X} platform operates at multiple scales of analysis, viewed from both geographic and literary perspectives.

Geographic scale

Cities are a distinctive kind of place in many respects, sharing the quality of geographic variability of lived experience with areas of other scales. Neighborhoods within cities are distinctive places themselves: Belgravia and Southwark are both in London, but are not similar—either in economic and social scientific terms, or in the literary imagination that is this project's focus. The same can be said of provinces within countries and districts within provinces. Authorial {X} provides one means for discovering within literature how places within places of any scale differ, and whether and how they have changed over time.

Analytic scale

The platform is designed to permit the close reading of particular works, at the scale of passages, and also facilitates the aggregation of those passages in several ways: across *authors*, by any of 17 genres (e.g. comedy, novel, bildungsroman) and 3 forms (prose, drama, and poetry); across *time*, by one of 13 literary communities (e.g. Romantic, Victorian, Modernist); and across *space* (by several dozen neighborhoods). These groupings are visualized *spatially*, as interactive dots and lines on a map, *temporally* in simple histograms; and *conceptually*, in word clouds of salient terms as measured by the TF-IDF statistic computed on the project corpus.

Data

Textual

The *Authorial London* corpus has been developed by manual and machine-assisted means. Initially, over 600 passages were hand-selected from approximately 80 works under copyright. The place references tagged in those passages were then used to search an indexed corpus of 690 texts in the public domain acquired from Project Gutenberg. The result narrowed the search space dramatically (from 690 to 220 texts), allowing the still arduous manual selection of several hundred more passages in a timely fashion. During the second round of manual selection numerous additional place references were identified, and the process repeated. Passage length varies significantly, from a sentence or two to several hundred words.

In addition to passages from authored works, the application presents georeferenced biographical essays for each of the 47 authors.

Geographic

All references to places—whether in featured works or biographical essays—are "place-reference" records, each linked to a spatial location. Their scale ranges from a single tavern to the entire city. A place may have multiple names, but link to the same geometry; for example "The Thames" and "the silver Flood" are from different works, referring to the same place and physical location. Cartographic representations are not limited to single points; many streets are displayed as lines. A modern basemap is supplemented by three geo-rectified ("warped") historical maps.

Graphical

A number of photographs related to locations within the biographical essays are also made available in the interface.

Platform details

The Authorial {X} platform back-end is built with the Ruby-on-Rails framework on a PostgreSQL database. Its custom front-end code leverages several JavaScript software libraries, including Leaflet for mapping and D3 for visualization. The Rails technology has enabled the efficient development of an administrative interface to the data, wherein a set of simple web-based forms for populating and editing the database are available to authenticated users. In this way, once an instance of Authorial {X} is initialized, non-technical users can develop data that will appear dynamically in the interface. The project is open-source, and its developers expect that improvements will be made by digital humanities developers over time.

"The world is the totality of facts, not of things" but facts do not speak for themselves; they have no voice. The life-world is the totality of human experiences. When people die, those experiences are lost, unless they are recorded in some way, becoming part of individual or collective memories. This includes Second World War survivors' experiences of the role of the war in their lives, over their subjective time, and the physical and social spaces that they have traversed. With our research, we aspire to explore novel ways to capture, preserve, curate, organise and communicate this set of experiences, stories, narratives, so that they can constitute a shared resource that people can augment, and that individuals as well as institutions can delve into, to find inspiration for new ways of conceptualising acceptance, tolerance and understanding, and how these new ways can be reflected into every-day practices and policies, and foundations for visions of our future.

The Second World War was one of the major transformative events of the 20th century. Millions of lives were lost crimes were committed, physical capital was destroyed, populations were displaced, families experienced extended periods of separation, and many Europeans, including young children were exposed to the horrors of War. Unlike many earlier wars when casualties were mainly confined to the battlefield, during this conflict civilians were also directly affected by warfare. About half of the European casualties of the war were civilians (including women and children). At the end of the war, millions of people were homeless, the European economy had collapsed, and much of the European industrial infrastructure had been destroyed. Reconstruction in the aftermath of the Second World War brought significant change to political, economic and social systems across most European countries and was the touchstone for the realization of the European project.

The trauma of these Second World War experiences and the upheaval it brought to ordinary people's lives continues to have a compelling resonance in contemporary European societies. Formal commemorative practices on local, national and international platforms draw attention to the bravery of combatants and pay tribute to those who lost their lives, during this and other conflicts, as demonstrated by the recent commemorations of the centenary of the First World War and the 70th anniversary of the Second World War. As the Second World War survivor generation disappears, their lived experience is also being lost. However, family story telling means that their personal stories continue to circulate. Individuals who have passed on their personal war stories to their descendants, along with these descendants, comprise contemporary European society and shape 'European identity'. From a psychological point of view, citizens experience all these war-related political and economic changes on a personal level and they develop their own personal stories which may differ from official political discourses. Since past stories transform our present image of the war, and past stories can save both us and our descendants from committing the same 'mistakes' in the future, it is important to uncover, save and preserve individual's personal and family war stories, and officially record them as a part of European cultural heritage. Our research seeks to develop a story telling platform and research framework which will allow for the collection of these stories. This will process material and narratives from three source types:

1. Resources provided by Second World War survivors which were originally collected at source / by the source (e.g. diaries, letters),
2. Resources provided by Second World War survivors that were later created in the form of memoirs or documentaries,
3. Resources created by third parties (family, children, others) and which may be of a variety of types like fiction / non-fiction works, scientific publications in the form of e.g. research dissertations, journalistic newspaper articles, posts in social media or blogs, etc.

They will be complemented by contributions from multimodal sources such as open data collections, closed archives, collections of pictures (drawings and photographs), video footage and sounds, etc.

We aspire to offer a unique access point for producing and annotating stories on the basis of impromptu / ad hoc ontologies that will be leveraged to construct trajectories of narratives over time. Besides a time-based order of the narratives, ontologies could relate key concepts, key emotions, and key arguments, in single narratives or over several narratives by the same or by different individuals. Part of the work can already start with narratives on existing community platforms exploiting the www.fleeinghitler.org infrastructure.

The Ibn Darraj Project: SpatioTemporal Reasoning Engine Based on Evidence Combination

Introduction

In historical statements, we face narrations that are vague in sense of persons, places, times, and events. This means that we have uncertainties and non-specificities about the persons and the events, and the time and place the event has taken place. These uncertainties are mostly caused by ignorance about the characters and events assignments, and definition of the boundaries narrowing down the time and space frames. Moreover, we have narrations that usually do not uphold each other, and have different validities or certainties. Putting these contradictory narrations together to judge about the most definite event needs a great effort, and is a hard task for unaided human mind.

Although its importance and utility, there are not any noteworthy research on spatio-temporal reasoning to combine evidences, or applying evidence combination methods (such as Dempster-Shafer Theory of Evidence) in spatio-temporal reasoning. Hence, this paper delivers a novel tool to compensate this deficiency.

Methodology

To reach this goal, we divide the problem to three main domains, and simplify the question to minimize the efforts and implementation cost of each step.

Extracting and Structuring Evidences

In this step, we model narrations as narration trees, such as *'A' says he has heard 'B' talking about [Event]*. Each of the narrators has a validity coefficient indicating the reliability of the narration made by the person. Then using the SRL (Semantic Role Labeling) methods (Gildea and Jurafsky, 2000), we structure the narrations to a standard form Jurafsky and Martin (2009). Hence, we have a bunch of narrations, and each of the narrations has a narration chain and a standard, structured event.

Finding Similar Events

In this step, using Natural Language Processing tools, we form [multiresolution] verb clusters that help us define the same events that have meanings in common. For example, killing, shooting down, hanging, and choking can be considered as different ways to end one's life, and we may put them in one cluster. These clusters are extracted from WordNet (Hirst and St-Onge, 1998), and define the degree to which we may merge events based on their verbs (Meng et al., 2013).

Evidence Combination

The main role of the reasoning engine is to combine different evidences to calculate the probability of a hypothesis. To do so, one can use the very familiar Bayesian inference method to incorporate different evidences using the Bayes theorem. However, this modeling cannot deal with non- specificities. For instance, if we have four persons A, B, C, and D as candidates of an assassination, we may assign probabilities to Assassins = {A,B,C,D} or other probabilities to subsets of the Assassins set. However, if we do not have crisp evidences defining the probabilities of each member we are unable to do inference where the subsets overlap. As a result, we cannot use the Bayes rule to combine evidences of Pr(A or B or C) and Pr(B or C or D) if we do not know Pr(B or C)or assume some other hypothesis for it.

On the other hand, there is a great advantage in using the Dempster-Shafer Theory of Evidence (DST) compared to the classical probabilistic reasoning based on the Bayesian Theory (BT). By DST, it's possible to take non-specificity into account as well as randomness, which was not possible in BT. In many problems, such as reasoning based on non-specific statements (which are modeled here as narrations), accumulated non-specificity (vagueness) may reveal more specific details. This is the main reason to use DST instead of BT.

It means that when each narration determines a non-specific time and place for an event, or these space-time pieces overlap each other, we are able to define precisely the most and least probabilities that the event has taken place in a specific portions of space-time. These probabilities are usually mentioned as lower and upper bounds of probability, and may be interpreted as Belief and Plausibility respectively (Zadeh, 1986).

Tools and Methods

The core element of the system is a reasoning engine that combines different pieces of evidence. The output will be total expected probabilities and the upper and lower bound of probabilities for different pieces of space-time. This task can be accomplished by efficiently succeeding in the following:

- Modelling space and time effectively, and
- Using the evidence combination methods to deliver the reasoning engine, mainly using Dempster-Shafer Theorem.

We used the CRMgeo model (Doerr and Hiebel 2013) that is standardized in ISO 21127:2014 as the space-time model. We have incorporated GIS tools (as done in Hirschfield and Bowers, 2001; and Fuhrmann et al., 2013) and standard ISO 8601:2004 to model space and time respectively. However, due to the rich and flexible ontology design of the CRMgeo model (Doerr and Hiebel, 2013) which is standardized in ISO 21127:2014, we switched to it as our main space-time model. We also benefited from the CRMinf argumentation model (Doerr 2015) to model the narrations.

At last, we implemented different evidence combination rules in R language to combine the structured narrations together, resulting in and reduced ambiguity and vagueness (Kohlas and Monney n.d., Barnett 1991).

An Example of a Toy Problem

The following figures are the output results of a reasoning over a toy problem of an airplane crash in different boroughs of London, and is plotted for each of the years in the 1930-1935 timeframe. Each plot is for a specific time (e.g. X1930 is for the year 1930). The values of the average probability of the crash in each borough are represented in decibels to better visualize the slight changes of probability in similar regions.

The problem is to combine the following five narrations to gether. The numbers in the parentheses are the validities and/or confidence of the statements.

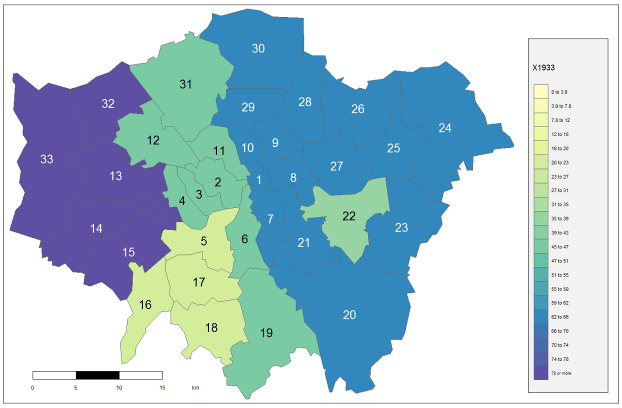
1. I think (70%) it was between 1930-33 that a plane crashed in the south east of London

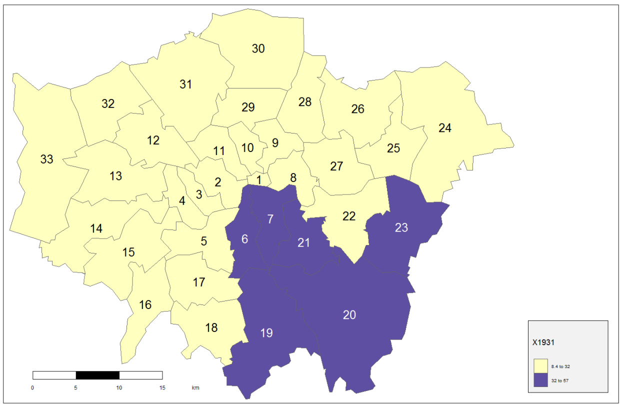
2. If I'm correct (90%) I heard my brother that he's somehow sure (80%) that it was between 1932-35 that the Air Union cargo plane hit the northern bank of the Thames river.

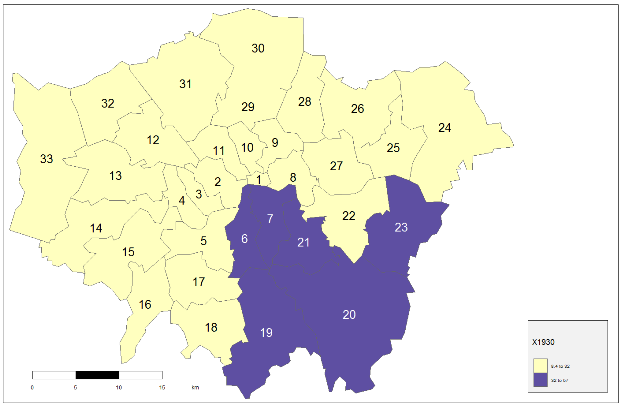
3. I cannot remember it clearly (60%) but in 1933 or 34 an airplane of a post company hit the eastern London.

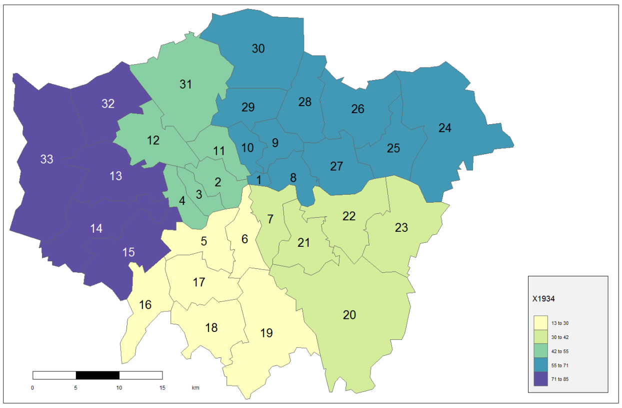
4. It's hard to remember (60%), but my father once told me (90%) that he witnessed an airplane crash in the center of London, Old London.

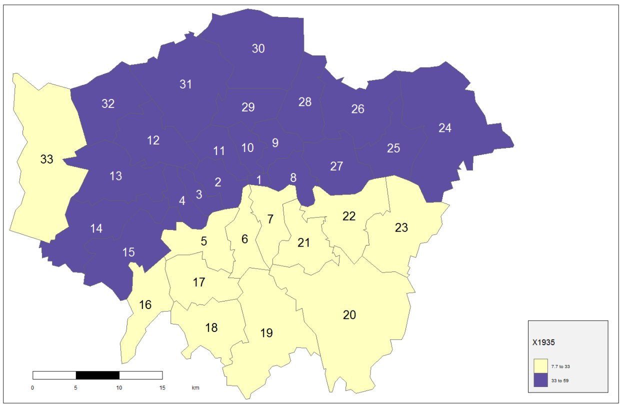
5. If I'm remembering correctly (80%), an airplane crashed the west London between the 1932-34.











About the Project Name

Nuh (Noah) ibn Darraj al-Nakhaʿı¯ (d. 182 AH/ AD 798), was the Shıʿite judge of Kufa, and later in his life, the grand judge of the eastern half of Baghdad. *Nuh*'s older brother, *Jamil ibn Darraj al-Nakhaʿı¯* was a prominent Shıʿite jurist in the latter part of the second Islamic century (AD 760s - 810s) (Modarressi, 2003)

Introduction

It frequently happens in the modern history that a certain cultural skill that used to be shared in a community or society is lost in the process of modernization. Over the last century, Japanese people have lost the basic skills to read *kuzushiji*, classical calligraphic renderings of Japanese characters (see Fig. 1). Since Japanese society ceased to use *kuzushiji* for publication after the Meiji Period (1868-), most Japanese today except trained experts are unable to read books printed with *kuzushiji* only 150 years ago.

However, from 2008 a group of scholars of Japanese literature have started calling attention to the need for providing younger generation with the tools to access their own past (Nakano, 2011 and Moretti, 2014). The *kuzushiji* project, which started in 2015, is an attempt to build a mobile learning application that provides resources and trainings for reading *kuzushiji*. We call the app the KuLA (*kuzushiji* learning application). It is a public humanities project, as well as an interdisciplinary project of Japanese Literature and Digital Humanities scholars. In this paper, we will briefly describe the features, workflows, and implementation of the KuLA.

Features of KuLA

Learning *kuzushiji* is essentially similar with learning a foreign language. What you need for learning it are as followings: 1) the basic knowledge about *kuzushiji*, especially of character shapes, 2) decent amount of exercises of reading actual texts, and 3) good mentors and fellows who will teach and motivate you.

For the reasons above the KuLA consists of the following three modules:

- **Characters module**, where the user will learn the basic knowledge about *kuzushiji*, especially about character shapes. The user can browse the list of *kuzushiji* characters and jump to the detail page of each character (see Fig. 2).
- **Reading module**, where the user will read actual texts written with *kuzushiji* for exercises. The user can also check their transcribed texts (see Fig. 3).
- **Communication module,** where the user will communicate with others via the network. This module will, for instance, enable the user to ask others how to read a specific *kuzushiji* characters by sharing photos taken by the user (See Fig. 4).

Workflow and Implementation

In order to create the teaching materials bundled with the KuLA we needed a lot of actual images of kuzushiji. For collecting them efficiently we developed a Chrome extension which enables to capture arbitrary image regions from the digital collection of pre-modern books provided by the National Institute of Japanese Literature. The images captured by the extension will be automatically uploaded to an web app built with Ruby on Rails. In this way we have gathered so far about 3,000 images of kuzushiji characters.

The mobile app was built with Ionic, a HTML5 mobile framework based on Apache Cordova and AngularJS frameworks. The use of HTML5 technology makes it possible to generate the distributions both for iOS and Android from a single source code. As the backend of the mobile clients we used parse.com, which provides basic server-side features such as user authentication and data storage.

Conclusion and Future Directions

KuLA was released both on Google Play and on App Store for free on 18 Feburary 2016. It has been downloaded more than 5,000 times in two weeks after the launch. The average review scores are 4.5/5.0 in AppStore (total 15 reviews), and 4.9/5.0 in Google Play (total 29 reviews). From these numbers we may say that our design strategy for building KuLA was successful.

We believe that it is a duty of humanities scholars to build the tools to access the past knowledge for further generations. And what makes Digital Humanities special in this regard among other humanities discipline is that it can directly provide those tools with the public with the help of digital media such as mobile devices.

Blacks In American Medicine Archive: Exploring Forgotten Stories

Evan Higgins
elh@mit.edu
MIT HyperStudio, United States of America

Kurt Fendt
fendt@mit.edu
MIT HyperStudio, United States of America

Josh Cowls
cowls@mit.edu
MIT HyperStudio, United States of America

Andy Stuhl
akstuhl@mit.edu
MIT HyperStudio, United States of America

Archival work has for centuries privileged the aggregation over the dissemination of rare and important content. And while this has been necessitated largely in order to preserve the objects within, it has particularly been harmful to marginalized communities whose narratives lie outside of mainstream consciousness. Thankfully, the affordances of digital humanities has opened up new avenues for these elusive materials, and the expansive histories they hold within, to reach a multitude of audiences.

The newest project at HyperStudio, MIT's Digital Humanities Center, the Blacks in American Medicine (BAM) archive innovates on this unique potential offered by digital media to promote and display never-before-seen materials. The BAM project features over 23,000 biographical records of African American physicians from 1860-1980 and countless primary documents associated with these practitioners and the African-American medical community at large. From numerous pieces of personal correspondence, such as a letter to the AMA pleading with them to hold the annual convention in a non-segregated locale, to unique biographical data that charts the ebb and flow of African Americans in medicine, much of the content within the BAM archive has never been available to a wide audience, and all of it has never been digitalized in a central location. Our archive incorporates both a focused study into the history of specific physicians and a broader analysis of the trends within the African American medical community to unearth untold chapters in the vast history of the black experience in America.

While still in the initial stages of this project, we are working on a number of intersectional methods to display this wealth of content. As with most of HyperStudio's archival projects, we are making sure that the content is discoverable by both scholars as well as more casual audiences. This begins by making sure that the content is encoded using established metadata standards such as Dublin Core, allowing to connect our high resolution primary materials and biographical records to other relevant archives. Additionally, within our site itself, we plan to integrate our Repertoire faceted browser, which allows for both a targeted search usingspecific criteria and the ability to explore interconnected documents that interest the user. Additionally, this project will feature our Chronos Timeline, which dynamically uses events and occurrences to present historical data. Outside of displaying content algorithmically and chronologically, we plan on incorporating geographic, visual and biographical tools to help novices and experts alike delve into this content in order to discover new stories and explore existing narratives. By allowing users multiple entry points, these cross-sectional methods of content interrogation will further highlight our project's unique ability to test traditional views of the African American experience, which focus on a few key moments that affected the larger populace than the long history of the people themselves.

Our job as custodians of this trove of content is to make sure that it is not only widely accessible but, more importantly, that it is intuitive and useful to our audience. A poster session at DH2016 will allow us to gather feedback from thought leaders in the field in order to facilitate the evolution of our product. This is a crucial step in making sure that our project has the impact, reach and power that it deserves.

At HyperStudio, the Massachusetts Institute of Technology's center for digital humanities, we use new media to discover and explore forgotten stories. By both focusing on specific people, places and details and zooming out to view trends and patterns, our methods and tools allow us to question traditional narratives and investigate emerging ones. This project, a collaboration with Pulitzer-Prize-finalist author and African-American science historian, Kenneth Manning, demonstrates the power of new/innovative archival approaches to discover and promote new content. This archive is a chance to articulate stories that have remained untold and question narratives that have remained unchallenged, and the Digital Humanities 2016 conference is the perfect place to deepen this discussion.

Abbreviations In Manuscripts – Systematization And Crowdsourcing By Ad Fontes

Tobias Hodel
tobias.hodel@uzh.ch
Universität Zürich, Switzerland

In an unprecedented and very successful crowd sourcing project, the most important resource for abbreviations in Latin and Italian has been digitised and is now freely available. The e-learning project Ad fontes managed to accumulate and systematize all 14'357 abbreviations contained in the most renowned collection, the *Dizionario di abbreviature* by Adriano Cappelli (Cappelli, 1928). The digitized and systematized abbreviations offer new ways to access handwritten texts. Besides enhanced search methods (with wildcards, uncertainty, abbreviation placement etc.) it will soon be possible to add new abbreviations and rectify entries that were handled incorrectly by Cappelli.

The poster presents the crowd-sourced digitisation of the printed Lexicon and considers specific problems and lessons learned while dealing with the crowd; it gives insights into new possibilities regarding the research of abbreviations, discusses possible ways to deal with abbreviations, and at the same time raises questions concerning requirements and nice-to-haves for an application that hopes to become an ever-growing resource to abbreviations found in historical sources.

Following Cappelli's model, each abbreviation is presented as a „facsimile" of a hand-written abbreviation followed by a transliteration of the letters present, the placement of the abbreviation symbol(s) in a grid, if applicable the category of context (e.g. legal or medical) as well as the period the manuscript stems from.

All this information could be identified by users without further knowledge of paleography or Latin and thus offered ways to allow non-experts to take part in the crowdsourcing process. In addition to Cappelli's system, we had the participants place the abbreviation symbols within a 3x3 grid. This allows the introduction of a new search parameter refining the search according to the positioning of abbreviation marks. Unlike the data indicated in Cappelli (for which only a very limited number of mistakes and typos were entered), the placement of abbreviation marks was highly problematic and needed to be corrected in most cases by expert validation. In a next phase we would not include this part in the regular crowd sourcing process, but instead have it done separately.

Within 23 days, all of the abbreviations contained in Cappelli were digitised by our crowd sourcing participants. Mobilising such a crowd was made possible by a highly connected academe and archivists (via mailing lists such as digital medievalist as well as social media). Apart from the option of remote online participation, we planned a crowd sourcing event at the University of Zurich that was supplemented by smaller events at universities in Oxford and Berlin.

The information gained allows – based on very provisional data – conclusions concerning the use of abbreviations in Latin manuscripts. Of the 9'000 most common words in Latin (according to the SLU corpus, Pavur, 2009) 1094 (12.2 %, roughly 13% if we subtract words consisting of 3 letters or less which are usually not abbreviated) could potentially be abbreviated, only taking basic forms of words into account (no flections or conjugations). Compared to the Vulgate, the data shows that of the 38'138 words occurring in the Bible, 1083 exist in abbreviated form. Therefore the data demonstrates what could be expected (Traube, 1907): The abbreviations were not especially or solely conceived for the use in handwritten Bibles but for a variety of texts. A digital Cappelli is thus able to show in a quantitative way what specialists already suspected.

The abbreviations are being offered through the platform Ad fontes (www.adfontes.uzh.ch, Kränzle and Ritter, 2004) as well as the web app App fontes (t.uzh.ch/adf). A batch download of all data including the images is possible.

The digitization and systematization of the abbreviations according to Cappelli opens possibilities not included in the printed version: Unidentifiable letters and/or letters that are not part of the roman alphabet do not need to be known by the user; instead, they can use wildcards in order to get satisfactory search results. Generally, uncertainties won't prevent a successful search, they will only increase the number of results.

Currently, a feedback loop (concerning emendations of the Cappelli) as well as the possibility to add further abbreviations are being developed. Especially the second part will once more use the power of a specialized crowd, at the same time assembling a resource for the use of everyone working with manuscripts.

By crowdsourcing the digitisation of the Cappelli by a heterogeneous group of people, we proved that there is an interest in and a need to deal with abbreviations (Pluta, 2016). With its new resource, Ad fontes will facilitate how abbreviations in handwritten documents are dealt with in the 21st century.

Annotating and Georeferencing of Digitized Early Maps

Winfried Höhn
winfried.hoehn@uni.lu
University of Luxembourg, Luxembourg

Christoph Schommer
christoph.schommer@uni.lu
University of Luxembourg, Luxembourg

Original early maps are usually only accessible for a small group of researchers and librarians because they are very old and sensitive, and could be easily destroyed. However, they are a valuable knowledge source for historical research, because they are also political and cultural evidences of its time. In the age of Digital Humanities, online access and information search in digitized historical documents and early maps allows people from all over the world to work with such artefacts of cultural heritage. However, the digitization solely generates images of the artefacts without any access to the semantics of the documents.

For most digital libraries of early maps (e.g. http://www.oldmapsonline.org/) the available metadata include only information about the map, e.g. author, title, size, creation date. Unfortunately, there is only little information about the data contained in the map. Tools for information retrieval in digitized early maps need to support users in typical queries like for instance:

- Development of places over time
- Toponym changes in the course of the history
- Position of the place from an early map on a modern map, if the place still exists.

Place markers and their text labels contain this information, for instance the place type town, village, village with church or a factory or mill. This makes the annotation and georeferencing of place markers a crucial task. This task is at the same time very challenging due to the nature of the manually created early maps, which contain a high variance in the used symbols. This gets even more complicated by the fact that a single map can easily contain many thousands of place markers. Therefore, proper tool support and automation of the annotation and georeferencing are of interest.

The Referencing and Annotation Tool (RAT) supports annotators in the task of identifying place markers in a digitized early map and helps to create a link to a modern map with minimum effort. Because many different symbols are used as place markers and they differ across maps, the user needs to select a template for each type of place marker and to manually annotate a small subset of the map. Based on this, the templates get adjusted; all parameters for the template matching are calculated to automatically preselect place markers with high confidence and assign them the most likely of the possible types. These annotations can also be added by hand and the automatically generated annotations can be corrected.

RAT facilitates georeferencing by suggesting the most likely modern places based on an estimated mapping between the coordinates of the pixel- and geocoordinates of the already georeferenced place markers. The number of suggestions can be further restricted through a phonetic search to places with names sounding similar to the name given on the map. This allows for identification of the modern place name using the historic name if the spelling has changed but the names still sound similar.

Currently, RAT is in a prototype stage which we tested with a range of 16th to 18th century maps. For instance, one of the maps in the test set contained 3809 place markers. An area with 47 place markers was manually annotated. Based on this initial annotation 3399 place markers were identified and 3339 of them were correct matches.

In other words, 98.2% of the identified markers were correct and 87.7% of the existing place markers were semi-automatically identified. A detailed description of the implementation and the functionality of an earlier version of RAT can be found in (Höhn et al., 2013) but the latest version uses a new template matching algorithm specifically optimized for maps where text, rivers and other structures are frequently next to the place markers and can disturb standard template matching algorithms.

We plan to reduce the manual work needed in all areas by identifying similar maps of the same region and time and exploiting their similarities to provide better suggestions for existing places and their georeferencing on new maps.

The »Hidden Kosmos« of scientific instruments in Alexander von Humboldt's »Vorlesungen über physikalische Geographie« – or: What on earth is an »Ariometer«?

Marius Hug
marius.hug@culture.hu-berlin.de
Humboldt-Universität zu Berlin, Germany

Christian Thomas
christian.thomas.1@staff.hu-berlin.de
Humboldt-Universität zu Berlin, Germany; Berlin-Brandenburgische Akademie der Wissenschaften

Abstract

In 1827/28 Alexander von Humboldt presented the scientific knowledge of his time in lectures which became famous in their own right as a milestone in the popularization of science as well as due to their apparent connection to Humboldt's most important work "Kosmos. Entwurf einer physischen Weltbeschreibung" (1845–62).

The project "Hidden Kosmos—Reconstructing Alexander von Humboldt's 'Kosmos-Lectures'"[1] is located at Humboldt-Universität zu Berlin. Within two years (ending in August, 2016) the project digitizes and virtually brings together eleven attendee's lecture notes (all that are known at the moment) of the "Vorlesungen über physikalische Geographie", the so-called "Kosmos-Lectures", coming from libraries, archives as well as private collections in Germany, Poland (Kraków) and Turkey.

The TEI-encoded transcripts of about 3500 manuscript pages will be published as a standard-compliant, deeply annotated and highly integrated corpus under CC by-sa.[2]

While the project's goal is to enable an intensive exploration of Humboldt's lectures, our poster will abstract a little from the impressive range of topics of Humboldt's lectures and focus on technical solutions applied in the project to make the corpus likewise fruitful to Humboldt researchers, the general public and Dhists.

Starter

On March 13, 1828 Alexander von Humboldt gave his 14th talk of the Kosmos-Lectures at Berlin's Singakademie.[3] At the end of his talk he told his audience:

> … für den technischen Gebrauch hat man von diesen neueren Entdeckungen eine Anwendung gemacht, durch die Einrichtung eines *Ariometers*, od. Wollmessers. Ein Lichtstrahl welcher bei einem feinen Faden Wolle vorbei geht, erleidet eine Beugung u. bildet farbige Frangen oder

> Ringe, die um so breiter erscheinen als der Faden zarter od. dünner ist.[4]

The topic of this lecture is fairly clear: Optical interference and the diffraction of light. The main instrument mentioned is an “Ariometer” for measuring the thickness of woolen threads. This at least is the conclusion from what the anonymous writer of this text tells us.

Formal setting

The project’s tag set strictly follows the DTABf-M (cf. Haaf/Thomas, 2015)[5] which is a specific DTA “Base Format” (DTABf) for *manuscripts*. This strict subset of the TEI P5 tag set provides “a balance between expressiveness and precision as well as an interoperable annotation scheme for a large variety of text types in historical corpora […].” (Cf. Haaf et al., 2014)

The tag set and corresponding RNG-schema are the basis for a homogeneous TEI-encoding of all documents by different encoders, i. e. typists from the (external) vendor—providing transcription and TEI-conformant annotation of the easier legible manuscripts—as well as our project team.

The linguistic analysis of texts at the DTA (incl. lemmatization and fully automatized normalization of historical forms) and their search engine enable an ideal exploitation of the attendee’s lecture notes in the context of the DTA corpora, where hundreds of other texts from Humboldt himself as well as his contemporaries, predecessors and successors can be accessed and linked to the Kosmos-Lectures.

Obviously, as we are dealing with different notes by several attendees of Humboldt’s lectures—i. e. still referring to the same oral presentation—a collation of the witnesses is one essential way of access. The similarities and differences between the witnesses call for collation tools. CollateX or juXta, for instance, are well known and established DH tools for completely automatized detections and visualizations of comparisons of two or more texts. They are of great value for our project (cf. Thomas, 2014/15) and we will illustrate this by making accessible collation sets during our poster demo.

Due to our TEI-encoding more options for evaluations are given:

1. Humboldt’s course is segmented chronologically into single lectures.[6] This is thoroughly done via <div type="session" n="[count]">. This approach enhances the possibilities of accessing parallel reading of the transcripts.

2. A systematic access to the sources is enabled due to referencing persons within the TEI documents (<persName ref="[ID]">) as a basis for an encompassing index of all postscripts linked to authority records.

3. A third way of accessing the Kosmos-Lectures will be a complete bibliography of all mentioned sources tagged with <bibl>.

Contentwise Resumption

Starting point was the “Ariometer” and the diffraction of light in the one manuscript quoted above. A use case would be to see what the other listeners noted. For example, one other attendee wrote:

> … durch die Beugung der Lichtstralen, indem sie durch einen engen Raum gehn, entstehn farbige Franzen, die man am besten erhalten kann, wenn man einen Lichtstral durch das Fenster bei einem dünnen Faden vorbei in ein dunkles Zimmer auf eine helle Wand leitet…[7]

Similarities between the two texts are obvious: light beams, diffraction, a woolen thread and coloured stripes of light. But while the first extract gives the impression of Humboldt being interested in measuring woolen threads, these clearly function as instruments for illustrating a physical phenomenon in the later passage.

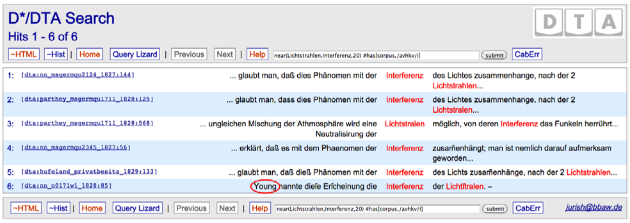
The natural attempt to search for “Ariometer” in our corpus gives no results.[8] We can derive from the context given in the quote above that Humboldt is talking about physical phenomena, but it would be helpful to have a protagonist. So let's refine our search:[9]

```
near(Lichtstrahlen,Interferenz,20) #has[corpus,/avhkv/i]
```

Looking at the results (see fig. 1) leads us to Thomas Young as well as Jung[10], which obviously only is a German version of the first. Next attempt:

```
near(*meter,/[JY]o?ung$/,20) #has[corpus,/avhkv/i]
```

And this leads to another *meter*, the “Circometer”. Maybe we couldn’t find the “Ariometer” since it doesn’t exist? To shorten the track here: A “Circometer” doesn’t exist either. What we are in fact looking for is the so-called *eriometer*.



D*/DTA Search

jurish@bbaw.de

Fig. 1: Result of the DDC-SearchWhat we are facing here is an inherent difficulty of our text type: attendee’s lecture notes. It’s always possible that the listeners misheard something. This is why 1) the deeply granulated TEI encoding of the project, 2) the technical solutions provided by the DTA and 3) text-comparison visualizations (being developed for our project’s) are absolutely necessary.

Summary

The following DDC-search leads to the third volume of the Kosmos (1850), where Humboldt is talking about the above mentioned physical phenomena: near("$p=ADJA

/Fran[szg]en/",/(Wolle|Interferenz)/,20) #has[corpus,/(avhkv|kosmos)/i]

About 30 years after his lectures the eriometer and the wool are no issue any more. The reason for this is not inherent, but a little research on the basis of other digitized sources reveals it: Whereas the real eriometer—the apparatus for measuring the fineness of woolen threads—, which Young used to demonstrate the diffraction of light in his famous *Lectures on Natural Philosophy* at the Royal Institution, became forgotten,[11] the *idea* of combining the craft and the theory (or the engineer and the scientist) succeeded:

> … das ähnliche Instrument dient dazu die Güte der Wolle zu messen, und die Natur der Weltkörper zu bestimmen.[12]

Apart from the implementation of means for collation it is obvious that linking to more (external) data-sets, as shown here, will add even further value to the project.[13]

Data-First Digital Humanities: How Adopting a Data-First Strategy Fosters Research, Collaboration, Pedagogy, and Scholarly Communication in the Digital Humanities

Todd Hughes
todd.hughes@vanderbilt.edu
Vanderbilt University, United States of America

Clifford Anderson
clifford.anderson@vanderbilt.edu
Vanderbilt University, United States of America

We propose a strategy for conducting digital humanities teaching and research that prioritizes publishing data above all other project activities. Drawing on our experience working with faculty, librarians, and graduate students on a critical edition in TEI of Charles Baudelaire's *Les Fleurs du Mal*, we demonstrate how adopting a data-first strategy fosters research, collaboration, pedagogy and scholarly communications in the digital humanities.

The *Corpus Baudelaire Project* began at Vanderbilt University in 2013, when a hybrid group of approximately ten scholars, who had recently learned how to encode literary texts in the TEI, aspired to do something practical with their new skills. The group developed a connection to Vanderbilt University Library's W. T. Bandy Center for Baudelaire and Modern French Studies; who exhaustively collects Baudelaire's works, including *Les Fleurs du Mal*. The work itself was published in four editions: 1857, 1861 (containing 35 additional poems, the *Tableaux parisiens*, and lacking six poems censored by the Second Empire), 1866 (including *Les Epauves* or *The Scraps*, and the six poems missing from the 1861 edition), and the posthumous 1886 edition. Participants in the *Corpus Baudelaire Project* are encoding all the editions using the critical edition apparatus in the TEI.

We describe our data-first approach to *Corpus Baudelaire Project*, which minimizes otherwise common tasks such as developing databases or coding interfaces, and argue for its advantage over alternative approaches in fostering collaboration, pedagogy, and new forms of publishing. We also suggest that our data-first approach may also productively be generalized to any digital humanities projects developing significant quantities of data.

A data-first approach differs from other forms of digital humanities scholarship by minimizing startup costs and reducing complexity. Whereas digital humanities projects aim above all to produce some form of online digital edition or interactive website, a data-first approach invests primarily in producing and sharing data with others. "It's the data, stupid!" is our informal slogan.

A data-first approach to DH involves at least three steps: licensing, curating, and publishing datasets online. The second two steps are likely to be iterative and emergent.

- **Licensing.** A data-first approach begins with the presupposition of making data openly available and reusable by other scholars. This not only implies attaching an open source license to the data, but also making certain that participants in the project understand the license and agree with its terms.
- **Curating**. A data-first approach implies that discussions about data curation start at the beginning of the project, not its end. How shall information be encoded? How to decide between alternative options? Are there emerging best practices and converging forms of representation? Documenting data and making available any accompanying schemas is also critical when taking a data-first approach.
- **Publishing**. A data-first approach requires that data be published for comment, criticism and reuse from the onset of the project. What are the best platforms for publishing digital humanities data? How can digital humanists provide access and get credit for their data?

By prioritizing these three activities above other forms of digital humanities, we simultaneously lower the barriers for participants to join our project while offering them the opportunity to publish and begin receive credit for their work almost immediately. Crucially, credit is allocated with respect to contributions, not by seniority or other hierarchical designations; the data bear witness directly to their creators.

Rebuilding Digital Harlem for Sustainability and Change

Ian R. Johnson
ian.johnson@sydney.edu.au
University of Sydney, Australia

Artem Osmakov
osmakov@gmail.com
University of Sydney, Australia

Background

Digital Harlem (DigitalHarlem.org), winner of the *American Historical Association's* 2009 Roy Rosenzweig Prize for Innovation in Digital History, was a bespoke php/js/MySQL application with 34 tables and over 9,000 lines of code. While bespoke programming may under some circumstances offer the shortest path to a particular outcome, a fixed database structure and bespoke codebase pose problems for sustainability (the codebase will require ongoing maintenance and retention of support for code which is no longer current), for transferability (knowledge and development work which is not directly transferrable to other projects) and for evolutionary change (modification can involve significant rewriting and programming expertise). For Digital Harlem both evolving requirements and external changes have forced the excavation and relearning of code long after development funding ceased, an experience which will be common for any project which seeks longevity beyond short-term project grants.

Conversion

In 2014/2015 we converted the Digital Harlem database to Heurist (HeuristNetwork.org). This allowed us to unlock the previously inflexible data structures and rigid interface, and refine the data model, enabling the project to start a campaign of data entry for a new research grant and focus. Where analysis of the data was previously restricted to three rather limiting search forms for People, Places and Events, the new version (Figure 1) opens up a full range of built-in data management functions and user-defined searches/filters, including multi-level faceted search. Search results can now be saved and visualised with maps, timelines, network diagrams and user-defined reports, as well as file and printed output.

The original public website was subsequently reimplemented, with minor external changes, as a reskinned view of the database running natively within Heurist (Figure 2). We moved significant elements of the interface - search forms, base maps, popup content, buttons – out of custom code into data. These data can be easily edited by the research team allowing them to extend the interface without technical assistance. Fixed form-based searches were replaced with saved faceted searches which can be added to or modified without programming.

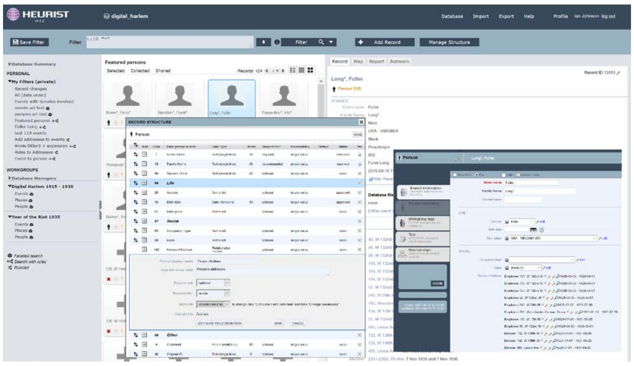

Figure 1. Digital Harlem - the standard Heurist interface (used by the research team)

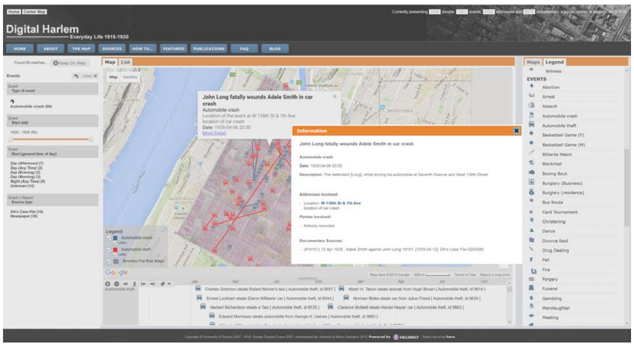

Figure 2. Digital Harlem - the reimplemented public interface with faceted search

Adaptability

The public interface is easily adaptable to other projects requiring a customised public search, mapping and timeline interface for richly linked entities. It is not tied to specific types of entity or relationship, as almost all customisation other than visual appearance occurs within the database content. The interface is built from reusable widgets in a responsive framework, using less than 1,000 lines of html, css, php and js code. New widgets can be added for additional types of interaction, although many projects will find the existing widgets adequate.

Sustainability

Heurist databases retain the inherent medium-term sustainability of an Open Source MySQL database at the backend, but reinforce this sustainability through the adoption of an identical structure across many diverse projects. The use of a single, well-documented database structure across all projects promotes the transfer of expertise and leverages the effort of code development - when someone requests Zotero synchronisation or the generation of GEPHI network files, the code can be written just once and every database inherits the capability. The same goes for any maintenance required to keep pace with the changing web environment and for bug fixing. Standard documented SQL queries, which can be run from any programming language, will work across all databases. A complete, fully documented XML data archive can be generated in a couple of clicks.

Conclusion

In this poster we will outline the sustainability and development benefits of the new implementation of Digital Harlem. By adopting an adaptable codebase (Heurist) which can run many heterogeneous projects we have leveraged development effort and benefits across Digital Harlem and several dozen other projects. For new projects, common data structures can be imported with a few mouse clicks from a clearinghouse of projects, adapted to specific needs and republished for use by others. Existing public interfaces can, with slightly more effort, be repurposed for new projects. A stable well-documented underlying data format also allows independent code development in a variety of languages.

If there is a final takeaway, it is that - while there will always be a place for bespoke, one-off code as a vehicle for experimentation - for the majority of projects, re-use of a shared codebase and body of expertise (where practical) will be more cost-effective, require less technical development and provide a better chance of longevity. Heurist offers one such generic solution which has allowed Digital Harlem to escape its self-imposed straightjacket of bespoke data structure and code; new data structures, research tools or public interfaces can simply be added without reengineering the system. Digial Harlem builds on the work of many preceding projects, and future projects can build on this experience without the cost of reinvention.

Digital Resources and Research Data in the Digital Humanities: The Digital Knowledge Store at the Berlin-Brandenburg Academy of Sciences and Humanities

Marco Jürgens
juergens@bbaw.de
Berlin-Brandenburgische Akademie der Wissenschaften, Germany

Sascha Grabsch
grabsch@bbaw.de
Berlin-Brandenburgische Akademie der Wissenschaften, Germany

The Digital Knowledge Store was developed from March 2012 to April 2015 at the Berlin-Brandenburg Academy of Sciences and Humanities (BBAW) and funded by the Deutsche Forschungsgemeinschaft (DFG). In this first project phase a search infrastructure enables centralised access to all digital resources of the BBAW was created. The DFG granted funds for a second period in which the Digital Knowledge Store will be expanded with a focus on deployment options and integration for partner research institutions.

The BBAW hosts over 170 research projects with over 1.2 million digital resources. For the first time these resources and their metadata were completely integrated into a central full text index and made accessible through an innovative user interface. The resources hosted at the BBAW vary widely in terms of content, formats and languages. The main part of the resources are provided as digital editions and translations in formats like XML, HTML and PDF but also as electronic catalogues, documentations, databases, digital full text collections and dictionaries. The Digital Knowledge Store can be queried in different languages via the morphologically analyzed index. We utilize a number of language technologies (Bing, DONATUS) to enable this multilingual search. The search also covers automatically and manually created metadata which enhance the resources, connect them semantically and provide additional information to the user. The metadata of all resources are provided as well via a machine readable web service (OAI-PMH) and in that way become part of the Linked Open Data Cloud.

The biggest challenge in building an interdisciplinary research data infrastructure like the Digital Knowledge Store was the heterogeneity of the digital resources created at the BBAW in the last 20 years. Hosted on different servers in different databases they vary widely in regard to content and access possibilities. It was the main task to access these data generically and bundle them in the central Apache Lucene index and in a metadata scheme adapted to the needs of the academy (based on OAI-ORE). Specific import modules were implemented for the various projects and resource collections which integrate the varying data structures of the research projects. Semantically connected suggestions are provided by integrating Semantic Web Technologies (e.g. DBpedia) and Text Mining components which extend the query term and invite the user to discover and explore the academy's projects.

The second project phase of the Digital Knowledge Store running until 2017 will expand its possibilities especially in terms of sustainability and availability. There is a heavy demand by academic institutions for sustainable longterm research infrastructures which can meet the specific requirements of research data in the humanities, e.g. the integration of heterogeneous resources and content handling. One important goal in the next stage is to broaden the target user group. The software components of the Digital Knowledge Store will be provided as an installation package. This will enable Partner institutions to run their own Knowledge Store adapted to their own digital resources. In order to coordinate further development and collaboration with future users an open workshop will be held in April 2016 in Berlin.

Another topic in the next project period will be the development of guidelines for the minimum structural and technical requirements that resources and metadata have to meet to be integrated easily into the index. The guidelines will include objectives for the (technical) quality of the resources and their metadata. These best-practice-recommendations can become a general recommendation in the digital humanities for building and maintaining resource collections and a reference on how to deal with the quality of resources and metadata beyond their specific use case. Our partner institutions will successively optimize and adjust them to their specific needs. Additionally workflows for the manual and automatic supply of metadata will be created and specified. Further development goals are the automatic evaluation and integration of user feedback into the query process as well as visualization components.

Visual Forms of Information Presentation and Their Place in Formal Digital Scientific Communication

Anna Kamińska
a.kaminska8@uw.edu.pl
University of Warsaw, Poland

The purpose of this paper is answering the question concerning the place of the visual transfer in the formal system of digital scientific communication. The question is important for scientists who publish or would like to publish their works in a visual way, because the question is connected with issue of the evaluation of the scientific achievements. The bibliometric impacts, like Impact Factor or Hirsch Index, respect only the publications that take part in the formal scientific communication. Attendance or absence of visual forms of information presentation in the formal scientific communication might influence the scientist's decision about presenting scientific works in a visual way and thereby popularise the idea of digital humanities.

The formal scientific communication is difficult to unambiguously define the cause of the fuzzy limit between formal and informal scientific communication. In general, before the publications become part of the formal scientific communication, they should be edited, reviewed, published and indexed in bibliography, bibliographic databases, scientific search engines (Nahotko, 2010; Pikas, 2006; Sapa, 2009). In this research the visual forms of information presentation were analysed using those four features of the formal scientific communication. Scientific papers, communication channels and bibliographies had to be digital and be accessible by Internet.

The visual forms of information presentation include forms using static or dynamic pictures as information media (maps, diagrams, infographics, 3D animations and movies) and textual digital publications whose design and navigation were strongly visual like *The Roaring 'Twenties: an interactive exploration of the historical soundscape of New York City* (Thompson and Mahoy, 2013). The visual forms of information presentation had to be about humanities topics.

Forty-one English-speaking digital humanities projects were collected by the Polish scientific literature and DH Awards project ("Digital Humanities Awards", n.d.). It is difficult to state what proportion of all digital humanities projects constitute the collected projects because of insufficient registration. Therefore, the generalisation of the research results is impossible. However, the analysis of the collected projects enables to notice problems in presenting information in a visual way with digital formal scientific communication and offer some solutions.

It was found that maps, graphs, movies and animations were most frequently published on websites connected with some specific projects of digital humanities, institutions or initiatives devoted to digital humanities, carrying out many projects. Very occasionally, they were found on scientific blogs, academic social networks such as academia.edu and general portals like Flick, YouTube or Vimeo. The analysis of the visual forms of information presentation proved that the collected material had not been previously edited almost in all cases. It seemed that the reverse tendency would be shown in case of websites on which the projects were published. Still, only few websites contained information concerning their editors. No information on the review of the visual forms of information presentation were found. After considering the place where they were published it turned out that the information including its review were found only in the multimedia "Vectors Journal".

Since the leading interdisciplinary bibliographic databases (like Web of Science and Scopus), subject bibliographic databases (like MLA International Bibliography) and scientific search engines (like Google Scholar) register only texts – the journal articles, the books or the conference proceedings, searching for visual forms of information presentation in these databases seemed to be pointless.In conclusion, the lack of review, unsatisfactory registration in bibliographic databases and scientific search engines were observed as the main problems for visual forms of information presentation to become part of digital formal scientific communication. In this place it is worth asking what should be registered – the movie, the animation, the diagram etc. or the place, where they were published (like website or multimedia publication). Not all visual forms of information presentation could be recognized as individual publications.

The author of this paper proposes some solutions how visual forms of information presentation might become part of digital formal scientific communication. Visual forms of information presentation or places where visual forms are published could provide ISBN, ISSN or DOI number and place the bibliographic data. Bibliographic databases and scientific search engines should change the current rules of registration.

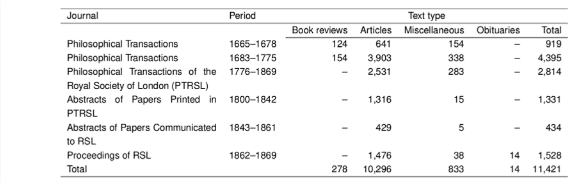
Big data are a potential source for quantitative research in the humanities, but typically they do not contain all relevant contextual meta-data (time, register/genre, social group, author, etc.) to be readily usable for social, historical or philological studies (cf. Schöch, 2013). Small corpora, in contrast, are typically carefully hand-crafted and provide rich meta-data as well as structural and linguistic data, but the application of data-driven analysis techniques is impeded by their small size.

We introduce a diachronic corpus of English scientific writing - the Royal Society Corpus (RSC) - adopting a middle ground between big and 'poor' and small and 'rich' data. The corpus has been built from an electronic version of the Transactions and Proceedings of the Royal Society of London and comprises c. 35 million tokens from the period 1665- 1869 (see Table 1). The motivation for building a corpus from this material is to investigate the diachronic development of written scientific English.



Journal	Period	Text type				
		Book reviews	Articles	Miscellaneous	Obituaries	Total
Philosophical Transactions	1665–1678	124	641	154	–	919
Philosophical Transactions	1683–1775	154	3,903	338	–	4,395
Philosophical Transactions of the Royal Society of London (PTRSL)	1776–1869	–	2,531	283	–	2,814
Abstracts of Papers Printed in PTRSL	1800–1842	–	1,316	15	–	1,331
Abstracts of Papers Communicated to RSL	1843–1861	–	429	5	–	434
Proceedings of RSL	1862–1869	–	1,476	38	14	1,528
Total		278	10,296	833	14	11,421

Table 1: Material used for the RSC

In terms of corpus building (see Figure 1 for a schematic overview), the sources for the RSC were obtained from JSTOR and include some but not all relevant meta-data (year of publication and authors, but not disciplines), structural data is partial and erroneous (e.g. scrambled pages, text duplicates), and the base text contains OCR errors. To move towards a cleaner and richer version of the corpus, an approach is needed that allows obtaining good-quality base-text data and relevant meta-data as well as structural and linguistic data with affordable effort. For this purpose, we use a combination of pattern-based techniques (e.g. by adapting the patterns for OCR corrections made available by Underwood and Auvil)[1] and data-mining methods (e.g. topic modelling (Blei et al.,2003)to approximate disciplines; cf. McFarland et al.(2013)for an overview of types of topic models applied to capture differentiation in scientific language). Additionally, to enrich the RSC with basic linguistic annotations, we build on existing tools adapting them to the diachronic material. For normalization we use VARD (Baron and Rayson,2008)with a model we trained on a manually normalized subset of the RSC, and for tokenization, lemmatization, segmentation and part-of-speech annotation we useTreeTagger (Schmid,1994)on the normalized texts. Inspired by the idea of Agile Software Development (Cockburn, 2001), we intertwine the actual corpus building with corpus annotation and analysis, continuously building new versions of the corpus whenever we see a recurrent problem in data quality. We work with a dedicated pipeline and keep the corpus-building process as modular and automatic as possible, applying manual work before the first automatic step. In the last step, the corpus is encoded in CQP format (cf. IMS Open Corpus Workbench (CWB) (Evert and Hardie, 2011)) and can be accessed via a CQPweb interface (Hardie, 2012)[2].

In terms of analysis, our main assumption is that due to specialization, scientific texts exhibit greater encoding density over time (Halliday and Martin,1993),resulting in a specific discourse type characterized by high information density (Crocker et al., 2015) that is functional for expert communication (but rather inaccessible to lay persons). Linguistically, this may be reflected in lexical compression (e.g. compounding, derivation) and syntactic reduction (e.g. relativizer omission, contractions). For instance, there is evidence from the Thesaurus of the OED (Oxford English Dictionary)[3] that affixation rises considerably as a means of word formation in scientific texts in the mid-17th century. For the identification that affixation rises considerably as a means of word formation in scientific texts in the mid-17th century. For the identification of further linguistic features possibly involved in denser encoding, we draw, on the one hand, on existing literature (e.g. Harris, 1991) and, on the other hand, on exploratory data-mining techniques (e.g. pattern mining as in Vreeken, 2010).

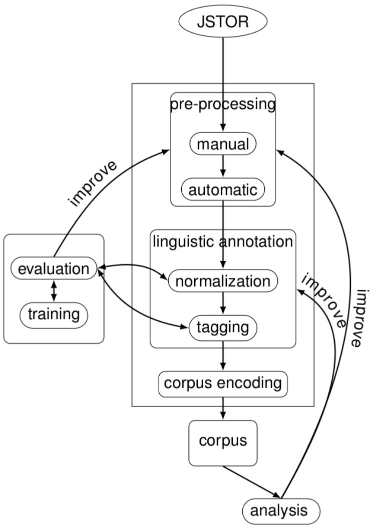


Figure 1: Corpus building steps

In the poster, we show the corpus-building process and selected analyses of diachronic development in the RSC with dedicated visualizations (Fankhauser et al., 2014).

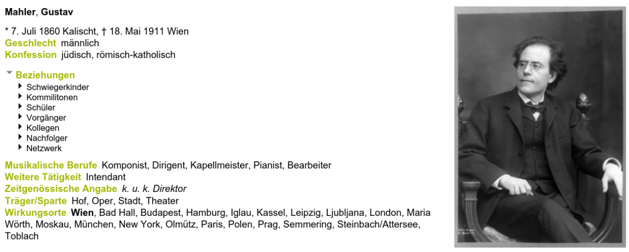
On the Distant Reading of Musicians' Biographies

Richard Khulusi
richard.khulusi@web.de
Leipzig University, Germany

Stefan Jänicke
stjaenicke@informatik.uni-leipzig.de
Leipzig University, Germany

The Bavarian Musicians Encyclopedia Online (Bayerisches Musiker Lexikon Online, BMLO) is a web-based platform that provides access to biographical information about musicians associated to Bavaria's music history (BMLO, 2016). Most of the musicians contained in the corresponding database had an active lifetime period living in Bavaria or a considerable influence on Bavaria. Initiated in 2004, the musicians database contains biographical data about nearly 28,000 musicians now. This suggests the rather global scope of the BMLO – underpinned by many musicologists worldwide using the BMLO for their daily work. The screenshot in Figure 1 shows the BMLO entry for the composer Gustav Mahler.



Mahler, Gustav

* 7. Juli 1860 Kalischt, † 18. Mai 1911 Wien
Geschlecht männlich
Konfession jüdisch, römisch-katholisch

Beziehungen
- Schwiegerkinder
- Kommilitonen
- Schüler
- Vorgänger
- Kollegen
- Nachfolger
- Netzwerk

Musikalische Berufe Komponist, Dirigent, Kapellmeister, Pianist, Bearbeiter
Weitere Tätigkeit Intendant
Zeitgenössische Angabe *k. u. k. Direktor*
Träger/Sparte Hof, Oper, Stadt, Theater
Wirkungsorte **Wien**, Bad Hall, Budapest, Hamburg, Iglau, Kassel, Leipzig, Ljubljana, London, Maria Wörth, Moskau, München, New York, Olmütz, Paris, Polen, Prag, Semmering, Steinbach/Attersee, Toblach

Figure 1: Biographical information about Gustav Mahler in the BMLO

A recently published article facilitates the profiling of musicians based on the BMLO (Jänicke et al., 2015). The profile of a musician of interest can be visualized, and according to biographical information, similar musicians are determined in a semi-automated process (MusikerProfiling, 2016) . A profiling result for Gustav Mahler is shown in Figure 2. Although the profiling system has been proven useful for the collaborating musicologists, it does not support generic research questions like "In which cities Roman Catholic conductors worked during the 18th century?" or "What are the differences and similarities among the careers of pianists and violinists?" Therefore, the musicologists desired a system that facilitates the dynamic exploration of musicians' characteristics with the help of interactive visual interfaces. The design of the resultant visualization system is outlined below.

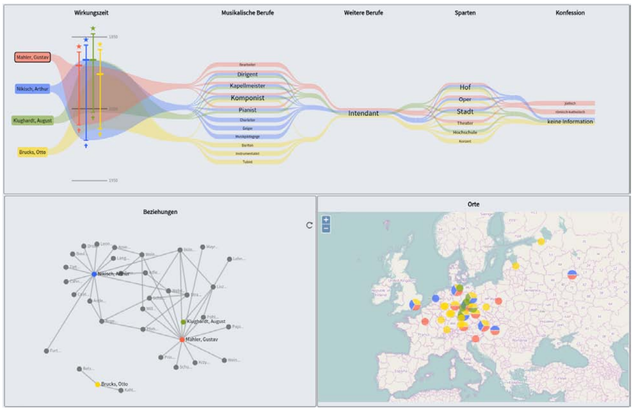


Figure 2: Interactive visual profiling of Gustav Mahler comparatively visualizes Mahler's profile to the profiles of the three most similar musicians in three views (Column Explorer, Relationship Graph, Map)

To support the dynamic exploration of musicians' biographies, we provide various views that visualize aggregate biographical information of musicians inherent in the database. For the divisions where musicians worked, we use a tag cloud (Fig. 3a). As musical (Fig. 3b) and further professions (Fig. 3c) are organized in a hierarchy, we apply a sunburst technique tailored for such structures (Stasko et al., 2000). A map plots all places of activity (Fig. 3d). Using GeoTemCo (Jänicke et al., 2013) for that purpose, occluding dots are clustered and metropolises of music history, e.g., Munich, Vienna and Berlin, are salient as large circles. To illustrate the denominations of musicians, we use again a tag cloud (Fig. 3e), and a pie chart to visualize musicians' sexes (Fig. 3f). Finally – based on the dates of birth, the first mentioned dates and the dates of death – we define an activity time for each musician. The aggregate of all activity times is shown in a timeline graph (Fig. 3g). With mouse interaction, each view can be used for filtering purposes. So, the investigation of rather generic research questions in musicology gets possible.

Figure 4 shows the filter steps required to explore in which cities Roman Catholic conductors worked during the 18th century. The first filter is applied in the denomination tag cloud (Fig. 4a) by clicking "römisch-katholisch"

(Roman Catholic). Then, we select "Kapellmeister" (conductor) in the musical profession sunburst plot (Fig. 4b). Finally, dragging a time range from 1700 to 1800 in the timeline (Fig. 4c) filters the dataset from around 28,000 to 72 musicians, and their places of activity get visible in the map.

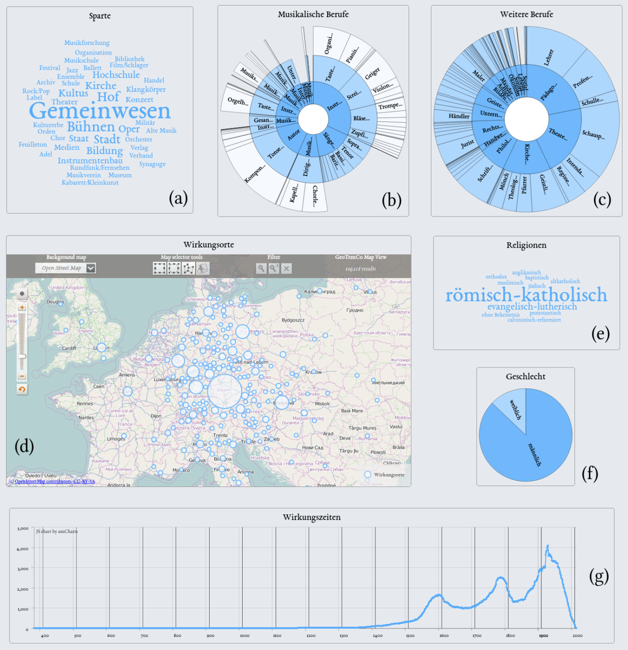

Figure 3: Seven visual interfaces to explore various musicians' characteristics

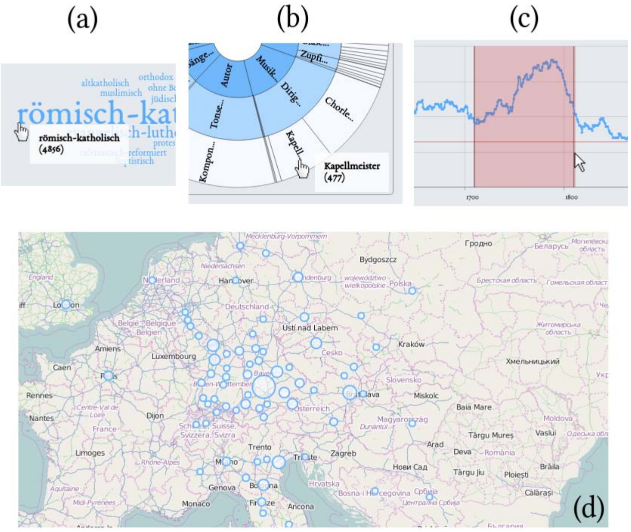

Figure 4: Exploring the question "In which cities Roman Catholic conductors worked during the 18th century?"

The system also supports the comparison of musicians groups. An example is given in Figure 5, which investigates the differences and similarities among the careers of pianists and violinists . We are using different colors to mark the attributes of violinists (yellow) and pianists (blue). The several views are slightly modified to support the comparative analysis. Looking at the result, some initial conclusions can be drawn:

- Although the database contains more violinists (Geiger) than pianists (Pianist), the profession of a pianist seems to be more multifarious, e.g., pianists had more musical and more further professions than violinists.
- The pianist profession is newer than the violinist profession.
- The ratio between male and female musicians is more balanced for pianists.
- Whereas Munich is the city where lots of pianists worked, violinists worked often in northern Bavaria, e.g., Bayreuth (772 x).

In our poster presentation, we will illustrate the above outlined design of the visualization system. In addition, we would demonstrate typical usage scenarios from the collaborating musicologists.

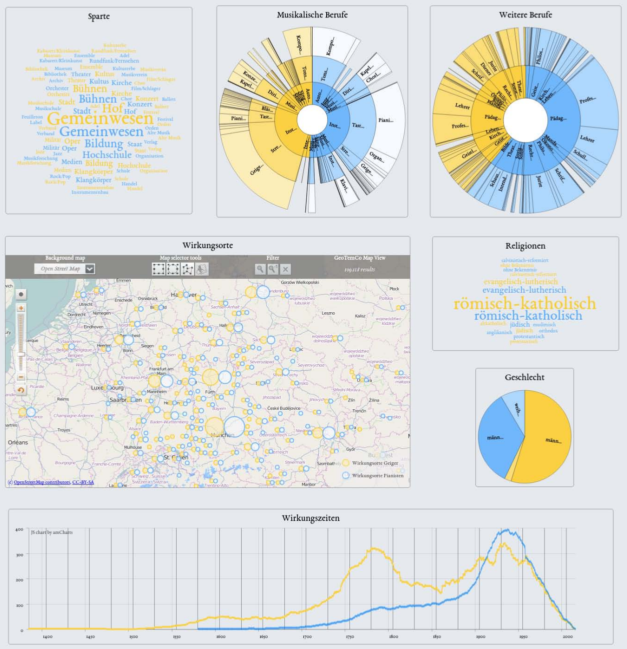

Figure 5: Exploring the question "What are the differences and similarities among the careers of pianists and violinists?"

The Encoded Medieval Antiphoner: an Open Access Digital Source for Music and Liturgical Pedagogy and Scholarship

Anna Ewelina Kijas
anna.kijas@bc.edu
Boston College, United States of America

This poster will provide an overview of the development of an open-access digital musicology project, *The Encoded Medieval Antiphoner: an Open Access Digital Source for Music and Liturgical Scholarship* at Boston College. This is a collaborative project between the Digital Scholarship Group and library staff at the Boston College University Libraries, musicologist Dr. Michael Noone, research assistants, and several external partners, including CANTUS database staff. In the summer of 2015 we began encoding a 14th century Franciscan Antiphoner using the Music Encoding Initiative (MEI), as well as developing an open-access site to present the manuscript as an interactive object for research and scholarly use. The original Antiphoner is in manuscript form bound between leather-covered boards containing 119 parchment folios with text and notation for antiphons and responsories for the entire annual calendar of saints' days (sanctorale). The main goals of this project will be presented in this poster. These include:

1. Making the Antiphoner interactive by building an open access and responsive website with a dynamic presentation layer that will include searchable content (metadata, notation, XML/MEI) and multimedia;
2. Using and developing open source technology to encourage and support further development in the open source community, as well as, sharing of documentation and data;
3. Contributing our data to the scholarly community through a collaboration with CANTUS, a database for Latin Ecclesiastical Chant; and
4. Developing software, workflows, and documentation that can inform future projects using similar technology.

This poster will explain our process and workflows, which have involved transcribing and encoding over 1500 musical incipits, texts, and metadata, contributing the data to the CANTUS database, a highly-respected digital archive and index of chants, as well as, implementing open-source software for a presentation layer and search/retrieval of the content. The digitized object will be presented using Diva.js an open-source software that connects with the API of the CANTUS database to pull in metadata, transcribed music notation, and bibliographic data that we have contributed to this database. We will also present a variety of functionality options that will make this Antiphoner interactive. Basic functionality, which is enabled in Diva.js, includes the ability to:

- view the manuscript side-by-side with metadata from the CANTUS database;
- run search queries on both the text and notation in the manuscript;
- select viewing options: pages (book), individual page, thumbnail/gallery view;
- zoom in/out; full-page view
- access a permanent link/URL for each manuscript page

Beyond the basic functionality listed above, we may explore additional features, such as the ability to display manuscript pages in non-chronological order side by side for comparison and analysis, or allow users to annotate, add metadata, and manipulate content within the manuscript through a framework like the Shared Canvas Data Model.

Additionally, this poster will highlight the collaborative aspect of this project and several positive outcomes, such as an interest to investigate rendering neume notation using Verovio rather than Volpiano font. Verovio is a software that renders MEI directly in a modern browser as SVG (scalable vector graphics: XML-based vector image format), however at this time it can only render MEI files that use Common Western Music Notation (CMN) elements and attributes, not those associated with the Neume module. Our combined interest and needs will allow us to explore this option that can benefit not only our project, but could enable scholars to contribute MEI files with their data into CANTUS and have their notation rendered using Verovio. This could potentially expand the mission of CANTUS Database to also provide access to MEI/XML data.

Moving Images and the Connection to other Media Types

André Kilchenmann
a.kilchenmann@unibas.ch
Digital Humanities Lab, University of Basel, Switzerland

Lukas Rosenthaler
lukas.rosenthaler@unibas.ch
Digital Humanities Lab, University of Basel, Switzerland

In film and media studies, there has always been a desire to annotate and analyze movies as easily as still images. Video is an interesting research object in historical and ethnographic research. The recordings then need to be transcribed. This could be a simple interview transcription, but in disciplines like sociology, or film and media studies, it can be more complicated. In this case, the scholar would also like to annotate the source, to describe the composition of the image, the soundtrack, or the movement of the camera. The question was always: how can we watch and describe a moving image at the same time?

The moving image has a continuous linearity and makes only sense in a dynamic state. So this medium is difficult to grab and the researcher is not able to write notes and commentaries direct to it. In contrast to an image, a moving image is always bound to technical devices [1]. This fact does not make it easier to annotate them. In the digital world today moving image research is better to do as before, because we can work with only one technical device now – namely the computer. This step is comfortable, but without a corresponding software awkward to do. If the researcher works with moving images, he needs software for the video file and software for the text processing. He has to switch at least between two (proprietary) programs.

At our lab we're developing a purely web-based virtual research environment (VRE) – a system for annotation and linkage of sources in arts and humanities (SALSAH). The project originated from an art historical research project about early prints in Basel (Incunabula Basiliensia). It allows for the collaborative annotation and linking of digitized sources [2] or to define and linking special regions inside the source (e.g. region of interest on a picture).

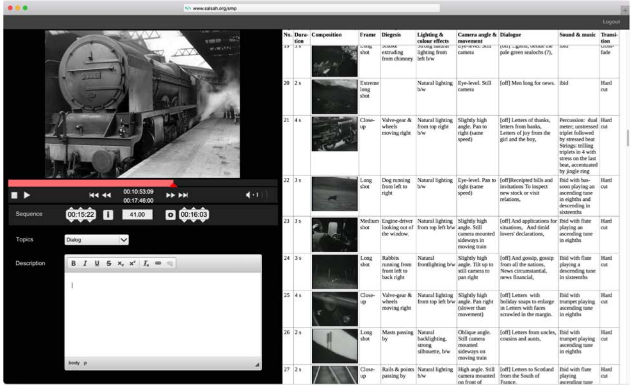
In the recent years the project grew enormously. Different projects from art history, history, media and cultural studies are using the SALSAH platform. They're all working with different kind of sources and meta data information. It doesn't matter which kind of data we're working with, because we're implemented a semantic graph database in the back-end; a triple store service based on the semantic web idea RDF (resource description framework). This data storage and long term preservation service is called KnORA: Knowledge Organization, Representation, and Annotation [3].

With the splitting of SALSAH into two parts (back-end and front-end) we have a properly RESTful API on the one hand and the possibility of various front-ends on the other side. The main page for the researchers remains SALSAH [4]. The idea is still the annotation and linkage of any kind of media. One module is the moving image transcription tool. It should be possible to bring images, text and audiovisual sources together as shown in figure 1.

An epic drama of adventure and exploration
2001: a space odyssey
2001: A SPACE ODYSSEY
A STANLEY KUBRICK PRODUCTION

Figure 1: "2001: A Space Odyssey" – Connect the movie with film posters, making of... scenes, screenplay and film stills

For a deep moving image analysis we want to have the possibility to connect a movie or just a sequence of it with related objects like screenplay, film stills or making-of...-descriptions. The connection of the movie with these additional objects and their own metadata information, enables a powerful (re)search possi- bility on the main moving image. The moving image module in SALSAH is not a standalone solution like other video analysis tools. The network behind every movie would be visible. Another difference with conventional video transcription tools is the representation of the transcription. Especially in film and media stud- ies the researcher has to describe different aspects in the movie: camera position, sound, actors, text etc. [5, 6] The result is a table based sequence protocol, as shown in figure 2 on the right hand side.



Sequence 00:15:22 41.00 00:16:03

Topics Dialog

No.	Dura-tion	Composition	Frame	Diegesis	Lighting & colour effects	Camera angle & movement	Dialogue	Sound & music	Transi-tion
19	3 s		Long shot	Smoke extruding from chimney	Strong natural lighting from left b/w	Eye-level. Still camera	[off] ...glens, beside the pale green sealochs (?),	ibid	Cross-fade
20	2 s		Extreme long shot		Natural lighting b/w	Eye-level. Still camera	[off] Men long for news.	ibid	Hard cut
21	4 s		Close-up	Valve-gear & wheels moving right	Natural lighting from top right b/w	Slightly high angle. Pan to right (same speed)	[off] Letters of thanks, letters from banks, Letters of joy from the girl and the boy,	Percussion: dual meter; unstressed triplet followed by stressed beat Strings: trilling triplets in 4 with stress on the last beat, accentuated by jingle ring	Hard cut
22	3 s		Long shot	Dog running from left to right	Natural lighting b/w	Eye-level. Pan to right (same speed)	[off]Receipted bills and invitations To inspect new stock or visit relations,	Ibid with bas-soon playing an ascending tune in eighths and descending in sixteenths	Hard cut
23	3 s		Medium shot	Engine-driver looking out of the window.	Natural lighting from top left b/w	Slightly high angle. Still camera mounted sideways in moving train	[off] And applications for situations, And timid lovers' declarations,	Ibid with flute playing an ascending tune in eighths	Hard cut
24	3 s		Long shot	Rabbits running from front left to back right	Natural frontlighting b/w	Slightly high angle. Tilt up to still camera to pan right	[off] And gossip, gossip from all the nations, News circumstantial, news financial,	Ibid with flute playing a descending tune in sixteenths	Hard cut
25	4 s		Close-up	Valve-gear & wheels moving right	Natural lighting from top left b/w	Slightly high angle. Pan right (slower than movement)	[off] Letters with holiday snaps to enlarge in Letters with faces scrawled in the margin.	Ibid with trumpet playing ascending tune in eighths	Hard cut
26	2 s		Long shot	Masts passing by	Natural backlighting, strong silhouette, b/w	Oblique angle. Still camera mounted sideways on moving train	[off] Letters from uncles, cousins and aunts,	Ibid with trumpet playing ascending tune in eighths	Hard cut
27	2 s		Close-up	Rails & points passing by	Natural lighting b/w	High angle. Still camera mounted on front of	[off] Letters to Scotland from the South of France,	Ibid with flute playing ascending tune	Hard cut

Figure 2: Example of the SALSAH movie player (top left) with the transcription tool (bottom left) and the sequence protocol (right)

The moving image is the main object in the new module. The film analyst can describe and annotate every scene with a simple transcription tool at the bottom of the SALSAH movie player (SMP). On the right hand side we can see the result of the transcription: the sequence protocol. The figure is showing just a simple example. The researcher can define the columns of the protocol by himself. Through the RDF triple store in KnORA it is possible to have the metadata depending on the research question. At the end it should be possible to export this table based sequence protocol as shown or like a subtitle file to use it with other media players.

Introduction

As more and more libraries, museums, galleries and archives are making their collections available online, it is becoming essential to develop methods for accessing these vast and valuable collections of cultural heritage easily and thoroughly. One of the promising approaches is to automatically identify the database records that refer to the same entity across different collections, which is called "record linkage". In the past, numerous approaches (Elmagarmid et al., 2007) have been proposed. Most of the existing approaches targeted to identify the same records in the same language. However, we aim to identify the same artworks in different languages.

Original Ukiyo-e print	Title	Database
	凱風快晴 (original title in Japanese)	The Edo-Tokyo Museum, Japan
	Gaifū kaisei (transliteration)	The Library of Congress, USA
	South Wind, Clear Sky (in English)	The Metropolitan Museum of Art, USA
	Vent frais par matin clair (in French)	French Photo Agency, France
	Helder weer en een zuidelijke wind (in Dutch)	Rijksmuseum, Netherlands
	Fuji bei schönem Wetter von Süden gesehen (in German)	Bildarchiv Foto Marburg, Germany

Table 1. The same Ukiyo-e print in different databases with titles in different languages

In our recent work, we have developed a method for identifying the same Ukiyo-e prints from databases in English and Japanese (Batjargal et al., 2014). This method is particularly useful since Ukiyo-e, the Japanese traditional woodblock printing, is engraving and many copies or variants of one particular work were made from the same woodblock, and most of these copies were scattered around Western countries in the 19th century, and now stored in museums and galleries in these countries. Most of the metadata of these databases are available only in English or in the native language of that country. Titles are mostly written either as the transliteration of the original Japanese title, or a translation in that language. Table 1 shows an example of an Ukiyo-e print whose copies are stored in databases around the world with titles in different languages.

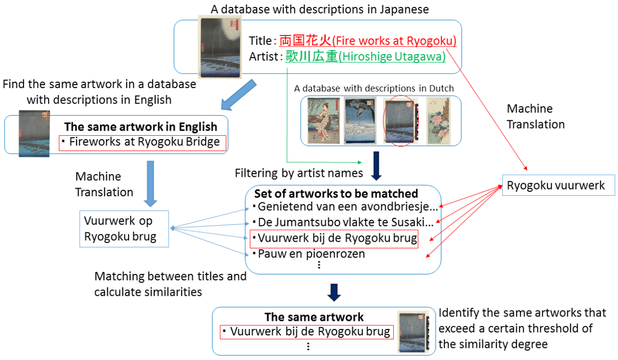
One of the effective approaches for identifying the same artworks from multiple image databases is to utilize image similarity calculations. Ukiyo-e.org (Resig, 2012; Resig, 2013) is the most successful example of identifying the same Ukiyo-e prints, which purely uses image similarities rather than textual data. The advantage of our approach is that we do not have to harvest all the data from the databases beforehand. This paper discusses the method for identifying the same Ukiyo-e records between Japanese and Dutch databases using textual metadata written in different languages.

Proposed approach

Here we explain our method for identifying the same Ukiyo-e records between Japanese and Dutch databases. The proposed method is divided into two main parts as shown in Figure 1. One is the literal translation of original Japanese titles into Dutch, and the other is to find the English title of the same artwork and then translate it into Dutch. The reason of having two different parts is that the translated titles of Ukiyo-e can be classified into two types, a literal translation of the original title, and a translated title, which depicts the scene or objects portrayed in the print that is not necessarily related to the original title. There are a considerable numbers of depictive titles in the translated English and Dutch titles of Ukiyo-e prints.

In the process of literal translation of original titles, first we translate the original Japanese title into Dutch by using a machine translation service (e.g. Google Translate or Microsoft Translator), and then we calculate the similarities between the literal translation and candidate Dutch titles using the similarity measure proposed in our previous approach (Kimura et al., 2015). Identified candidates are narrowed down from a Dutch database using the artist name of the original title.

In the process of using English titles, first we identify the corresponding English title(s) of the original title using the method proposed in our previous approach, then we translate the English title(s) into Dutch using a machine translation service, and then we calculate the similarities between translated Dutch title(s) and candidate Dutch titles using the same similarity measure as the literal translation process. Finally, we integrate the results of two processes and identify the same artworks that exceed a certain threshold of the similarity degree.



A database with descriptions in Japanese
Title : 両国花火(Fire works at Ryogoku)
Artist : 歌川広重(Hiroshige Utagawa)
Find the same artwork in a database with descriptions in English
A database with descriptions in Dutch
Machine Translation
The same artwork in English
・Fireworks at Ryogoku Bridge
Filtering by artist names
Ryogoku vuurwerk
Machine Translation
Set of artworks to be matched
・Genietend van een avondbriesje…
・De Jumantsubo vlakte te Susaki…
・Vuurwerk bij de Ryogoku brug
・Pauw en pioenrozen
Vuurwerk op Ryogoku brug
Matching between titles and calculate similarities
The same artwork
・Vuurwerk bij de Ryogoku brug
Identify the same artworks that exceed a certain threshold of the similarity degree

Figure 1. An illustration of the proposed method. Red arrows are the literal translation process and blue arrows are the process of using English titiles.

Experimental evaluation

We have conducted experiments to evaluate the proposed method. The experimental data is shown in Table 2 and the experimental results are shown in Table 3. In these experiments, we utilized the artworks of Hiroshige Utagawa.

Language	Database	Number of available Ukiyo-e prints of Hiroshige Utagawa
Japanese	The Edo-Tokyo Museum	32
English	The Metropolitan Museum of Art.	133
Dutch	Rijksmuseum	207

Table 2. Experimental data

	By employing the literal translation of original titles	By employing the English titles	Combining the literal translation and English titles
Number of correctly identified titles within top 5 ranks (percentage)	20/32 (0.6250)	14/32 (0.4375)	22/32 (0.6875)

Table 3. Experimental results

Conclusion

We proposed a method for identifying the same Ukiyo-e prints across multiple databases using textual metadata written in different languages, particularly Japanese and Dutch. By using English titles as an intermediate text, we can find not only literally translated titles but also “depictive” titles, which are common in translation of Ukiyo-e prints’ titles that cannot be identified by a simple word-to-word matching. Our preliminary experiments showed reasonable results in identifying both literally translated titles and depictive titles. As the future work, we plan to extend the proposed method to other humanities databases.

1 Million Dutch Newspaper Images available for researchers: The KBK-1M Dataset

Martijn Kleppe
martijn.kleppe@kb.nl
National Library of the Netherlands, The Hague

Elliott Desmond
d.elliot@uva.nl
University of Amsterdam

The visualisation of news through photographs has exploded since the second half of the 20th century (Kester & Kleppe 2015). Press photographs are not only being used more often in all sorts of media, historical photographs are also increasingly being reused. In some cases the reuse of these images leads to a recontextualisation of the photograph. A well-known example in the Dutch context is a photograph of Dutch socialist party leader Pieter Jelles Troelstra who is known for a failed attempt to overthrow the royal family in 1918. When Troelstra’s failed coup d’état is being discussed in history textbooks, the text is very often accompanied by a photograph of Troelstra holding a speech. However, research has shown that this photo was not made in 1918 but in 1912 when Troelstra was advocating the introduction of women’s suffrage (Kleppe 2013).

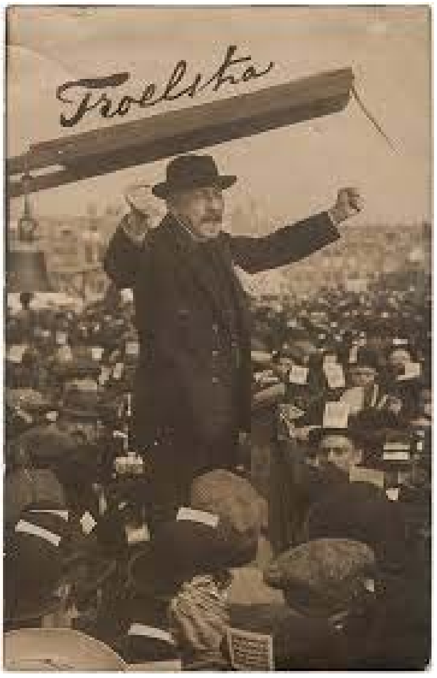

Figure 1. Photograph of Dutch socialist partyleader Pieter Jelles Troelstra giving a speech during a demonstration in 1912 while the photo nowadays often is used for Troelstra’s coupe d’etat of 1918. (photograph by Cornelis Leenheer. Source: IISG Amsterdam)

This example illustrates that in the field of history and visual culture there is a need for the thorough study of the origin and reuse of visual materials. However, methods that are employed to analyse the (re)use of visual materials are cumbersome and labour-intensive since Humanities researchers tend to analyse their sources manually (Burke 2001). To estimate the increase in the use of pressphotographs in Dutch newspapers, Kester & Kleppe (2015) e.g manually analysed a sample of 385 newspapers and 5.877 pressphotographs of the period 1870-2013, creating the *Foto’s in Nederlandse Kranten (FiNK) (Photos in Dutch Newspaper)* dataset (Kleppe, Zeijl, Kester 2014). To find the recurring use of the Troelstra image, Kleppe (2012) followed a same approach by manually analysing over 5.000 photographs in 400 history textbooks, creating the *Foto’s in Nederlandse Geschiedenisschoolboeken (FiNGS) (Photos in Dutch History textbooks)* dataset (Kleppe 2012).

While manually created and annotated datasets such as *FiNK* & *FiNGS* contain rich & well-annotated data that can be reused for all sorts of research questions, their scope remains limited given its labour-intensive creation process. To find the recurring imagery in the FiNGS dataset, Kleppe (2012) e.g. manually created and assessed all images and metadata, leading to inevitabel human errors. However, digitised historical imagery is increasingly becoming available allowing researchers to undertake the first steps in the field of 'Visual Big Data', following the footsteps of Barry Salt's study on the characteristics of opening shots of 20th century films (Salt 1974) and Scott McCloud work on the visual language of Japanese manga and comics from the West (McCloud 1994). More recent, the work of Lev Manovich on exploring large scale visual datasets such as Manga Comics (2012), Time covers, and selfies (Manovich & Tifentale 2015) is seen as a new way of what he calls doing 'cultural analytics' (Manovich 2012).

While the focus of these studies is on characteristics of the images, others using large scale image datasets focus on the recurrance of imagery in different types of contexts, aiming 1) to assess the impact of scholarly images online (Kousha 2010), 2) to analyse the reuse of digital images of cultural and heritage material on the internet (Terras & Kirton 2013) or within a closed dataset (Resig 2014; Reside 2014) and 3) to detect poetic content in historical newspapers (Lorang et al 2015).

To cater their research questions, these scholars all created visual datasets on their own. However, large datasets containing photographs that are available for researchers are scarce. Only within the Computer Vision and Natural Language Processing community we found some datasets (Ordonez et al, 2011; Chen et al, 2015a; Chen et al, 2015b; Hodosh et al., 2013), but these are mainly created for training purposes of algorithms, not for Humanities research questions.

Therefor this poster presents the *KBK-1M* dataset, that was created specifically for (Digital) Humanities researchers. This dataset contains a collection of 1,6 million captioned images of the period 1922-1994, extracted from Dutch digitised newspapers stored in the Dutch National Library (KB) newspaper archive. The images cover black & white photographs, sketches, line-drawn cartoons, and line-drawn weather forecasts and are available as year-by-year ZIP files at the National Library of the Netherlands. A request for access can be submitted to dataservices@kb.nl. On our poster, we will describe how we obtained the images and what types of research questions it could tailor.

Introduction

Sentiment analysis and opinion mining methods are established for automatically summarizing information shared by users in product reviews or in social media platforms like Twitter, Facebook or more specific fora (Liu 2015). These approaches can be categorized into coarse-grained and fine-grained methods: The first focus on assigning a polarity (positive, negative, neutral) and optionally an intensity to a text snippet (Täckström and McDonald 2011; Pang and Lee 2004). The latter additionally aim at detecting the opinion holder (for instance a specific person mentioned in a news article) and the target (for instance a specific aspect of a product in a review) (Hu and Liu 2004; Popescu and Etzioni 2005; Jakob and Gurevych 2010).

Transferring such methods to the analysis of literature leads to at least two questions: Firstly, are polarities for this domain as helpful as for the analysis of reviews? Secondly, how can such methods from sentiment analysis be improved, and what can they contribute to literature analysis?

Regarding the first aspect, resources to measure the occurrence of words which are associated with different emotions have been developed for English but, to the best of our knowledge, not for German (Mohammad et al. 2015). Secondly, it should be noted that research in German sentiment analysis is still comparably limited (counter examples are Ruppenhofer et al. 2014; Klinger and Cimiano 2015; Remus, Quasthoff, and Heyer 2010). In addition, sentiment analysis has mainly focused on the Web, like social media, and product reviews. However, the analysis of emotions and sentiment in literature has been proven to be of interest and value (Mellmann 2007; Winko 2003). A prerequisite for a quantitative approach is that emotions are (at least to some extend) a surface phenomenon (Hillebrandt 2011, p. 154), i.e., that words carry information such that it is possible to infer "private states" of specific emotions (Wiebe, Wilson, and Cardie 2005).

Our two main contributions are: (a) We make German dictionaries of words associated with seven fundamental emotions publicly available, and (b) perform a case study on Kafka's "Amerika" and "Das Schloss" regarding emotion analysis to support literature studies with a focus on complex non-factual phenomena and the analysis of personality traits. All resources and software used in this paper are made publicly available at http://www.roman-klinger.de/emotion/.

Materials and Methods

The goal of this work is to detect different emotions represented in literary texts. Psychological research offers different models to categorize emotions. The most common ones include Plutchik's wheel of emotions (Plutchik 2001) and Ekman's definition of fundamental emotions (Ekman 1999). A discussion of relevant context is offered by Russell (Russell 1991). We opt for roughly following the structure of Ekman's definition of emotions and focus on *anger* (Wut), *disgust* (Ekel), *fear* (Angst), *enjoyment* (Glück), *sadness* (Trauer), and *surprise* (Überraschung) and *contempt* (Verachtung).

To track emotions over the whole text, we assign an emotion score es(*e*, **t***ab*) to a subset of consecutive tokens **t***ab* from textual position *a* to position *b* as

$$\mathrm{es}(e, \mathbf{t}_{ab}) = \frac{1}{|D_e|} \sum_{i=a}^{b} \mathbf{1}_{t_i \in D_e}$$

where *De* is a dictionary containing words expressing the specific emotion *e* and 1 t ∈ *D* is 1 if and only if $t_i \in D_e$ and 0 otherwise. This score corresponds to the number of tokens which are in a window and in the respective emotion dictionary, normalized by the dictionary size.

To track the development of the emotions over the whole text, we apply a sliding window approach which is parameterized by window size w such that *b* = *a* + *w* – *1* (which can be interpreted as a smoothing parameter). To allow for a character oriented analysis, we assign an emotion score as in the sliding window, but for windows around each mention of such character in the text, with an additional normalization based on number of character mentions. Each token and dictionary entry is normalized by mapping to lower-case and stemming with the Porter stemmer (Porter 2001).

As a resource for the emotion dictionaries, two authors of this paper manually selected words from different sentiment polarity, subjectivity, and emotion resources in German and English (translated to German) into the emotion categories (Waltinger 2010a; Waltinger 2010b;

Remus, Quasthoff, and Heyer 2010; Mohammad and Turney 2013). We semi-automatically enriched this resource with synonyms (Naber 2005; Wermke, Kunkel-Razum, and Scholze-Stubenrecht 2010).

Experiments and Conclusions

As an estimate for the difficulty of emotion assignments, we performed an annotation experiment of 300 words (stratified sample from all emotions in the dictionary mentioned above) with fluent speakers of German. In 85 % of all words two out of three annotators agree on the same emotion, however, only in 46 % of of all words, three annotators agree on the associated emotion.

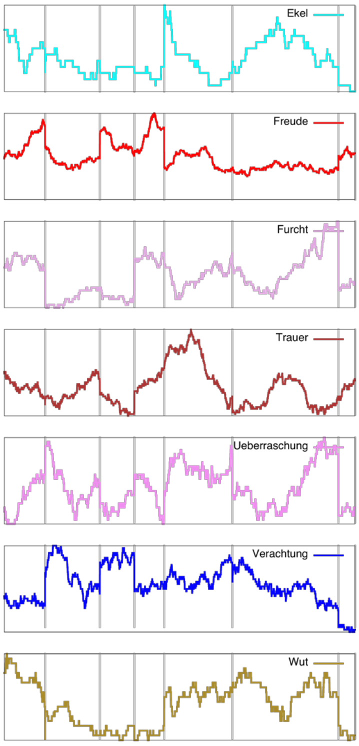

Figure 1: Tracking fundamental emotions in Kafka's "Amerika". The vertical grey lines indicate the start of each chapter. The horizontal axis denotes sequential positions in the text. The vertical axis denotes relative frequencies of the respective emotion.

As a use-case, we apply our methods to Franz Kafka's "Der Verschollene" ("Amerika") and "Das Schloß". Especially the latter is interesting as a comprehensive emotion-focused manual analysis is available (Hillebrandt 2011). It is narrated in third person and interesting from an emotion analysis point of view, as attribution of specific emotions to the protagonist is difficult (Hillebrandt 2011, p. 165).

The development of emotions in Figures 1 and 2 visualize the outcomes of our analyzes. In "Das Schloss", the strong increase of surprise towards the end is striking (most indicative words are "neu", "schnell", "plötzlich", "ungeduldig"). Another example for an eye-catching peak of fear is shortly after start of chapter 3 ("ängstlich", "Gefahr", "unruhig", "Gewalt"). In "Amerika", one striking characteristic is the decrease of enjoyment after a peak in chapter 4 ("gut", "Mutter", "glücklich") followed by disgust in chapter 5 ("unerträglich", "Elend", "schrecklich", "beschmutzt"). Emotions for each mention of a selection of characters in "Amerika" and "Das Schloss" are shown in Figures 3 and 4.

Creating A Management Plan For A Cultural Heritage Project – Best Practise

Carina Koch
carina.koch@uni-graz.at
University of Graz, Austria

The project "Repository of Styrian Cultural Heritage" aims to build a digital archive of cultural heritage objects to make digitized and scholarly annotated collections from various institutions (archives, museums or universities) available for the public. To implement accurate retrieval functionalities and special visualizations a consistent data pool is indispensable. Furthermore, to guarantee data longevity and the possibility to analyse, re-use or add to the collected data, a well-documented management plan is of great importance. Contrary to possible assumptions that the increasing number of similar portals means that comparable documentations already exist in abundance, most portals either do not have any kind of documentation (e.g. Kulturerbeportal-Niedersachsen, BLO, DG-Kulturerbe) or strongly focus on details (e.g. metadata and mapping guidelines or specify controlled lists for comparability) (e.g. bavarikon, DDB, Europeana, museum-digital, MIMO). They do not offer extensive guidelines, especially for the creation of digital collections from scratch. At the Centre for Information Modelling in Graz we designed a management plan for this project according to the OAIS reference model and taking into account aspects concerning research data management (e.g. Puhl et al., 2015), for all partners involved.

Because we gather data from more than one preservation infrastructure (e.g. FEDORA-based repository GAMS) and deal with a variety of resources, from text-centred materials and images to museum objects and artefacts from various contexts (e.g. criminology or archaeology), the designed strategy is generic and expandable. The poster will show systematic strategies regarding different aspects ranging from evaluation to content curation and data re-use. The steps include:

Analysis & Evaluation: The starting-point is to evaluate and analyse the structure of the diverse sources. It involves a discussion about the goal and scope of the project in general as well as possible publication scenarios and functionalities for the collected data. At this stage, communication between technically skilled humanists and specialists for the respective collections is crucial. This collaboration saves time and effort in later stages of the project. Based on this foundation, workflows and data models exactly suited to the needs of the specific institution, including legal aspects, can be established.

Modelling & Metadata Generation: After these evaluations, a data model, including obligatory object descriptions as a minimum requirement for all object types along with rules for metadata creation, has to be developed. Furthermore the depth of the annotation and the use of controlled vocabularies for semantic enrichment have to be defined.

Quality Control & Preserving Data: Quality control of data is an integral part and takes place at various stages, during data collection or digitization. Already existing digital data has to be reviewed and if necessary revised according to the defined rulesets. In this respect, the documentation of data provenance (origins of data, revision agreements and transformation scenarios) is an essential step. Gathered and harvested data has to be transformed from proprietary file formats to suitable storage formats. Internationally recognized standards like DC for basic descriptive metadata, TEI for manuscripts or LIDO for museum objects are recommended to maximize possible re-use and interoperability of the data. For the web portal, all objects are going to be mapped to EDM. The model forms the common ground for the general object description and semantic enrichment.

For long-term preservation, platform-independent systems and open-source software like a Fedora-based repository should be used (e.g. Stigler, Steiner 2015). All objects need persistent identification, which ensures its availability and citability.

Access & Dissemination: Based on consistent data, various search options (filter, facet or advanced) can be implemented. Next to a general representation for all artefacts, elaborate object-specific functionalities and visualizations, like the possibility to thumb through manuscripts or view postal routes of correspondence on a historic map, can be offered.

Adding & Re-use: The possible re-use of data and the addition of new objects or scientific findings as well as the further enrichment of metadata also have to be considered. Adding information according to the defined guidelines guarantees the same quality for re-use, whether for follow-up research, teaching or browsing.

The poster will generally introduce the approaches to a common web portal for a variety of digital resources. It will present a best practice model for an interdisciplinary, cross-institutional cultural heritage project, based on experiences concerning data preservation, consistent metadata description and enrichment. In this respect it also provides guidance to implement a long-lasting expandable digital archive.

Geography Of Russian Poetry: Countries And Cities Inside The Poetic World

Elizaveta Kuzmenko
lizaku77@gmail.com
National Research University Higher School of Economics, Russian Federation

Boris Orekhov
nevmenandr@gmail.com
National Research University Higher School of Economics, Russian Federation

Our paper is dedicated to two major problems: the first problem is the digital one and the second problem is connected to the humanities. The first problem involves automatic extraction of named entities, and the second problem is connected to the usage of toponyms in poetic texts. Correspondingly, our research comprises two parts: automatic processing of a huge amount of texts from the corpus of Russian poetry and revealing major trends in the functioning of toponyms during the history of the Russian poetry from 18 to 20 centuries.

Our research is based on the data from the poetic corpus which is a part of the Russian National Corpus[1]. This corpus includes the main texts belonging to the Russian poetry from all the periods of its history, up to the 20th century. The principles of text selection in the poetic corpus are described by its creators (Grishina et al., 2009). The size of the corpus is approximately 11 million word tokens.

Up to the present moment, research papers considering toponyms in the Russian poetry described a concrete toponym from the perspective of an isolated text or a particular author (see, for example, Mednis, 1999). Our approach is quite different: we describe tthe geography of Russian poetry as a whole, consistently to the framework of distant reading (Moretti, 2005; Moretti, 2013). Thus, the result demonstrates global trends in the usage of toponyms in Russian poetry as a system.

We used two different technologies to extract geographic entities from poetic texts, and the comparison of these two approaches is one of the results of our research. The first technology is a proprietary commercial software Textocat[2], which is based on machine learning with the use of nonfictional texts as a training sample. The creators of this software claim that the F1-measure for the retrieval of named entities is 0.75. However, it is expected that the performance would be much lower in the case of poetic texts, because the language of poetry differs radically from the language of prose.

The second approach we use is a self-made tool for the extraction of toponyms based on the dictionary of geographical names. We are forced to create such a tool because there is no open-source software for the extraction of toponyms for Russian. As a basis for our dictionary of geographical names, we use the list of toponyms from the Wikipedia.We compared the figures retrieved with our approach to the ones resulting from Textocat. We used for evaluation a sample of toponyms consisting of countries and cities. The comparison showed that Textocat retrieves only 25.7% of country names and 19.3% of city names that are found with our tool. In addition, Textocat makes a lot of mistakes; for example, locative pronouns *там* 'there' and *где* 'where' are retrieved among geographical entities. The words *страна* 'country' and *город* 'city' are also included by Textocat in the list of found toponyms.

As we can see, the dictionary-based approach proves to be more efficient, and in further results we consider only the data extracted with this method.

First, we will look in detail on the names of countries extracted from poetic texts. The distribution of mentioning countries is presented in Table 1 (six most popular countries are taken):

Country	Number of times it is mentioned
Russia	2744
France	283
Italy	241
Poland	201
Lithuania	160
Greece	159
Egypt	151

Table 1. The most frequently mentioned countries

The distribution of names for all the world countries is presented on Figure 1. Before building this map, the frequencies of countries' names were normalized, so we counted the number of poetic pieces in which the name was met, not the occurrences.

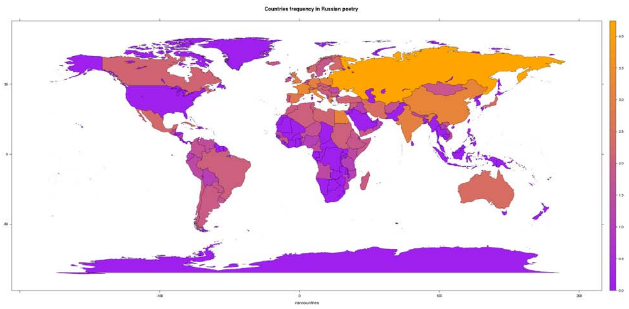

Figure 1. Frequency of countries' names in the Russian poetry

It is not surprising that Russia takes the first place on this list. The top of the list is occupied mainly by the European countries. The second place goes to France, because its influence on Russian culture was immense: in the 19th century French was even the main language of communication for Russian aristocracy. Italy can be found on the third place, despite the fact that it is very important for the poetic mythology in the 19th century, and it was the main geographical location for the poetry of the eminent Russian poets Batyushkov and Baratynsky.

It should also be mentioned that the Russian poetry does not favor exotic countries and it is primarily occupied with the European neighbors of Russia (Poland, Lithuania, Greece). The only African country in the top of «poetic» countries is Egypt, which is renowned for its ancient mythology and pyramids with considerable poetic potential.

The second exotic country in our list is India, and it is followed by countries of the specific «Russian East», which includes Georgia and Iran. The most popular country from the Middle East is Lebanon. If we take a look at the contexts in which Lebanon is used, we see that this country is mostly mentioned due to the cedars of Lebanon. It is unexpected that Lebanon appeared to be more frequently mentioned than the Northern European countries (Finland, Norway, Denmark).

Now we will consider mentionings of city names in Russian poetry. The frequency of names for European cities can be seen on Figure 1. This map reflects mentioning of cities with frequency lower than 690. Thus, we drop such cities as Moscow (with frequency of 2470), Rome (with frequency of 1135), Paris (771), and Saint Petersburg (695). Let us note that Rome is more frequent in Russian poetry than Paris, although France dominates Italy in the list of countries' mentionings. Also, we do not mark on the map those cities whose frequncy is lower than 4.

As we can see from the visualization, the most «poetic» cities from the point of view of Russian poets are concentrated near Moscow and Saint Petersburg, and also in Ukraine and Northern Italy. Ukraine was a part of Russia during the history of Russian poetry, but the specifically Russian territory demonstrates uneven distribution of mentionings, whereas Ukraine is densely populated with poetic cities. The Crimea draws attention as the most «charged» with poetic cities, though it is not a big territory itself. Sea coasts of Southern Europe generally provide us with cities popular among Russian poets.

Continental Europe is not frequently mentioned in the poetry, with an exception of the capital cities of Prague and Warsaw. The blank spaces can be found throughout the territories of France and Germany. Scandinavian cities also don't have considerable amount of mentionings within the history of Russian poetry.

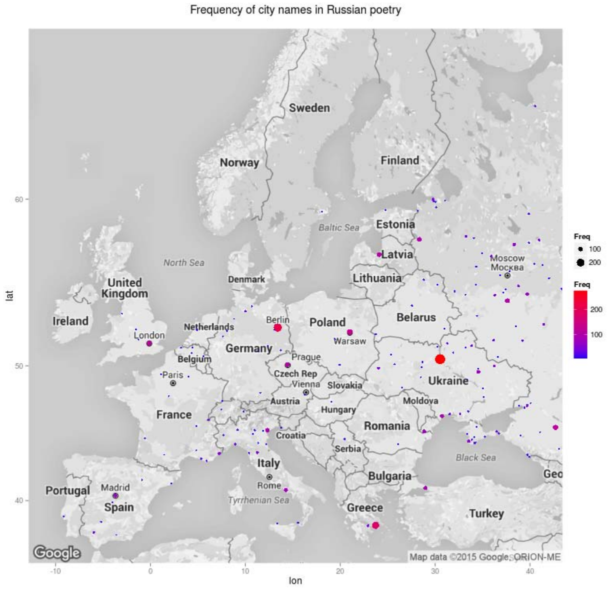

Figure 2. Frequency of city names in the Russian poetry

Another interesting opposition lies in the distribution of mentionings for Romanic and Germanic cities. As we can see, Russian poets prefer the cities of Italy, France, Spain and Belgium, whereas cities of Britain, Germany and Netherlands appear to be less poetic. Probably, the reason underlying this distribution is not the language, but the confession. Apparently, Russian poets prefer catholic countries to the protestant ones, and Vatican itself can be found on the 17th place judging by the frequency of mentioning countries in the Russian poetry.

To sum up, mentioning of toponyms presents interesting data which can be used to reveal trends in the poetry, and those trends help to describe Russian poetry as a system. It is impossible to notice such patterns with manual or visual analysis of poetic texts, but it can be achieved through digitalization of poetry and computational analysis of the texts.

In future we plan to extend our research towards extraction and interpretation of other types of geographic entities: water bodies, geographical places, regions, streets, eminent buildings and locations. This would require dealing with the change of names throughout the time periods. We also plan to investigate the usage of geography in the particular poets' works.

The Holy and the Godless – Cultural Stereotypes Featured in the Language of the Polish Medieval Hagiography. A Corpus-based Study

Anna Ledzińska
ledzinsk.a@gmail.com
Institute of Polish Language, Polish Academy of Sciences

My poster presents a work-in-progress focused on the language of the Polish medieval Latin hagiography. The main subject of my research are the words and expressions denoting the holy and the godless extracted from the corpus. Therefore my poster concentrates on four main topics:

1. The Corpus of the Polish Medieval Hagiography itself

2. Delimitation of the field of study within the linguistic material in relation to historical circumstances and cultural landscape of the Polish Middle Ages

3. Methodology of the research

4. Questions arising and first results.

1. At present the Corpus consists of three main types of texts – *Vitae, Miracula, Translationes - Lives, Miracles and Translations of the bodies of the Saints*. It comprises about thirty texts, it is nearly 500 000 words. Firstly, I would like to explain the reasons of such a selection of the components resulting in the expected homogeneity of the whole body of texts (from the linguistic as well as cultural point of view): **a.** established time frame and limitations concerning authorship and place where a given text was written (Starnawski, 1993), **b.** the phenomenon of mixing of the literary genres within particular groups of texts, **c.** last but not least - the preservation of the texts and the existence of critical editions of the majority of them. Secondly, I describe technical parameters of the Corpus (Piotrowski, 2012): XML format, microstructure and typography of the texts encoded according to the TEI Guidelines (P5), morphosyntactic mark-up with TreeTagger (Schmid, 1994). The Corpus is being analyzed using multi-tool platform TXM (Heiden., Magué, Pincemin, 2010).

2. The starting point of the investigation is the scheme of the seven virtues and seven vices with their subdivisions, popular in the European Middle Ages, sometimes represented in manuscripts in the form of two seven-branched, multi-leaved trees, each part of which is meticulously subscribed with a respective Latin expressions (Marchese, 2013). This traditional set of vices and virtues is being compared with the list of words of the Corpus. At the same time, apart from the historical and literary data mentioned above, other elements of character description, such as epithets, comparisons and attributes connected strictly with each of the saints and their opponents are searched and analyzed (Sinclair, 2003; Stubbs, 2001). As a result I expect to obtain a huge lexical resource containing the most eminent vocabulary of the subject, which will open the prospect of further research. It should be noted that the antithetic tension between the good and the bad one was particularly emphasized in the tradition about the Bishop Stanislaw murdered by the King Boleslaw II the Generous. Because of the great importance of the Saint himself and of the wide spread narration about the Episcopal/royal conflict, it is very interesting to observe how it is echoed (or ignored) in the histories of other saints.

3. Since the texts considered were written in a very long period - between the end of the 10th and the end of the15th century - the linguistic material is studied mainly in a diachronic perspective, although there are other possible applications, which require dividing the Corpus into parallel sub-corpora. The possible research questions in this case include: **a.** comparing and contrasting the image of male and female Saints, **b.** comparing Dominican, Franciscan and other traditions, **c.** showing the dialogue between the hagiographers of the two Patrons of the Polish Kingdom: St. Stanislaw and St. Adalbert, **d.** shedding some more light on Polish saints and sinners in the context of the European Middle Ages (in the future).

4. The main question is two-fold: what are the most frequent features and virtues ascribed to the Polish medieval saintly men and women and, on the contrary - features and vices used to describe sinners/bad people? Then, does it change in time and is this change congruent with what we know about the transformation of the models of sanctity and the image of "the Other"? All these problems, as well as other issues mentioned above (point 3) can only be solved by a complex analysis of textual data combining methods of the corpus linguistics and those of the literary and historic studies. The Corpus I present is meant to be a starting point for such complex studies.

Taking VIVO into the Past: Adapting the VIVO Researcher Profile System to Historical Persons

Thea Lindquist
thea.lindquist@colorado.edu
University of Colorado Boulder, United States of America

Alex Viggio
alex.viggio@colorado.edu
University of Colorado Boulder, United States of America

This poster will explain the concept behind and report preliminary results of an in-progress project, VIVO for Historical Persons (VIVO4HP). This project is an experiment to reuse and extend the VIVO-Integrated Semantic Framework (ISF) ontology to accommodate historical persons, using early Stuart diplomats (1603-1649) as a use case. VIVO4HP investigates whether VIVO can be reasonably adapted to represent and facilitate discovery of structured biographical data about historical persons. It represents a foray into the adaptation of existing systems to historical purposes interesting to humanists, the VIVO user community, and semantic web researchers.

VIVO (Börner et al., 2012) is an open-source semantic application that represents modern academic research communities. VIVO's purpose as a researcher profile system is to represent scholars, their interests, activities, and accomplishments, and the networks among them. The VIVO-ISF ontology interlinks researcher biographical data in meaningful ways to enable discovery, analysis, and visualization of scholarly networks. It does this, in part, by reusing and extending a number of established ontologies already integrated with the VIVO-ISF, such as Friend of a Friend (FOAF) and the Bibliographic Ontology (BIBO). Additionally, we are evaluating external ontologies relevant to the use case that could be imported into the system. Given VIVO's origin in academia and active user community, a number of efforts are underway to extend the ontology in areas like aerospace and agriculture; however, little experimentation has occurred in the humanities let alone in the historical context.

Our investigation aims to assess whether VIVO can be reasonably adapted to represent and facilitate discovery of biographical data about historical persons, a humanities use case that corresponds closely to its original purpose. Our initial work focuses on historical persons belonging to a specific professional community – early Stuart diplomats, that is, the diplomats who served James I and Charles I of England in the first half of the seventeenth century. The test data is derived from the *Oxford Dictionary of National Biography* (*ODNB*) (Matthew and Harrison, 2004; Goldman, 2005-13), the standard British biographical source. They are supplemented by event data on the diplomats' missions from *A Handlist of British Diplomatic Representatives* (Bell, 1990). VIVO4HP will make the data available as linked data, a flexible format that encourages data sharing and integration. Thus the data will lend themselves to a variety of projects and applications for subsequent analysis, evaluation, and visualization.

We are undertaking this work as a multi-stage, iterative process. The first step is to manually create profiles in VIVO for a limited number of diplomats to identify issues with the source data, default ontology, data mapping and transformation, and online display. The second is to make adjustments to the ontology and online display to address gaps. The third is to automatically ingest *ODNB* data into VIVO, using custom scripts where possible to address data mapping and transformation issues. The final step is to augment the profiles with other data sources, such as historical sources, other web sites, and linked data.

A variety of issues surface related to working with humanities data (Posner, 2015) in an environment that was not necessarily built to accommodate them. General issues with historical data include dealing with data ambiguity (e.g., dates, spelling variations), incomplete biographical information, individuals' identities (e.g., using noble titles instead of their personal names), and historical geographies. The *ODNB* data was created with another purpose in mind and thus can be incomplete and either untagged or not tagged to the specificity necessary for certain types of data that might be desirable to represent for our use. Finally, since VIVO is meant to represent a researcher's professional life, it does not incorporate some of the personal, political, or social aspects desirable for representing historical persons.

How we are able to deal with these issues, and the level of intervention required, will play an important role in our assessment of VIVO's utility for the discovery and representation of historical persons and whether the outcome merits the investment required to further extend it for this purpose. We hope that VIVO4HP will provide a basis that others can build upon to represent, facilitate discovery of, and share data about historical persons in the online environment.

Digital Humanities Pedagogy as Digital Liberal Arts: A Framework for Curriculum Development

Brandon Locke
blocke@msu.edu
Michigan State University, United States of America

The Lab for the Education and Advancement in Digital Research (LEADR) is a new initiative of the Michigan State University Department of History, Department of Anthropology, and Matrix. LEADR's role is to integrate digital humanities and digital social science methods into courses in affiliated departments. In its first two years of operation, LEADR has partnered with 40 instructors to add digital components to 63 courses, interacting with around 1600 students. These partnerships varied from a single hour-long workshop to semester-long experiential courses in digital research.

While some courses are specifically designed as Digital History or Digital Anthropology, most of these courses are standard Anthropology and History courses composed of majors from all across campus. For courses such as these, LEADR has begun to frame these digital projects and activities as an extension of the core values of the liberal arts: the skills essential for individuals to participate in civic life, including the ability to seek information, to engage, analyze, and criticize this information, and to communicate their views in an effective manner. It is these fundamental liberal arts skills, in the context of 21st century information and communication that LEADR develops through on to disciplinary, content-based coursework.

This poster will illustrate LEADR's framework for developing Digital Humanities and Social Science curricula that contribute to understandings of emerging disciplinary methods while developing essential skills for students in broad-ranging domains. The four competency goals are:

Information Literacy is defined by the American Library Association as "the set of integrated abilities encompassing the reflective discovery of information, the understanding of how information is produced and valued, and the use of information in creating new knowledge and participating ethically in communities of learning (2016)." This goal utilizes ALA's framework to fulfill the information literacy frame, while focusing specifically on finding, evaluating and using primary sources and datasets relevant to the course.

Digital Literacy is the ability to think critically about the effect of media and web technology on communication and writing, and the ability to create scholarly content in a variety of different forms. There is a focus specifically on web publication, and methods for scholarly multimodal writing, as well as an understanding of power and influence on the web.

Data Literacy is the ability to critically use, curate, process, and produce data and data-driven analysis. This goal draws upon Data Information Literacy, a framework developed primarily for graduate students in the sciences, to teach some of the most crucial data skills, and makes them applicable for undergraduate students across disciplines (Carlson, et al. 2011).

Computational Analysis lessons are grounded in disciplinary methodology, and illustrate the ways in which scholars are using computationally-aided methods to conduct research. In addition to using computational analysis to explore and analyze sources, it also holds value in its ability to challenge students to think differently about a resource - to break down the way we convey information and think about ways to work through those abstractions.

The poster will include a description of each of the competency goals, their theoretical grounding, some examples of what specific skills or outcomes may be included in each, and an example of its application in a content-specific exercise.

In LEADR, there have been three clear benefits from early experiences with the framework. The framing is useful when speaking with faculty members who may be skeptical or unfamiliar with the Digital Humanities. Many who are skeptical of digital methods have often become familiar with Digital Humanities as a new set of methodologies and practices aimed at disrupting and displacing older methods, or as a flashy way to get students interested. Instead, by introducing course modules as a method for teaching longstanding objectives in new contexts, digital work is seen as less gimmicky, and more essential to the development of undergraduate students. The framework has also been a valuable tool for organizing teaching and instruction partnerships for the courses. The collaborative nature of digital projects and the variety of skills required calls for the involvement of scholars, researchers, and technology specialists in teaching and course management. The framework allows for more clear and open communication between partners, and clarifies the necessary skills and objectives needed. Finally, the framework has ensured that exercises are designed with student development in mind, rather than working back from a desired final project.

Conjuring up the Artist from the Archives: Ivar Arosenius. Digitization and Coordination of Archives for Enhanced Accessibility and Research

The Swedish Literature Bank

How can our understanding of an artist be deepened and developed through digital materials and methods? How can we develop tools for a better understanding of previous practices in conjuring up, modifying and curating artists and works of art in museum exhibitions, publications and studies? What ideological and practical considerations and presuppositions have governed the presentations that have formed the artist for the public consideration?

These are questions we investigate through a three-year project about Ivar Arosenius, a Swedish artist and writer. His main body of work was produced during the last few years that led up to his untimely death in early 1909, only 30 years of age and within months of his big breakthrough. During the subsequent years and decades, his substantial production earned him recognition posthumously both nationally and internationally, and today he is one of the most renowned Swedish artists.

At the core of the project is the development of a digital archive that collects the digitized material from several sources, both public and private, into a central repository, allowing scholars and the public to view, filter, and combine the entirety in new ways, and, through public APIs that we make available, explore, activate and make use of this rich material on various platforms. In addition to this, the project has also instigated a number of studies of what knowledge and aspects can be added through different technological developments, as well as what knowledge and values are lost or threatened in a digitization process. The poster focuses on two advanced studies; the processes involved in translating a physical archive into a digital, and methods through which to give body, context, and affect back to a digitized material. In the former study, we follow the material as it travels from the manuscript vault into the digitization studio, mapping all the actants involved in shedding it of its physicality. This is a translation process that functions to rephrase the archival material with the purpose of making it mobile and conform to those protocols that define something as being digital. This rephrasing does not only remove physicality, but does also introduce a whole new vocabulary that in many ways replaces the one that art historians, archivists and conservators use to describe the manuscripts.

The latter study explores material pertaining to Arosenius' home in Älvängen, torn down in the early seventies after decades of neglect. Using the archive as a source, a virtual model is assembled in a game engine where the connection between artist, art and place is investigated to catch the way Arosenius has translated his surroundings and to contextualize the documents of the archive.

As with the digital archive, with this interactive reconstruction we aim to construct a synthesis of a heterogeneous and sometimes conflicting material that can be used both as an access-point to the life of Ivar Arosenius and his art, and as a repository: built on a source material consisting of archival photos, local stories and historic maps, paintings, 3d-scanned artefacts, sound recordings, and inventories of both the belongings of the artist and his family, and of the vegetation on his lands, the digital construction is a knowledge-model containing all the material pertaining to this part of the artists' life. As such, of central interest for the study is how to communicate interpretative practices to the user, balancing an incomplete source material with the need to create a space that can inspire affect.

Just as the archive contains a translation of Arosenius' home, first into documents and files, and later, when digitized, into bits, the reconstruction of Arosenius' home is a translation of bits into context. It is an investigation into both the limits of the **archive view**, that which the archive lets us perceive, and the produce of activating and giving depth to the archive by bringing it together with the site of its origin. In the study, we frame the act of digitally reconstructing a site as an iterative research method of investigation and translation between different media, that allow a disparate material to be collected, studied, and processed simultaneously. Arosenius' Älvängen is at the centre of this study as it is the locus of the art, and also the place of the life that the archive tries to represent. As such, it is the archaeo-archival embodiment of the artist's archive.

The project involves a number of departments and divisions at the University of Gothenburg as well as the Swedish National Museum in Stockholm, and the Museum of Art in Gothenburg.

The Latin of Matthew of Cracow (c. 1345–1410) – a corpus based study of his language and style

Jagoda Marszałek
jagoda.marszalek@ijp-pan.krakow.pl
Institute of Polish Language, Polish Academy of Sciences

The poster illustrates the problems arising when attempting to describe the language used by the author flourishing at the turn of the Middle Ages and the modern era. It shows how a corpus-based linguistic analysis can tell us more about author's language and stylethan the traditional stylometric techniques. It also presents an example of the authorship attribution research of an anonymous medieval treaty carried out with the help of digital tools.

Matthew of Cracow (c. 1345–1410) is considered as one of the greatest theologians of the Eastern Europe Middle Ages as well as one of the most important representatives of the Polish Scholasticism. He was born in Cracow, probably into a family of German ancestry. After completing his initial education in his native city, he went to Prague, where he entered the Charles University and where he became professor of theology. He was involved in the establishment of the University of Heidelberg, University of Chelmno (Poland) and later in the project of bringing to life the Academy of Cracow. He died on March 5, 1410, in Heidelberg. Matthew belonged to the followers of the *via moderna* trend of Scholasticism and is known as a zealous reformer of the Catholic Church. He is an author of more than 70 treatises, from which the most famous are *Rationale operum divinorum*, *De squaloribus Curiae Romanae* and *Opuscula Theologica* (Nuding, 2007).

The poster will present the results of the Matthew's idiolect analysis. It will focus on language change between the late Middle Ages and the early Renaissance, as one of the main goals of the study is to trace two technolects used by authors living in this period, namely Scholastic and Humanistic Latin. Scholastic Latin is defined as a variant of late Medieval Latin, the language of science and the university community in use between 12th and 14th century (Herren, 1996: 124). Its main characteristics are excessive formalism, the use of impersonal narrati on and the pursuit of semantic precision to the detriment of aesthetic and literary values. As a result, Scholastic Latin became a highly technical language, employing countless number of theological and philosophical terms (Bourgain and Hubert, 2005: 62). With the raise of the Renaissance the language of the scientific treatises underwent a significant transformation has been transformed. Imitation of the works of Virgil and Cicero made scholars to change their own way of writing. From now on they will be using the idiomatic structure, the lexis and the rhetorical and stylistic techniques characteristic – at least in their opinion – of the Classical authors (Knight and Tilg, 2015: 4; Tunberg, 1996: 130). Many of the features of Matthew's idiolect seem to follow this new tendency and it is very important to establish how big influence it had on the style of his writings.

The research is based on the corpus of Matthew's works which includes five editions published between 1930-2011 and consists of over 60000 words. It contains both his original treaties, namely *De contractibus, De squaloribus Curiae Romanae, Sermones de sanctis, Lectura super Beati Immaculati, Opuscula Theologica*, and an anonymous medieval work, often attributed to Matthew – *Ars Moriendi*.

The present study uses the methods developed by the computational stylometry and corpus linguistics and includes among others concordance, collocation and keywords analysis. The software employed for this purpose is the TXM platform – an open-source environment based on CQP and R and providing tools for NLP pre-processing, quantitative analysis together with clear metadata model (Heiden, 2010). Thanks to the TreeTagger coupled with the Latin language model file, TXM makes it possible to annotate Latin text with PoS and lemma tags, and as a result allows to perform advanced queries. In addition to frequency lists for any token property (type, lemma, PoS), the built-in CQP search engine lets generate lists for syntactic constructions specific to Classical and/or Medieval Latin, such as the accusative with infinitive or the possessive dative construction. The R package stylo (Eder et al., 2013), on the other hand, allows to trace similarities between anonymous *Ars Moriendi* treatise and the original Matthew's works.

In thatthe poster shows how the use of the Digital Humanities methods can support the traditional analysis of a writer's language and style and help to ascertain the authorship of various texts coming from different ages.

Edit Histories and Literary Turf Wars: John Ashbery, Academic Criticism and Wikipedia

Jim McGrath
james_mcgrath@brown.edu
Brown University, United States of America

How is cultural authority visualized in social media through the publication, revision, and erasure of citations? This poster highlights the social dimensions of Wikipedia's creation, revision, and dissemination. Many of us may be familiar with the mechanics of knowledge production on Wikipedia: the "citation needed" requests that follow unattributed information on Wikipedia pages, the lengthy revision histories available to interested readers, the use of bots as well as human editors, the privileging of public domain images (among other dimensions). Attention will be paid to the interfaces of the Wikipedia and its articles: their performative dimensions as sites of cultural authority, the edit histories of articles and the forms of gatekeeping revealed in patterns of page revisions, and the visualization tools created by the Wikipedia community to visualize patterns in composition and citation. More broadly, I want to situate the investments in particular patterns and performances of curation and citation present in Wikipedia within the larger context of modes of cultural production found on the web, focusing particular attention on forms of erasure and practices that, for various reasons, disavow or ignore investments in citation and attribution: screencapping, the creation of image macros, and other transformative uses of cultural objects on Twitter, Tumblr, and other platforms.

I use Wikipedia pages related to poet John Ashbery to highlight the ways ideas of literature circulate in one of the world's largest and most accessible encyclopedic resources. I am interested in Ashbery because of his literary stature in the eyes of segments of North American and global audiences. Additionally, Ashbery creates particular challenges for scholars (and other readers) interested in periodization and reception history; he has ties to several literary coteries across time and space (the New York School, L=A=N=G=U=A=G=E poetry), his work has been praised by scholars, journalists, and MTV (among other audiences), andhe continues (as of this writing) to publish new material that unsettles the work being done to cement his legacy. The various editorial and citational practices involved in creating and revising that legacy on Wikipedia can tell us much about the impact of academic and scholarly works, the privileging of certain modes of reading and cultural analysis, and the various investments in certain ideas about the value of poetry that circulate on the web. Wikipedia is an extremely visible and malleable public space where competing claims about aesthetics collide and re-collide.

Free FannyPacks: A Model for the Easy Digital Publication of Archival Periodical Material

Kevin McMullen
mcmullen.kevinm@gmail.com
University of Nebraska-Lincoln, United States of America

The nature of nineteenth-century culture, particularly literary, publication, and print culture, meant that many female writers plied their trade in periodicals. Even many American writers who we think of today primarily as novelists—Harriet Beecher Stowe, for instance—first published much of their material in periodicals. Stowe's *Uncle Tom's Cabin* first appeared serially in *The National Era*, an abolitionist newspaper. But writers like Stowe gained and have maintained notoriety in part because their work also existed in book form. Many writers whose work remained trapped in periodicals have since fallen off the literary map, their writing accessible only in increasingly fragile and scattered print runs of newspapers held in libraries and archives, or on microfilm. Attempts to digitize cultural heritage material in periodicals have been far spottier than comparable attempts to digitize books for a variety of mostly practical reasons.

Over the past decade or so, scholars such as Kenneth Price, Susan Belasco, and Meredith McGill have argued for both an increased acknowledgement of periodicals and periodical writing as a key site of intellectual and literary exchange in the nineteenth century, and the increased utilization of digital tools for the editing, study, and dissemination of periodicals.

While the advent of the digital archive has afforded well-documented possibilities for the recovery and, more importantly, dissemination of previously unknown and/or largely inaccessible material,

digital transcription, encoding, and publication of literary texts still remain skills that many academics feel are well beyond their technical capabilities. This means that many of the people best positioned to undertake such recovery work—literary scholars and other subject-specialists—are held back merely by a technological learning curve that they feel is too steep.

For the past year I have been using basic and widely-available digital tools and resources to build a digital archive of the newspaper writing of the nineteenth century American writer Fanny Fern, who, in the 1850s, was the highest-paid periodical writer in the country, writing for the widest circulated American periodical of its day. The project, *Fanny Fern in The New York Ledger* (http://fannyfern.org) is the first attempt to make available the full run of Fern's newspaper columns. Using the Drupal content management system, I have been making TEI-encoded transcriptions of Fern's columns, high-resolution digital images of the complete *Ledger* issues, and brief critical apparatuses about both Fern and the *Ledger* available for free public and scholarly use. While the digital methods and tools used to construct my project were fairly simple, the functionality and appearance of the finished product belie the relative ease (from a technical standpoint) of its creation. But the *Ledger* is just one paper and Fanny Fern is just one writer, albeit a significant one. "There are countless other periodicals and writers, particularly women writers, that deserve this sort of attention," I thought. "If only other 19th century lit scholars could see how easy this is!" And an idea was born.

I already had a relatively simple TEI template designed to handle the metadata, textual content, and linking of digital image files for periodicals. I had an XSLT style sheet that converted the TEI to HTML. I had project documentation for how I had set up my own domain name and hosting space (using Reclaim Hosting, a web hosting service specifically designed for educators and students). I had documentation about how I had installed and configured Drupal. I had documentation about how I had incorporated the HTML of the transcribed newspaper columns into the Drupal architecture. And I had documentation about how I had tweaked and played around with the design of the site. In short, I had everything anyone would need to build his or her own digital archive; all they would need is the content. If I could just share these files and instructions with other literature scholars, scholars who themselves are experts and masters of all kinds of content, then piece by piece and site by site, the gaps in literary and historical scholarship could to begin to close, be it ever so slightly. While I knew this had long been one of the (increasing number of) mantras of digital humanities, I now felt that I had the means to do my small part to contribute to its realization. Thus, using *Fanny Fern in The New York Ledger* as an example and template, I plan to soon begin providing other literature scholars with a single package, a package that contains the tools and instructions they will need to construct their own digital archives—I'm going to start handing out FannyPacks.

Geared mainly for those wishing to gather and display texts in a digital environment, these FannyPacks (a zipped collection of files) will include the needed TEI templates, style sheets, and thorough but simple documentation about digital imaging, hosting setup, and Drupal installation and execution. Scholars with a bit of tech savvy can choose to begin hosting their own projects right away. For those looking to first experiment before fully diving in, Reclaim Hosting easily allows for multiple subdomains to be hosted under an existing domain free of charge. Thus, I will provide testing space on my "fannyfern.org" domain where users can download their own installations of Drupal and experiment with adding their own content. While I have chosen to take the time to encode Fern's newspaper columns in TEI—for the preservation, interoperability, and potential for enhanced functionality of the files and their content—there are some users who might wish to simply "get their material out there" using HTML. Drupal's graphical user interface allows for the easy input of basic or full HTML. Thus, users unfamiliar with or not wanting to take the time to encode in TEI could simply encode their transcriptions in basic HTML and paste them into Drupal's GUI. The setup of both Reclaim Hosting and Drupal also provide ample opportunity for student involvement in the creation of such projects.

Projects such as *Fanny Fern in The New York Ledger* and those facilitated by the FannyPacks occupy a scholarly space somewhere between large-scale, institutionally-hosted TEI-based projects such as the *Willa Cather Archive* or *Walt Whitman Archive* (both of which are well-funded and boast a host of technical and subject specialists) and a low-cost collaborative TEI repository such as the TAPAS Project (http://tapasproject.org). While not requiring any institutional technical resources, projects based on the FannyPacks model possess greater customization and more autonomy than TAPAS projects. And, in the world of nineteenth-century American women's literature at least, there seems to be a desire for just such a model. A recently created listserv of the Society for the Study of American Women Writers (SSAWW) is geared specifically to those scholars already working on or interested in creating digital projects devoted to American women writers. And initial communication on the listserv has made clear the appeal and potential of a method and means for facilitating the publication of digital scholarly content centered around women writers, particularly periodical writers. But while my main and initial goal will be to work specifically with nineteenth century literature scholars, particularly scholars of women's literature, the FannyPacks certainly have a broader application and could be adapted to fit any manner of digital archival project.

My poster will thus provide a brief overview of my current project, *Fanny Fern in The New York Ledger*, a discussion of the project's potential to serve as a model, and specifics of the FannyPacks and their creation, distribution, and application.

Notes

[1] While there have been a number of large-scale newspaper digitization projects, most of them have been undertaken by large commercial entities that charge a fee for access to the content and provide material of mixed quality. Readex and Proquest are two of the more popular services, and genealogy

site Ancestry.com has also undertaken its own mass digitization of government records, census data, and newspaper and periodical material; all three charge for access to the content. While these services can certainly be useful for certain types of research work, the quality of the digitization, particularly transcription, is in nearly all cases quite poor, with transcriptions being derived from optical character recognition (OCR) software, which often has difficulty accurately transcribing the small and often smudged print of nineteenth-century periodicals.

[2] See Price and Belasco's introduction to their edited collection, *Periodical Literature in Nineteenth-Century America*. Charlottesville, VA: University Press of Virginia, 1995. Also, see: Belasco. " *Whitman's Poems in Periodicals*: Prospects for Periodicals Scholarship in the Digital Age." *The American Literature Scholar in the Digital Age*. Ann Arbor, MI: University of Michigan Press, 2011; McGill, Meredith. *American Literature and the Culture of Reprinting, 1834-1853*. Philadelphia: University of Pennsylvania Press, 2003.

[3] Perhaps the most relevant example of a digital recovery project, for the purposes of my presentation, is the *Women Writers Project* (http://wwp.northeastern.edu), now run out of Northeastern University and directed by Julia Flanders. Begun in 1988, the project has been instrumental in the recovery of rare or inaccessible work by early modern women writers (the project covers a period from 1526-1850, although the vast majority of texts are from the sixteenth and seventeenth-centuries). In addition to providing access to digitally encoded texts, the project has also provides various research and teaching materials. However, the *Women Writers Project* is only accessible with a paid subscription and does not deal with periodicals.

Notoriously Toxic: The Language and Cost of Hate in the Chat Systems of Online Games

'Notoriously Toxic' presents a preliminary study of the language and impact of hate speech in the chat systems of online games. Developed by a group of researchers in game studies, computational linguistics, sociolinguistics, and law and guided by an overall tripartite feedback model broadly corresponding to shielding potential victims from harm, educating those who casually engage in hate speech, and censuring those who persist in abusing their fellow players, the hope is that research-driven technical and social interventions might slowly shift online discourse norms away from casual, vicious, and potentially dangerous speech. Identification at scale of textual expressions of toxic behavior in online environments is a necessary, empirical preliminary aspect of this work to understand the prevalence and cost of online hate, as is qualitative cultural studies of the games and their player populations. A recent example of qualitative framing work in this area was the 'Mapping Study on Projects Against Hate Speech Online' released in 2012 by the British Institute of Human Rights for the Council of Europe project, *Young People Combating Hate Speech in Cyberspace* (The British Institute of Human Rights Council, 2012). That report provides terminology and an environmental scan of processes aimed to limit hate speech online and offers suggestions as to new procedures. It, along with an examination of the reporting systems implemented across a host of online games, computational modeling of the language prevalent in these chat systems, and a study of work in the political sphere to defuse hate speech prior to its catalyzation of violence, serve as the foundation for this research.

Recent inquiries into the toxic elements of gaming cultures have primarily focused on communication outside of a game environment. For example, critical discourse analyses of player posts to online gaming forums found that heteronormative undertones of the World of Warcraft player community creates a culture of hostility toward LGBTQ communities (Pulos, 2013) and the same forum's adamant disavowal of feminism have made community conversations about gender roles and/or equality all but non-existent (Braithwaite, 2013). Similarly, Gray's (2012a; 2012b; 2012c) ethnography of Xbox Live demonstrates the constant barrage of gender and racially motivated harassment faced by women of color who opt to communicate with teammates via voice chat. Finally, community leaders' adamant position of gender based harassment being a 'non-issue' is summarized by Salter and Blodgett (2012), whose case study of Penny Arcade's (a popular webcomic and organizers of PAX, a successful annual gaming convention) dismissal of its responsibility in perpetuating rape culture and SXSW Interactive's recent declaration that conversations about harassment in the games space can by definition not be civil (Sinders, 2015) is indicative of an industry that is highly resistant to change unless external pressure is applied. Taken together, this scholarship is evidence that toxicity exists across gaming culture writ large, and is not isolated to a particular game or specific player community.

Studying this phenomena at webscale and in the ephemeral environments of multilingual online chat systems is complex and requires a multidisciplinary approach bridging core strengths in the humanities, such as cultural criticism, with strengths in social psychology, the data sciences, and linguistics. Studying the socially destructive behavior as manifested in online gaming platforms encourages innovative approaches to this problem. One corpus examined as part of this research is comprised of the chat logs produced by the player base in Riot Games' League of Legends (League). As of January 2014, League had ~27 million unique players every day each playing no less than 20 minutes and a peak concurrency of 7.5 million people who collectively have logged billions of hours of total play time for the game since 2009 (Sherr, 2014). Given that the game is a global phenomenon, the chat logs contain harassment in virtually every language.

Based on the UN framework provided in the International Covenant on Civil and Political Rights (1976), Susan Benesch generally defines hate speech as '. . . an expression that denigrates or stigmatizes a person or people based on their membership of a group that is usually but not always immutable, such as an ethnic or religious group. . . . Speech may express or foment hatred on the basis of any defining feature of a minority or indigenous people, such as ethnicity or religion – and can also denigrate people for another "failing", such as their gender or even their location, as in the case of migrants' (Benesch, 2014, pp. 20). This broad but inclusive definition is further elaborated upon by Nazila Ghanea in reference to the *International Convention on the Elimination of All Forms of Racial Discrimination* (ICERD) in the establishment of a spectrum from least to greatest: discriminatory speech, hate speech, incitement to hatred, incitement to terrorism, and incitement to genocide (Ghanea, 2013, pp. 940-1). The characteristics of these definitions reflect the significant impact that hate speech acts have on the establishment and enforcement of personal and communal identity and the need to identify such acts in order to preserve those identities. In his discussion on Carey's ritual model of communication as applied to cases of hate speech, Clay Calvert explains how hate speech initializes and perpetuates the subordination of one group over another (Calvert, 1997). Calvert notes that hate speech acts, specifically focusing on the repeated utilization of racial epithets, construct reality in the speaker, audience, and target members of the discourse through the creation and maintenance of mental schemata similar to the functions of other speech acts: 'In particular, racist speech helps to define who minorities are and how others think about minorities, facilitating their unequal treatment' (Calvert, 1997, pp. 12). This construction is harmful in its immediacy to the target as well as in the long-term situation as it perpetuates unequal power structures based on criteria of identity (Calvert, 1997, pp. 15-16). The construction of reality based on hate speech acts is also relevant to a discussion of online environments as the textual communication serves as a large social aspect of both on- and offline environments.

Toxicity consists of verbal expressions and behaviors that serve to destabilize groups. It is unclear whether toxic behavior is directed to elicit particular responses, and hence systemic, or reactionary, emotional, and hence, situational. Frequently, the term 'troll,' or 'trolling,' is used synonymously with toxicity. Regardless, these behaviors are necessary to address because they are a key factor in the outright hostility of online gaming environments to those perceived as other. This destabilization maps on to offline models of gender, race, class, ethnic, national, linguistic, and abelist-based hate speech. A fertile ground for this analysis is in the virtual worlds of online gaming. For example, Kou and Nardi (2013), in their research on League of Legends, found that antisocial behavior destabilizes online communities but is addressable by social code and regulatory systems.

The targeted examples in online gaming environments show a concentrated sample of toxic behavior that is pervasive in every online environment. Studies have documented antisocial behavior and toxic speech in most digital platforms (O'Sullivan & Flanagin, 2003). Whether considering flaming on 1980s and 90s USENET forums, social media fueled outrage on contemporary politics, or in-game, text-based conversation in multiplayer games, toxicity can be motivated by emotional, intellectual, political, or other causes and as such correlates strongly with the modes and consequences of offline hate speech. Understanding online toxic behavior in ways that allow for moderation of its causes and effects first requires an understanding of how to study the concrete manifestation of this behavior—the text produced by users of a system. The challenges faced by this research are many: the writing styles are heavily infused with jargon, the orthography is non-standard, the chat stream only represents one channel of communication, and the communities are fluid.

In response to these challenges, an approach grounded in machine learning and NLP was tested. Using a small subset of the available data, a classifier based upon developed to separate players toxic from non-toxic players yielded a precision of 0.77, a recall of 0.79 and an F-score of 0.78. These results are encouraging, and along with training on a larger data set, secondary factors such as player avatar gender, length of match, and others were also preliminarily tested and found to have small influencing effects. These results suggest that there are concrete, detectable semantic and syntactic patterns in the harassment levied at players in these games. Connecting these findings to mechanisms for shielding, reforming, and censuring players, and to frameworks for understanding the social and psychological costs of being effectively locked in a room with one or more individuals determined to verbally abuse a peer is the more complex task of the cultural and ethnographic studies of digital communities.

Instituto de Investigaciones Bibliográficas, Universidad Nacional Autónoma de México - UNAM, Mexico

Esta presentación describe el proceso de creación de la Red de Tecnologías Digitales para la Difusión del Patrimonio Cultural (RedTDPC), cuyo objetivo es generar conocimiento interdisciplinario y buenas prácticas en la aplicación de tecnologías digitales para la difusión del patrimonio cultural en México.

Antecedentes

La digitalización del patrimonio cultural es fundamental para su difusión a nivel mundial[1]. Para los países en desarrollo que tienen un importante patrimonio cultural, existen numerosos obstáculos en términos de infraestructura y gestión. En México, uno de estos obstáculos es la conceptualización de lo digital como un ámbito secundario dentro del sector cultural. Aunque existe una creciente mención de la importancia de trasladar los contenidos culturales a medios digitales, es muy poco lo que realmente se traduce a la práctica (Priani, 2012). Por otra parte, han existido proyectos aislados, pioneros en la digitalización del patrimonio[2] y organizaciones como la RedHD, que han servido como nodos para discutir estos temas. En el 2014 se llevó a cabo el 1er Congreso de Patrimonio Cultural y Nuevas Tecnologías organizado por el INAH donde se mostró que si bien México desarrolla aplicaciones de tecnología para la preservación e investigación del patrimonio hay poco trabajo en temas de difusión.

Creación de la RedTDPC

En este marco y atendiendo a una convocatoria del CONACYT,[3] se creó la RedTDPC en abril de 2015, con un programa académico encaminado a identificar actores[4] y encontrar sus temas en común. Los temas que se han identificado hasta el momento son:

- La importancia de debatir políticas públicas, tipos de licencias y derechos de autor.
- Las relaciones no siempre equitativas entre las industrias creativas y las instituciones
- La pertinencia de hacer investigación de campo previa al desarrollo de proyectos, dada la diversidad de México en términos de accesibilidad.
- Políticas y buenas prácticas de digitalización, preservación y difusión de objetos culturales.

Discusión

Si bien la creación de la Red se entiende como un logro en términos de gestión institucional, es necesario resaltar las dificultades para su desarrollo:

1. Falta de coherencia entre requisitos institucionales y objetivos de la Red

El CONACYT hace hincapié en que las redes deben apoyar el 'desarrollo económico y tecnológico'[5], sin embargo articular la importancia de la difusión del patrimonio cultural en estos términos es complicado. En muchos sentidos, la creación de esta Red ha permitido pensar en un espacio que equilibre en términos humanísticos esa exigencia. Al mismo tiempo, la Red se formó dentro de un programa que establece procesos burocráticos a los que es necesario apegarse, pero que no están definidos institucionalmente, lo que ha conducido a que la toma de decisiones sea lenta y se dedique mucho tiempo a temas operativos de la Red, restándole tiempo a la discusión de los temas sustantivos, algo que eventualmente podrá cambiar.

2. Ausencia de definiciones conceptuales

La propia definición de "difusión" es problemática y ha merecido parte de la reflexión de la Red. La RAE[6] define esta palabra como: 'propagar o divulgar conocimientos, noticias, actitudes'. Es la palabra divulgar, la que a veces se encuentra en oposición a difusión: la primera sólo dedicada a los pares académicos, y la divulgación al público en general (Gándara, S/F).[7]

Otra problemática es la poca documentación que existe en México sobre cómo trabajar en la difusión del patrimonio con herramientas digitales. Son pocas las instituciones mexicanas que cuentan con áreas dedicadas a la experimentación y acumulación de conocimiento en torno a estas prácticas. Casi siempre, son empresas privadas las que realizan los proyectos. Esto no es negativo en sí porque permite que las industrias creativas encuentren una fuente de trabajo. Lo que sí es necesario es que estas empresas regresen esa reflexión y experiencia a las instituciones.

3. Prospectivas

Hasta ahora se ha trabajado en la organización de encuentros académicos, que son el tipo de actividades que pueden llevarse a cabo fácilmente dentro del modelo institucional en el que se creó la Red. La mayor dificultad para el futuro es fortalecer la reflexión en temas como: legislación, accesibilidad, públicos, documentación, sustentabilidad, crowdsourcing, y cuyo trabajo se traduzca en acciones concretas en esos ámbitos. Es decir, pasar de responder a las necesidades institucionales para iniciar un proceso de producción de conocimiento.

Trabajo a futuro

El siguiente objetivo de la Red es lograr que estas reflexiones se traduzcan en proyectos específicos de difusión a través de nuevas tecnologías para poder ampliar el conocimiento a través de la experimentación.

Challenges in Setting up a Digital Humanities Centre in Romania

Corina-Elena Moldovan
corimoldovan@gmail.com
Babes-Bolyai University, Romania

The Transylvania Digital Humanities Centre (DigiHUBB) is an emerging Digital Humanities Centre based in the Babes-Bolyai University of Cluj-Napoca, Romania. The Centre was officially established in April 2014 within the Faculty of Letters. As is evidenced in other cases, DigiHUBB exists because of the commitment of scholars experienced in various fields related to Digital Humanities.[1] The primary goal of DigiHUBB was to create a collaborative network connecting DH activities within the University and beyond, that first took into account the importance of communicating the vast global impact that DH research and practices have today. The centre defined itself as impact-oriented, with an emphasis on innovation related to research, teaching and creative activities. While following the path of other prestigious DH Centres around the world, DigiHUBB aims to develop its own expertise coming from the distinctive regional specificity of Transylvania that benefits from a multicultural and multilingual cultural heritage, which has not been sufficiently explored with modern tools till now.[2]

The importance of analysing the different ways in which a DH centre is built was stressed by Claire Warwick in her seminal essay "Institutional models for digital humanities" published in the *Digital Humanties in Practice* (Warwick, C., Terras, M., Nyhan, J., 2014). The cases analysed in the chapter - the creating of the Center for Digital Research in the Humanities at the University of Nebraska-Lincoln and the Digital Humanities in Mexico - were considered representative for the way they illustrated the institutional environment and the particularities of diverse "particular academic, political, cultural and economic realities" (http://blogs.ucl.ac.uk/dh-in-practice/chapter-9/).

This paper is a commentary on the manner in which a DH Centre is established in an Eastern-European country[3] and the challenges that exist within the traditional structures and mentalities at different levels -- the academia, the policy-makers and the society in the larger sense. The poster will focus on the strategies that DigiHUBB has, at different levels – education, research and innovation, collaboration with the IT industry. It will also point out similarities between other post-revolutionary experiences and learn if there could be a kind of specificity that could give our centre a uniqueness that will make it relevant internationally. We will compare this challenge with other interdisciplinary endeavours in Romania. The argument in this paper strongly resonates with the thematic implications addressed in this conference – the "social, institutional and multicultural aspects of digital humanities" (http://dh2016.adho.org/cfp/).

In approaching this report we have observed several paradoxes that could easily exemplify the challenges that an innovative approach faced in both the institutional environment and the investment in the research framework in Romania. In the first place, the rapidity with which DigiHUBB gained international support and assistance[4] was tempered by the resistance of the existing research structure, although it is well-known that Romanian research in general is less internationalized and under performing in all major university rankings.[5] In the second instance, although the IT industry in Romania, and especially in Transylvania, is productive and lucrative, it addresses the quotidian aspects of digital work and not the innovative part. Moreover, there is a visible mismatch between the skills needed by the knowledge market and the qualifications provided by the academia.

The challenges that DigiHUBB faces are complex and they target, as our paper will show, several important issues that go from the generic ones (the misunderstanding of the concept, the lack of confidence in its epistemological value, the supremacy of the published paper book over electronic publications, the absence of systemised pedagogy in Digital Humanities, the minimal funding from the

University or governmental institutions) to more specific ones, which are more challenging to engage with.

DigiHUBB has been involved in a variety of activities related to the Digital Humanities since its inception: in January 2014 the keynote speaker for the inaugural conference was professor Susan Schreibman from Maynooth University; this was followed by a conference held by doctor Julyanne Nyhan, from UCL, in March and many informal meetings with other key members of the Digital Humanities community. The lobbying and promoting Digital Humanities also included participation to national academic events, publishing articles on the theme[6]; the following step was to set up a training event, so in April-May 2015 DigiHUBB organized a one week workshop on TEI and data visualisation financed by NeDIMAH and the European Science Foundation, and co-organized a symposium on textual digital analysis within the Babes-Bolyai University.[7] There was a strong involvement in networking and studying the activities of other DH centres in Europe. We also succeeded to introduce an MA module on scholarly edition that will start in 2016.

In the process of setting up our centre we had to fight a very specific way of relatedness that still characterizes post-revolutionary Romanian society, which we can be characterized as "non-digital humanist", as it is, in most cases, individualistic, speculative, traditional, and change-resisting, in comparison with the collaborative, hands-on, innovative and co-creative features of Digital Humanities[8].

Understood as a HUB, our centre has multiple possibilities of offering innovation, at all levels of the research-economic-social chain. We also consider it as a new cultural model, a real co-working space opened to all the actors of our multicultural and multilingual region.

Notes

[1] Some of the DigiHUBB's members were directly involved in Digital Humanities, like text editing or mapping, others expressed their interest in Digital Humanities as a discipline and an object of study. The DigiHUBB members come from different fields, like linguistics, geography, literature, computer science, art history, etc.http://centre.ubbcluj.ro/digihubb/.

[2] There is a lack of collaborative projects concerning big historical events important for Transylvania and Romania, as the "1918 Centenary" where DigiHUBB could evidently have an important contribution.

[3] Romania is, at the moment of this proposal, one of the last East-European country that entered the Digital Humanities circuit.

[4] Immediately after its creation DigiHUBB was put on the "Around DH" map (courtesy to Alex Gill from Columbia University Libraries), http://www.arounddh.org/. The response of the Digital Humanities Community to the first call for assistance launched on Humanist Discussion Group was impressive.

[5] As reported in http://ec.europa.eu/research/horizon2020/pdf/country-profiles/ro_country_profile_and_featured_projects.pdf#view=fit&pagemode=none.

[8] „The digital humanities, therefore, not only widens the scope and processes of disciplines within the university, but contributes to national innovation agendas, creating new possibilities for the traditional scholar within an increasingly competitive academic and economic context. As such, the collaborative nature of digital humanities research contributes to the innovation ecosystem, understood as the productive interaction between people, ideas, flows, processes and outputs." (Byrne, T. and Schreibman, S. (2015).

Collecting Judgments on Artworks Through a Similarity Game

Giovanni Moretti
moretti@fbk.eu
Fondazione Bruno Kessler, Italy

Sara Tonelli
satonelli@fbk.eu
Fondazione Bruno Kessler, Italy

Rachele Sprugnoli
sprugnoli@fbk.eu
Fondazione Bruno Kessler, Italy

We present PAGANS (Playful Art: a GAme oN Similarity)[1] a playful activity to be performed by pairs of users in order to collect similarity judgments about artworks. The final goal of this task is to have indicators concerning how people perceive artworks and how they judge their similarity. We are also interested in comparing such judgments with the opinion of art curators, and see whether users' contribution can be integrated in the arrangement of a virtual or physical exhibition in view of a crowd-curation approach (Ridge, 2014).

PAGANS foresees the involvement of a pair of users at a time, who play in parallel. Each of them plays the same game independently: similarity was not explained and participants were asked to follow their intuition. A final score, presented as a sort of "aesthetic affinity score", is obtained by comparing the two judgments and how much they overlap. The game could be played online, but so far the collection method has been tested in real-world scenarios, where both players are physically in the same place and one researcher is available to give feedback after the completion of the activity.

The game itself is as follows: a virtual card representing an artwork is given (the card with a red pin on the right of the table in Fig. 1), while a set of other 10 cards is displayed to the user. (S)he has to drag and drop on the round target the cards in order of similarity to the given card, until all images on the table are ranked.

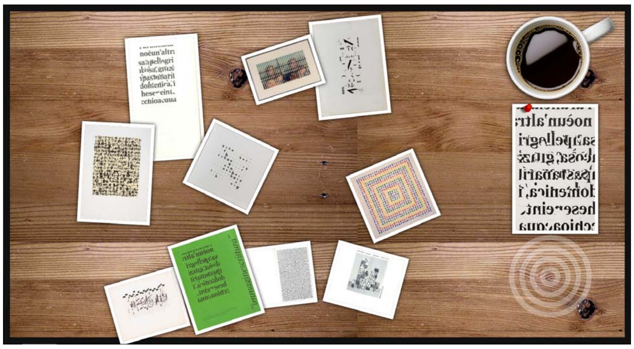

Fig. 1: Game interface

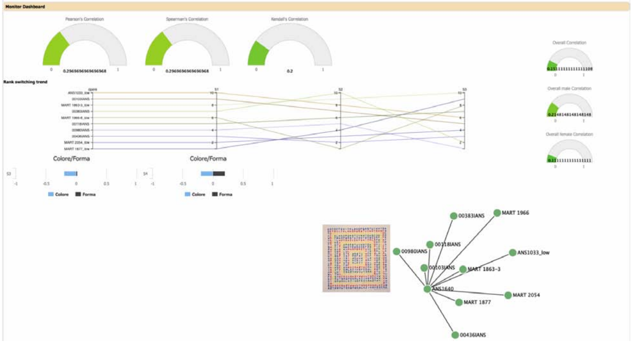
When both players have completed the task, they enter information about gender and age, and then the system shows the dashboard displayed in Fig. 2. The Pearson's, Spearman's and Kendall's coefficients (Hauke and Kossowski, 2011) are three metrics that measure with slight differences the players' agreement on the similarity judgments (the higher the value, the higher the agreement). This score is presented to the players as their aesthetic affinity score. The best affinity is reached when the players choose the same ranking, since there is no 'gold standard' order. Players' affinity is also compared with the ones displayed on the right of the dashboard: the average score obtained by other pairs previously participating in the game ("Overall correlation"), the average agreement among all male players, and that of female players. Another useful information is the "Rank switching trend": for each artwork to be ranked, the picture shows if the two players put them in the same order (straight line) or if they switched some positions.

Each picture displayed in the game was pre-processed with the LIRE tool[2] that extracts automatically image-related features such as color and shape. These features are used to provide information about the similarity judgments provided by the players, specifically if similarity relies more on color or shape information. Finally, the system outputs on the fly a network, where each node is one of the artworks in the game and the distance from the central node (i.e. the pinned card) is proportional to the average rank assigned by the two players.



Monitor Dashboard

Fig. 2: Players dashboard

PAGANS was presented during Researchers' Night 2015 in Trento (Italy) as a game for pairs of players, allowing us to collect around 170 game sessions in few hours. The game environment proved successful in engaging players also thanks to some gamification strategies. For instance, every hour the system automatically displayed a message assigning two free museum entrances to the players currently involved in the game. Besides, we kept track of the best affinity scores, and we identified the "winning pair" of the night. This boosted competition, with players trying to beat the highest score.

The goal reached with this first experiment was twofold: on the one hand, some verbo-visual works from

"Archivio di Nuova Scrittura" (Ferrari, 2012) were displayed in digital form for the first time, reaching an audience that would not necessarily see them in an exhibition. Since the game included four possible similarity sessions, around 50 artworks were shown. These works are usually kept in the archive of MART[3] and MUSEION[4] museums, not visible to the public. A second advantage of PAGANS is that we were able to collect in a short time several similarity judgments, which will be used to investigate which features related to images and possibly to persons' age and gender correlate best with similarity. These analyses are currently in progress.

A Workflow for Encoding and Publishing Inscriptions

Elli Mylonas
elli_mylonas@brown.edu
Brown University, United States of America

Scott DiGiulio
scott_digiulio@brown.edu
Brown University, United States of America

US Epigraphy (USEP)(Bodel, 2015), directed by John Bodel at Brown University, is a venerable project – its roots are in a printed handbook, which was instantiated as an HTML based website at Rutgers in 1997 (Bodel et al., 1997). In 2003, Prof. Bodel moved to Brown and USEP was converted to a more automated, data-driven site. It has gone through several implementations since that time, following the state of the art in humanities computing/DH and conforming to the practices of our library development team.

The project's goal is to identify, document and create new editions of classical inscriptions in American collections, as well as to teach digital epigraphy. The inscriptions are organized geographically by collection. The project collaborates with international epigraphic consortia such as Eagle (EAGLE, 2015) and will remain conformant with their encoding schemas and vocabularies. In addition, it is one of the active contributors to the Epidoc schema for epigraphy (Elliott et al., 2015).

The current USEP front end is written in Django, and is powered by a SOLR index. XML transformations occur at two points: when the inscriptions are ingested into SOLR, and when they are displayed - the latter transformation takes advantage of SaxonCE and therefore takes place in the user's browser.

Our choice of Django for a front-end framework was driven by the environments used by our library developers – it means that we need a developer to work on the project, either library staff or a skilled student programmer. Our choice of Saxon CE to generate our display was driven by our need to modify the display easily outside of the development environment and is easily replaced.

Inscriptions are added to the collection as they are identified, with minimal information (location and a bibliographic reference or "unpublished") and iteratively enriched. Although major collections are represented, new inscriptions are always being found in small collections or in storerooms. Gradually, all inscriptions in USEP are edited to have detailed metadata, a full transcription, more complete bibliographic information and images.

The project has received some funding over the years, but has functioned continuously with basic university support. Staff include

- a faculty director
- technical management and consulting, as well as programming support provided by the library
- a graduate student/postdoc manager in charge of the encoding workflow and proofreading (along with the director) and other improvements
- graduate student encoders and collaborators outside Brown, who either contribute editions or whose students contribute editions.

Almost all USEP encoding is done by newly minted encoders or colleagues who aren't working on it consistently, it is important to make the process easy and as error-free as possible. The project is also used in digital epigraphy seminars, and the Oxygen forms allow graduate students to focus on their epigraphic work while also engaging with the decisions and activities of text encoding. We also want to make it easy for the manager to add inscriptions to the website and to modify the display and controlled vocabularies.

The components we have developed to satisfy these criteria are

- Forms in Oxygen Author mode with controlled vocabularies and proofreading transformations to assist encoders. USEP uses the Epidoc schema and a modified version of its XSL/CSS files.

- An Oxygen framework configured as an add-on to disseminate the forms, to propagate updates automatically, and to be accessible beyond Brown.
- Controlled vocabularies and shared bibliography are stored on the web, so encoders are always using the latest version.
- GitHub to store our working corpus, images, XSLT stylesheets, bibliography and controlled vocabularies. Currently, GitHub functions as our public repository, but we intend to store all USEP sources in the Brown Digital Repository when the editions are more stable. The USEP data repository on github also hosts XSL for our display transformation.
- Server side Git scripts to automatically initiate the SOLR process when any changes are committed.

Currently, encoders are trained by the encoding manager and technical manager. Their work is proofread for epigraphic accuracy by the project director and encoding manager and screened for XML validity by the encoding manager and the technical manager. Once initial encoding is done, any further corrections or editing are handled by project members. The encoding manager pushes the finalized inscriptions to GitHub, triggering the SOLR indexing process, which then makes the new inscriptions live on the Usepigraphy website. These last few steps are an iterative process, as it is important to publish inscriptions quickly, and our process makes it easy to correct mistakes. Because the XSLT and CSS are also treated as data, the encoding manager can modify the inscription display as well which makes changes to the display much more nimble than if the project had to rely on the developers.

UpCASE – A Web Application for Building and Maintaining Language Resources

Claes Neuefeind
c.neuefeind@uni-koeln.de
University of Cologne, Germany

Francisco Mondaca
f.mondaca@uni-koeln.de
University of Cologne, Germany

Mihail Atanassov
matanass@uni-koeln.de
University of Cologne, Germany

Introduction

UpCASE (Upload, Correct, Annotate, Search and Export) is an open source web application[1] that provides researchers and lay people a wide range of options for viewing, evaluating, editing and enriching text collections. It is conceived as a multifunction web application where users can upload text documents in different formats, including scanned texts whose characters are automatically recognized by Optical Character Recognition (OCR). While being able to search the uploaded text, users can correct, annotate and also export it into different formats.

Motivation and Background

UpCASE is the result of years of work with Romansh texts and lexical resources. Romansh[2] is the smallest of the four national languages in Switzerland with approximately 50.000 native speakers (Furer, 2005). Despite several actions by official organizations, e.g. the ratification of the *European Charter for Regional and Minority Languages*,[3] Romansh is on a continuous retreat and is by now considered an endangered language. The main motivation of our work was to create a suite of tools to support the Romansh language community in building and maintaining language resources for Romansh. However, UpCASE is not restricted to be used within this particular context.[4] Our interest here is to show the relevance of using tools like UpCASE for small languages in general, since in the European Union alone there are more than 100 languages, many of them having little or no support by official institutions.[5]

We present UpCASE together with a specific historical text collection, namely the *Romansh Chrestomathy* (RC) compiled by Caspar Decurtins (Decurtins, 1888-1919). The RC comprises texts from four centuries reflecting the different idioms of Romansh[6] and is recognized as the most important historical text collection of the Romansh language (cf. Egloff and Mathieu, 1986: 7). It contains approximately 7500 pages covering a wide range of different topics, text types and genres, and therefore is an excellent basis for the compilation of a text corpus. All in all, the RC can be seen as a monument for language, speakers, and culture of Romansh in Switzerland, and as such constitutes an exception for small linguistic and cultural communities (Rolshoven, 2012).

The RC text corpus was created in two successive projects funded by the German Research Fund (DFG). In the first project, the RC was digitized and its characters recognized by OCR. The main objective was to correct the OCR output to provide a digital full text version of the RC. Due to the characteristics of the RC as a multilingual historical text collection of a small language, with varying orthographical standards and almost no digital lexical resources available, the correction of OCR errors could not be solved in a fully automatic manner (Rolshoven, 2012). Instead, we implemented a web-based editing tool allowing native speakers to participate in the task of OCR correction.[7] In a follow-up project the corrected texts were enriched with part-of-speech (POS) tags. As in the treatment of OCR errors, a fully automatic POS-tagging procedure could not be applied to the RC (Neuefeind, 2013). First we compiled a lexical resource by digitizing lexica and generating inflected word forms. On this basis, we approached the linguistic annotation with a semi-automatic procedure, combining lexical lookup (resulting in mostly ambiguous tags) with manual correction and supervision, thus adapting the collaborative methodology from the DRC-project (Mondaca and Atanassov, 2016).

Features and Technical Aspects

UpCASE brings together the experiences of both projects, combining the key features of collaborative corpus construction, enrichment and maintenance in a single web application. While existing tools mostly focus on a particular use case like collaborative correction (e.g. Wikisource[8]) or collaborative annotation (e.g. WebAnno[9]), we connect these functionalities in a full workflow from raw to enriched text. UpCASE is based on several state-of-the-art web technologies such as Spring WebMVC, Spring Data, JAXB, and JQuery. The data is persisted in a document-oriented NoSQL database (MongoDB), whose records are structurally similar to JSON objects. The use of JSON enables a straightforward communication with other resources. Using predefined REST (Representational State Transfer) interfaces, distributed language systems may be used for data enrichment, without the need of complex data conversion.[10]

Using robust and scalable software on server side, and lightweight, clean and interactive components on client side, UpCASE offers different views in order to improve its usability. There are options to treat the collection as a whole, e.g. for searching, statistics and exporting, or to modify the data at hand, e.g. to edit, annotate or enrich. After importing text documents (or scanned images of texts which are OCR'ed), the text is indexed with Lucene and made accessible through an editable directory tree together with a full text search access. The stats view offers some basic statistical information about the text collection. In the export view, the user can choose different formats, e.g. plaintext or XML, to export the whole collection or parts of it. At the document level, each token is represented by a clickable widget, which opens a modal window containing different views – depending on user rights – associated with specific functions, e.g. editing, correction or annotation. The edit view allows the user to modify the text, e.g. to correct errors produced in the OCR process. The view contains both the editable word form and the relevant part of the scanned image with its highlighted position. The annotation view allows the user to create annotations like POS-tags on the fly, thus allowing complex searches on the search view.

Summary

Our presentation gives an overview of UpCASE and its basic functions, focusing on features for corpus maintenance, extension and enrichment. While in the first place we present a Romansh language resource, the concepts and features of this use case can be transposed to other text collections and languages. Thus UpCASE can be seen as an approach to technologically and methodologically support the preservation of the cultural heritage of regional and minority languages.

Notes

[1] Code and license can be found at https://github.com/spinfo/upcase. UpCASE is delivered as Maven-based Java-project, with an embedded servlet container and database. To install and run the tool, only Java and Maven are needed.

[2] The official denomination for Romansh according to the federal constitution of Switzerland is Rhaeto-Romanic. In this paper, the term Romansh denotes Rhaeto-Romanic as spoken in the Canton of Grisons (Liver, 2010).

[3] http://www.coe.int/t/dg4/education/minlang/

[4] For UpCASE is fully open source and can be used as API, it can be extended to be used with languages other than Romansh, e.g. by implementing extensions for language-specific issues (like different charsets, encodings, lexical resources, etc.).

[5] http://www.eurominority.eu

[6] Romansh is not just one single and consistent language. In fact, it can be subdivided into 5 main idioms, namely Sursilvan, Sutsilvan, Surmiran, Puter and Vallader, all of which have an independent orthography (Gross, 2004: 13). Alongside, in 2001 the Canton of Grisons introduced Rumantsch Grischun as official literary language meant to canopy the individual idioms.

[7] http://www.crestomazia.ch. For comparable approaches at a larger scale see (Holley, 2009), among others.

[8] http://www.wikisource.org

[9] https://webanno.github.io

[10] To demonstrate the possibility to interact with a remote resource, we added a customized translation feature for the particular use case presented here. We make use of the Pledari Grond (PG), an online dictionary for Romansh that we have developed in collaboration with the Lia Rumantscha (http://www.liarumantscha.ch). A web service delivers a list of translations for a selected token by directly querying the PG. When no results are returned, the user can optionally enable a notification supplying the PG editorial staff with a request for translational support.

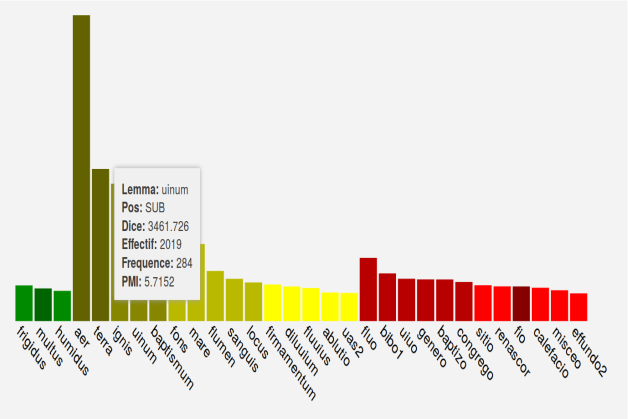
Latin was one of the most widely used languages in European history. In its spoken and written it was the language of daily communication, law, literature, and science for over fifteen centuries on the territory stretched from Spain to Germany to Poland and from Sweden to Croatia to Italy. The geographical, chronological and functional variation is reflected in a large number of texts which, in turn, gave rise to a vast body of secondary literature. These multifarious resources, though, even if by now partly available in digital form, remain still widely dispersed and do not easily lend themselves to integrated search.

medialatinitas.eu (Nowak and Bon, 2015) is a web mashup which aims at meaningful integration of textual, lexicographic and encyclopaedic resources for Latin. Apart from improving access to the data, the main goal of the presented application is to challenge the separation of linguistic competence and real-world knowledge in vocabulary description, as both components should effectively cooperate in comprehension of the Medieval Latin text and culture. The *medialatinitas.eu* may also compensate for major deficiencies of the resources (separate electronic text collections, for instance, covering only small proportion of the texts preserved etc.), as well as of the poorly designed interfaces and query engines they are made available through.

The heterogenous content (both academic and community-based dictionaries, thesauri, gazetteers; corpora and text collections; encyclopedias, document and image repositories, library catalogues etc.) has been interlinked only to the degree needed for its unified query. As a result, the data integration takes place mainly at the level of the web interface which thus constitutes presentational layer and a point of access to the services running in the background. When first visiting the page, users (be it lexicographers, linguists, historians etc.) come across a basic autocomplete search field: here, they can ulate the query phrase (as for now only lemma search has been implemented) which is next processed and despatched to both locally and distantly running services. The results are subsequently returned and displayed on the main page as a set of separate widgets, each of which may contain a concordance, a table, or another of data visualisation (timelines, charts, maps, lists etc.). As a whole, the widgets contribute to extensive description of linguistic and cultural properties of the lexical units.

The *medialatinitas.eu* attempts to address the drawbacks of popular dictionary aggregators in which the very fact of juxtaposing multiple resources seems often to suffice as their raison d'être. Destined for scholarly users, the *medialatinitas.eu* will make a heavy use of graphical hints and narrative devices such as interpretative notes and explicative commentaries which will accompany visual data representations in particular. On click, every widget will provide an interested user with fuller description of selected semantic or distributional properties of the word and constitute an entry point to an instance of CQPWeb (corpora), eXist-db (dictionaries), or R dashboard.



Lemma: uinum
Pos: SUB
Dice: 3461.726
Effectif: 2019
Frequence: 284
PMI: 5.7152

Barplot representing computed co-occurrences of the lemma AQUA "water" in the *Patrologia Latina* corpus (data fetched from an R session exposed as an OpenCPU API; the chart generated with the *d3.js* library).

The external resources are exploited through their public APIs. This is also the case of the locally hosted services. Yet, their role is by no means limited to only exposing data, since they also serve to enrich, compute on and prepare data for subsequent display. For instance, an R session is exposed to the web application through the OpenCPU API (Ooms, 2014) and permits computation on corpusand lexicography resources: the rcqp package (Desgraupes and Loiseau, 2012) is used to connect to the CQP engine (Hardie, 2012), A. Guerreau's scripts for lexical statistics allow to find co-occurrences of the lemma in the corpus, and the wordspace package (Evert, 2014) is employed to calculate word similarities based on word's distributional properties.

In spite of the relative variety of technologies and formats used, the *medialatinitas.eu is* planned to be developed in a modular way, so the users could contribute their widgets as R or JavaScript code snippets responsible for self-contained functionalities.

Time Series Analysis Enhances Authorship Attribution

Jeremi K. Ochab
jeremi.ochab@uj.edu.pl
Jagiellonian University, Poland

Introduction

Long-range correlations in texts – emerging even in dictionaries and allowing to differentiate genres (Montemurro and Pury, 2002) – prove that structures larger than necessitated by syntax exist. They might reflect organisation of literary works, and be one of authorial fingerprints.

Stylometry, however, have not exploited the information carried by memory longer than one clause apart – other than use of n-grams (e.g., Eder, 2011). Existing studies include investigating: sequences of (un)stressed syllables (Pawłowski, 1998; 1999); sentence lengths (Drożdż et al., 2016); transferring long-range correlations between letter and word sequences (Altmann et al., 2012).

To quantify correlations in a script, successive symbols can be treated as a time-series with symbolic values (Stanley, 1992) or numeric positions on a word frequency list (Montemurro and Pury, 2002; Ausloos, 2012), see Fig. 1. Below, I use information extracted from such time-series as features in machine learning (ML) methods to increase accuracy of authorship attribution (AA) in a benchmark literary corpus.

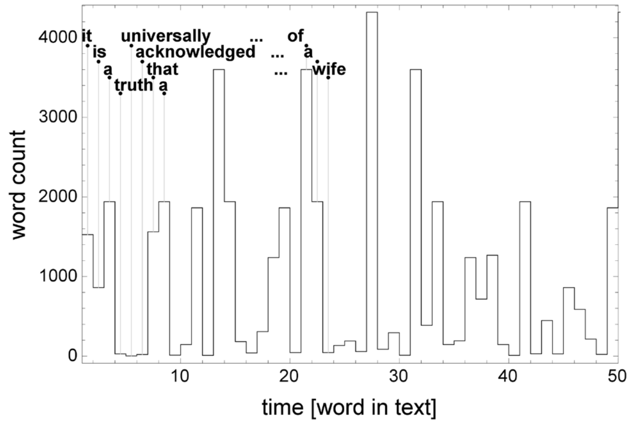

Figure 1 A book translated into a time-series: *x*-axis corresponds to the position of a word in a text; *y*-axis corresponds to the total number of times the word appears in the book

Methods

Complexity measures

For a series, defined as ranks of words at consecutive positions in a text, following measures are used (formatted as **Quantity**: *ML features*):

Power spectrum: *psLen*, *psExp*

Power spectrum *S(f)* of a series at a frequency *f* can be interpreted as the strength of correlation of the series with itself at word-to-word distances *1/f*. As Fig. 2 illustrates, it is described well by two parameters: the length *psLen* of the high-correlation plateau and the slope of its decay *psExp*.

Predictability: *pred*

As the name suggests, it measures how well can the next step in a series be predicted given previous steps (see definition: Stone, 1996).

Fano factor exponent: *fanoF*

Fano factor measures signal autocorrelation, especially in fractal processes (Thurner et al., 1997), as one takes increasingly bigger chunks of text – similarly to the slope of power spectrum or detrended fluctuation analysis (Grabska-Gradzińska et al., 2013).

Entropy rate of word variation: *entExp*, *entConst*

The entropy is maximal for equiprobable word occurences, and minimal when a single word is always used. As one reads a text, new words appear and the entropy grows, and saturates. *entExp* and *entConst* are characteristic time and a multiplicative constant of such a growth.

Static entropy: *entLocM*, *entLocSD*

For a window of a constant length moving across the whole text, the entropy fluctuates. Parameters *entLocM* and *entLocSD* are its mean and standard deviation.

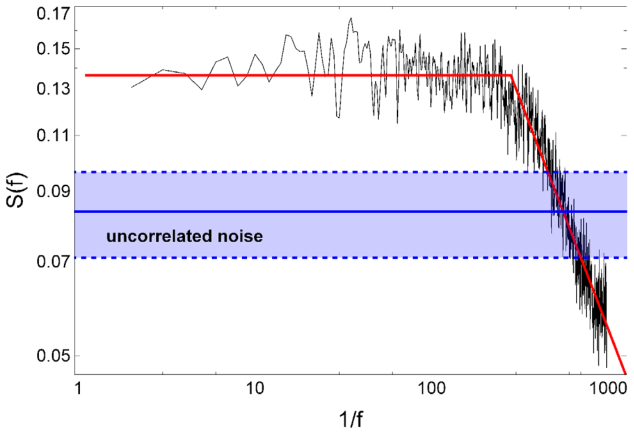

Figure 2 Power spectrum *S(f)* of the time-series as a function of word-to-word distance 1/f

Algorithm and parameters

AA was performed with the R package *stylo* (Eder et al., 2013) with settings: delta distance (Burrows, 2002), 1000-fold cross-validation, one book of each author in the training set. (None of the other ML methods (Stamatatos, 2009; Jockers and Witten, 2010) implemented in *stylo* did significantly better than Burrows's delta.)

Since on this corpus about 90 most frequent words (MFW) are needed for 100% accuracy, only the first ten were used as features, which left room for improvement. Having precomputed all the eight measures, they were appended to the feature list.

Data

A corpus (Rybicki, 2015) comprising 27 classic British 19th c. novels of 11 authors was used (see Fig. 3, where each leaf is a shorthand for a novel's *Author_Title*). The reason for choosing this corpus is that many AA algorithms have been tested on it, and they perform very well, not least thanks to its size.

Results

Authorship attribution

AA algorithms at best use 6-grams (Eder, 2011), whereas the correlations may reach hundreds of words, as demonstrated in Fig. 2. The results in Tables 1-2 show that the measures from Sec. 2.1 can aid ML. As a proof of concept, Fig. 3 shows a cluster analysis based exclusively on these complexity measures; although imperfect, it strongly indicates that the temporal characteristics contain traces of authorial style.

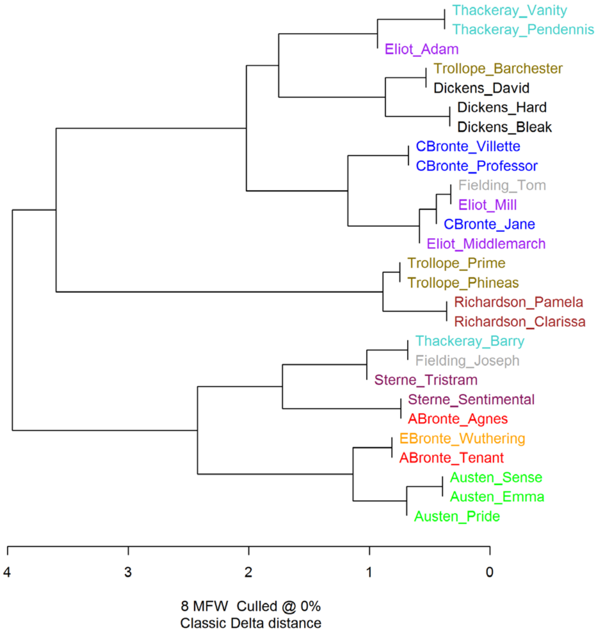

Figure 3 Cluster analysis of the corpus based only on the eight complexity measures

Informativeness of complexity measures

Surprisingly, *psLen* is not correlated with paragraph lengths (cf. Kosmidis et al., 2006). Its smallest values 280-300 come, intriguingly, from Austen and Anne and Emily Brontë, while the largest 370-390 from Dickens, Thackeray and Trollope.

Note that correlated features (see Tab. 3 for a summary) worsen performance and should be eliminated. Remaining parameters are expected to contain non-overlapping information. Further, PCA analysis showed that *psLen* and *entLocM* contain the most distinctive information. Tables 1-2 show that indeed these parameters most significantly aid ML.

Conclusions

This preliminary study shows that measures reflecting long-range word-to-word correlations carry authorial information and enhance stylometric ML methods. More complex features than words and n-grams are needed.

The HathiTrust holds one of the largest collections of digitized published work in the world. With nearly 14 million volumes ("Currently Digitized", HathiTrust.org), it is a challenge to create mechanisms to understand and interpret a collection of this size. The HathiTrust+Bookworm (HT+BW) project presents ways to behold that textual content through interactive visualization. In this poster, we present new work from HT+BW in applying visualization as an complementary, rather than center, tool for supporting better comprehension of large collections. Whereas HT+BW has previously been used in standalone contexts with pre-determined metadata, we present work in two new areas: 1) allowing scholars to analyze custom personal collections from within the larger corpus; and 2) use of HT+BW as a supplement to other uses of the HathiTrust Research Center.

Context

The vanguard of big text data was the realization that we had more books than a person can read in a lifetime (Crane, 2006). At the scale of current collections, such as that of the HathiTrust, it would take many years to read only the *titles* of all the digitized works. Such a scale presents opportunities for new forms of inference about historical, cultural, and linguistic trends. However, because of the necessary abstractions away from qualitative reading to quantifiable features in these texts, the underlying biases of the collection are not always apparent to a scholar. HT+BW seeks to address such problems.

HathiTrust+Bookworm (HT+BW) is a project seeking to adapt the generalized analytic tool Bookworm (http://bookworm.culturomics.org) to the large scales and unique needs in the HathiTrust Research Center. The HathiTrust is a consortium of institutions collecting millions of digitized works, and its research center seeks to support scholars in the large-scale insights that such a collection can accommodate. HT+BW is built on the HathiTrust Research Center's Extracted Features Dataset (Capitanu et al., 2015), a publicly-released dataset of page-level counts for important features, such as text frequencies. The dataset contains nearly 8 terabytes of data for 1.8 billion pages across 4.8 million books, with plans to grow three-fold in 2016.

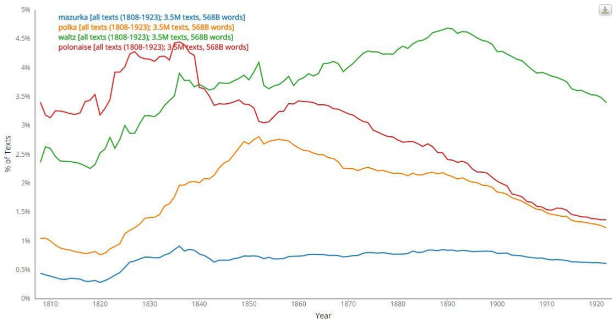

Figure 1: Comparing multiple topics over all texts

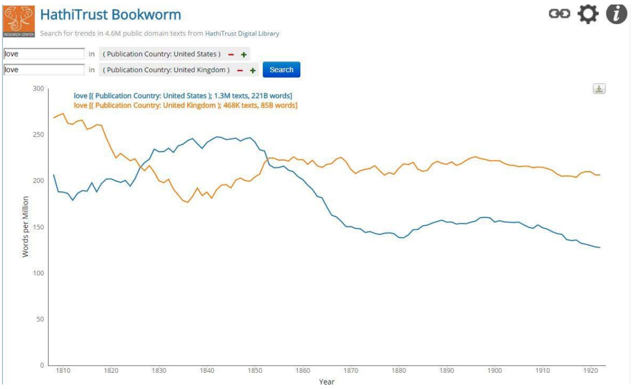

love in (Publication Country: United States)

love in (Publication Country: United Kingdom)

love [(Publication Country: United States); 1.3M texts, 221B words]

love [(Publication Country: United Kingdom); 468K texts, 85B words]

Figure 2: Comparing a single topic in multiple facets of the collections (US-published and UK-published books)

Approach

The strength of HT+BW is in detailed querying and faceting. In contrast to the Google Ngrams Viewer, for instance, scholars do not have to compare term usage across the entire corpus. Rather, they can peer within highly particular facets; for example, one can visualize longitudinal trends for the word "love" for only those books that were both published in the US and classified as literature (Figure 2). This ability becomes much more valuable when comparing across different facets, so that the usage trend of "love" can be compared between literature and general non-fiction works.

Our current work extends faceting to custom groupings of the collection — personal subsets called *worksets* — in the Hathitrust Research Center (Jett, 2015). Worksets can be visualized in Bookworm in a manner similar to visualizing any predetermined metadata-based facet. The affordances this allows include:

- generating descriptive statistics for a particular research domain, such as late 19th century best-sellers;
- creating two worksets, one of early-career and one of late-career authors, and comparing how theme words occur in either case; or
- using HT+BW over a collection derived from other scholarship, such as (Ted Underwood's fiction data).

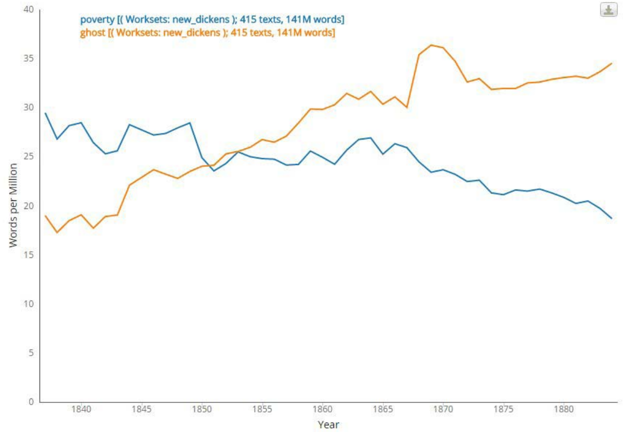

Figure 3: Comparing terms used in a 2000-volume scholar curated workset

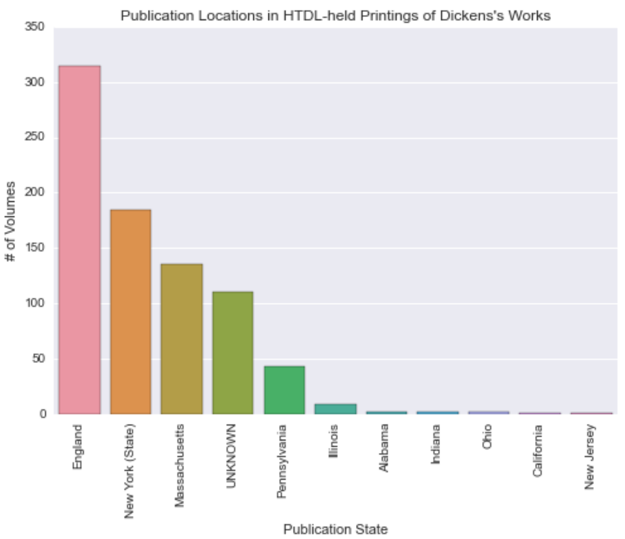

Figure 4: Comparing facet counts for "publication state" within a workset, using HT+BW public API.

In addition to workset access, HT+BW is being used for "widget" access to support other activities within the broader HathiTrust Research Center. Most importantly, this includes search. When searching for individual works, or building a workset, it is not immediately clear what relationship the relevant results have to the underlying contours of the dataset. For example, the widget-style visualization of a researcher's query for "Beijing" or "Istanbul" would reveal that those terms are biased toward 20th century work (as these places were earlier referred to by other names).

The primary development challenge of the HT+BW has been the technical hurdles inherent to the scale of the HathiTrust's collection. We have improved the ingest process for Bookworm to allow for lower level optimizations, a gain applicable to other projects' use of Bookworm. Query performance is robust at the scale of unigrams for 4.8 million volumes, though it remains to be seen how this will be scaled to larger n-grams and more volumes.

Conclusion

The HT+BW project is providing richer, more flexible access to the large holdings of the HathiTrust Digital Library, with a goal of supporting humanists in probing questions about historical, literary, or cultural trends in published literature.

Notes

HT+BW is supporting the development of Bookworm as a standalone, collection-agnostic tool. Our technical contributions are available at https://github.com/Bookworm-project and https://github.com/htrc. HT+BW is built upon publicly-available data from the HathiTrust Digital Library (https://sharc.hathitrust.org/features) and metadata (https://www.hathitrust.org/hathifiles).

HT+BW is supported by NEH Implementation Grant HK-50176-14. Any views, findings, conclusions, or recommendations do not necessarily reflect those of the National Endowment for the Humanities.

The Digital Humanities community spans disciplines, academic and professional ranks, and the full spectrum of student education. This community self-defines in myriad ways, which poses challenges to faculty, librarians, staff, and others working to design curriculum, support skill development and methodological fluency, allocate resources, and develop services in the Digital Humanities. The authors of this poster conducted a year long, multi-pronged, campus-wide study to gain a greater understanding of how individuals across a large research intensive university campus include Digital Humanities methods in their research and pedagogy, what their data needs and preferences are, where these parties need greater support, and where additional opportunities for partnerships within and across departments, colleges, and units.

Given the desire to provide a unified and complementary set of services, curriculum, resources, and collaborative possibilities, representatives from the libraries, one college, and a multi-disciplinary lab within another college at a research intensive university jointly designed and implemented a campus-wide survey and targeted, in depth interviews that equally reflected the Digital Humanities related missions of the aforementioned units. This poster demonstrates a collaborative model for assessing and cultivating a Digital Humanities community at a large research intensive university.

Michigan State University, home to MATRIX, H-Net, and WIDE, has been active in Digital Humanities and Social Sciences for more than two decades. Serendipitously, MSU Libraries, the College of Arts and Letters, and the Department of History each sought to build on this strength at the same time through a program of hiring. Amidst this constellation of Digital Humanities activity and inspired by the example of the University of Colorado, in which the university library conducted a Digital Humanities needs assessment, the authors resolved to conduct a data-driven analysis of the Digital Humanities environment on campus. To do so, the authors reached out to units known to the community in addition to disciplines less engaged with

Digital Humanities. The collaborative, cross-institutional nature of this needs assessment design is foundational as a model for other institutions to evaluate and enhance their own community and offerings.

The assessment model developed for this study adopted a holistic approach, focusing on current use and interest in methods and tools, programming languages, types of data used, data sources, and preferences for data access, preferences relating to collaboration, workshops and training sessions, and an inquiry into limitations and barriers to using digital and computational methods. The 20-minute long survey received 421 responses, including a strong turnout from key humanities and social science departments, including History, Anthropology, Linguistics and Languages, English, and Writing, Rhetoric, and American Cultures. Survey results were supplemented with ten hour-long interviews with faculty and graduate students about their use of digital methods and support on campus. Some respondents were selected by the survey convenors ahead of time, while others volunteered through the survey responses.

The results of the survey are being used at the unit level as well as university-wide at differing scales to face specific needs within units as well as to strategize campus-wide collaboration and capacity-building initiatives. The authors are using data at the unit level to augment support, services, and partnerships for pedagogy, research, data management, and skill development. Results are also being used to inform campuswide community building initiatives through outreach, strategic developments among units, and larger initiatives through the Office of Research.

This poster presents a model for developing a campus-wide Digital Humanities needs assessment intended to provide strategic information for multiple units on a large research intensive campus. By reviewing this model, other universities and colleges will come away with strategies for identifying what types of collaborations between colleges, departments, programs, labs, and libraries can improve DH pedagogy and research, what resources, activities, and services are needed to support those collaborations, as well as approaches for engaging those that are interested in the Digital Humanities but are not yet active participants. The poster presentation will include data derived from the needs assessment in addition to Digital Humanities community building solutions inspired by the data.

Curating Community: Building A Communications Strategy For The European Association For Digital Humanities

Eliza Papaki

James O'Sullivan
josullivan@psu.edu
Pennsylvania State University

Antonio Rojas
antonio.rojas@upf.edu
Universitat Pompeu Fabra

Summary

This poster will seek to illustrate the enhanced communications presence of the European Association for Digital Humanities (EADH) since 2014, and measure the impact of its action in building a community of geographically-dispersed members. It will outline the strategies undertaken by the EADH in furthering its communications initiative, for which a number of Communications Fellows have been activated on the organisation's communications policy in an effort to promote the work of digital scholars across the European region. Accounts of this activity will be further contextualised by theoretical discussion on the evolution of social media and Web-based communications across academia.

Introduction

This poster will seek to illustrate the enhanced communications presence of the European Association for Digital Humanities (EADH) since 2014, and measure the impact of its action in building a community of geographically-dispersed members. The poster will outline the strategies undertaken by the EADH in furthering its communications initiative over the last 24 months, during which a number of EADH Communications Fellows have been collaborating on the organisation's communications policy in an effort to promote, more broadly, the work of digital scholars across the European region. Accounts of this activity will be further contextualised by theoretical discussion on the evolution of social media and Web-based communications across academia.

Communications Fellows

As noted, in an effort to engage further with the international Digital Humanities community in respect to news, events, and opportunities, the EADH has motivated a diverse group of four junior scholars tasked with strengthening the Association's public interactions. The self-directed goals of the Fellows are as follows:

- Publish news, announcements and CfPs relevant to the European community of digital scholars
- Document projects undertaken in Europe in recent times and feature them in a slider to promote access and collaboration between members
- Ensure quality of language, as well as accuracy and detail of information, across all official EADH correspondence
- Increase community engagement through social media, particularly Facebook, Twitter, and LinkedIn
- Enhance the profile of relevant scholars and scholarship from across Europe's various Digital Humanities projects, centres, and initiatives
- Curate and disseminate information across a variety of European languages, enhancing the cultural diversity of the organisation's communications

Social Media

The social media revolution that has spread into the academy in recent years has shifted scholarly communications towards participatory technologies. Collectively, these social technologies are now dominating the ways in which users interact across the Web. In an effort to foster a network of researchers which embraces diversity, one must take advantage of the networks of exchange facilitated by these platforms. Initially, the focus of the fellows was oriented towards social media, Facebook, Twitter, and LinkedIn. These channels have proved essential in the collection and distribution of relevant information, and have contributed to the advancement of Europe's community of Digital Humanities scholars. Currently, the EADH engages with 2373 followers on Twitter, 491 users on Facebook, and 85 users on Linkedin. In the context of this networking activity, the EADH collaborates with associate organisations, AIUCD, Dhd, Nordic DH, and DH Benelux as well as with the Alliance of Digital Humanities Organizations (ADHO) to increase the synergies and the visibility of its members.

Discussion

This poster will illustrate the presence and performance of the EADH on social media, provoking discussion with attending researchers on their personalised use of social media and their future aspirations in regards to the employment of social media in promoting Digital Humanities research across regional and global contexts. Furthermore, the poster will present metrics on the success of this particular communications drive, as well as detail various strategic decisions, such as how to structure a Facebook group for a scholarly community, and the benefits and drawbacks of each.

This study explores the integration of various methods including photogrammetry, laser-scanning, GIS, and textual analysis in order to create a more holistic understanding of a castle ruin. The case study is the medieval castle *Burg Hohenecken* in the city of *Kaiserslautern* in southwest Germany. The project is divided into two main components: the visual and the textual components. The objectives of the visual component are to merge a laser-scan and a photogrammetric model, thus combining the measuring strength of laser-scanning with the visual aesthetics of photogrammetry. Once digitized as a merged 3D-model, the castle can be virtually controlled and examined, providing an opportunity to potentially reconstruct the castle (using *Autodesk 3DsMax*). Hypothetical reconstructions from the various construction and expansion periods with assist in studying the castle's function throughout time. The textual component, consisting of 70 letters (1212-1560 A. D.), provides historical context concerning the castle, its inhabitants, and correspondence.

Laser-scanning and 3D photogrammetric technologies have been in rapid advancement for over 20 years beginning in the disciplines of geography and mathematics (Kersten et al., 2004); specifically in photogrammetry and geodesy (Vosselmann and Maas, 2010). Academics have developed a variety of techniques and devices in order to adapt the technologies for archaeological purposes (Remondino, 2014). The intricacies of archaeological sites have pushed the devices to their limits, allowing for the production of newer devices more suited for rough terrain and countless blind spots due to walls, vegetation, and elevations. The location of the castle atop a mountain adds to the difficulty of acquiring photos encompassing the entire castle in one take (Gonzo et al., 2004). As a result of these challenges, a terrestrial laser-scanner, an aerial drone with a mirror-less camera, and a terrestrial DSLR camera, were used.

The visual component consists of two part: the laser-scanning and the photogrammetry. The Riegl VZ-400 laser-scanner (with an attached DSLR camera) was provided by the Institute of Geography at Heidelberg University. We conducted 22 scans, manually linked via tie-points (placed within overlapping areas) in the proprietary software, *RiSCAN PRO*. This model was meshed in *Meshlab* using the *Ball-Pivot* method.

The photogrammetric data was collected using a Sony NEX-7 camera attached to an aerial drone built by the IWR (Interdisciplinary Center for Scientific Computing) at Heidelberg University, and a hand-held Nikon D3300 SLR camera (provided by the University of Nebraska-Lincoln). The eight rotor drone took 385 photos up to 100 meters above the castle in a predetermined course, capturing views not completely collected by the laser-scans. The remaining 1,351 photos were done terrestrially with the Nikon D3300 SLR camera. *Agisoft Photoscan Pro* was used to align the 1,736 photos, generate the dense cloud, the mesh, and the texture.

The textual component regards the information extracted from the letters, including names and inheritances of the *Hohenecken* lineage, physical locations within the surrounding environment, and construction details of the castle. This data builds a network of communication within a past landscape and pre-existing structures of the castle. The locations in the letters will be geo-referenced in GIS allowing the landscape to be visualized rather than imagined, thus reconstructing the environment of the past utilizing primary and secondary sources.

This project is a work in progress, with an anticipated completion by May 2016. An updated status can be viewed online (http://www.jamescoltrain.com/970.Aaron/) in which the letters and models have been uploaded. A virtual tour (using *Unity*) of the reconstructed 3D-model, based upon textual evidence will allow users to "walk" through and explore the castle. The purpose is to analyze the historic functions of the castle and its significance in the regional landscape, contributing to its preservation and enhancing the knowledge of the regional architecture.

Introduction

Computer-assisted text analysis is now witnessing the phenomenon of ever-growing computer power and, more importantly, an unprecedented aggregation of textual data. Certainly, it gives us an unique opportunity to see more than our predecessors, but at the same time it presents non-trivial challenges. To name but a few, these include information retrieval, data analysis, classification, genre recognition, sentiment analysis, and many others. It can be said that, after centuries of producing textual data and decades of digitisation them, the scholars now face another great challenge - that of beginning to make good use of this treasure.

Generally speaking, the problem of large amounts of textual data can be perceived from at least three different perspectives. Firstly, there is a need of asking new research questions that would take advantage of thousands of texts that can be compared. Secondly, one has to introduce and evaluate statistical techniques to deal with vast amounts of data. Thirdly, there is a need of new computational algorithms that would be able to handle enormous corpora, e.g. containing billions of tokens, in a reasonable amount of time. The present study addresses the third of the aforementioned issues.

Stylometric techniques are known for their high accuracy of text classification, but at the same time they are usually quite difficult to be used by, say, an average literary scholar. In this paper we present a general idea, followed by a fully functional prototype of an open stylometric system that facilitates its wide use with respect to two aspects: technical and research flexibility. The system relies on a server installation combined with a web-based user interface. This frees the user from the necessity of installing any additional software. Moreover, we plan to enlarge the set of standard stylometric features with style-markers referring to various levels of the natural language description and based on NLP methods.

Multi-aspectual Document Representation

Computing word frequencies is simple for English, but relatively complicated for highly inflected languages, e.g. Polish, with many word forms, resulting in data sparseness. Thus, it might be better first to map the inflected forms onto *lemmas* (i.e. basic morphological forms) with the help of a morpho-syntactic tagger, and next to calculate the lemma frequencies.

Most frequent words or lemmas as descriptive features proved to be useful in authorship attribution. However, for some text types or genres they do not provide sufficient information to tell the authors apart, e.g. see (Rygl, 2014). Moreover, in other types of classification tasks, where the goal is to trace signals of individual style, literary style or gender, it usually turns out that they appear on different levels of the linguistic structures. Thus, one needs to enhance text description.

In practice, every language tool introduces errors. However, if the error level is relatively small and the errors are not systematic (i.e. their distribution is not strongly biased), than the results of such a tool can be still valuable for stylometric analysis. Bearing this in mind, we have evaluated a number of language tools for Polish, and selected types of features to be implemented:

- length of: documents, paragraphs or sentences (a segmentation tool),
- morphological features
  - word forms or tokens and punctuation marks,
  - pseudo-suffixes (last several letters),
  - lemmas (from WCRFT2 morpho-syntactic tagger for Polish (Radziszewski, 2013))
- grammatical classes
  - 35 grammatical classes defined in the tagset (Szałkiewicz and Przepiórkowski, 2012) of the Polish National Corpus (Przepiórkowski et al., 2012), e.g. pseudo-past participle, non-past form, ad-adjectival adjective; recognised by WCRFT2,
  - parts of speech (by grouping grammatical classes),
  - grammatical categories, e.g. gender, number, person, etc.; (WCRFT2),
- sequences
  - lemma sequences (e.g. potential collocations),
  - sequences of grammatical classes (bigrams or trigrams - hints about the grammatical structures),
- semantic features
  - semantic *Proper Name classes* – recognised by a Named Entity Recogniser Liner2 (Marcinczuk, 2013),
  - *lexical meanings* – represented by synsets in plWordNet (the Polish wordnet); assigned by Word Sense Disambiguation tool WoSeDon (Kędzia, et al., 2015)
  - generalised lexical meanings – more general meanings from plWordNet, e.g. *an animal* instead of *a cheetah*,
  - formalised concepts from a formal ontology SUMO that plWordNet is mapped to,l
  - exicographic domains from wordnet.

Semantic features go beyond a typical stylometric description, but allow for crossing borders between the style and the content description.

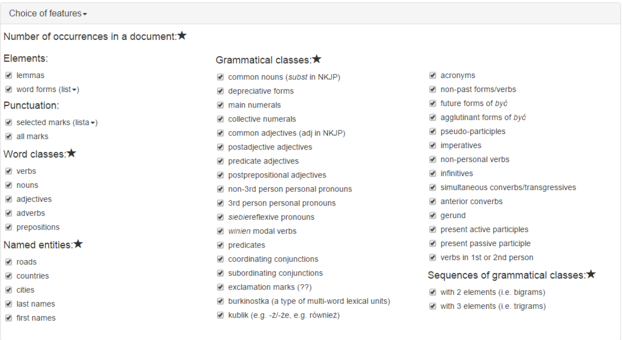
There are no features overtly describing the syntactic structure, as the available parsers for Polish express too high level of errors. The set of features can be further expanded by user-defined patterns expressed in the WCCL language (Radziszewski et al., 2011) that can be used to recognise binary relations between words and their combinations.

WebSty allows for testing the performance of the aforementioned features in different stylometric tasks, several case-studies will be presented on a set of Polish novels.

Processing and Results

The proposed system follows a typical stylometric workflow which was adapted to the chosen language tools and other components of the architecture (see Section 4).

1. Uploading a corpus of documents together with meta-data in CMDI format (Broeder et al., 2012) from the CLARIN infrastructure.
2. Choosing the features for the description of documents – done by the users (see Fig. 1).
3. Setting up the parameters for processing (users).
4. Pre-processing texts with the help of language tools.
5. Extracting the features from the pre-processed texts.
6. Calculating feature values.
7. Filtering and/or transforming the original feature values.
8. Clustering the feature vectors representing documents.
9. Extracting features that are characteristic for different clusters.
10. Presenting the results: visualisation or export of data.



Choice of features▾

Number of occurrences in a document:★

Elements:

☑ lemmas
☑ word forms (list▾)

Punctuation:

☑ selected marks (lista▾)
☑ all marks

Word classes:★

☑ verbs
☑ nouns
☑ adjectives
☑ adverbs
☑ prepositions

Named entities:★

☑ roads
☑ countries
☑ cities
☑ last names
☑ first names

Grammatical classes:★

☑ common nouns (*subst* in NKJP)
☑ depreciative forms
☑ main numerals
☑ collective numerals
☑ common adjectives (adj in NKJP)
☑ postadjective adjectives
☑ predicate adjectives
☑ postprepositional adjectives
☑ non-3rd person personal pronouns
☑ 3rd person personal pronouns
☑ *siebie*reflexive pronouns
☑ *winien* modal verbs
☑ predicates
☑ coordinating conjunctions
☑ subordinating conjunctions
☑ exclamation marks (??)
☑ burkinostka (a type of multi-word lexical units)
☑ kublik (e.g. -ż/-że, e.g. również)
☑ acronyms
☑ non-past forms/verbs
☑ future forms of *być*
☑ agglutinant forms of *być*
☑ pseudo-participles
☑ imperatives
☑ non-personal verbs
☑ infinitives
☑ simultaneous converbs/transgressives
☑ anterior converbs
☑ gerund
☑ present active participles
☑ present passive participle
☑ verbs in 1st or 2nd person

Sequences of grammatical classes:★

☑ with 2 elements (i.e. bigrams)
☑ with 3 elements (i.e. trigrams)

Fig.1 Choice of features GUI

The step 5 can be performed as: simple counting of words or lemmas, processing and counting annotations matching some patterns or running patterns for every position in a document. This is why a dedicated feature extraction module comes into stage, namely *Fextor* (Broda et al., 2013).

Filtering and transformation functions can be built into the clustering packages (see below) or implemented by the dedicated systems, e.g. *SuperMatrix* system (Broda and Piasecki, 2013).

The WebSty architecture can be relatively easy adapted to the use of any clustering package. The prototype is integrated with *Stylo* – an elaborated clustering package dedicated to stylometric analysis, and *Cluto* – a general clustering package (Zhao and Karypis, 2005). Stylo offers very good visualisation functionality, while *Cluto* delivers richer possibilities for formal analysis of the generated clusters. The obtained results are displayed by the web browser (see Fig. 2). Users can also download log files with formalised description of the clustering results.

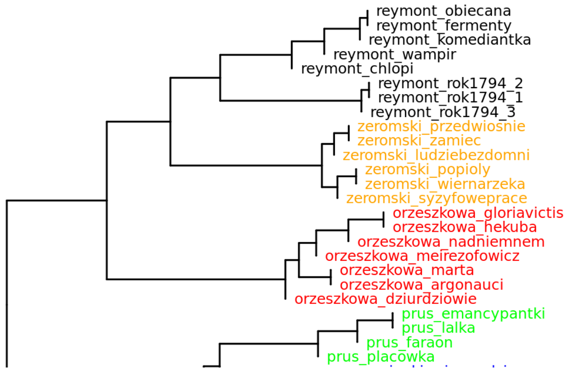


Fig.2 Stylometric results

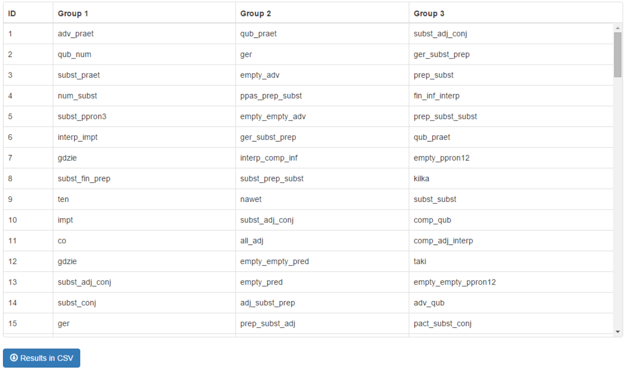
Moreover, features that are characteristic for the description of individual clusters or differentiation between clusters can be identified. Ten different functions (implemented in Weka[1] (Witten et al., 2011) and SciPy packages[2]), based on mathematical statistics and information theory, are offered. The ranking lists of features are presented on the screen for interactive browsing (Fig. 3) and can be downloaded.

The system has a web-based user interface that allows for uploading input documents from a local machine or from a public repository and enables selecting a feature set, as well as options for a clustering algorithm.

Technical Architecture

Application of language tools is inevitably more complex than calculating statistics on the level of words or letters. Moreover, processing of Polish is mostly far more complex than English (in terms of the processing time and memory used). Thus, higher computing power and bigger resources are required. In order to cope with this, the entire analysis in WebSty is performed on a computing cluster. Users do not need to install any software - which might be non-trivial particularly in the case of the language tools. The system processes the documents using a parallel and distributed architecture (Walkowiak, 2015).



ID	Group 1	Group 2	Group 3

14	subst_conj	adj_subst_prep	adv_qub
15	ger	prep_subst_adj	pact_subst_conj

Fig.3 Browsing significant features identified for the extracted clusters

The workflow is as follows. Input documents are processed in parallel. The uploaded documents are first converted to an uniform text format. Next, each text is analysed by a part-of-speech tagger (we use WCRFT2 for Polish (Radziszewski, 2013)) and then it is piped to a name entity recognizer - Liner2 (Marcińczuk et al., 2013) in our case. After the annotation phase is completed for all texts, the feature extraction module comes into stage, i.e. Fextor (Broda et al., 2013). Clustering tools requires input data in different formats: sparse or dense matrices, text (ARRF, Cluto format) or binary files (R objects, Python objects). Thus data received from the feature extraction for each input file has to be unified and converted. The extracted raw features can be filtered or transformed by a range of methods inside the clustering packages or in a system for distributional semantics called SuperMatrix (Broda and Piasecki, 2013). Finally, the R package Stylo (Eder et al., 2013) or a text clustering tool called Cluto (Zhao and Karypis, 2005) are run to perform exploratory analysis, e.g. multidimensional scaling.

To prevent the system from overloading and long response time the input data size is limited to 20 files. However, large text collections can be processed, if they are deposited in the dSpace repository.[3] All corpora in dSpace can be annotated stored for further processing. Therefore, it is only left to run feature extraction and clustering tools inside WebSty.[4]

Conclusion and future plans

The paper presented opened, web-based system for exploring stylometric structures in Polish document collections. The web based interface and the lack of the technical requirements facilitates the application of text clustering methods beyond the typical tasks of the stylometry, e.g. analysis of types of blogs (Maryl, 2012), recognition of the corpus internal structure, analysis of the subgroups and subcultures, etc.

The system is currently focused on processing Polish. However, as the feature representation is quite language independent, we plan to add converters for for other languages.

A new approach to libraries in the Digital Humanities: the case of "Fonte-Gaia"

Elena Pierazzo
elena.pierazzo@u-grenoble3.fr
Université Grenoble Alpes, France

Filippo Fonio
filippo.fonio@u-grenoble3.fr
Université Grenoble Alpes, France

Claire Mouraby
claire.mouraby@upmf-grenoble.fr
SID2 Grenoble, Université Grenoble Alpes, France

One of the much discussed topic of the digital humanities as an infrastructure concerns the role of libraries, which are not only the place where knowledge has been preserved for centuries (if not millennia), but also they represent the ideal partner for researchers and research centers, since they preserve most of the objects studied by scholars. Libraries have been identified as major actors for the preservation of digital artifacts (Van Zundert and Boot, 2012; Pierazzo, 2015), and many have engaged in such activities (Stanford Library, Brandeis University, British Library, for instance). In the same time the creation and the provision of digital libraries has now become almost normal, with most research libraries digitizing at least some part of their beholding and putting them online.

Although preservation and digitization are indeed of a fundamental importance, it is arguable that the mission of a library in the age of the digital can be extended even further. At the University of Grenoble a new and ambitious project has started. The idea is to transform the library of Italian Studies (which has a privileged status within the French library system) into a cultural hub, thanks to the tools and approaches offered by the Digital Humanities. The project is called "Fonte Gaia" (happy source), a name that plays with the double meaning of the Italian word "fonte", which means "fountain" (like the fountain in Siena from which the project is named) and "source" as in the sources of knowledge (the books); the "happy" refers to the conviviality of sharing such knowledge. The project is the expression of a larger consortium of libraries beholding considerable Italian books collections (Paris, Padua, Bologna, Rome, for now), and includes several components, surrounding the provision of a digital library, offering access to books digitized in Grenoble and in the other partner libraries. The digitized books will be offered in correlation with a series of tools and facilities for users: to annotate them; to create digital editions based on the same; to create reading paths and exercises. A funded PhD student is now investigating the functionalities and the ergonomics of an interface offering so many options to the users. The project has a strong pedagogical component: from the involvement of BAs and MAs students in the workflow of production of the eBooks, to PhD studentships, to the hosting of interns from Italy and France, to the organization of an French-Italian summer school for digital editing (starting summer 2016) and workshops; on that context a partnership with the ITN DiXit has been put in place.

In addition to these initiatives, two periodical publications are being proposed: first an informal un-journal (inspired by the format of un-conferences), where a group of early career researchers animate a polyphonic blog on topics rotating around Italian Studies and the time of digital; and second a more formal, peered-review scholarly journal which will be focused on libraries, Italian Studies and digital humanities. While this latter is still at the planning stage, the former has already started in April 2015 with great enthusiasm and success, with encouraging numbers of visits and good feedback from scholars, librarians and the Open Access environments in Italy and France. In fact "Fonte Gaia" adopt a strict golden OA policy for all the contents that are generated under its label, as well as for the content that are harvested; "Fonte Gaia" actively engages in the diffusion of OA policies and initiatives.

On the research side, "Fonte Gaia" incubates and fuels several small and medium research projects, providing support to early career researchers and other scholars in the mounting of digital humanities projects. At moment we have just started a project on metadata standards to open up our content to a linked data approach; two other new projects are in the phase of elaboration, one centered on the private archive of one of the most prominent translator of Italian literature in French between the end of the Nineteenth and the beginning of the Twentieth century, and the second on the census and digital cataloguing of Italian manuscripts possessed by the libraries of Grenoble. Connected to this latter, a module for virtual exhibition will be developed.

One of the aspects that make "Fonte Gaia" standing out from other similar initiatives is a partnership on equal basis between research and teaching centers and libraries. The different sets of complementary competences and experiences are at the base of the creation of a center of cultural animation, as well as preservation and production in a digital context. The pedagogical vocation shared by teachers and librarians are also shaping a unique learning environment with a strong hands-on component coupled with theoretical and ethical teaching. This ethos reflects also on the research and cultural heritage components of the project, making of "Fonte Gaia" a pioneering experiment of bringing together people, expertise and innovation.

This type of partnership is a genuine revolution in the French context, where traditionally the relationship between librarians and scholars is more a matter of a polite sharing of spaces,often verging on indifference, rather than one of active cooperation. In fact, since its inception this equal governance of "Fonte Gaia" has produced astonishment (luckily sometimes curiosity as well) among the members of the two categories as it challenges their tradition, their missions and their working methods. We take this as proof that we have to persevere.

Agréger le passé en ligne: Euchronie, le passé ici et maintenant!

Sébastien Poublanc
sebastien.poublanc@gmail.com
Euchronie, France

Rémy Besson
remybesson@gmail.com
Euchronie, France

Euchronie est un projet collaboratif francophone s'inscrivant dans le domaine des humanités numériques. Partant du constat qu'une abondante production de contenu sur le passé est autopubliée sur le web francophone, le projet vise créer une base de données en centralisant, collectant, indexant et hiérarchisant dès leur parution cette multiplicité de contenus.[1] Contemporains de l'essor de la blogosphère, puis des humanités numériques, de l'autoproduction dans le domaine musical tout autant que de la diffusion de la photographie amateur en ligne, ces contenus ont pour double spécificité d'émaner de chercheur.e.s et d'être autopubliés sur le web.[2]

La base de données ainsi créée prend la forme d'un site web hébergé par Huma-Num, la très grande infrastructure de recherche numérique pour les SHS. Pour parvenir à créer rapidement un corpus d'étude, la collecte de données est facilitée par l'utilisation du plug-in PressForward pour WordPress. Libre et gratuit, aisé à prendre en main par des chercheurs néophytes en humanités numériques, il autorise la recopie partielle de pages produites sur différents sites web et réseaux sociaux, mais aussi de vidéos et de fichiers audio. Dans le même temps, l'agrégation des contenus s'accompagne d'une éditorialisation fondée sur la hiérarchisation des données : nous proposons un nouvel agencement basé sur l'ajout de métadonnées. Strictement normées, ces dernières permettent une catégorisation fine (chronologie, thématique et aire géographique) qui constitue l'une des principales valeurs ajoutées du projet.

Pour développer le contenu de la base de données, chaque membre du comité éditorial d'Euchronie est chargé de la veille d'un ensemble de sites défini en fonction de son domaine de spécialité. Pour chaque actualité publiée, le responsable éditorial s'assure qu'il s'agit bien de l'expression d'un point de vue, sans prise de position partisane : il s'agit de la dimension qualitative de la sélection. D'autre part, le responsable éditorial n'est pas amené à faire une sélection sur des critères plus restrictifs tels que l'intérêt historiographique du contenu ou une quelconque adéquation avec une ligne éditoriale que la plateforme souhaiterait défendre. Au contraire, la volonté à la base de la création de cette plateforme est d'être un lieu de rencontre entre différents types de discours sur le passé. À ce titre, l'aspect collaboratif du projet est primordial : dans la mesure où l'indexation est avant tout pensée comme une interaction sociale, les usagers de la plateforme sont aussi invités à proposer l'agrégation de billets ou sites qu'ils et elles ont identifiés. Enfin, un billet de synthèse est publié chaque semaine sur le blog du projet. Dans celui-ci, chaque membre du comité éditorial y présente brièvement les trois meilleurs contenus de la semaine.

Le site web permet ainsi de rendre compte d'une écriture de l'histoire de moins en moins logocentrée et de plus en plus intermédiale, c'est-à-dire écrite et visuelle, parlée et sonore, interactive et collaborative. Euchronie est ainsi un outil créé par et pour des spécialistes, tout autant qu'un point d'entrée pour les passionnés du passé.

En phase de développement, le projet dispose d'un financement assuré par plusieurs laboratoires de recherche en histoire et information-communication. Au 1er novembre 2015, son comité éditorial se compose de 19 membres séniors et juniors en France, Suisse et Canada, tandis que la première version de son corpus agrège 100 références, tant au format textuel que vidéo et audio. La mise en ligne du site est prévu pour l'année 2016 et sera donc visualisable lors du colloque. Un blog Hypotheses regroupe l'ensemble des informations relatives au projet.

La création de notre poster doit permettre de présenter l'outil et d'échanger autour des problématiques liées à la construction d'un corpus dans une perspective de Digital Public History. Nous désirons notamment rencontre les développeurs de PressForward pour partager nos retours et comparer notre projet avec Digital History Now.

University of Helsinki

Sami Paavola
sami.paavola@helsinki.fi
University of Helsinki

Background

The Commens Digital Companion (http://www.commens.org) was born in 2012-13, when the Helsinki-based Commens site, designed by Mats Bergman and Sami Paavola, merged with the Brazilian Digital Encyclopedia of Charles S. Peirce, founded by João Queiroz. The new international Companion brought together two established on-line resources of Peirce research – the Commens Dictionary and the Digital Encyclopedia – and added new tools, such as the news service and the bibliography.

The Original Commens

Commens was originally developed as a Finnish Peirce studies website by Mats Bergman and Sami Paavola. It functioned as the virtual home for the Helsinki Metaphysical Club, and offered resources for students and researchers in both Finnish and English. The original Commens was opened in February, 2001. In 2003, Bergman and Paavola introduced the Commens Dictionary of Peirce's Terms, a dictionary of Peircean terminology built from original Peirce quotes. The Dictionary proved to be the most successful part of Commens; together with the Digital Encyclopedia, the Dictionary forms the backbone of the new Digital Companion. More than 700 quotes were transferred from the old Dictionary to the new platform.

Why "Commens"? Why a "Digital Companion"?

Peirce introduced the concept of the "commens" or "commind" in his correspondence with Victoria Lady Welby in 1906. Although a rare and partly obscure neologism, the term has proven to be both suggestive and useful. When Bergman and Paavola created the original Commens, their goal was a web site that would serve as an enabler of scholarly communication as well as a free resource for researchers and students - and hence "Commens", a term that suggests community and sharing of knowledge. The new version of Commens has also been developed in this spirit; it moves us several steps closer to the original aim by providing new possibilities for user input and collaboration.

In addition to evoking the original Digital Encyclopedia created by João Queiroz, the term "Digital Companion" refers to the emphasis on the new forms of publication that Commens provides. Unlike traditional, printed companion volumes, Commens grows and evolves through user input.

Primary Contents

News

Commens collects news pertaining to Peirce studies and closely related fields. The news are divided into categories, such as "academic meetings", "calls for papers", and "publications". An archive of all news items is provided on the news page. In addition, news with a set date, such as meetings and deadlines, are listed in the "Upcoming Events and Deadlines" sidebar block on the news page and the front page as well as the Commens calendar. All registered members may add news to Commens, as long as the entries relate to Peirce studies in some manner. All news items are supervised by the site editors, who have the right to remove any inappropriate entries.

Dictionary

The Commens Dictionary consists of original quotations, in which Peirce defines or characterises his technical terms. This collection of quotes does not lay claim to completeness; the dictionary aims to offer representative samples of Peirce's terminological definitions. It is intended to serve as an aid for researchers and students. All quotes are associated with sources (such as manuscripts or journal articles) added to the bibliography. Only editors and contributors may add and edit the contents; but all registered users may add comments (such as suggestions for new quotes and corrections). The comments are monitored by the site editors, who have the right to remove any inappropriate comments.

Encyclopedia

The Commens Encyclopedia contains original research articles related to different aspects of the philosophy and life of Peirce. The articles are peer reviewd according to academic standards.

Bibliography

The Commens Bibliography is an open-ended biographical database that contains both primary and secondary Peirce research sources. The bibliography provides the source references for the Commens Dictionary. All registered users can add records to the bibliography as long as the entries relate to Peirce studies in some manner. The bibliography is supervised by the site editors, who have the right to remove any inappropriate entries.

Excerpta Constantiniana: From Palimpsest to a Digital Edition of a Medieval Encyclopaedia

Dariya Rafiyenko
dariya.rafiyenko@uni-leipzig.de
University of Leipzig, Germany

The aim of the poster is to present a digital edition of the *Excerpta Constantiniana* (*Excerpta* further on), a Byzantine encyclopaedia written in Ancient Greek in Constantinople in the 10th century (edited by de Boor, 1903, 1905; Büttner-Wobst, 1906; Boissevain, 1906; Roos, 1910).

The underlying research project belongs to the field of Classical and Byzantine Philology and is devoted to the edition of an important historiographical source. The goal of this poster is interdisciplinary: it aims to define the role of the editor and the concept of the presentation of a historical source in the digital environment.

The *Excerpta* was planned as a large-scale encyclopaedia in multiple volumes. It consists of several thousand separate extracts (excerpts) that were taken from about three dozens of Ancient Greek and Byzantine historiographical works. The extant parts of the *Excerpta* contain about 560 000 words (it is believed that almost tenfold is lost). We possess two original manuscripts of the *Excerpta* (each of the two for a different volume of *Excerpta*) that distinguish themselves through a remarkable *mise-en-page*: for the purpose of navigation in the content several hundred notes and pictograms have been placed on the margins of the manuscript (see image 2).

The digital edition of the whole work is in the preparatory phase; a section from the *Excerpta* have been edited exemplary, to be more precise, 24 pages (about 9 000 words) from the original manuscript *Vaticanus graecus* 73. The manuscript itself is a palimpsest. The text of the *Excerpta* has been washed off in the 14th century and overwritten, leading to a limited legibility of the original text (see image 1). Standard solution in such a case would be to publish the facsimile of the manuscript and to prepare a historical-critical edition of the text. However, the publication of such a damaged text proved itself to be of little value for the reader not versatile in deciphering palimpsests. Moreover, the traditional layout of a historical-critical edition is not suitable for displaying the *Excerpta*. The biggest challenge here is a faithful reproduction of the notes and pictograms on the margins that are important for the understanding of the text.

The *mise-en-page* of the *Excerpta* was pivotal for the development of the concept of this digital edition. A *pluralistic* approach to the text was taken as a basis. The goal was to ensure the presentation of the text in multiple *views* (displaying perspectives), most important of which were the *document-focused* and the *text-focused* perspectives (cf. Pierazzo and Stroke, 2011; Rehbein and Gabler, 2013; Muñoz and Viglianti, 2015). In doing so three main views were chosen: (i) a digital reconstruction of the manuscript (*topographical view*), (ii) a diplomatic transcription (*document-focused view*), and (iii) a normalized, historical-critical version of the text (*text-focused view*).

- **Topographical view**: The topographical view includes the digital reproduction of the original as a two-dimensional, detailed representation of the surface. In other words, it means that the earlier text of the manuscript, significantly enlarged, has been digitally replenished with stylus on the touchscreen (see image 1 and 2). To my knowledge this method has not been used in the reconstruction of the palimpsests before and therefore represents a novel way of displaying original texts. Its uniqueness lies in the combination of human expertise and the current technical possibilities.
- **Document-focused view**: In this view, the text is reproduced as true to the original as possible. The design of the original is visualized, especially the layout of the text and the navigation elements in it (see images 2 and 3). Wherever possible, the original orthography is reproduced. Nevertheless it is also possible to switch to the normalized orthography within the same view. The reader can therefore choose between modern and medieval punctuation, between the spelling containing original abbreviations, or expanded text, etc.
- **Text-focused view** (see image 4): This view has the layout of a modern edition, the orthography is largely normalized. An option is provided to highlight different types of content, such as quotations, places, personal names, peoples, etc.

Technically the concept of the edition is implemented as follows. The topographical view is produced as images. The transcription of the original text for the document- and text-focused views is made according to the TEI/XML standards. Phenomena encoded with tags are divided into larger *blocks*. The main blocks are:

- *Physical condition of the manuscript and physical structure of the text*: physical damage of the manuscript, legibility of the text, page and line division at the locations where they are not connected with the logical structure of the text (see below);
- *Logical structure of the text, as well as all the elements of the layout, which support navigation in the text*: units such as volumes, chapters, excerpts; elements of the design that refer to this classification (e.g. larger spaces in text intentionally left blank); pictograms and marginal notes;
- *Orthography of the manuscript*: original punctuation, accentuation, abbreviations and ligatures;
- *Normalized orthography*: modern punctuation, word boundaries (missing in the manuscript), uppercase and lowercase letters according to modern standards;
- *Contents of the text*: quotes, names, places, peoples, and other items.

The web presentation is created on the basis of XSLT. The transformation of separate blocks of tags is modeled for each view individually. The final presentation is styled with Cascading Style Sheets (CSS). It is planned to publish the edition online by mid-2016.

Mapping Imagined and Experienced Places: An Exploration of the Geography of Willa Cather's Writing

Emily J. Rau
emilyjanerau@gmail.com
University of Nebraska-Lincoln, United States of America

Gabi Kirilloff
gkirilloff@gmail.com
University of Nebraska-Lincoln, United States of America

Introduction

The American novelist, Willa Cather, was an extensive traveler whose experience of and attachment to places greatly influenced her writing. As an author whose novels are traditionally regarded as depicting fictional versions of real places, Cather's novels are particularly suited for an examination of the artistic relationship between real and imagined places. The effects that geography had on Cather's work are demonstrated not only by her fiction, but also by her recently published letters, many of which include vivid descriptions of geographic places. This project explores the relationships between real places and those depicted in Cather's writing by creating a series of digital, interactive maps. Using both text analysis and digitally cartographic tools, we examine the differences between Cather's first-hand experience of place and her mental conception of place.

Methodologies

Our project employs two distinct approaches in order to gain a better understanding of the representations of place in Cather's works; the first approach is concerned with Cather's references to real locations and the second explores fictional places. We created digital maps using ArcGIS, a geographic information system designed to capture and analyze geographical data. The first series of maps we created examine place on a global scale. They provide readers and scholars with a visual representation of the places Cather lived in and traveled to, the places she wrote about in 200 of her letters, and the places she references in her novel *My Ántonia*. In order to create these maps, we first had to extract spatial data from the correspondence and *My Ántonia*, which we accomplished by using preexisting information encoded in the Willa Cather Archive's XML and by using the Stanford Named Entity Recognizer.

The second series of maps examine space on a more intimate scale. These maps compare Cather's fictional depictions of the town of Red Cloud Nebraska with the geographic layout of the town at the time Cather experienced it in the late 19th century. In this project, we used ArcGIS to create a map of Red Cloud, NE, circa 1890, based on data provided by the Webster County Assessor's Office and historic information gathered from the Nebraska State Historical Society. The map is interactive, so that each location includes historical information and a photo, when available. From this historic and geographic data, we constructed interpretive maps of two fictional versions of Red Cloud found in Cather's fiction: Black Hawk of *My Ántonia* (1918) and Sweet Water of *A Lost Lady* (1923).

Results

The maps we created helped us to expose Cather's engagement with real space, highlighting moments when she departs from mappable, physical space into the realm of imagination. Further, by uncovering these intricacies and depicting them in maps, readers can perform interpretive work concerning Cather's production of fictional space. The world map of *My Ántonia* indicates that cities within Nebraska are mentioned frequently, as are Eastern European countries. This result makes sense since the novel centers on Eastern European immigrants living in Nebraska. However, more granular Eastern European locations, such as specific cities, do not appear in the novel. Surprisingly, the majority of European cities mentioned are in Italy. This suggests a correlation between Cather's personal experience and the places she writes about, as she visited Italy, but never visited Eastern Europe. Similarly, the local map of *My Ántonia* highlights Cather's reliance on personal experience, as it correlates closely to the historic map of Red Cloud. Scholars have often emphasized that Cather based Jim Burden's home on her grandparents' house, in the northwest part of town. However, the map of the novel reveals that Jim's home is beside the Harlings' house in the southwest part of town, which is the location of Cather's childhood home. In the novel, Cather transplants the internal details of her grandparents' home into the location of her childhood home.

Future Work

The eventual goal of this project is to incorporate all of Cather's letters and novels into our maps and to create additional maps of Cather's other fictional depictions of real places. Expanding the texts used would provide a more nuanced picture of the places Cather writes about. In addition, including more texts will allow users to better query the data, asking questions such as, which of Cather's novels include the most references to places she experienced first-hand? Do Cather's fictional depictions of Pittsburgh and New York align as closely with reality as her re-imaginations of historic Red Cloud? Creating additional maps will allow for an exploration of the ways in which Cather's frame of spatial reference shifts among these works.

Motivation

"Citation is the core of scholarship" Neel Smith and Chris Blackwell state in their paper on the CTS/CITE Architecture (Smith et al., 2012). A citation like "Athenaeus, *Deipnosophists*, edition of Kaibel (1887), book 1, chapter 3" can refer to only one string of Greek words and it is valid for every printed copy of Kaibel's edition. Such a citation identifies an object of study uniquely, and it is "independent of any implementing technology". But such a citation scheme is hardly machine readable, and the digital processing of citations becomes more and more important in the humanities. To support this task, the CITE Architecture 1 was designed. Adopting the international standard of URNs 2, unique, complete and machine readable scholarly citations, so called CTS URNs can be generated.

Figure 1: Screenshot of *CTRaCE* showing the CTS URN greekLit:tlg0008.tlg001.perseus_grc3:1.3:

Although the CITE Architecture is a substantial basis, it does not provide an interface to intuitively make this capability accessible to humanities scholars. This paper aims to fill this gap. We designed the web-based application *CTRaCE* that first of all allows the browsing and reading of texts provided in the corresponding canonical format. With basic interaction functionality, *CTRaCE* supports easy creation of a digital citation of an arbitrary text passage as a CTS URN. As it can also be used to resolve existent CTS URNs, *CTRaCE* fulfills the major requirements for the processing of manually generated digital citations necessary for digital scholarship.

Technical Basis

CTRaCE is based on Canonical Text Services (CTS), which – part of the CITE architecture – addresses two fundamental needs in digital scholarship: (1) the citation of textual units, and (2) their retrieval. To accomplish the transition between classical and digital citations, CTS use Uniform Resource Names (URNs). The top-level structure of a CTS URN 3 has the following format:

cts:urn:namespace:work:passage

As URNs are organized hierarchically from left to right, each component increases the precision of the corresponding reference. The *namespace* component is the top level division of the system. As we use the Perseus Digital Library 4 as demonstration corpus, one of the namespaces is "greekLit", which identifies works in ancient Greek that are preserved through manuscript tradition (Smith et al., 2012). The *work* component specifies the document the URN refers to. It is divided into *textgroup.work.version.exemplar* from which the last two parts are optional. For example, the URN

cts:urn:greekLit:tlg0008.tlg001.perseus_grc3:

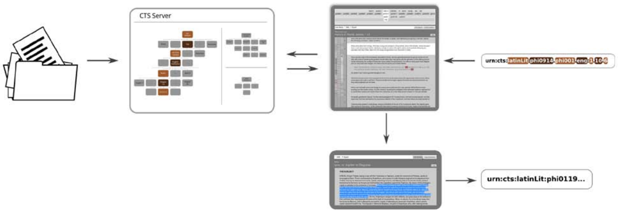
refers to Kaibel's edition of "Deipnosophists" (tlg001), located in the textgroup that contains works by Athenaeus (tlg0008). Generating a URN representation for each text, the CTS architecture organizes the whole corpus in the form of a tree with inner nodes representing the hierarchical structure among the texts, which are the leaf nodes of the tree.

Each individual text further has a canonical citation scheme assigned. As the hierarchy of texts varies depending on genre – a play might be arranged by acts and scenes while a poem uses verses –, this scheme is flexibly designed. Additionally, the URN can be further refined with the *passage* component that specifies a continuous part of the text – even on character granularity if necessary.

cts:urn:greekLit:tlg0008.tlg001.perseus_grc3:1.2@καὶ[2]-1.3@δρ

refers to the "Deipnosophists" part that ranges from the second occurrence of the string "καὶ" in the second chapter of the first book until the first occurrence of "δρ" in the third chapter.

Figure 2 displays an overview of our CTS based architecture. Though the scalable CTS implementation (Tiepmar et al., 2014) we use as server infrastructure supports any text in Unicode, we built our application with the idea to operate with texts in TEI 5 format that often include styling markup, which can be used for visualization purposes. *CTRaCE* is a client side web application communicating with the CTS server using the CTS protocol 6. In the following section, we explain the design and the functionality of *CTRaCE* in detail.



CTS Server

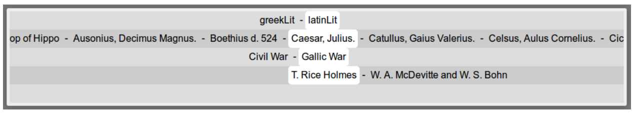
Figure 2: Architecture overview

User Interface

The CTS architecture is a robust basis for digital citations, but due to its technical nature, tools need to be built upon the architecture to leverage its functionality in an intuitive way to humanities scholars. We present *CTRaCE* for that purpose, an example screenshot is shown in Figure 1. It focuses on supporting the following three tasks:

- browsing and reading texts in the CTS system
- creating and exporting citations using CTS URNs
- resolving CTS URNs by visualizing the cited text and its surrounding context

CTRaCE is designed to display the content of a single URN, always shown as parameter in the address bar of the internet browser. Everything related to the citation this URN points to is drawn with a white background in three view components, which we explain below.



greekLit - latinLit

op of Hippo - Ausonius, Decimus Magnus. - Boethius d. 524 - Caesar, Julius. - Catullus, Gaius Valerius. - Celsus, Aulus Cornelius. - Cic

Civil War - Gallic War

T. Rice Holmes - W. A. McDevitte and W. S. Bohn

Figure 3: Navigation component

The **navigation component** shown in Figure 3 is placed in the header section of the user interface and can be used to browse through all available documents. It is derived from the ontology of the CTS system described above. Each row represents one level of the URN parts that identify a text. If appropriate metadata such as authors or titles are available, we display these labels instead of URN identifiers as fallback. Each text in this tree can be selected via mouse click for close reading.

CTRaCE displays texts as one continuous scrollable block, which for optimal performance is loaded in chunks. To the left of the text, we implemented a **distant view component** showing the citation structure in relation to the visible portion of the text. We therefore adopt a visualization method called Icicle Plot (Kruskal et al, 1983) that shows hierarchical relations in a compact way. Figure 4 shows a screenshot of this view. The underlying text uses a three level hierarchy to create a citation: book, chapter and section. Each gray-bordered rectangle in the view represents a node within the citation structure. The leftmost rectangle labeled with the URN of the document represents the root. Inside each node's rectangle, we provide information about their direct children regarding the citation tree. Since the document contains eight books, the same number of alternating shaded rectangles is drawn inside the root node. We provide quick navigation through the document using mouse clicks on these inner rectangles. Depending on the document position, the corresponding citation nodes are drawn in the remaining columns with the leaf nodes aligned to the text. As the text shown in Figure 4 is only part of the first chapter, there is only one node rectangle in the second column. Additionally, the white rectangles depict which part of a node is defined by the current URN, and the blue rectangles represent the visible portion of a node.

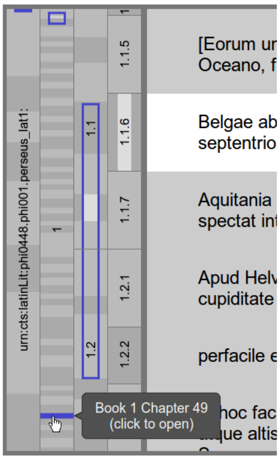


Figure 4: Distant view component

The text of the document is shown in the **text reader component** in main area of the screen. As the text chunks are loaded from the server, they are transformed into HTML code. So far we implemented two rendering methods as shown in Figure 5. The XML view mode displays the text including its markup in a syntax highlighted, indented fashion. The Styled view mode only displays the text using the markup information to style it appropriately. For example, <head> tags will be rendered bold, <note> tags indented, etc. The user can switch between both modes while viewing the document.

When generating a new digital citation with our application, basically the current URN is changed. There are two possibilities to do so. First, the scholar can click on one of the labels of the nodes in the distant view component. This selects the corresponding entire citation node.

Second, the user can mark the desired text passage in the text reader component with the mouse, and then click the "Set Citation" button. The updated URN then represents the selected text passage. Finally, a popup dialog helps to export the URN or the text it is referring to. This includes the possibility to generate a link pointing to our web application showing the generated citation.

Conclusion

The proposed *CTRaCE* interface is based on Canonical Text Services in order to provide an online service to generate citations of digital text editions. Such a front-end allows humanities scholars not only to close read texts, but also to identify and retrieve text passages of interest. The interface offers the possibility to generate and export citations of textual works down to the character level. Moreover, *CTRaCE* is a service that is capable of resolving existent or with *CTRaCE* generated citations by opening the referenced text passage.

As of now, *CTRaCE* is a very helpful tool for humanities scholars who want to produce machine readable citations. Future steps in the development of *CTRaCE* include visualizations of different kinds of annotations on a CTS passage produced by different scholars to facilitate the collaborative work on a shared text of interest.

Acknowledgments

Parts of the work presented here is the result of the project "Die Bibliothek der Milliarden Wörter" funded by the European Social Fund. We additionally want to thank Monica Berti for the valuable input and discussion about use cases for our application.

The possibilities for widening the spectrum of research questions by adopting new computational methodology seem to be almost unlimited for literary scholars with considerable programming skills. Researchers with little or no such skills, however, have to rely on user-friendly tools. Simple word counts are still among the most common, and admittedly often very useful features used in computational text analysis. Usually, linguistic annotations are needed for using more complex features in the analysis of style or content of a literary text. For example, a researcher might want to investigate style in terms of syntactic preferences by applying stylometric analysis on part-of-speech tag n-grams, to run topic modelling on specific word types only or to characterize the way an author describes figures by extracting all the adjectives that refer to a named entity. All these examples require of the scholar to first extract linguistic information from the text and use that information to define complex features.

Computer linguists have developed several tools for the various tasks of natural language processing (NLP) that can automatically analyze a digital text and annotate it with such information. In the present spectrum of solutions for NLP tasks, there is a gap between tools for rather simple tasks and full programming frameworks which require significant programming skills. The one end of the spectrum is represented by WebLicht,[1] a web service that allows users to upload and process single files very comfortably. On the other end are GATE,[2] NLTK[3], BookNLP[4] and the Darmstadt Knowledge Processing Repository (DKPro).[5]

DKPro provides a programming framework in which many such NLP tools can be combined into an analysis pipeline. The pipelining approach is especially useful, often even necessary, when one NLP tool needs the annotations provided by another NLP tool in advance for extracting more complex linguistic features. DKPro thus provides access to tools like sentence splitters, tokenizers, part-of-speech taggers, named-entity recognizers, lemmatizers, morphological analyzers and parsers in many languages.[6]

While making NLP significantly easier by integrating many NLP tools into a single framework, the use of DKPro still requires a substantial knowledge of technologies like UIMA, Java and Maven. To further lower the skill threshold for literary scholars to use complex NLP output in computational text analysis, DARIAH-DE (the German branch of the European project Digital Research Infrastructure for the Arts and Humanities, funded by the German Federal Ministry of Education and Research) developed the DARIAH-DKPro-Wrapper (DDW).[7] The DDW bundles a pipeline with a set of commonly used NLP components into a java program to be executed with a single command. As DKPro in general, the wrapper provides transparent access to a whole set of different NLP tools which are downloaded as needed behind the scenes. Command line options and configuration files allow users a considerable degree of control over the pipeline and its components, giving partial access to DKPro functionality without requiring any programming knowledge. The DDW also solves the problem of different input and output formats of the tools, offering a unified access. Therefore, the DDW positions itself in between the two ends of the aforementioned spectrum: It runs locally, allows for the processing of multiple files and can be configured to a considerable extent to one's own needs. Whereas the user of classical DKPro is a UIMA programmer, the DDW can be used by anybody who can copy a command into the command line. Nonetheless, the DDW in some cases offers more features than other more advanced solutions, as DKPro supports more tools and languages. It also integrates Stanford NLP and supports the highly efficient Treetagger. A list of components available for both DKPro and the DDW can be found of the DKPro project page.

Furthermore, the DDW stores its output in a tab-separated plain text format inspired by CoNLL2009.[8] The format provides information on paragraph id, sentence id, token id, token, lemma, POS, chunk, morphology, named entity, parsing information and more. This format can be comfortably accessed in common scripting languages for further analysis, i.e. it can be directly read as a dataframe object in R or Python Pandas; it can even be opened in a common datasheet editor like Microsoft Excel.

Scripts connecting the output format to popular text analysis tools like the R package *stylo*[9] are currently under development. Dariah also prepared some tutorials explaining how to use the wrapper and showing the use of the output format in research in three use cases.[10]

This poster will present the DDW and its file format as a new and comfortable means of providing linguistic annotations, thus significantly lowering the threshold for using complex NLP-based features in computational literary analysis.

Mapping Languages Performance by Performance

Sandy Ritchie
tr7@soas.ac.uk

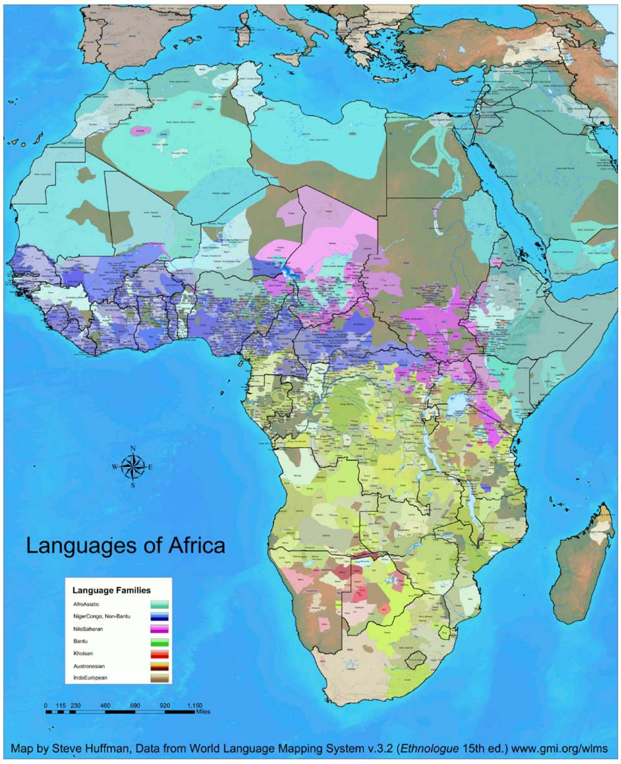
Karolina Grzech
298351@soas.ac.uk
SOAS, University of London, United Kingdom

This presentation introduces Language Landscape (LL) - an online, open access language mapping resource, which adopts a 'performance-based' approach to mapping languages.

Language maps play a crucial role in increasing our understanding of the geographical distribution of linguistic groups (Lameli, 2010). Many language maps represent languages either as polygons or points. Each polygon in Figure 1, or point in Figure 2, represents a language of Africa.



Map by Steve Huffman, Data from World Language Mapping System v.3.2 (*Ethnologue* 15th ed.) www.gmi.org/wlms

Figure 1: polygon-based map of African languages (credit: Steve Huffman/Ethnologue)

While these maps are useful for gaining a general insight into the linguistic makeup of an area, there are issues with the way they represent language communities. Languages are not commonly spoken by a monolingual population who live across a continuous area with discrete boundaries. Language boundaries are fluid, and both individuals and populations are often highly multilingual, for example in some sub-Saharan African settings (Lüpke and Storch, 2013), and also in many large cities (Extra and Barni, 2008). A notional "centre" for a language is also problematic. Speakers of a language are typically dispersed across a large area, meaning that a single point chosen to represent that community can only represent some important cultural centre (Dahl and Veselinova, 2006).

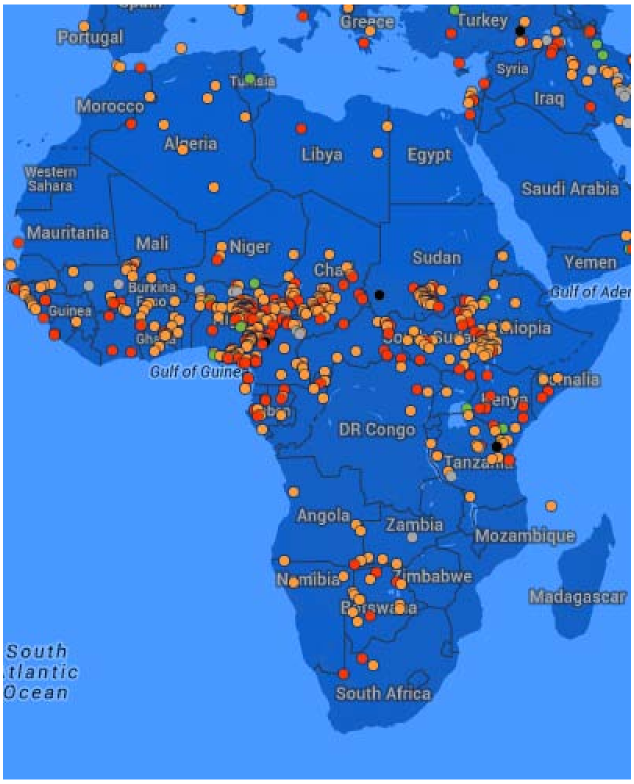


Figure 2: points-based map of African languages (credit: The Endangered Languages Project)

Both polygon- and points-based maps represent languages as monolithic entities which have an existence separate from their speakers, cf. the notion of "competence" (Chomsky, 1965). An alternative way to view languages is as "communities of practice" (e.g. Wenger, 1998; Eckert, 2000) - loose associations of individuals who participate in shared social practices.

One way to represent the spread of communities of practice is to map recordings of community members' performances, because these represent a moment in which speakers participated in a community of practice. Coupled with rich sociolinguistic information about speakers' backgrounds and repertoires, a map of these performances represents not only all the places in which a language is spoken, but also who speaks it, and which other languages those speakers speak.

We have adopted this performance-based approach to language mapping on our website languagelandscape.org.

The website is designed to enable anyone with an internet connection to create an account and add recordings of their languages to a world map. Other users can then access these recordings by browsing or searching the map. In order to encourage as many contributions as possible, we do not have any specific requirements for the type of data submitted. The metadata categories on the website are based on the International Meta Data Initiative (IMDI) standards and are stored in a relational database.

The language maps available on Language Landscape do not represent languages as polygons or single points, but rather as a series of points which indicate the locations where language recordings were made. The maps on LL are also, in this sense, "point-based", since points are used to represent languages, but crucially these points indicate the locations of performances of a language, rather than the language itself. For example, the map below shows recordings of English added to the website, which may be taken as a proxy for (some of the) locations around the world where English is spoken:

English is a West Germanic language that was first spoken in early medieval England and is now the most widely used language in the world. It is spoken as a first language by the majority populations of several sovereign states, including the United Kingdom, the United States, Canada, Australia, Ireland, New Zealand and a number of Caribbean nations. It is the third-most-common native language in the world, after Mandarin Chinese and Spanish. It is widely learned as a second language and is an official language of the European Union, many Commonwealth countries and the United Nations, as well

Figure 3: Language Landscape map of the English language

We believe that given a critical mass of contributors, the website could become a useful tool for a range of potential audiences. Contributions are currently skewed towards places where digital infrastructure is well established. However, technological advances mean that in 5-10 years the network will be available to more people. Resources like our website, which concentrate on promoting audio and video content in minority languages, will play a crucial role in convincing new users that the internet is a useful and valuable tool for communicating remotely.

In order to encourage more contributions, we target students who have expressed an interest in languages through their course choices. We have helped university students in London, Croatia, Germany and Poland to run projects, and have run outreach projects with 12-13 year olds in a school in East London. Promotion of the site on social media has also resulted in members of the public contributing recordings to the site.

We hope that the website will contribute to efforts to increase the number of languages and cultures currently represented on the web. We want to provide a platform where people feel comfortable representing their own language and culture in the way they see fit, rather than feeling compelled to participate in one of the dominant cultural forms which make up so much online content (e.g. Kornai, 2013).

At the Sussex Humanities Lab we are building collaborations and networks to support and develop new forms of digital humanities. Our vision is to ensure that information scientists, literary theorists, media scholars, designers, practitioners, technologists, philosophers, social scientists and historians collaborate to serve the fundamental roles of humanities research. Sussex Humanities Lab builds on a long standing interdisciplinary culture at Sussex and is developing a programme that considers our digital past and digital futures. This is reflected in our four guiding research strands:

- Digital History and Digital Archives
- Digital Media and Computational Culture
- Digital Lives, Memory and Experience
- Digital Technologies and Digital Performance.

Comprising a team of lecturers, research fellows, PhD students, technicians, and senior faculty, we are interested in developing new research areas across our multi-disciplinary team. Each strand reflects the seed initiatives of the Lab and are a starting point for our research journey. We are dedicated to developing and expanding research into how digital technologies are shaping our culture and society, as well as the way we go about our research. To this end we are developing a number of research projects, grants and network bids. Examples of our current research include:

- **Playing Tag: Identifying Emotion in Oral History Collections:** Although large collections of video and audio files recording oral history testimony have been collected, archived, and aggregated in digital formats, the way we use these files remains largely analogue: We sit and listen and watch them. Research methods from other fields have great potential for the automatic analyses of emotions from postural movements and vocal inflections. By bringing together scholars from the field of oral history and the histories of emotion, social scientists using interview methodologies, sonic and video studies, corpus linguistics, and linguistic anthropology, this research lays the foundations for a new approach to the analyses of oral history collections.
- **Automation Anxiety:** This research explores methods by which the humanities might evaluate contemporary cultural anxiety about automation. From self-driving cars, through high-frequency trading to military drones and organised swarms of shelf-stacking robots, our era is marked by a fascination with a fresh wave of automation technology. This new "rise of the machines" is characterised by the replacement of human decision making with reliance on algorithms, machine learning and other computational techniques whose fitness for purpose cannot be clearly understood by those whose lives they affect (Carr, 2014). The focus of this research is on the cultural anxiety associated with these new technologies and we seek to develop methods, approaches and tools that might be used to analyse and understand it. The question of method is particularly pertinent given that the humanities are themselves being automated. Indeed the debates around digital humanities reproduce much of the anxiety around automation itself. This research addresses the way in which, to paraphrase Ruppert, Law and Savage (2013), automation is increasingly both the *material* of culture and the apparatus for *knowing* that culture.
- **Sonic Ecologies and Socialities:** This research brings together new understandings of how we sensorially engage with sound across digitally mediated bodies and computational environments. Our research is inspired by an eclectic range of perspectives, from performance studies and musicology (Coyne, 2010) to neuroscience, philosophy, sensory ethnography and digital aesthetics (Back 2007; Bidelman and Krishnan, 2009; Fazi and Fuller forthcoming). Common concerns amongst these perspectives are: (1) new modes of sensory perception, the sonic mediation of experience, and the possibility of algorithmically addressing such modes and mediations, (2) the augmentation of bodies and sensory methods for tracing and capturing soundscapes, and (3) new performative and compositional methods for creating and curating soundscapes that incite alternative politics of sensing.

Other activities of the Lab include: visiting fellows scheme, workshops and seminar series.

Textual Communities

Peter Robinson
peter.robinson@usask.ca
University of Saskatchewan, Canada

Barbara Bordalejo
barbara.bordalejo@arts.kuleuven.be
KU Leuven, Belgium

This poster presents the public version of the Textual Communities scholarly editing environment, describing its underlying principles, its innovative structure, and its functionality. It updates the presentation of Textual Communities given as a poster at DH 2013 in Lincoln, Nebraska.

Study of literary works that exist in many different forms is one of the most important and difficult tasks in the humanities. The number of forms a work may have —eighty-four fifteenth-century manuscripts and printed texts of Chaucer's Canterbury Tales, more than eight hundred manuscripts of Dante's Commedia, and five thousand manuscripts of the Greek New Testament — is both testimony to their significance and a challenge to scholars. In order to understand these texts and how they relate, we have to discover as much as we can of how they came to be written and disseminated. Only then can we seek to establish how they might best be read and prepare texts (in the form of scholarly editions) for scholars to use. The work of building archives of primary materials for this work is daunting and prohibitive in the old lone scholar method. Many large editing projects have opted for a team approach, exploring the possibilities of crowd-sourcing for processing large amounts of textual data. The challenge is to coordinate this work in a way that produces high-quality, useful results. The Textual Communities workspace enables every aspect of the scholarly process: defining, transcribing, and linking textual materials for a digital archive or edition; collating the witnesses and adjusting the collation for optimal scholarly use; analyzing the results of the collation to create an understanding of the relations among the manuscripts; and for marshaling and managing a community of participants with an array of community building tools.

There are many editorial tools under development and a few that are already functional. There are two defining features that make Textual Communities different from the rest: its integrated participant and document management systems, and its mapping of fundamental document-entity structure. These features correspond to two underlying principles: that the work of amassing large corpora of textual materials is best accomplished by a well-managed community of interested participants from within, but also potentially from outside the academy; and that for the resulting materials to be useful, their relationships must be clearly articulated.

As its name suggests, Textual Communities is designed for gathering and organizing multiple participants around a common editorial project. It supports a wide range of relational structures, from a carefully crafted team to ad hoc community built on crowd-sourcing. Crucially, it enables definition of roles in the project with varying degrees of access to project materials and of authority to do the work of processing these materials, and oversight over other participants. It is also built on an ontology of text, document and communicative act to identify and relate the produced transcriptions ("texts"), the exemplars they derived from ("documents," usually in the form of a digital image of a particular witness), and the intellectual construct they instantiate (the communicative act or "work", or our preferred term, "entity"). Thus anyone interested in John Donne's poem "The Good Morrow" will find various "texts" (transcriptions) of this work as found in the extant "documents" (the poem as it is found in each of the manuscripts and printed books that contain it).

Textual Communities itself enables uploading of digital images of primary and linkage of these images with a transcription space. The user supplies information for each document, which defines the text that is to be transcribed and its relationship to the source document and entity. The user also defines the structure of the document, which is rendered behind the visible transcription in TEI conformant XML. The transcription area, which is automatically linked to the source image, can also support any XML markup that is desired or required for intelligent transcription of the source document. The collation area (based on CollateX) offers full regularization and editing facilities, to enable creation of optimal collations for scholarly use.

This open-source tool is available free of charge for use and adaptation by anyone anywhere. Development of this tool is funded by a generous grant from the Canadian Foundation for Innovation with the support of the Digital Research Centre at the University of Saskatchewan.

This poster will be accompanied by a live demonstration of the editorial workspace.

Multivalent reuse of web data about temporary art exhibitions: the Exhibitium project

Nuria Rodríguez-Ortega

Our proposal aims to display the analysis techniques, methodologies as well as the most relevant results expected within the Exhibitium project framework (http://www.exhibitium.com). Awarded by the BBVA Foundation, the Exhibitium project is being developed by an international consortium of several research groups [1]. Its main purpose is to build a comprehensive and structured data repository about temporary art exhibitions, captured from the web, to make them useful and reusable in various domains through open and interoperable data systems.

The Exhibitium project aims to face the new challenges posed by the data-driven society respect to the production, management, use and distribution of digital cultural content. Specifically, the question that we want to respond is: how to take advantages of the universe of data related to cultural activity distributed through the Internet to generate value at very different levels (academic research, new critical narratives, cultural management, economic development, processes of social and cultural transformation, etc.)? Accordingly, multivalency, as a key notion of the new knowledge economy (Roney et al., 2012), is the guiding axis of the Exhibitium project.

To think on a precise working prototype, we have adopted as a central object of our research the art exhibitions that regularly held galleries, museums and art centers, since they produce a very large and heterogeneous set of data that can potentially be captured by means of web mining strategies.

For that, we have developed a technology infrastructure, which has been implemented in two dimensions:

a) A computing prototype consists of two modules operating in a complementary manner: Beagle, an automated data capture system which extracts information about art exhibitions from any web source; and ExpoFinder, a system for collecting and enhancing the information captured by Beagle (http://www.expofinder.es).

b. An aggregate of three data analysis and visualization platforms (SylvaDB, Techne Coword © and Geowave), which connect with the Beagle-ExpoFinder system using an automated export application [2]. (See in figure 1 a simplified diagram of the system).

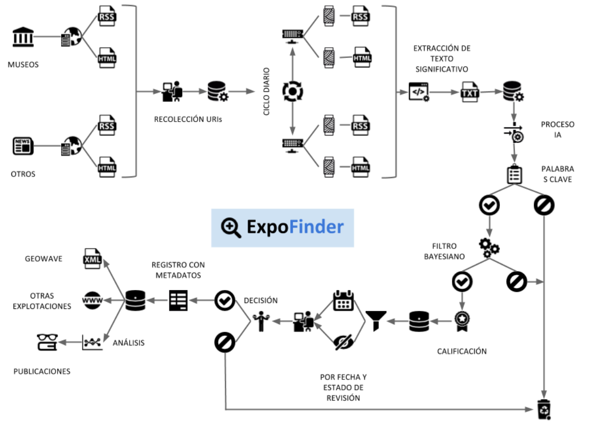

Figure 1. Simpiflied schema and flowchart

As regards the theoretical framework, Exhibitium faces the phenomenon of art exhibitions according to the actor-network theory (ANT) developed by Bruno Latour (2007), that is say, as complex cultural phenomena resulting from of a series of relationships established between heterogeneous human and no human actors -artists, curators, exhibition centers, funding agencies, publishing companies, artistic movements, artistic themes, etc.- that constitute dynamic networks among them. The application of the actor-network theory to the field of art exhibitions raises an interesting perspective, since the emphasis, rather than on the exhibitions themselves, is placed on the «mediation» processes (production, distribution, reception, etc.) as part of a social system in which the power relations that characterize the cultural institutions are unveiled.

Consequently, the Exhibitium project aligns with the growing research field oriented to explore complex networks in art and humanities (Schich, 2014). Particularly, we are using two types of methodologies.

a) Network analysis strategies through a graph database (SylvaDB) that we have structured according to an ontology specifically developed for the project (see figure 2).

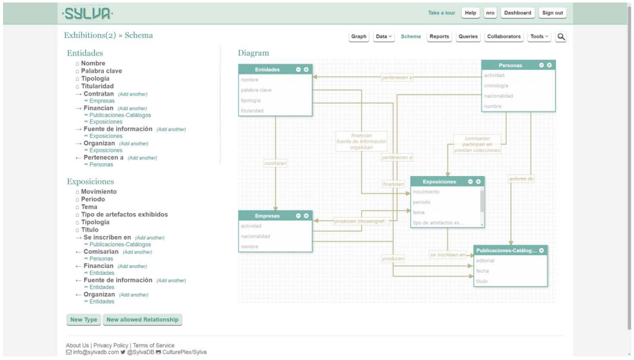

Figure 2. Ontology of the "temporary art exhibition" domain in the SylvaDB interface

b) KDD (Knowledge Discovery in Databases) techniques, specially the co-word analysis strategy (He, 1999) [3], which are mainly oriented to the discovery of implicit knowledge in large repositories of structured data (Echevarría and González, 2009; Rodríguez Ortega et al, 2015).

Through these analyses we are getting a set of graphs that is allowing us to discover correlations between certain artists, centers, curators, financing institutions, themes and geo-spatial contexts. Note that the configuration of clusters of this nature, understood as network of strong relationships established between their nodes, can be read as power structures operant in a certain domain.

The conceptual and methodological differences existing between the co-word analysis strategy, which extracts the actors and their relationships directly from the data processing, and the network analysis strategy, based on a scheme previously established (ontology) that derives from our direct observation of the real world, it is allowing us to make interesting comparisons between how we understand the domain "art exhibitions" and what (implicit) structure emerges naturally from the processing of the keywords associated to this field.

Along with this knowledge -key to develop new critical narratives-, the discovery of certain patterns is also providing a prospective knowledge about possible and future trends in the field of temporary art exhibitions, which can be strategically used by exhibition centers or other stakeholders (tourism companies, entertainment industries, etc.) in their decision-making processes.

In addition, these methods of analysis are allowing us to investigate the peripheries that are also associated to the field of art exhibitions as a result of the prevalence of some institutions which centralize the flow of public among other things due to their media impact capacity. To facilitate the social visibility of those initiatives usually unknown we are proceeding to integrate the Exhibitium data in the Geowave system, a georeferenced platform to manage cultural content.

Notes

[1] They are: iArtHis_Lab (http://www.iarthislab.es) and Khaos (http://khaos.uma.es) at the University of Málaga; Techne, ingeniería del conocimiento y del producto (http://www.ugr.es/~tepo28/quienes_somos_es.php) at the University of Granada; and CulturePlex at the University of Western Ontario (http://www.cultureplex.ca).

[2] Since the nature of this text does not allow us to provide a detailed explanation of such system, we suggest to see the site http://admin.expofinder.es/test/xmlrpc/ [Viewed: 28/10/2015].

[3] The co-word strategy is based on a basic principle: all actors in a network, regardless of their nature, can be represented by words or descriptors (actually, this is how the data are represented mostly in bibliographic repositories). Natural relations of co-occurrence of words in data repositories form a network that can be analyzed and mapped. The words that co-occur more frequently form clusters that can be analyzed as networks with strong links; at the same time, it is possible to analyze how these networks change throughout different periods of times or geo-spatial contexts. For example, we can analyze how the network generated by an artist (i.e., Picasso) changes according to the geographical provenance of the data (exhibitions in Spain, Europe, USA, Latin America, etc.).

tara.andrews@kps.unibe.ch
Universität Bern, Switzerland

In the last few years, several of the bodies that govern higher education and research in Switzerland – the swissuniversities council, the Swiss National Science Foundation (SNF), and the Swiss Academy of Humanities and Social Sciences (SAGW) – have placed an increasing focus on the importance of appropriate and sustainable handling research data, and in particular research data in the humanities. As ever more research in the humanities includes collections of digital data, these Swiss bodies are putting a significant investment into building an infrastructure capable of maintaining it. Against this background, the SNF has begun to focus in particular on the scholarly text edition; beginning in 2017, all SNF-funded edition projects are expected to be digital and to contain some strategy for long-term preservation (Swiss National Science Foundation, 2015). One of the purposes of the SNF-funded project "The Chronicle of Matthew of Edessa Online" is to experiment with forms of digital critical edition of texts that can be preserved and maintained in the long term.

The Chronicle is an Armenian-language historical work, written in the early 12th century, covering nearly two centuries' worth of the history of the medieval Near East, up to and including the establishment of the Crusader County of Edessa. The text survives in at least 35 manuscript copies, all from 1590 or later. Digital methods have been used since the beginning of the edition work in 2008; this includes full transcriptions of the individual manuscripts in a TEI-compatible markup system, automatic collation of the textual variants, computer-assisted stemmatic analysis, and systematic editorial analysis of the variant texts (Andrews, 2009). Since the work began, however, there has been significant progress in thought about how to represent textual variants in digital space, most particularly with the adoption of the variant graph (Andrews, 2014; Dekker, Hulle, Middell, Neyt, and Zundert, 2014; Jänicke, Geßner, Büchler, and Scheuermann, 2014; Schmidt and Colomb, 2009).

In this poster session we will demonstrate the ways in which, beginning with the variant graph concept, we are implementing all aspects of the edition in a graph database model – the textual collation itself, analysis of the manuscripts and stemmata, the identification of events, timelines, persons, and places that normally occupies much of the commentary of the edition, and the annotations that together with these identifications will comprise the full commentary. Since it is a graph, the data becomes straightforward to transform directly into the Resource Description Framework (RDF) required for compatibility with the SALSAH database provided by the SAGW-funded Data and Service Centre for the Humanities, which is the nascent repository for all humanities research data within Switzerland and guarantees long-term API-addressable accessibility to the data itself (Rosenthaler, Fornaro, and Clivaz, 2014). Moreover, in the construction of the graph model we draw upon relevant sets of standards and tools, such as the TEI Guidelines (http://www.tei-c.org/) for description of the textual features, CIDOC-CRM (http://www.cidoc-crm.org/) to express information about the documents as objects and for notations of time and place in a manner suitable to use with tools such as Topotime (Grossner and Meeks, 2014). We are also participating in the DARIAH-DE Working Group on Digital Annotations in order to ensure that our working methods are methodologically and practically compatible with best practice in humanities research.

The result of the project will be a digital edition whose constructed text, scholarly commentary, and individual manuscript witnesses will be fully accessible through a machine-queryable API. The web user interface will be built entirely on this API; in that way, no intellectual content will be embedded in the interface, only to be eventually lost when or if the interface disappears. The manuscript texts and a version of the edition itself will be available to download in TEI and ePub formats, for print consumption, archiving, or further offline analysis.

Development of a Support Tool for Categorizing Ukiyo-e's Pictorial Themes: A System to Deal with Visual Features and Similarities

Shinya Saito
saitos@fc.ritsumei.ac.jp

Keiko Suzuki
suzukik@fc.ritsumei.ac.jp
Ritsumeikan University, Japan

I. Introduction

This research aims at supporting categorization of ukiyo-e (Japanese woodblock prints) by developing an original, data-visualization system. As a part of the system development, this case study focuses on the prints' visual features—how the system can help analyzing them by simulating the analytical process. Our investigation of the ukiyo-e research's process helps us identifying what the researchers actually need to know and how to deal with it.

II. Research process

For developing the system, we take an example of pictorial theme of "Otohime," who is these days explained as a mythical princess, living in Ryugu or the Dragon Palace at the bottom of the sea. Princess Otohime or comparable others related to the Dragon Palace have appeared in many stories with versions and variants through history, whose prolificness their ukiyo-e imagery reflect. Thus, we need to pay our attention to this kind of pictorial themes' extensibility in intertextuality, or in this case, inter-imagery, by which one image refers to, exploits, or recycles another. For comparing and analyzing the heroin's visual features thoroughly, the following 9 visual features of hers are chosen as indexes: 1. headdress; 2. hairstyle; 3. frills; 4. scarf; 5. Chinese fan; 6. Chinese-style clothes; 7. collar; 8. apron; and 9. Urashima. Checking the indexes leads researchers to understand the degree of similarity in different ukiyo-e prints, and generate hypotheses about what kinds of factors affect specific ukiyo-e production as well as historical changes in Otohime's overall imagery.

III. System development

Recently, data visualization, both its technology applicable for many fields and methodology, has been systematically developed (Mazza and Berre, 2007; Tufte, 1983). In order to pursue the above-mentioned purpose, we are developing the SALOMONIS system (Fig.1) which can load an ukiyo-e dataset encoded in JSON (JavaScript Object Notation) format. The following list shows how SALOMONIS visualizes the data.

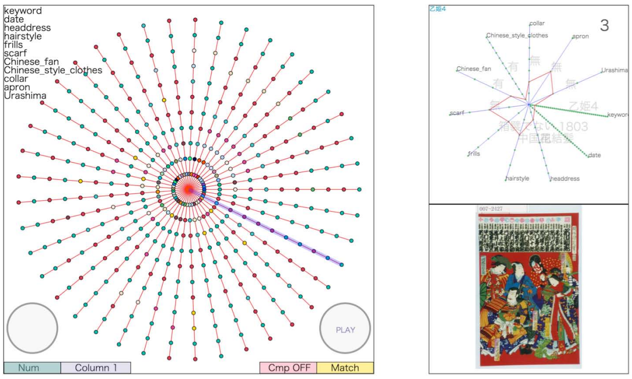

Fig. 1. Layout chart of SALOMONIS

A. Entire dataset and records

In the system, a record is visualized as a line, each of which is arranged in a radial manner. As a result, SALOMONIS visualizes the records, i.e., the entire dataset, as a circle (Fig.2).

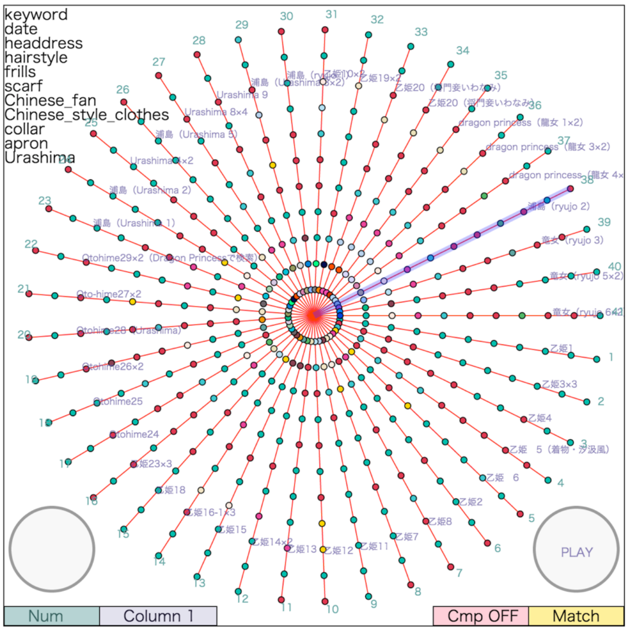

Fig. 2. Visualization of entire dataset

B. Columns

As mentioned above, a line indicates a record, and each record includes columns that correspond to indexes. Our system visualizes columns as dots, plotted on the line. Each color of the dots indicates different value of the column.

In the case of the Otohime dataset, it has 41 records and 11 columns with 9 visual features and the print's production year and keyword. Therefore, 41 lines are arranged, each of which has 11 dots (Fig.3).

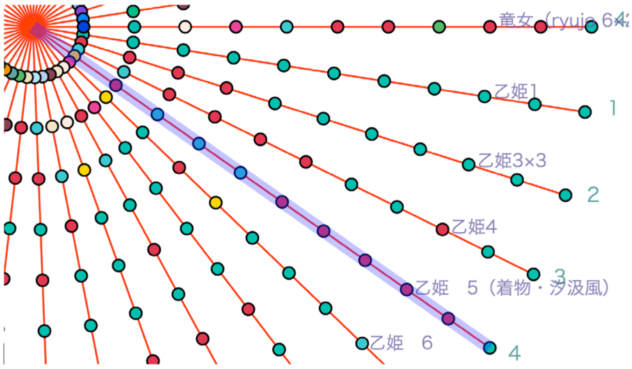

Fig. 3. Visualization of columns

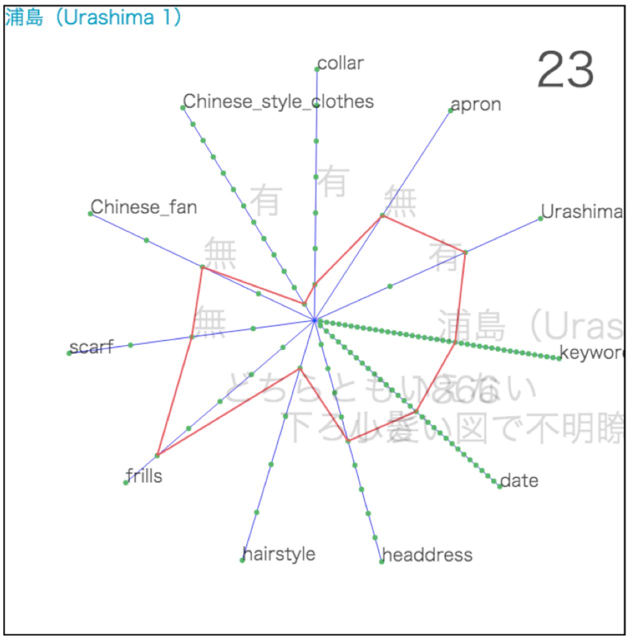
C. Interactive function

As each line is linked to an ukiyo-e print, when the user puts the mouse cursor on a certain line, a chart appears with its corresponding ukiyo-e's 9 visual features plus its production year and keyword, mentioned on the above (Fig.4). Using this interactive function, the user can compare ukiyo-e in a speedy and accurate manner.



>Fig. 4. Chart that indicates ukiyo-e's features

D. Similarity-screening function

When the user chooses one ukiyo-e as a reference point, then pushing the "Play" button, the system starts automatically screening how the other ukiyo-e are similar or not to the chosen one. Depending upon the degree of the similarity, lines of the ukiyo-e appear highlighted with colors. For example, when one ukiyo-e shares 80 percent or more similarity with the chosen one in terms of the visual features, the line appears in orange. In the case of 60 percent or more, green; 40 percent or more, yellow; and 20 percent or more, red (Fig.5).

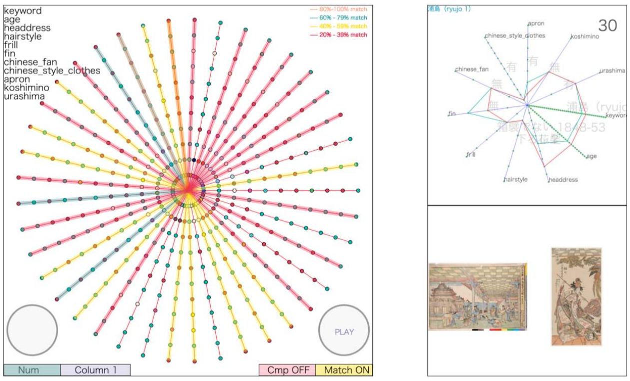


Fig. 5. Similarity-screening function

E. Visual Sort function

Furthermore, this system has visual sort function. Using this, all records are sorted based on the similarity in a radial manner.

IV. Discussion

The system proved its efficiency as it not only saved the time for the analyses but also suggests new ways to think about the prints. Right now, however, we are still in the developing stage, planning to test the system by applying it for more cases.

Das von der Deutschen Forschungsgemeinschaft (DFG) geförderte Projekt eComparatio wird seit 2014 als Kooperationsprojekt des Lehrstuhls für Alte Geschichte der Universität Leipzig und des ICE (Interdisciplinary Center of E-Humanities in History and Social Sciences/ Forschungsstelle am Max-Weber-Kolleg für kultur- und sozialwissenschaftliche Studien an der Universität Erfurt) entwickelt. Das Kernstück der Anwendung ist ein Modul zum Vergleich von Textausgaben, das auch die Erstellung eines Variantenapparates für digitale Editionen antiker Autoren ermöglicht. Die Zahl der Vergleichstexte ist beliebig, ebenso das Eingabeformat (TXT, HTML, XML, JSON, PDF). Die Anwendung wird frei skalierbar sein, so dass der Umfang der zu vergleichenden Texte nicht beschränkt ist. Das Ergebnis (Kollationierung) soll in Form von Listen als Apparat (positiver oder negativer Apparat) oder auch in beliebiger anderer Form ausgegeben werden können. In einem weiteren Modul ist für Autorenreferenzen bei der Abfrage von online-Datenbanken die Anbindung an das Referenzsystem CTS (Canonical Text Services) ermöglicht worden. Im bisherigen Verlauf des Projektes ist es gelungen, die Grundfunktionen des Tools zu implementieren und es in die Lage zu versetzen eine beliebig große Anzahl an Texten miteinander zu vergleichen. Dabei sind drei unterschiedliche Ansichten entstanden, die es dem Benutzer ermöglichen, das Ergebnis aus verschiedenen Perspektiven zu betrachten. Die Detailansicht zeigt einen Text und markiert entsprechende Unterschiede zu anderen Texten. Die Parallelansicht (siehe auch Abbildung) zeigt alle Texte nebeneinander und markiert die Unterschiede farbig. Die Buchansicht schließlich zeigt wieder nur einen Text an und visualisiert die Varianten im Stile traditioneller Printeditionen unter dem betreffenden Abschnitt. Zu betonen ist dabei, dass der Ausgangstext für den Vergleich bei jeder Ansicht frei wählbar ist und sich somit nicht auf einen zu bevorzugenden Haupttext festgelegt bzw. eine Gewichtung der Textzeugen vorgenommen wird.

Die Visualisierung und Ergebnissicherung ermöglicht zum einen, einen schnellen Überblick über die Text- und Editionsgeschichte verschiedener in digitalisierter Form vorliegender Werke zu erlangen. Darüber hinaus eignet sich das Tool als Hilfsmittel zum Kollationieren bei der Erstellung beliebiger kritischer, historischer bzw. genetischer Editionen.

Im Rahmen zweier Folgeprojekte in Kooperation mit Prof. Christopher Blackwell von der Furman University in Greenville, SC, von denen eines sich derzeit (Stand: Oktober 2015) in der Antragsphase (DFG) befindet und das andere bereits bewilligt worden ist (Andrew W. Mellon-Foundation), wird zunächst auf Basis einer Kooperation mit dem De Gruyter-Verlag und der durch ihn bereitgestellten digitalen Ausgabe der Bibliotheca Teubneriana Latina Online die Basis für eine kanonische CTS-Referenzierung geschaffen. Auf dieser Grundlage wird das eComparatio-Vergleichstool dazu dienen, sämtliche digital zur Verfügung stehenden Exemplare eines Textes durch eine CTS-Anfrage zu vergleichen, zu visualisieren und für die Ergebnisse die jeweiligen Textpassagen auch mit einer maschinenlesbaren Referenzierung zu versehen. Ein solches Verfahren kann dabei als wesentlicher Schritt der Qualitätssicherung der digitalen Datengrundlage an sich angesehen werden. Gerade im Falle der Altertumswissenschaften, in denen bereits früh umfangreiche, abgeschlossene Korpora (TLG, BTL u.a.) vorlagen, ist ein nächster Schritt ein Ausbau dieser Datengrundlagen in die Tiefe, d.h. hinsichtlich der zahlreichen verschiedenen Editionen und Textausgaben.

Darüber hinaus wird in einem USE-Case am Beispiel der Periklesvita des Plutarch in Verbindung mit der Zitationsanalyse aus dem von 2008-2013 durch das BMBF geförderten Projekts eAQUA des Lehrstuhls für Alte Geschichte der Universität Leipzig ein praktisches Beispiel gegeben, inwiefern CITE/CTS als Grundlage einer neuen Form des Annotierens und Kommentierens dienen kann:

Der Zitatonsgraph dient zur automatischen Erstellung eines Testimonien-, eComparatio zur Erstellung eines Variantenapparates. Das Verhältnis der verschiedenen Texte zueinander (Varianten des Haupttextes und der enthaltenen Fragmente/Zitate/Parallelstellen) soll darüber hinaus durch die im Rahmen des Projektes von den amerikanischen Projektpartnern entwickelten Erweiterung Canonical Graph Services (CGS) visualisiert werden.

Nach seiner Fertigstellung wird das Tool als freier Webservice für Forschung und Lehre zur Verfügung gestellt. Davon können Handschriften-Digitalisierungsprojekte, Editionsprojekte sowie Projekte profitieren, die sich Spezialfragen einzelner Textpassagen widmen; es ist auch für Seminararbeiten, d.h. den Einsatz in der Lehre geeignet, da es sowohl von Nicht-Editionsphilologen als auch von Editionsphilologen eingesetzt werden kann.

Da es sich bei dem Tool in erster Linie um ein Mittel zur Visualisierung handelt, ist es in hohem Maße für die Präsentation in Form eines Posters geeignet. Geplant ist die Darstellung des gesamten Workflows anhand eines Beispiels, von der Eingabe unstrukturierter Textdokumente bis hin zu den drei oben genannten Visualisierungsformen sowie erster Ergebnisse der begonnenen Folgeprojekte.

Introduction

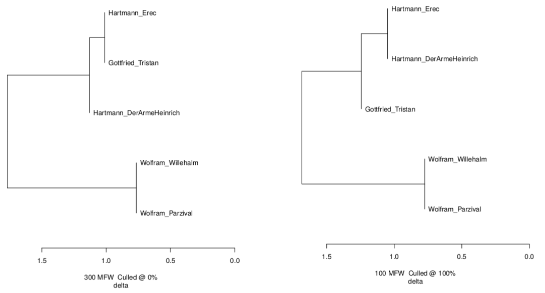
In this paper, we describe computer-aided authorship testing on the Middle High German (MHG) text *Apollonius von Tyrland* written by Heinrich von Neustadt (HvN) in the late 13th century. Being based on a Latin original, HvN is suspected to incorporate other sources into the translation. We investigate assumptions regarding a segmentation of this text into parts supposedly tracking back to different sources. Our objective is it to provide a) clarification on the validity of this segmentation and b) on features that show the difference in origin of the segments. In particular, we distinguish between features related to content and to style.

Contents and Style

Comparing frequency distributions over frequent words has been established as a state of the art method for contrasting style across different literary texts (cf. Eder et al. (2013)). Quite recently, (Herrmann et al., 2015) proposed to define style as a property constituted by "formal features which can be observed quantitatively or qualitatively" (p. 44). An important aspect of it is that style has to be based on observable features.

We propose to make a clear cut between content and style: To measure stylistic differences, we restrict the selection to words appearing in every text of the corpus, thus are observable in each text, assuming that this is a simple way to exclude words that are markers of content. Content words (that presumably only appear in a subset of the texts) do not contribute to this understanding of style. They, in contrast, are extracted by filtering the MFW with a stop word list containing all the function words in a language. We refer to the sets of feature words extracted for a text with **content words** and **style words**.

To validate this idea, we analyse five MHG texts by three authors with the R stylo package (Eder, 2013). Figure 1 shows results for the content (a) and style (b) words. The higher similarity of *Erec* and *Tristan* in (a) compared to *Der arme Heinrich* reflects that both narratives feature knighthood as a main theme. In contrast, the narrative in *Der Arme Heinrich* involves more religious themes (faith, god), which is also reflected in the frequency tables. This distinction is clearly based on content. If we focus our analysis on style words, as in (b), we see the clustering according to authors. Thus, distinguishing frequent words of a corpus in style and content words can give us better insights into the results.



(a) Clustering analysis using content words.

(b) Clustering analysis using style words.

Figure 1: Comparison of different groups of high frequent words and their performance on a clustering task on MHG text by three different authors. Due to largely uniform editing of MHG text in the 19th century, normalisation can be neglected (Kragl, 2015).

Dissecting Heinrich von Neustadt: Apollonius

Nr.	Verses	Origin
1	1-2,905	Latin original
2	2,906-15,118	Insertion
3	15,119-17,382	Latin original
4	17,383-20,589	Insertion

Table 1: Partition of Apollonius according to Bockhoff and Singer (1911).

Nr.	Verses	Title
1	2920-4126	The fight with Gog and Magog
2	4126-6068	The adventures in Galacites
3	6069-7186	The duel in Syria and the Robinson Island
4	7187-10594	Bulgare war and imprisonment in Nemrot
5	10595-13512	The adventures in Chrysa
6	13517-14929	The return to Tarsus
7	17282-20639	Closing

Table 2: Subparts identified in the third section of Apollonius, identified by Bockhoff and Singer (1911).

Bockhoff and Singer (1911) formulated two hypotheses regarding the internal structure and origin of the ca. 21K verses long text, regarding both the overall structure (Table 1) and the internal structure of one segment (Table 2). To get an impression of which paragraphs can indeed be found as a distinctive group using content words and style words respectively, we split the text into 71 segments of equal length. These segments are then clustered with Stylo, using delta as a similarity measure.

Our baseline consists of randomly assigning distances between the segments, drawn from a uniform distribution. We sample baseline results 1000 times. The baseline results give an impression on how well an uninformed method overlaps with the hypothesis classification introduced in Section 3. Comparing these to the results of our methods can inform us on which method goes in line with the hypothesis as opposed to a random classification.

Features	Part	Recall		Precision		F-score	
		BL	CA	BL	CA	BL	CA
Content words	Historia Apollonii 1	0.46	0.56	0.19	0.4	0.19	0.47
	Adventure	0.33	0.23	0.66	1.0	0.44	0.37
	Historia Apollonii 2	0.30	0.88	0.16	0.44	0.21	0.59
	Final apotheosis	0.19	0.45	0.17	0.25	0.18	0.32
Style words	Historia Apollonii 1	0.46	0.56	0.19	0.21	0.19	0.31
	Adventure	0.33	0.28	0.66	0.92	0.44	0.43
	Historia Apollonii 2	0.30	0.75	0.16	0.33	0.21	0.46
	Final apotheosis	0.19	0.72	0.17	0.5	0.18	0.67

Table 3: Results of the clustering analysis for style and content words respectively regarding the overall structure hypothesis of Apollonius. Since clustering methods do not provide class labels for an evaluation of the performance with respect to precision, recall and F-score, we need to map the clusters onto the parts of the hypothesis. This is done manually in such a way that F-score is maximised. BL: Baseline, CA: Cluster Analysis.

Regarding the first hypothesis (Table 3), we observe that for both feature sets the F-score lies above the baseline for all parts except the third. This seems reasonable since this part is suspected to be based on different sources and therefore might be more heterogeneous both in content and in style. Style seems to be more homogeneous (F-Score above baseline) throughout the entire text whereas content seems to be heterogeneous especially in the adventure part introduced by HvN (F-Score below baseline). This is in line with the hypothesis, considering that HvN's insertions report on different adventures.

Features	Part	Recall		Precision		F-score	
		BL	CA	BL	CA	BL	CA
content words	The fight with Gog and Magog	0.43	0.75	0.26	0.6	0.32	0.67
	The adventures in Galacites	0.36	0.50	0.32	0.5	0.34	0.5
	The duel in Syria	0.39	0.25	0.25	0.11	0.31	0.15
	Bulgare war	0.26	0.33	0.48	0.8	0.33	0.46
	The adventures in Chrysa	0.24	0.5	0.43	0.71	0.31	0.59
	The return to Tarsus	0.25	0.83	0.3	0.71	0.29	0.77
style words	The fight with Gog and Magog	0.43	0.75	0.26	0.375	0.32	0.5
	The adventures in Galacites	0.36	0.25	0.32	0.25	0.34	0.25
	The duel in Syria	0.39	0.5	0.25	0.33	0.31	0.4
	Bulgare war	0.26	0.5	0.48	0.46	0.33	0.48
	The adventures in Chrysa	0.24	0.4	0.43	0.67	0.31	0.5
	The return to Tarsus	0.25	0.33	0.3	0.4	0.29	0.36

Table 4: Results of the clustering analysis for style and content words respectively regarding structure of the parts of Apollonius attributed to Heinrich von Neustadt. Final part has been removed from the discussion due to its short length.

Analysing these heterogeneous parts further (second hypothesis, Table 4), we see heterogeneity in terms of content for all but one part, *The duel in Syria*. *The duel in Syria* seems homogeneous in style whereas *The adventures in Galacites* shows tendencies towards a heterogeneous style.

Conclusion

Both feature sets show similar tendencies and support a major part of the hypotheses by Bockhoff and Singer (1911) regarding parts suspected as insertions. Nevertheless, differences in content cannot clearly confirm the suspicion that HvN incorporated other sources. He might have created additional adventures by himself. Bockhoff and Singer (1911) do not cite sources from which HvN copied narratives, making it difficult to tackle exactly. Overall differences in style are much less significant than differences in content, which is in line with the hypothesis.

You Better Monetize! Monetization Strategies in Publishing and Disseminating Digital Scholarly Editions

Anna-Maria Sichani
anna-maria.sichani@huygens.knaw.nl
Huygens ING- KNAW / DiXiT, Netherlands, The

Aodhán Kelly

University of Antwerp / DiXiT

The digital scholarly edition is an academic product that attempts to remediate the theory and practice of print-based textual scholarship with computational methodologies. Although a vast amount of scholarly exertion is directed towards the exploration of digital editing as a scholarly enterprise (concepts, standards, technologies), significant discussions of sustainable models for publishing and disseminating the digital edition are rather infrequent. Such a practice could be explained mainly because digital editions are often developed as multi-institutional projects based on short-period funding and often every development and financial planning stops by the end of the funding period. Furthermore, as publication and distribution were procedures originally carried out by publishing houses, scholars and editors now find themselves ill-equipped and unprepared in coordinating such strategies. On the other hand, Open Access rhetoric advocating for "freely used, modified, and shared" scholarly content, put constantly into question principles of revenue generation strategies and their application.

In digital scholarship, there is obviously a cost for creating and maintaining a scholarly resource in the long-term. If these costs are not covered by a grant or by the institution, then the project must design and implement some sort of financial plan to cover it. This cost is not always treated as a price covered by the demand side (audience) or as a means to make profit - unlike in the world of commerce and publishing. It might, thus, be useful to re-think in what ways 'price' and 'value' could become interconnected in the web era. Such discussions around economic models were evident in the GLAM sector since the advent of the web, but have yet to become a major discussion in scholarly editing circles.

We would like to situate our exploratory approach within a broader discussion that challenges our traditional ideas towards the completion, publication, dissemination and sustainability of digital editions. Specifically, we will focus on economic models or monetization strategies as integral parts of a sustainability plan while embracing a strong Open Access ethos. How can we enrich the still burgeoning field of digital editing by contemplating the commodification and sustainability of our published scholarly outputs, by exploring current practices used in web publishing and e-commerce?

This research attempts to offer a state-of-the-art of current trends and business models strategies of distribution of digital content: subscription models and related price discrimination and audience segmentation principles, freemium and lite versions, referral discounts, value-added and tiered services, digital marketing, online advertising, derivatives, multimodal and customised formats for diverse purposes and audiences, etc. Our approach proposes a modular - in a "mix 'n' match" style - strategy for the monetisation of scholarly editions for their post-publication life, in which agents of digital editing projects could choose, combine and customize monetisation solutions for their digital scholarly editions in order to secure their sustainable future and impact in the long-term.

Corpus of Ioannes Dantiscus' Texts and Correspondence dantiscus.al.uw.edu.pl

Anna Skolimowska
annaskolimowska@gmail.com
University of Warsaw, Poland

Ioannes Dantiscus (1485–1548) was a humanist, author of neo-Latin poems, outstanding diplomat in the service of Polish King Sigismund I Jagiellon and Queen Bona Sforza, and then the Senator of the Polish Kingdom as the Bishop of Kulm (1530/33–1537) and Ermland (1537–1548). The final office was also connected with the post of president of the Royal Prussian Council.

Dantiscus' correspondence forms the largest collection of letters (over 6,000) in Central-Eastern Europe, related to the Polish royal court and its partners across the world during that period. Among Dantiscus' 656 correspondents we find rulers, politicians, knights, banquers, humanists and scholars, including especially Nicolaus Copernicus and Erasmus of Rotterdam.

The project "Registration and Publication of the Correspondence of Ioannes Dantiscus", carried out over nearly thirty years at the University of Warsaw (Laboratory for Editing Sources, Faculty of "Artes Liberales"), currently includes two elements:

1. Traditional print publication of the series **Corpus Epistularum Ioannis Dantisci** (appearing in print since 2004 in editorial collaboration between the University of Warsaw and the Polish Academy of Arts and Sciences in Cracow; seven volumes have appeared to date, including three volumes of source texts, two volumes of inventories, and two volumes of studies and commentaries.)

2. Web publication entitled **Corpus of Ioannes Dantiscus Texts and Correspondence** (letters, poems, diplomatic memorials, envoy's speeches and records), dantiscus.al.uw.edu.pl, first published in July 1, 2010.

The "Corpus of Ioannes Dantiscus Texts and Correspondence", with an interface in English and Polish, presents in extenso transcriptions of the primary sources enriched with elaborate critical apparatus. It also contains detailed inventory data on the entirety of Dantiscus' correspondence (sender, addressee, incipit, dating, data on the original source, data on publication in print) and all the Latin texts written by Dantiscus (778 letters, 107 poems, 7 speeches, 15 memorials, 36 records, 1 other text) collected in the "Corpus of Ioannes Dantiscus' Latin Texts", as well as a selection of other correspondence texts (letters to Dantiscus, Dantiscus' letters in German). The selection of texts edited so far was based on the research needs of the program as a whole. Plans for the future envisage publication of the complete "Corpus of Ioannes Dantiscus' German Texts" (letters and documents). The web publication also serves as a first draft for the print publication of the Corpus Epistularum Ioannis Dantisci.

In order to present the source texts online, a custom-designed system of digital registration and annotation for Renaissance correspondence was created, combining transcriptions encoded in accordance with TEI Guidelines, and a relational database that stores a rich set of metadata. All this meticulously collected data offers great potential for further research along many diverse lines. As an example, encoding of references to places and individuals mentioned in this large body of texts allows us to map areas of interest and influence for correspondents or to track their itineraries. Focusing only on people, it is possible to reconstruct parts of social networks of the time, analyzing not only obvious links between correspondents but also references to people co-occurring across the documents. Other areas of scientific investigation have been opened thanks to encoding of variance across extant sources, regularized and original orthography, and other transcriptional features.

The adopted TEI-based approach allows for single source publishing workflow for both the printed series and the web resource, helping to achieve high standards of quality and consistency across publications. As the project and its predecessors span over two decades, technological choices have to be revisited from time to time. The current relational-database-based publishing system, with roots in the early nineties, is planned to be replaced with a native XML database and publishing solution, better suited to satisfying needs for flexible querying of the existing data. Future plans also encompass the integration of visualizations, both to assist research carried out by project collaborators and to provide different ways of engagement with this rich resource, thus broadening its potential audience.

Linking Graph with Map for the Purpose of Historical Research

Historical data exploration tool - the middle ages moravian nobility case study

Studies over connectedness of acquired data and their dependence on space and time offer us deeper knowledge of the historical period and also new possibilities of research. In the classical historical science, scholars rarely explore the area between geography (in particular the dependency of phenomenons and people on the environment) and history (social and genealogical context). Thus, we want to create a tool, which allows a parallel observation of geographical and social connections. For this purpose, we will use an experimental data sample of the Moravian nobility in the high and late middle ages. Studies of social elites and their land property offer good conditions for merging several approaches. Simultaneously, there are some difficulties based primarily on the nature of the dataset.

The key part for the creation of a reliable model is the quality of temporal and spatial aspects of the historical data on input. In the 13th century, predicates (nicknames based on the nobility's place of residence) are spreading through the Bohemian lands . Since then we have information about their domains, castles, and strongholds. Further parts of domain as villages were recorded very rarely, because nobility does not need physical documents of their property ownership or property transactions. In contrast, donations from the ruler to the nobility are in better shape. The ecclesiastical institutions have the most detailed evidence of the property because individual monasteries regularly recorded all of their ownership. It was legal protection against a possibility of usurpation by the nobility. The Church evidence can help us with the reverse reconstruction of some nobility estates - if a nobleman had donated or established a monastery or a church. Simultaneously to these phenomenons, the numbers of noblemen began rising and their properties allow us their inclusion into the wider social linkage (as a lineage).

Qualitative change, in field of usable data, brought year 1348, when Land tables (and registry for real estates) was reformed. Two registers for each part of the territory (with capitals in Brno and Olomouc) were established. So called "desky trhové" (libri contractuum, quaterni contractuum) theoretically capture all of the transactions of hereditary estates. Suddenly, we can explore the world of minor trades and speculations of the high and lower nobility, which primarily had not been selling whole domains or at least villages to the Church, but, on the contrary, they had been selling fields or part of villages and their accessories - courts, mills, taverns, and ponds. Next series of the Land book called "knihy půhonné" (libri citationum, quaterni citationum) show us accusations between nobility and in many cases also decisions of the Land Court. Most of the entries is related to a controversial property or unlawful occupancy of villages or their parts, which shows us how much uncertain the property law was. However, accusations about bandit behavior (siege of castles and strongholds, conquering villages, robbery and capturing of subjects) are very rare. Number of social links compared to previous era grew exponentially and for the first time we can observe the nobility as a quarrelling community.

All these specificities of mentioned historical data brought us to an idea of developing an exploratory application that would provide all necessary methods to get a new insight to these datasets. The application itself is based on the combination of modern web technologies (html5 canvas, javascript, d3, leaflet…), visualization techniques and statistical methods. This could bring an complex overview of historical datasets and provide an ideal way to study "hidden" relations. The spatial distribution of data is best explored with the map. For exploration of temporal aspect, the map has to be extended with some cartographic methods and visualization techniques: animation, brushing, filtering or highlighting. These techniques could also be used in the graph view of this application as graph is the most effective way to display and analyse relations over our dataset. In our prototype we will also provide a timeline view which will display the temporal aspect only. The main advantage of this timeline is the possibility to show both duration and existence of phenomenon in particular dates.

This application could be used for further relevant historical research but also as a demonstration of the potential of linking different visualization techniques for extending the functions of historical data exploration. Presented tool will be available on hde.geogr.muni.cz.

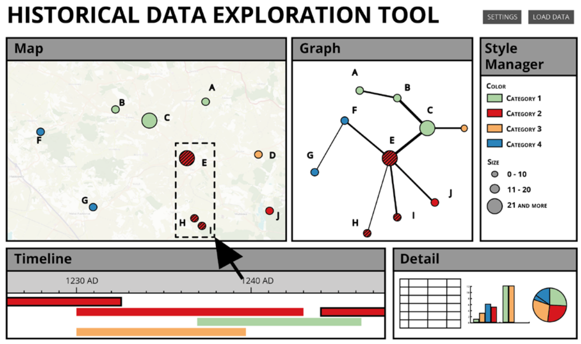

Fig1 : The scheme of the prototype application

New Facets Of The Multimedia Annotation Tool ELAN

Han Sloetjes
han.sloetjes@mpi.nl
Max Planck Institute for Psycholinguistics, Netherlands, The

Olaf Seibert
Olaf.Seibert@mpi.nl
Max Planck Institute for Psycholinguistics, Netherlands, The

Introduction

ELAN is a multimedia annotation tool that is being developed by “The Language Archive” (https://tla.mpi.nl), a department of the Max Planck Institute for Psycholinguistics. It is applied in a variety of research areas within the humanities and beyond; it can be useful in any type of research that includes audio and/or video recordings and analyzes these qualitatively or quantitatively (or both). A general comparison of characteristics of this and other, similar tools can be found in the report of a workshop organized at a gesture conference in Lyon (Rohlfing et al., 2006). This poster with demo is intended as a general introduction to its main functionalities, with an emphasis on the latest developments. Most of these new developments have been executed within CLARIN (Common Language Resources and Technology Infrastructure, http://clarin.eu) projects in the Netherlands and in Germany.

Adding and sharing comments

One of the new developments concerns a commentary framework that improves collaboration of annotators working in a team setting. Comments are pieces of text linked to a segment of the media and possibly to a tier (a tier is an annotation layer). They can be used to store notes, remarks or questions concerning a fragment for later use or for discussion with a colleague. Much alike the way comments in word processors are used. The comments can be shared via email, a file sharing (cloud) service (such as Dropbox) and/or via the back-end of the DASISH Web Annotator (DWAN, http://dasish.eu), a web service for storing annotations (comments) to online content (e.g. web pages). Comments can sometimes be annotations on annotations, but their content and purpose are usually not obvious parts of a (final version of a) transcription.

Another recent development is the possibility to associate parts of a transcription to a language identifier (e.g. ISO 639-1/3 code, http://www.iso.org/iso/home/standards/language_codes.htm) in an explicit way. Among these parts are tiers, entries in a controlled vocabulary and individual annotations. The language attribute of tiers can be used for selecting or sorting tiers in the user interface, when exporting or searching.

Connecting to web services

A preliminary implementation of interaction with WebLicht web services (Hinrichs et al., 2010) was presented at the Digital Humanities conference in 2013. Since then this implementation has been modified and updated in several ways. The address of the services called by ELAN are no longer hard wired but instead the user can select a service (representing a parser or tagger etc.) from a list that is obtained from the WebLicht framework itself. The features mentioned above more tightly embed ELAN in the CLARIN world.

Interrater agreement

Other important changes are the new functions for assessing interrater reliability. For many annotation tasks it is important to have an idea of how well annotators are instructed, to what extent annotators agree in their observations and how consistent these are. A simple comparison method solely based on extent and overlap of co-occurring annotations on tiers of two annotators is now complemented by two third party algorithms that take chance agreement into account. One calculates a Cohen's kappa value by first applying a matching algorithm to the segmentations created by two raters (Holle and Rein, 2015). The other calculates a degree of organization by applying Monte Carlo Simulations to segmentations produced by multiple raters (Lücking et al., 2011). It is now possible to perform agreement calculations for an entire corpus, where the user can specify which tiers (i.e. which types of events) need to be assessed.

Automatic segmentation and labelling

ELAN allows to create annotations manually, which means that the user can inspect the media stream, identify relevant segments and create annotations using the mouse and/or the keyboard. We have been involved in several projects that aim at integration of tools for semi-automatic segmentation and labelling of the media. A first version was presented in 2013; within the AUVIS (https://tla.mpi.nl/projects_info/auvis/) project the algorithms have been improved and the user interface further streamlined. Information technology experts specialized in analyses of digital video streams closely collaborated with gesture researchers to improve the algorithms for automatic gesture detection and categorization (Schreer et al., 2014) while specialist in speech recognition cooperated with language documentation scientists on better algorithms for speech segmentation and speaker diarization (Rieber and Bardeli, 2013). Although the automatically created segmentation is often not accurate enough to completely replace manually created annotations, these technologies can already be applied in a scenario in which the automatic approach creates the segmentation which is then manually corrected.

Mirjam Blümm
bluemm@sub.uni-goettingen.de
Göttingen State and University Library, Germany

Digital resources in the humanities – text, images, audio and video files – show large variation in terms of quality and provenance, while at the same time constantly increasing in number. As a consequence, requirements for digital (and collaborative) editing, annotating, and modelling of data are subject to constant change. Digital editions, for instance, no longer just offer the potential to annotate text and images through established standards (XML/TEI), but also to retrieve entities in an interoperable format (RDF) and to link them to other digital objects (LOD) in other editions, databases, and archives. The digital annotation of both text and/or image data can be published as a digital object itself. Thus, the relation between digital objects turns into a research object in itself, which can be explored, analysed, and searched by a given set of tools and technologies.

A fundamental challenge, however, is that a vast – and still continuously growing – amount of digitised sources is not searchable via one interface or entry point. Search results of numerous different archives, libraries, or other databases cannot be compared automatically; and search requests – as they have to be performed in a de-centralised manner – cannot be (centrally) saved and re-used. Established generic models, together with the necessary expertise in dealing with individual project data as digital objects, are still lacking practice and broad usage in digital humanities and cultural studies. This applies for both data modelling as well as for long-term archiving and persistent publishing of primary digital data.

The proposed poster will illustrate these core aspects of generating, modelling, archiving, exploring, and presenting humanistic research data from a structural and methodological perspective. The digital infrastructure DARIAH-DE is developing a repository for humanities' research data (https://de.dariah.eu/repository) to be archived and published in a sustainable and persistent way, allowing for re-use, citation, preservation, and further exploration:

- Persistent Identifiers, e.g. Digital Object Identifiers (DOI), enable scholarly users to identify research data distinctly. They serve as a crucial pre-condition for archiving, retrieving and citing primary digital data not only in science, but in the humanities as well.
- The modelling of digital objects with established standards (CIDOC, SKOS etc.) and formats (RDF) provides the basis for generating links, thus allowing for generating new knowledge on objects, collections, and/or corpora. Modelling data with the RDF standard allows for linking different objects and therefore accessing information, which can be encoded in variable formats and stored in different databases and archives. The poster will show some practical examples for generic search across TEI-encoded corpora.
- Digital data collections can serve as innovative sources for humanities' research. As such, they can potentially generate new knowledge. Which are mandatory prerequisites for dealing adequately with information in image- and object- orientated research? Which standards for structuring research data apply, enabling a comprehensive search functionality also across heterogeneously structured data collections and archives? The poster will also present the DARIAH-DE Data Federation Architecture, a set of different tools and services creating innovative options of data management, e.g. accessing and linking heterogeneous data sources of various provenances, analysing existing distributed data collections as well as services to generate data and schema interoperability.
- The poster will show how repositories can help users of varying research disciplines to model, store, and publish their data in a standardised, interoperable way, allowing for re-use, sharing, and further exploration.

The poster will accompany a hands-on workshop adressing these questions in more detail, together with (potential) users. DARIAH-DE will present its repository, its features, the Data Federation Architecture and other tools and services related to dealing with and modelling of humantistic research data via demonstrations and hands-on sessions, enabling participants to actively explore the services also with their own data.

The Latin Batrachomyomachia Collection

Petra Sostaric
petrasostaric2011@gmail.com
University of Zagreb, Croatia

Sinisa Jovcic
sinisa.jovcic74@gmail.com
VERN University of Applied Sciences, Croatia

The topic of our project follows closely the theme of this conference: the digital humanities have been a bridge between the past and the future in the field of classical philology, and the identity of the classical scholar has imperceptibly but steadily been merging with a digital humanist identity. As humanist translations from Greek to Latin receive more and more attention, it would be useful to have translations of specific texts collected, organized and made machine-searchable to enable further scholarly study, instead of having them scattered as scanned manuscripts in different repositories. Usually text collections offer a corpus of national literature (e.g. *CroALa*) or specific periods (e.g. *Biblioteca Digital del Pensamiento Novohispano*). This project focuses on a single text: the aim of this project is to produce an online collection of Latin translations of the Greek mock-epic *Batrachomyomachia*, consisting of 300 lines. The *Batrachomyomachia* had long been attributed to Homer and attracted much attention as such; it was even considered Homer's best work by some. The revival of Greek studies in the West in the Renaissance lead to a lively production of translations from ancient Greek into Latin, even of what is now considered minor works and authors. The interest did not disappear after the Renaissance and the production of humanist translations of different works continued. The last Latin translation of the *Batrachomyomachia* was to appear in the 18th century, penned by a renowned Mexican humanist, Francisco Javier Alegre. Unfortunately, humanist translations are seldom included into existing online text collections. The database of Italian Renaissance Latin poetry, *Poeti d'Italia*, does not include a Latin *Batrachomyomachia* under the name of Renaissance humanist Carlo Marsuppini, nor is there the Latin *Batrachomyomachia* by Joachim Münsinger von Frundeck at the *CAMENA* database of neo-Latin poetry. The interest of modern day digital humanists for this mini-epic does not reciprocate the interest of the earlier humanists who used Latin as their medium of choice, but as translations from Greek to Latin have been coming into classicists' focus in recent years, this kind of collection will certainly prove itself useful.

The aim of our project is to collect as many Latin translations of the *Batrachomyomachia* as possible (many are already in the public domain as they have been digitised by various institutions; they will be transcribed by researchers in this project) and make them machine searchable and available online for further scholarly study. Our application will be used for uploading .docx documents and their conversion into xml files while erasing unnecessary tags. Every word will be saved in a lexicon and a table with information on the word's position in the lexicon and in the text. The search will be conducted through a MySql query with word and context as a result. The project will also include Greek to Latin text alignments (micropublications done in *Perseids*) and educational material: quizzes developed especially for teaching Greek while enhancing the learner's Latin skills with material taken from the Greek and Latin *Batrachomyomachias*. The material collected in this project will be useful to teachers, students and researchers.

Complex Networks-Based Approach to Russian Rhyme History Description: Linguostatistics and Database

Olga Sozinova
oa.sozinova@gmail.com
Higher School of Economics, Moscow, Russian Federation

Introduction

Russian rhyme was described thoroughly in the 20th century, especially by M. Gasparov (Gasparov, 2000). Though we now have a powerful tool to analyze rhymes further in the form of the poetic corpus of the Russian National Corpus (henceforth RNC), not much recent research has been carried out in this area (Orekhov, 2015). As I am particularly interested in visualizing corpus data, I applied graphs to rhyme analysis.

Rhymes are convenient entities to be described in graph terms. In a rhyming pair, words are nodes, and rhyme relationship between them is an edge between nodes. Certain properties can be assigned to the nodes and to the edges. For example, word nodes may contain grammatical information and rhyme edges may bear all the rhyme classification (meter, position, etc.).

Furthermore, nowadays, there are tools available for storing graph information in a database. Information from such databases can be retrieved easily and in several formats.

My aim was to build a graph database using the data from the poetic corpus of the RNC. I want to show that the manual research done previously can be supported and extended in a vivid graphic way.

Graphs can provide us with much information about rhyme diachrony:

- Degree of connectivity in different periods (different rhyming tendencies);
- The longest path (chain of rhymes) and clusterization (popular rhymes in different periods);
- Tendency flow from exact rhymes to inexact (requested by parameter of exactness in the different periods);
- Appearance of the dissonance rhymes;
- Tendency flow in rhyming types, position;
- Domination of a certain rhyming type within the rhymes of one poet.

Data

The whole poetic corpus of the RNC was used for analysis. The data covers 775 Russian authors, born between 1658—1939. Overall, the corpus contains 85,996 documents, 229,968,798 words.

Analysis

Technical work included the following steps:

- Transcribing words in a rhyme position;
- Retrieving rhymes from poems according to the phonetic transcription;
- Rhyme classification;
- Building new nodes and edges in the graph database.

I used Python for rhyme extraction and classification and a Neo4j database for storing the data.

As I could not find any available modules for Russian transcription, I made this module myself using the transcribing rules from [http://www.philol.msu.ru/~fonetica/index.htm]. The module takes into account almost every rule, but the exception word lists are quite small.

The rhyme extraction algorithm I used was the following. The Python program finds all the tags <rhyme-zone> (tagged everywhere except blank verse) in the XML documents with poems (last words in lines). Then the program tries to find a possible rhyming pair within 4 lines before and after the current rhyme-zone word. Afterwards comes the transcriptions comparison; if stressed vowels are the same, then the process of classification begins. If the stressed vowels are different, then the dissonance rhyming type is checked.

The classification of the rhymes was based on (Surkov, 1962), (Kvjatkovskij, 1966) and (Timofeev, 1935). I took 8 parameters into account:

- Exactness (exact or inexact);
- Richness (rich or poor);
- Depth (deep or not);
- Ending (open or closed);
- Position of the stressed vowel (male, female, dactyl, hyperdactyl);
- Rhyming type (paired, crossed, encircling);
- Assonance;
- Dissonance.

As soon as a new rhyming pair is found and classified, new nodes and edges are automatically created in the graph database. If any of the words existed in the database before, then an edge is created to the existing node; otherwise, a new node is created.

Results

For now, I have rendered several graph images for certain poets with approximately 30% of their rhymes. In Figure 1 there are 2570 rhymes from the poems of P. Vjazemskij. Figure 2 shows 3866 rhymes from the poetry of A. Pushkin.

From the figures, we can see that connectivity in Pushkin's graph is much higher than in Vjazemskij's graph. Furthermore, the graph of Vjazemskij's rhymes demonstrates certain clusters which can be analyzed in detail.

I plan to continue my research and obtain other graphs for the whole epoch. I hope that further work will provide the information I listed in the introductory part, especially regarding connectivity and clusterization over different time periods. Quantitative analysis remains to be done as well. Firstly, I would like to look at the graph patterns, and then go deeper into calculations of graph characteristics and their interpretations.

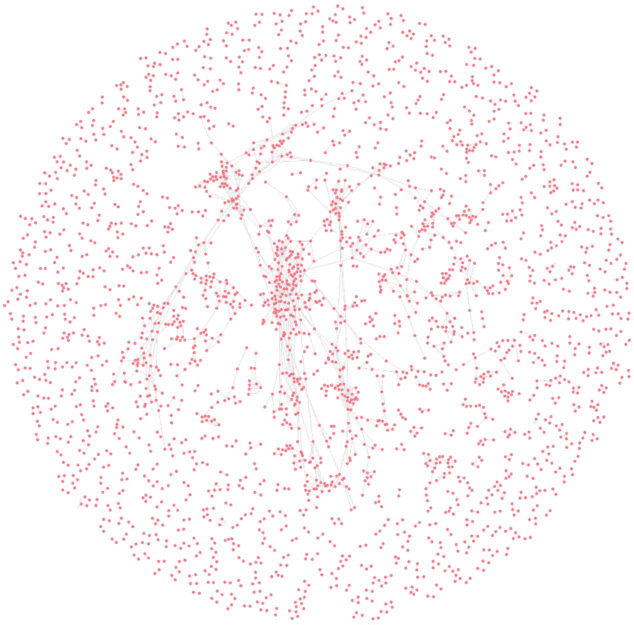

Figure 1. Graph of the 2570 P. Vjazemskij's rhymes

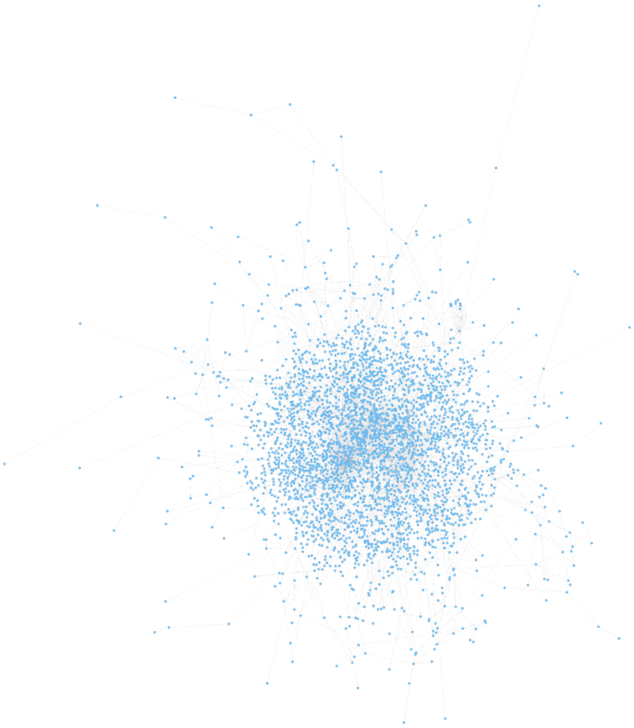

Figure 2. Graph of the 3866 A. Pushkin's rhymes

Cantus Network – a Semantically Enriched Digital Edition of Libri Ordinarii of the Salzburg Metropolitan Province

Christian Steiner
christian.steiner@uni-graz.at
Karl-Franzens-Universität Graz, Austria

Introduction

For many centuries, the metropolitan province of Salzburg played a key role in the cultural history of Austria. The digital availability of the many surviving liturgical musical sources which form an important part of this cultural heritage is therefore of great importance. This research project aims at investigating the records that survived as manuscripts and describe the practice of liturgical and musical acts of worship. Liturgical ordinals, called libri ordinarii (LOi), are key sources for this transmission, as they include a short form of the entire rite of a diocese or a monastery. Prayers, readings and chants are given as abbreviations (incipits).

This poster examines the technical background to the project and specifically the transformation process into TEI as well as the creation of semantic web knowledge representations of the liturgical occasions/functions and the chants based on existing relational databases.

The object: Liturgy and music in the medieval metropolitan province of Salzburg

A liber ordinarius usually includes all the information required by an individual institution (church, monastery) or a group (diocese, group of monasteries) for their services. This includes the incipits of chants, readings and prayers for the liturgy of the hours, mass and processions as well as rubrics that provide instructions on how and when particular liturgical acts should be carried out.

The rubrics often contain indications of how the chant is to be performed and are thus able to provide important information on chant performance practice. However, this information cannot be utilized without in-depth examination of the LOi: thus, scholarly studies have to include a critical transcription of the Latin texts, followed by an in-depth analysis of the origins of the liturgy and the commentaries.

The aim: Reconstruct the development of the liturgy in the Salzburg metropolitan province by Semantic Enrichment

The research project's aim is to reconstruct and produce a synoptic study of the emergence and development of the liturgy in the Salzburg metropolitan province, based on the surviving LOi in the region. A primary task was the transformation of the ordinarii from docx into TEI. A Java algorithm parses the docx on word-level in order to create the desired TEI-Output. The encoding in TEI consequently allows a detailed transcription of textual phenomena and the reference between texts. This is the basis for an in-depth analysis of the different traditions and variants of the LOi.

The LOi as a textual genre need enriched editions, which cannot be fully provided in printed forms. The project will provide the multi-layered texts digitally working with a controlled vocabulary. This resource will be of particular interest for the international efforts on cataloguing the manuscript heritage and research on the history of liturgy, which will be able to refer to the controlled vocabulary via Semantic Web technologies and Linked Open Data. The data from the existing relational databases cantusplanus.at and cantusdatabase.org will be converted into semantic web knowledge representations (SKOS, OWL). With the usage of these standards, we can secure the long-term use of the data created.

The long term perspective: The technical infrastructure

The digitized and enriched objects will be managed, published and long-time archived in GAMS (Geisteswissenschaftliches Asset Management System). GAMS is an OAIS-compliant Asset Management System based on the Open Source software FEDORA and further developed by the Austrian Centre for Digital Humanities at the University of Graz.

GAMS focuses on the long-term availability and flexible use of digital content. The repository builds upon a webservice-based (SOAP, REST), platform-independent and distributed system architecture, a largely XML based content strategy, the support of XML based import and export standards (METS, DIDL, etc.) and the use of standardized data and metadata formats. All data objects in the system receive a persistent identifier (PID) and can thus be explicitly cited.

During the ingest process of the objects into the repository, the TEI documents can be semantically enriched through content-specific controlled vocabularies. Information will be extracted from the content document, for instance Dublin Core metadata or user-generated RDF triples for subsequent processing like complex search requests, the generation of indices and data visualization. For the storage and retrieval of RDF triples, an openRDF Sesame repository is accessed through a web service.

The manuscripts in the project will be presented with an interface, which allows navigating the data in the ways mentioned above, including elaborate multi-criteria search support by drill down methods. GAMS includes an efficient Imageserver (IIPImage) which allows seamless navigation and zoom in high resolution images.

EDM in Use: Collecting Metadata for a Regional Cultural Heritage Portal

Elisabeth Steiner
elisabeth.steiner@uni-graz.at
University of Graz, Austria

The Europeana Data Model (EDM) aims to provide an abstract and formal specification for the delivery of data to Europeana. The model is meant to replace the older Europeana Semantic Elements (ESE) definition. Though Europeana still accepts data provided in ESE, the newer model means to provide a richer set of description possibilities and fine granulation in the distinction of the provided digital heritage object (provided CHO) and one or more digital representations thereof. Most notably, EDM is designed to provide Linked Open Data (LOD) of the described resources (cf. Berners-Lee, 2006). Thus, data providers are encouraged to switch to EDM and to take advantage of the extended potential.

The project "Repository of Styrian Cultural Heritage" will build a digital archive of cultural heritage objects, i.e. a common web platform where all partners (3 universities, 2 museums, and the local government) will expose metadata on their Styrian specific collections and holdings. As the nature of digitized objects ranges from text-centered materials like manuscripts or correspondence to images like historical photographs to museum objects of various contexts, an abstract data model for representation and retrieval was needed.

In a first step, the metadata core categories obligatory for all partners and content types were defined: They roughly correspond to Dublin Core (DC) and DCTerms and will form the basis of the web portal: institution, title/description, person/creator, time, place, object type, media type.

In a second step, this abstract model had to be converted into a formal specification of how to provide the metadata for a harvesting mechanism. The process of choice was OAI-PMH, either in form of an OAI-PMH interface or as an OAI 2.0 compliant XML-file. Harvesting of metadata on diverse cultural heritage objects naturally calls for the application of EDM expressed in XML. Thus, the abstract metadata core categories are mapped to EDM properties and formalized as XML elements and attributes. EDM is a powerful yet flexible tool, therefore a standardized application profile had to be developed for the project.

An important consideration is the integration of controlled vocabularies and norm data. EDM offers the possibility to do so, yet the incorporation of geographical coordinates for instance calls for the modelling of the place name in the edm:Place element and not in dc:coverage or dcterms:spatial.

At the end, the EDM XML data is integrated into the OAI-PMH stream. The goal is to arrive at a recommendation on data structure for the contributing institutions, a process which is currently underway.

Using EDM offers obvious advantages in the context of a harvesting portal: as it was specifically designed to capture the field of data aggregation from various sources, it offers a good spectrum of possibilities to address the difference between the original (i.e. analog) cultural heritage object (edm:providedCHO) and available web resources (edm:WebResource), but also sets these two aspects in correlation (ore:Aggregation).

The conception of a least common denominator template is achieved relatively easy though this is surely not a trivial task, taking into consideration the flexibility and integration potential of the model. Another important aspect needs constant supervision during the project: maintaining metadata quality and how to fill the template accordingly. What type of annotation of person forenames and surnames should be used? What set of keywords? What date format? What controlled vocabularies are vital? How to deal with uncertainties and fuzziness inevitably occurring in such datasets? These questions need to be addressed in cooperation with the scholars working on the collections, clarifying that these annotations will determine the accurateness of search and the quality of data retrieval and representation on the web portal. With regard to the (re-)use as Linked Open Data, special attention is given to the annotation with suitable norm data.

EDM offers a good framework for use in harvesting contexts, especially where various content types are present. Nevertheless, the experience in the project has shown that offering a technical concept is only half of the story: To achieve formal data interoperability and to simultaneously populate this model with comparable content categories is the great challenge in this context. Only with such a homogenous data basis the resulting web portal will be able to offer features like timelines, map-oriented visualisations and other discovery mechanisms. The poster will introduce the project's so far approaches, solutions and lessons learned from this point of view.

Making George Washington's Financial Documents Accessible: Transcription, Data, and the Drupal Solution

Jennifer Elizabeth Stertzer
jes7z@virginia.edu
University of Virginia, United States of America

Erica Fallon Cavanaugh
efc8d@virginia.edu
University of Virginia, United States of America

The George Washington Financial Papers Project exists at the intersection of two challenges editors currently face: managing complicated editorial work and navigating the world of digital publication. By focusing on a particularly difficult and dynamic dataset—financial documents—work has advanced on three interconnected fronts: 1) developing document templates for both traditional financial documents, such as account books and ledgers, as well as receipts, journals, and memoranda; 2) developing taxonomies and data visualizations; and 3) constructing an open-source content management/editorial/publication platform. The work has resulted in the development of both an open-access digital edition of Washington's financial documents as well as the groundwork of Drupal for Editors prototype—a Drupal-based, open-source, editorial/publication platform—providing editors with a stable, flexible, and powerful platform to build engaging digital editions of financial documents.

In 2013, The Papers of George Washington received a grant from the National Historical Publications and Records Commission (NHPRC) for the perfection and population of the content management database (DocTracker) with Washington's three major ledger books; preparation of Gouverneur Morris's 1811-1816 account book and its entry into the content management database in partnership with the Gouverneur Morris Papers at the New-York Historical Society; and the completion of a primary version of a web interface that will provide users with free access to the edition's entire content and permit downloading and data manipulation.

During our partnership with DocTracker we helped design a viable content management and customized editorial workflow solution built on the proprietary, commercial database software FileMaker Pro. DocTracker allowed us to manage both document records and content identifications, and associate both with transcriptions. But as a publication platform it was limited because of its use of XML. We investigated alternative publication options and decided on Drupal, a highly-configurable open-source content management system. We determined Drupal to be the best publication solution for several reasons: 1) at its core, Drupal is a database in which imported content can be mapped to fields, allowing for robust displays and searching, querying, and browsing; 2) Drupal is accessible, both in terms of cost and usability and has a large user community; 3) both the backend (content/data) and frontend (website interface) are managed in the system; and 4) Drupal is open-source and its core and add-on (module) code are developed and actively maintained by a large international developer community.

Drupal has allowed the project to confront the numerous challenges inherent in these documents: (1) different types of financial documents are formatted in distinct, though standardized, ways, and the formatting of financial documents carries implied meanings; (2) transactions are full of dittos, abbreviations, and short hand, that raise a question of what kind of fields should be created to capture the transcription and clear text, thereby making both the text and content searchable; (3) the documents present issues of currency, valuation, and barter; and (4) a hierarchy of documents exist, and therefore the same transaction may be recorded in a day book, account, and ledger, etc., generating multiple instances of the same transaction.

Indeed, one of the primary goals of the Project is to make accurate transcriptions of the documents *available*, in keeping with the long tradition of the Papers of George Washington documentary editing project. However, the types of information, or the "data," contained in these documents are not easily *accessible* using common search and query techniques. The challenges, as described above, make it impossible to simply transcribe and put online, ready to be searched and understood document transcriptions. The solution involves a combination of transcription and corresponding data fields (where dittos, abbreviations, and short hand have been expanded), node references associating various content types, and term references connecting taxonomies. Additionally, Drupal provides a place to develop and manage taxonomy lists for specific content types, such as financial documents, to enhance the grouping and sorting of content and be used to identify relationships between different types of content.

Developing this system has challenged us to think creatively about all aspects of the editorial and publication process, resulting in innovative ways for users to explore, analyze, and interact with content. This poster and hands-on demonstration will explore these issues and the technological solutions to make these documents available, as a free online resource as well as highlight strategies for content searchability, including annotation, glossaries, indexes, and linking.

The Models of Authority Project: Extending the DigiPal Framework for Script and Decoration

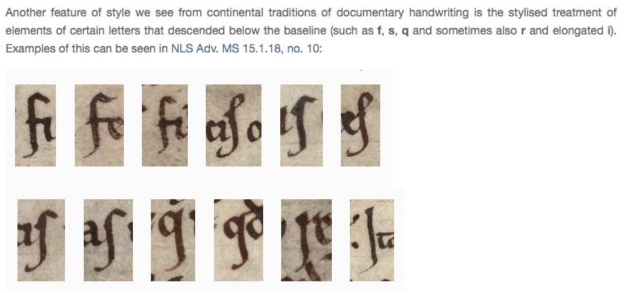
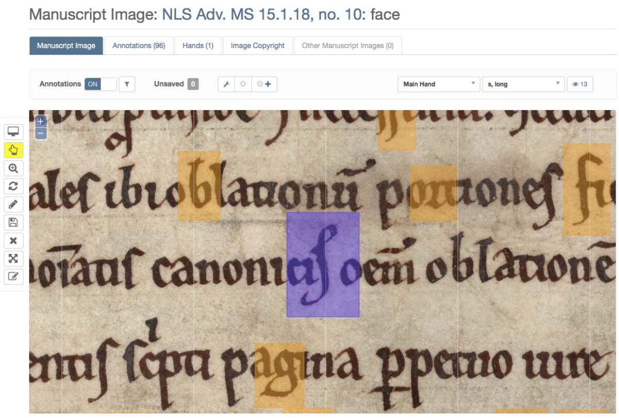
The DigiPal project for palaeography has featured in previous DH conferences (Stokes 2012; Stokes *et al.* 2014; Stokes 2015). It includes a generalised framework for the description and analysis of handwriting, initially applied to Old English of the eleventh century but subsequently extended to Latin, Hebrew, and decoration (Stokes *et al.* 2014); it incorporates a novel model for describing handwriting (Stokes 2012); and a recent addition allows the embedding of linked palaeographical images into prose description (Figures 1 and 2; see also Figure 3). The purpose of this poster is to present new developments which form part of two further major grants, one of which is the Models of Authority project (see also Exon 2015). Specifically, the focus here is on the incorporation of textual content into the model for handwriting.

It is well known that features of handwriting depend not only on the type of manuscript and the social context of production, but also on the text itself, and the absence of this has always been a weakness of DigiPal (Stutzmann 2012; Stutzmann 2013). For Models of Authority, in contrast, a key premise is that the development of government in medieval Scotland is reflected in the choice of visual models behind the layout and handwriting of royal and local documents: this choice probably drew primarily on English counterparts, but elements from papal bulls, among others, are also visible (Broun 2015). It is helpful to note further that the text of these documents is relatively formulaic: this is common of charters in general, as noted in particular by the Charters Encoding Initiative (CEI) and utilised effectively by the Anglo-Saxon Charters project (ASChart), among others. However, connections between diplomatic formulae and script remain largely unexamined, at least in a digital context; certainly digital projects are underway that analyse the relationship between script and document (two examples are PUhMA and MoM-CA), but freely-available online frameworks are still lacking that allow queries like 'show me images of **d** that appear in witness-lists of episcopal charters, and let me compare them with those of dispositive clauses'. Hence a key question of Models of Authority is whether matching the palaeography to the diplomatic formulae in this way might reveal new information about how the documents were put together, what models may lie behind them, and therefore how the nascent Scottish government may have seen itself particularly in relation to the English and Papal chanceries.



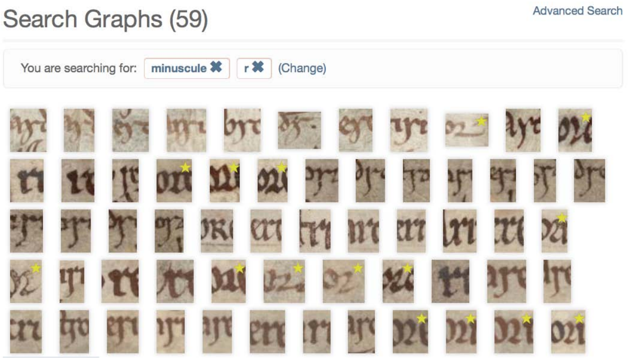
Another feature of style we see from continental traditions of documentary handwriting is the stylised treatment of elements of certain letters that descended below the baseline (such as **f**, **s**, **q** and sometimes also **r** and elongated **i**). Examples of this can be seen in NLS Adv. MS 15.1.18, no. 10:

Figure 1: Sample of Embedded Annotations in Palaeographical Description (Webber 2015). All images are linked by the framework to their full context in the manuscript page.



Manuscript Image: NLS Adv. MS 15.1.18, no. 10: face

Figure 2: The Graph of **s** (fourth across in Fig. 1 above) in its page context.

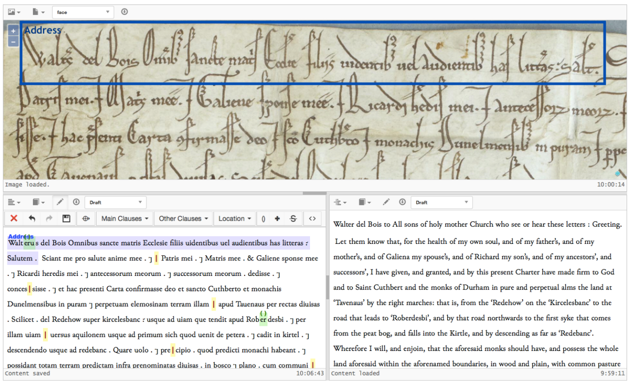


Search Graphs (59)

You are searching for: minuscule ✖ r ✖ (Change)

Figure 3: Sample forms (graphs) of **r** in the Models of Authority database. Examples of 2-shaped **r** are starred.

The DigiPal framework has therefore been extended by adding a generalised textual component, such that arbitrary marked-up texts (transcription, translation, codicological description, and so on) may be associated with palaeographical annotations and images and displayed in parallel with them (Figures 4–6). This allows the exploration of correlations between palaeographical forms and the corresponding text, comparing in this case the different clauses in the documents not just in terms of the text (as done in ASChart and others) but also as images of the corresponding clause in different documents. The integration of this into the DigiPal model for handwriting (described by Stokes 2012) therefore allows detailed palaeographical querying, such as filtering for images of all the letters with ascenders that appear in the address clause of the charter, or looking for variation in letter-forms in the witness lists. The former is of considerable interest because chancery scribes often add decorative elements to ascenders of letters, particularly in the first line of the text (visible in Figure 4), a practice which derives from Papal and ultimately Merovingian diplomatic practice; for the latter query, names of witnesses are normally written by the main scribe at the same time as the rest of the text but in some cases may also have been added later (Broun 2011, 258–65 and 280–7), so identifying differences in writing here can also be very significant. Beyond charters, the digital model generalises to other forms of linking from structured text to structured annotation, for instance at the glyph-by-glyph level advocated by Stutzmann (2013), and is also being applied elsewhere (Exon 2015).



Address
Walterus del Bois Omnibus sancte matris Ecclesie filiis uidentibus uel audientibus has litteras : Salutem . Walter del Bois to All sons of holy mother Church who see or hear these letters : Greeting.

Let them know that, for the health of my own soul, and of my father's, and of my mother's, and of Galiena my spouse's, and of Richard my son's, and of my ancestors', and successors', I have given, and granted, and by this present Charter have made firm to God and to Saint Cuthbert and the monks of Durham in pure and perpetual alms the land at 'Tavenaus' by the right marches: that is, from the 'Redehow' on the 'Kircelesbanc' to the road that leads to 'Roberdesbi', and by that road northwards to the first syke that comes from the peat bog, and falls into the Kirtle, and by descending as far as 'Redebanc'. Wherefore I will, and enjoin, that the aforesaid monks should have, and possess the whole land aforesaid within the aforenamed boundaries, in wood and plain, with common pasture

Figure 5: Example query showing text and image of witness lists in private charters.

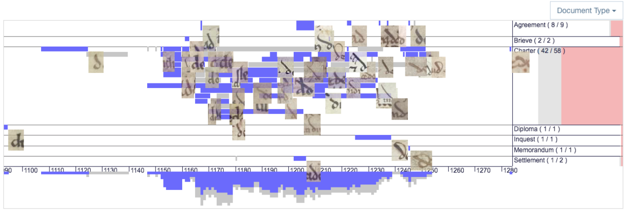

Figure 6: Prototype overview/timeline indicating shapes of **d** in documents of different type.

This addition of text introduces considerable complexity to the system, since it seeks to connect very different views of the original document: as transcription, translation, image and annotation; as scribal product (a set of interconnected and interacting letters) and diplomatic product (a set of textual formulae); an overview of the current architecture is shown in Figure 7. This integration of different views goes to the heart of an ongoing challenge in Digital Humanities, as perhaps best represented by the competing 'textual' and 'documentary' views in the TEI (2015; Pierazzo and Stokes 2011; see also Stokes and Noël 2010).

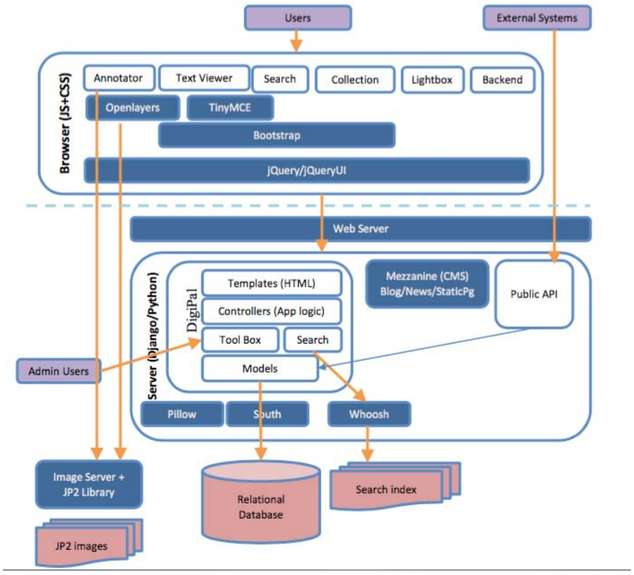

Figure 7: Overview of the current architecture

The proposed poster will therefore present the existing framework and integrated model, addressing the complexities described above. Live demonstrations will be available of Models of Authority, and of other instances of the framework such as DigiPal, Exon, and some that are not yet publicly available.

Diachronic changes of the Russian Presidential Addresses to the Federal Assembly: From the perspective of archetype key words

Mao Sugiyama
sugiyama.mao0420@gmail.com
Osaka University, Japan

The purpose of this study is to investigate diachronic changes of the Russian Presidential Addresses to the Federal Assembly (RPAFA) given by Russian Presidents, Boris Nikolayevich Yeltsin, Vladimir Vladimirovich Putin and Dmitrii Anatolievich Medvedev. This study proposes political archetype key words (PAKW) and provides a fine-grained classification of presidential speeches.

Russian presidents have given a number of annual speeches. Among them, the RPAFA, which started in 1994, has drawn text-miners' attention. In one recent study, Jashin (2010), argues the importance of "political archetype key words" (PAKW) in the RPAFA through one text from each president: Yeltsin in 1996, Putin in 2000 and Medvedev in 2008. While thought provoking, Jashin's observation has two fatal issues: (i) his observation is based on raw frequencies of each lexical item, and (ii) the speech texts that he uses are arbitrarily limited. That is, he only uses three of the speeches, one from each president, without providing reasons for not using all the texts. Thus, the tendencies observed by Jashin cannot be straightforwardly generalized to tendencies of the presidents; Rather, they may be tendencies of the year. Though the notion of the PAKWs is useful, a further investigation of the PAKWs is needed.

In order to overcome the insufficiencies in Jashin's study, the data set must be reexamined. The data used in this study includes the following:

1. the full set of RPAFA speeches (22 texts in total)
2. the 30 most frequent content words as PAKWs

Importantly, this study intentionally excludes function words because only content words can convey political messages.

The result of the correspondence analysis using a frequency matrix of the PAKWs in each RPAFA file is given in Figure 1 and Figure 2.

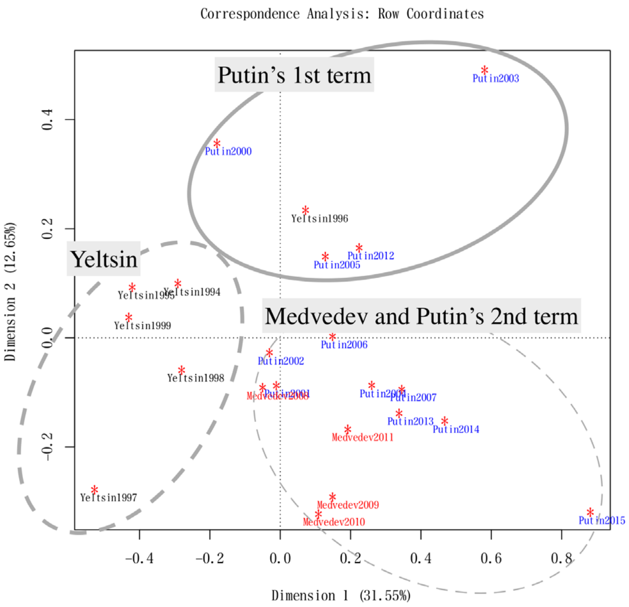

Figure 1 The textual distribution

According to Figure 1, we can roughly classify the speeches into three large categories: Yeltsin on the leftmost circle in a bold dotted line (hereafter, Y dimension); Putin's first term circled with a solid line (henceforth, P dimension); and Medvedev and Putin's second term traced by a fine dotted circle (thence, MP dimension).

Figure 2 shows PAKWs that each text frequently uses. Words observed around the Y dimension are highly relevant to national reconstruction, such as *власти* 'authority-GEN', *государственной* 'state-GEN-FEM', *органов* 'organ-GEN-PL', *деятельности*'activity-GEN'. Putin in the P dimension prefers to use words as like in Yeltsin, but Putin tends to use words related to *Russia* such as *Россия* 'Russian-NOM', *российской* 'Russian-GEN-FEM' in his first term. In the MP dimension, the figure shows that the presidents frequently used words related to the life of citizen like *жизни*'life-GEN', *люди* 'people-GEN-PL', экономика 'economy-GEN', *сфера* 'sphere-PREP' and правительство 'government-subject case'.

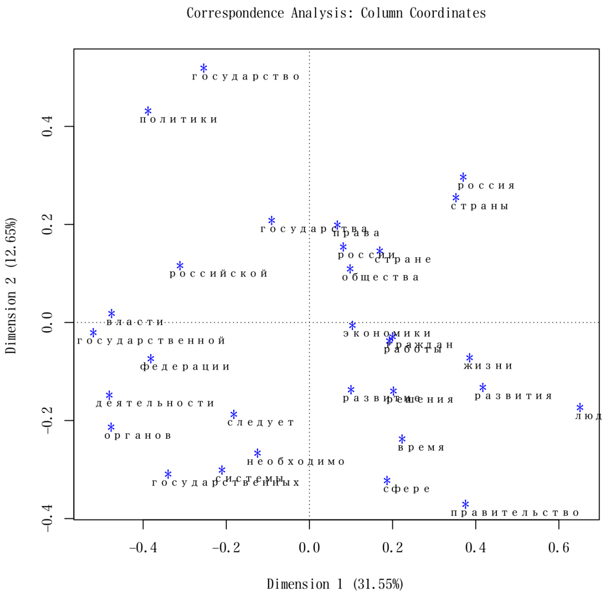

Figure 2 The distribution of PAKWs

The observation based on the distributions of the PAKWs suggests that the classification based on the correspondence analysis in Figure 1 is attributed to the historical backdrop. Let us consider Figure 2, which corresponds to the result of Figure 1. In the Y dimension, Yeltsin frequently uses words related to *state*. In other words, he expresses concern through words related to 'state'. This is primarily because the Russian government was in confusion due to the collapse of the Soviet Union, and Yeltsin's primary policy was to construct a democratic political system. A lexical overlap in the Y and P dimensions indicates that Putin inherited Yeltsin's policy, but the use of *Russia* refers to a change of approach to reconstruct Russia from Yeltsin's administration. The MP dimension includes the PAKWs related to non-authorized citizen or nation. This is attributed to development of the country. That is, after enhancement of the Russian political infrastructure supported by Yeltsin and Putin's first term, the primary political attention has shifted to improvement of social-infrastructure in Medvedev and Putin's second term.

To sum up the investigation from Figure 3 and Figure 4, the use of PAKWs in the RPAFA provides political attitudes of the presidents. That is, the 30 most frequent content words show background political issues of the time. This study concludes a possible implication in supporting the political discourse analysis theories.

Ruthenian Metrica: technological aspects of the electronic publication

Yury Anatoliyovych Svyatets
devotee@i.ua
Oles Honchar Dnipropetrovsk National University, Ukraine

Ruthenian (Volhynian) Metrica is a complex of books of acts of ruthenian (from Ruthenia) series of Crown Chancery of the Polish-Lithuanian Commonwealth. 29 books in which more than 3,5 thousand acts are entered were a part of the Metrica. The main part of documents is written in the Cyrillic letter of Ruthenian language. Other part of acts is written down by the Latin letter on Latin or Polish. Copies of confirmations (privilea) and the decision of royal court are entered in books (decrees). Therefore Ruthenian Metrica consists of books of two types: blotters and books of decrees. Each act has the original name. All acts are rather precisely dated. Documents of the Metrica can be divided into two categories conditionally: simple and compound. Compound documents usually contain literally entered copies of other acts (vidimus) in the structure. Usually entered as private-law acts (for example, wills or donative), and decisions of local courts.

For the purpose of ensuring broad access for historians to documents of the Ruthenian Metrica on department of history of the Oles Honchar Dnipropetrovsk National University (Ukraine) the project on creation of the Web publication of such complex of sources is carried out. Implementation of the project assumes creation of an online-resource in which will various opportunities of presentation and the analysis of documents are integrated.

The concept of the Web version of a complex of acts of this book provides possibility of simultaneous display as the digitized images of pages, and their paginal transliteration in a text format. Access to all acts of the book is provided from the initial page where the general register is placed (fig. 1). The register allows to open its PDF version according to the name of the document or at the choice of number of a leaf to pass to the corresponding Web version (fig. 2). In each case the accompanying information on a place of storage of the original of the act is submitted. It is possible to see documents both in a hand-written form, and in the transcribed (fig. 3). As the cursive writing still kept portable letters, and in the electronic text means of HTML transferred such feature of the letter. It is possible to increase the digitized image of the page of the document in a separate window, having activated the reference (fig. 4). The hypertext structure is comfortable also that regarding the electronic text it is possible to bring later references to the connected documents of other books of Ruthenian, Lithuanian or Crown Metrica, magistrate or territorial government or judicial books both archival, and published. Similar additions can concern a personnel, toponyms or hydronyms, groups of documents, special terminology, etc. For transition between pages of the book the corresponding interactive references in a type of numbers of sheets are provided in the top and lower part of the displayed document. The user can always return to the general register of acts of the book from any looked-through page according to the universal reference "Register". The marking of text part on the basis of the TEI standard allowing to process the free text is in the long term planned.

At this stage quality of images of pages of the book rather low in connection with a digitizing of a monochrome microfilm on which they were finished shooting as a backup copy of storage more than three decades ago. Respectively esthetic registration of insufficient level. However in this case images carry out rather confirmation function, allowing the user, to get acquainted with paleography of acts and to make sure of correctness of the transcribed text and if necessary to offer the specifications. Replacement of images on better is defined not so much technological, how many by legal and financial factors.

This project is interesting also to that it has also didactic value. Such form of submission of documents carries out functions as visual aid in which various samples of paleography of a Ruthenian cursive writing and the corresponding transliteration, and the simulator for creation of the Web version of the case of hand-written sources are presented.

Regional Digital Humanities Consortia: An Emerging Formalization of Informal Network Ties?

John Christopher Theibault
jtheibault@gmail.com
PhillyDH

The infrastructure supporting digital humanities work has evolved in a sometimes convoluted pattern of highly resourced large scale initiatives and small scale informal initiatives that lead to durable models that then scale up. Prime examples of informal structures becoming increasingly formalized until they become important features of the digital humanities infrastructure include CenterNet and THATCamp. Understanding such emerging informal initiatives and charting their development to scale is important for determining the essential ingredients of digital humanities infrastructure.

This poster presentation will identify and explore a new informal infrastructure for digital humanities work that has emerged in the last five years: Regional consortia of digital humanities practitioners. These regional consortia bring together people from a range of institutions within a defined geographical area. They can be distinguished from, on the one hand, state and national digital humanities groups that organize conferences and edit journals and require paid membership, as well as digital humanities centers located in a single institution or formally constituted groups with explicit criteria for admission, and, on the other hand, not visibly organized interactions in active digital humanities regions, even if those interactions are frequent in practice. Paris and London might serve as prominent examples of the latter, as neither has developed an informal network despite being highly active digital humanities practitioners. In fact, a central question about the presence of regional consortia is what need is being met by taking on an organized form at all, as opposed to just "getting together"? It has been frequently noted that digital humanities infrastructure is highly unevenly distributed. Will successful examples of regional consortia in some regions inspire or provide a framework for a widening support network in underserved regions? Or will it lead to consolidation of already established digital humanities communities?

I identify eleven regional consortia that have organized themselves with enough visibility to enable study (ten in the United States and one in Europe): DH SoCal, PhillyDH, NYCDH, Boston DH, Virginia DHC, TexasDH, Florida DH, SFBay DH, Detroit DH, Keystone DH, and DigHum Berlin. The framework is heavily tilted towards organizations in the US, and it is possible that there are comparable organizations in other countries that I have failed to uncover. As far as I can determine, each of these groups emerged more or less spontaneously from local initiatives, rather than being directly modeled on one another. I am not including DHBenelux or DH Nordic in my analysis though they share some of the same markers of spontaneous creation "from below," because both have formally become affiliates of EADH and thus have taken on characteristics of national organizations. Many of them (though not all) share a close association with THATCamp. Either they came into being as part of the process of organizing a THATCamp or they were result of a THATCamp session. At a minimum, they exist virtually, as either a website, a twitter feed, or a listserv, or often all three. Usually, they also have face to face meetings of some kind. While most regional consortia have emerged in regions with at least one significant digital humanities center located at a major university, one of their most conspicuous features is that they are all expressly not housed at a single institution and are open to anyone interested in digital work in the region. Indeed, most appear to encourage outreach to under-resourced local cultural heritage institutions as part of their activities. Costs are kept very low, though some regional consortia have explicit institutional support from universities in the region, while others rely strictly on members' support, drawing on institutional resources that individuals control.

The earliest regional consortium to establish an online presence, DH SoCal, first posted in March, 2010. Because such regional consortia are so new, they are still in the process of defining their missions and organizational structures. In almost all instances, an important reason for reaching out across institutional lines in a region is a perception that the range of skills/technical expertise required for digital projects is too great for any one institution to have them all. Regional consortia become a forum for sharing expertise. At the same time, as noted above, regional consortia act as evangelizers for digital projects, to encourage local cultural heritage organizations to embrace digital work. So the other primary function of consortia is to publicize local digital projects to a wider public. Membership in these consortia vary greatly in terms of the distribution between students, faculty, librarians, and representatives of cultural heritage organizations. This poster will compare and contrast the membership, statements of purpose, and activities of these various consortia to see if there are core features that may help future groups organize.

The poster will focus on Photogrammar (photogrammar.yale.edu), a web-based platform for organizing, searching, and visualizing the 170,000 photographs from 1935 to 1945 in the United State's Farm Security Administration and Office of War Information (FSA-OWI) Archive. Our poster session will include two parts – a physical poster and demonstrations of how to use Photogrammar. The goal is to highlight how we used digital humanities methods such as text, image and spatial analysis to increase discoverability of a photograph archive while also changing humanities scholarship related to the FSA-OWI.

For the poster, we will first outline how Photogrammar is changing scholarship in media studies, visual culture studies and 20th century United States cultural history. In order to build support for and to justify government programs during the Great Depression and World War II, the FSA-OWI set out to document America and the successful administration of government services. They produced some of the most iconic images of the era and employed prominent documentary photographers such as Arthur Rothstein, Dorothea Lange, Gordon Parks, and Walker Evans, all of whom shaped the visual culture of the era both in its moment and in American memory. Unit photographers were sent across the country. The negatives were sent to Washington, DC. 170,000 negatives were collected and for decades, scholars have argued that FSA-- OWI archive is a collection about rural poverty in the American south and Dust Bowl. Photogrammar shows that mapping the photographs challenges decades of scholarship on one of the most prominent visual culture archives in the United States.

The photographers took pictures across the nation, which leads to new questions about the breadth and depth of the archive and goals of the federal government during the era. Questions include why the United States federal government sought these images and how individual photographers' ways of seeing impacted the archive. We will then turn to the methods used to reframe and visualize the photographs that are changing scholarship on and the discoverability of the FSA--OWI collection. We will focus on three techniques: automated geo-referencing and CartoDB to map the photographs, TF--IDF and cosine similarity to surface related photographs based on their captions, and facial recognition software to make the collection searchable by faces (OpenBR).

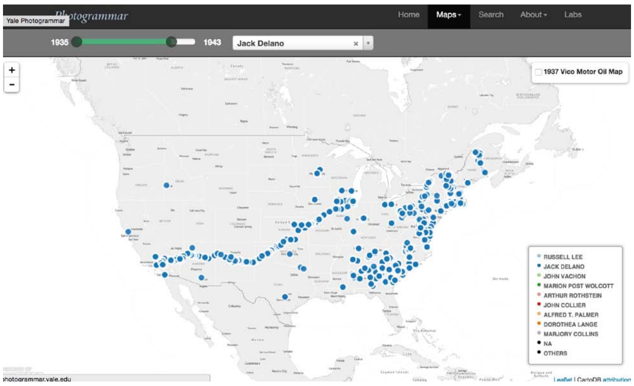
Along with the poster, we will offer demonstrations of the site. We will highlight the multitude of features on the site such as tracking photographers as they move across the country and how users can explore the collection through the archival system developed by Paul Vanderbilt in the 1940s to organize the collection. We will also share new Labs that are in development in order to receive feedback from the international DH community.



We are also excited to share with participants of DH2016 how we built Photogrammar and to speak with them about how they could apply these methods to their archives and humanities data. In addition, we are eager to learn from participants about additional techniques that might augment Photogrammar.

Automatic quotation detection in Russian nonfiction texts

Nataliya Tyshkevich
natalie.tysh@gmail.com
National Research University Higher School of Economics, Moscow, Russia, Russian Federation

1 Introduction

We present work in progress to automatically extract quotation constructions. We claim that it is possible to infer markers that introduce quotation even for the languages without grammaticalized reported speech forms. The object of our study is not the quotation itself, but the canonical context of quotation. We rely on the concept of context as a term with a "hole" (Gabbay and Lengrand, 2008). The context with a quotation as filling for the "hole" has formal features, which we consider as parameters of quotation canon in terms of the canonical typology (Corbett et. al, 2012). We specialize in direct written quotations, which can be distinguished by the reader exactly because of its heterogenity.

We used semi-supervised machine learning techniques to discover contribution of individual predictors to the quotation distribution in Russian nonfiction texts and to build a working prototype of quotation classifier. The classifier does not need any particular text corpora on the final stage, using it only as training data. It predicts probability of sentence to contain a quotation with accuracy of 85%. The objective of the research is to create a machine-learned model that would distinguish between citations and non-citations and arrange the quotation boundaries. The paper presents such a model trained on Russian data. As a result importance of different contextual features can be measured.

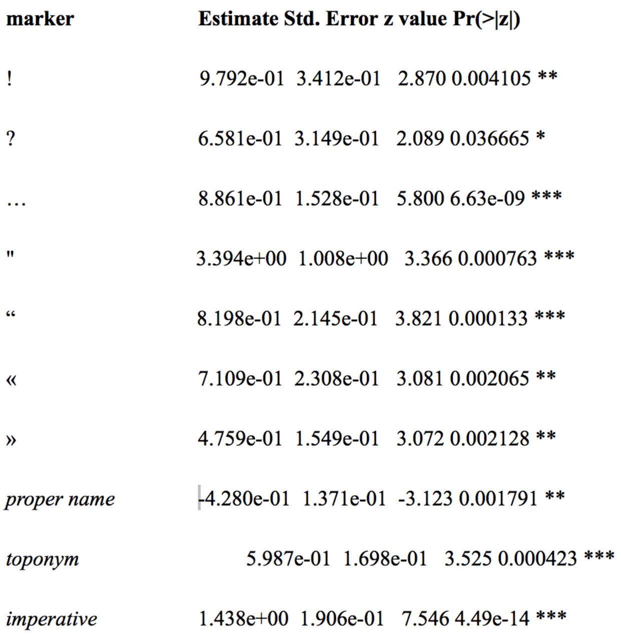
Our model can be used both by scholars and by ordinary readers, unaware of intertextuality issues, and our achievements are undoubtedly useful for a wider class of problems, identifying heterogeneous fragments in the text.

2 Dataset

The material for the training sample is based on the dictionary of Russian literary quotations (Dushenko, 2005) and on the corpora of Russian nonfiction texts from the web-project "Zhurnal'ny Zal" (ZZ) (http://magazines.russ.ru/). We formed 24761 search queries and extracted approximately 1200 sentences, containing quotations from the dictionary and 1200 sentences without any of them. Semi-automatic filtering of false quotative sentences and correcting of quotations boundaries gave us the training corpora of 1000 quotation sentences with the correct boundaries, 1000 sentences without any quotations and 1000 examples of quotative sentences with false borders. At the machine learning stage we divided it to two complementary sets for training and testing respectively.

3 Features

We define overt quotation markers as the most relevant context features for identifying the quote. We examined these features in the tagged corpora and built a logistic regression model, providing us with the most significant markers and their combinations (Fig. 1):



marker	Estimate	Std. Error	z value	Pr(>|z|)	
!	9.792e-01	3.412e-01	2.870	0.004105	**
?	6.581e-01	3.149e-01	2.089	0.036665	*
…	8.861e-01	1.528e-01	5.800	6.63e-09	***
"	3.394e+00	1.008e+00	3.366	0.000763	***
“	8.198e-01	2.145e-01	3.821	0.000133	***
«	7.109e-01	2.308e-01	3.081	0.002065	**
»	4.759e-01	1.549e-01	3.072	0.002128	**
proper name	-4.280e-01	1.371e-01	-3.123	0.001791	**
toponym	5.987e-01	1.698e-01	3.525	0.000423	***
imperative	1.438e+00	1.906e-01	7.546	4.49e-14	***

Figure 1.

That allowed us to exclude the most unimportant features from our final model.

4 Model

The main learning property of the Binary Machine was distinguishing between the presence and absence of a particular marker in certain parts of a sentence. Thus, we built two classifiers:

1) dividing the examples into quotative and non-quotative;

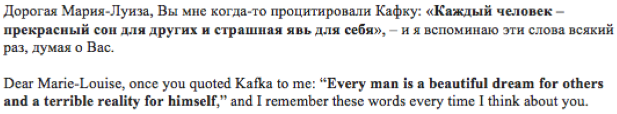
2) pointing out the quotation boundaries.

The final response was based on the cumulative response of the two classifiers. The first machine would give a positive response with a probability 0.7 and more, whereas the second classifier would activate choosing the most relevant hypothesis out of the potential set of quotation boundaries. Support Vector Machines method is commonly applied for classification tasks. We used a modification of this method, Support Vector Classification, because it gives a best fit to our binary data type.

5 Results

The two classifiers have shown positive results with the quotation classifier accuracy of 0.86 and borders classifier accuracy of 0.83.

The greatest confidence in the quotativeness of the fragment results from the presence of the quotation marks. Without them the precision of the evaluations decreases, but not critically. What is important is that our model is not oriented to the quotation marks, the most obvious marker, it analyses all the relevant features in the sentence. For example, for the quotative sentence with overt quotation marks (Fig. 2) probability was estimated as 99%, and the same sentence with cut quotation marks was evaluated as 98% quotative.



Дорогая Мария-Луиза, Вы мне когда-то процитировали Кафку: «**Каждый человек – прекрасный сон для других и страшная явь для себя**», – и я вспоминаю эти слова всякий раз, думая о Вас.

Dear Marie-Louise, once you quoted Kafka to me: “**Every man is a beautiful dream for others and a terrible reality for himself**,” and I remember these words every time I think about you.

Figure 2.

The final version of the program allows one to automatically mark quotes in an untagged text with the permissible share of errors. It works best with nonfiction texts and operates either plain text, or group of texts, or one sentence. Also it can be re-learned on the following set of interchangeable input data for training sample: the set of relevant quotation parameters, a list of standard quotations and group of texts for context-mining. We expect this method to be rather flexible and applicable to other text corpora.

Project COLEM for CREATE (University of Amsterdam) Adapting NPL-Tools for Creating an Orthographic Layer for Early Modern Dutch Texts

Wouter van Elburg
w.m.vanelburg@uva.nl
University of Amsterdam, Netherlands, The

Tessa Wijckmans
t.m.wijckmans@uva.nl
University of Amsterdam, Netherlands, The

The seventeenth century Dutch language did not know a standardized spelling. Because of this, many different spelling variants of the same word (i.e. *ik* and *ick*, both meaning *I*) coexist. This may largely be the result of an author's own preferences, background or the book printer he used. Software to standardize, analyze or process texts is mostly developed for modern Dutch, so processing historical texts with natural language processing (NPL) tools or analysing such texts on stylometric aspects is problematic. Due to the orthographic variation of historical texts, software will not always recognize words that have the same meaning, but different spelling.

For project COLEM we want to normalize spelling differences by having digital re-speller tools form a standardized spelling variant, that could help software better understand the texts. We investigate the possibilities to provide the original text with an orthographic layer containing the normalized words. In this way, the original texts and its morfo-syntactic information are still accessible and it will be possible to search both the original text and the layer. This, for instance, will ease research to language evolution.

The Java software VARD2 (Baron 2011; Baron and Rayson, 2008) seems to be a useful tool for this purpose. This tool was originally created to normalize old English texts, but can be adjusted to other languages. VARD2 will compare the words in the input text with an incorporated, but easily adaptable wordlist (a .txt-file). We replaced the default wordlist with a Dutch lexicon and we trained VARD2 on texts of two different seventeenth century Dutch authors: Simon de Vries and Gotfried van Broekhuizen. Texts of these authors are characterized by a significant different orthography and this could therefore help us to train normalizers and test them on different spelling forms existing within the Early Modern Dutch language.

We trained VARD2 by replacing the variants in the historical texts with a normalization. VARD2 will present suggestions for normalization by using four methods of which just one is language dependent (a modified version of the Soundex phonetic matching algorithm that is based on English phonemes). Two other methods, that of letter rules and that of known variants, we adapted by replacing the default .txt-files 'letter rules' and 'known variants'. The last method, a normalized Levenshtein Distance, does not need to be adapted, since it is language independent.

In this presentation we will show the performances of our trained VARD2 tool. We will focus on a specific amount of problems the tools run into, like uncommon words, clitics and combined words. We will also investigate the possibilities of the Norma tool (Bollman, 2012) and TICCLops (Reynaert, 2014). By comparing the results that various tools offer, we will decide what tool(s) is/are most successful in dealing with these problems. This could give us ideas for follow-up research or the development of tools for normalizing Early Modern Dutch, but probably also for normalizing other languages with unstable orthographies.

Notes

[1] It is not known who exactly was responsible for the spelling as it was printed. But due to there being examples of texts printed by the same printer that use radically different spelling forms it is plausible that the author of the text was responsible for the spelling.

[2] VARD is an acronym for Variant Detector.

[3] Norma is written in C++11, though bindings for Python are provided as well.

[4] TICCLops v.0.2(Text Induced Corpus Clean-up online processing system) is a web application (offered in a JavaScript interface) that is intended to detect and correct typographical errors and OCR (optical character recognition) errors in text. It is usable for every language, since it bases its replacements on the input corpus by making Most Frequent Words-list. However, TICCLops is probably less usable for providing a text with an annotation layer, because the replacements take place in the texts itself, without preserving an original version of the text.

One of the best sources to get an insight in how various subjects (e.g. history, Latin, home economics) were instructed to children and teenage pupils in the past, are the textbooks that were used in various pedagogical systems. They can teach us how knowledge in these various subjects was ordered and presented and how one tried to transfer this knowledge – a fact that is recognized, e.g., in the multifarious work of researchers working on the collections of the National Museum of Education (Rotterdam) or the Georg Eckert Institute for International Textbook Research (Braunschweig). This type of publications, however, is often overlooked in the creation of library collections. The main reason for this is that textbooks, and other connected teaching materials (such as curricula, didactic plates and pedagogical journals), are generally considered to be only relevant for a brief period of time, namely for as long as they are used in a didactic context. They are continually replaced by more recent materials, and only become the object of study again when one wants to reconstruct past teaching.

This poster depicts the efforts at the University Library of the KU Leuven (Belgium) to preserve and prepare such didactic material, created in a Belgian context and thus mostly written in French or Dutch, for present and future research. It also presents how specific corpora of textbooks are catalogued and digitized to facilitate their study, and details the concrete plans to further unlock these didactic sources through more advanced digitization enabling distant reading (starting from an exploratory pilot study focusing on history textbooks). By presenting this case, it illustrates the current results and the future possibilities of the collaboration between researchers and library staff in the context of specific Digital Humanities projects, and documents the ambition of various divisions of the University Library to continue to foster such collaborations (Verbeke, 2014 and Truyen-Verbeke, 2015).

The poster first describes the origins and content of the collection of textbooks and related didactic materials within the Library of Psychology and Educational Sciences, a division of the University Library at KU Leuven. It then details how this unique collection is being catalogued by the staff of the Metadata Unit. This is done according to a specifically developed data model (using the resource management environment in the library software *Alma*) which both ensures maximum compatibility with the general library discovery system (currently *Primo/Limo* at the KU Leuven), as well as the provision of detailed metadata which is needed in the context of an academic study of these teaching materials. The next part discusses the various ways in which this collection is or can be used by researchers, as well as the various selections which have been made in the context of specific research projects (e.g. by focusing on representations of Belgian-Congolese (post) colonial history in Belgian secondary school education since the Second World War, cf. Van Nieuwenhuyse, 2014 and 2015). It details how research projects of this kind determine a corpus of teaching materials, smaller than the entire collection, which are studied in more detail through a close reading of the physical materials, but which also form a priority category of items to be digitized by the Digitization Unit of the University Library. At present, this digitization offers high-end photographic images of the relevant books (using a Qidenus Smart Book Scan, 2 Nikon D800 cameras with 36 million pixels used in a color-calibrated workflow, producing RAW, TIF and JPEG files), but the ambition is to extend this to the creation of a machine-readable textual corpus which enables distant reading as well (with the intention that this distant reading will supplement, not supplant, close reading; see Moretti, 2013 and the varying interpretations of Moretti's intentions in Serlen, 2010, Khadem, 2012, and Ross, 2014). The poster therefore closes with a brief presentation of the OCR (Aletheia, ABBYY Finereader Engine, ocrevalUAtion) and NER (INL Attestation tool, Stanford NER tool with Europeana Newspaper extension) technology used at the University Library of KU Leuven, building on previous experience gathered in the context of a Succeed-project (Alloing-Verbeke, 2014 and Verbeke, 2015).

Introduction: The Core Project EGI-Engage

This paper introduces into a new Science Gateway, developed in the framework of the European Horizon 2020 project EGI-Engage (Engaging the Research Community towards an Open Science Commons). EGI-Engage

> aims to accelerate the implementation of the Open Science Commons by expanding the capabilities of a European backbone of federated services for compute, storage, data, communication, knowledge and expertise, complementing community-specific capabilities (EGI-Engage).

Within EGI-Engage there are several clusters of research infrastructures, representing different research communities.

The Arts and Humanities are represented by DARIAH, building the DARIAH Competence Centre (DARIAH CC).

In this paper we focus on transdisciplinary collaboration in the framework of eLexicography in cultural context.

In the last decade it becomes almost impossible to image excellent science without support of e-Infrastructures in the sciences. However, although various research areas, such as medicine, chemistry, and physics, mostly depend on the availability of advanced research infrastructure, the area of Arts and Humanities is still not utilizing the available infrastructure at their full potential, especially but not exhaustively on the example of EGI infrastructures.

To overcome this gap, DARIAH CC aims to provide a wider and more efficient access to, and use of, research e-Infrastructures at EGI level, including transnational access as well as joint research and networking for users coming from the areas of the Arts and Humanities.

The first step in achieving this goal is by providing end-user support, at both technical and service level. One way of fulfilling this mission is by providing a workflow-based Science Gateway.

Customising the Long Tail of Science (LToS): Science Gateway and the Semantic Search Engine (SSE) for the Humanities

For the specific research domain of eLexicography, a Science Gateway is adapted and tailored to meet the needs of the user community coming from the field of Arts and Humanities or, in a more general case, from the Social Science and Humanities. Technically the Science Gateway is based on the generic purpose grid and cloud user support environment (gUSE/WS-PGRADE; LPDS [2015]) as well as gLibrary technologies (INFN [2015]).

The new gateway provides access and compute services for data residing in distributed grid and cloud storages, generic applications, as well as computational resources. The usefulness and evaluation of the specific Science Gateway is demonstrated with two specific pilot applications: "Storing and Accessing DARIAH contents on EGI" (SADE), and "Multi-Source Distributed Real-Time Search and Information Retrieval" (SIR). After the end of the EGI DARIAH CC, it results will be contributed to DARIAH-EU through the DARIAH Virtual Competence Centre 1 "eInfrastructures", which will take appropriate means to support and maintain the results.

From the Semantic Search Engine (SSE) you can search in parallel and in more than 100 languages across various Linked Data repositories:

1) the e-Infrastructure Knowledge Base (KB) containing more than 30 million resources belonging to thousands of semantically enriched Open Access Document Repositories and Data Repositories search results are ranked according to the Ranking Web of Repositories.

2) several resources that are essential for the Arts and Humanities SADE use case in context of cultural lexicography. In this poster we focus on Biodiversity and linguistic diversity and show results for European Repositoris dealing especially with this topic, e.g. Europeana, Cultura Italia, Isidore, OpenAgris and Bio2RDF.

Others can simply added using the configuration options. According to the Humanities requirements, further possibilities are at the moment investigated to be included, e.g. AGROVOC, GEONAMES, GERMANET, ISLEX as well as DBPedia. Furthermore, the team is investigating into supporting ALE workflow opportunities.

From the SSE one can right now search for your plant names and get a full list of results according to the EGI-ontology. Figure 1 gives an overview on the science gateway archidecture:

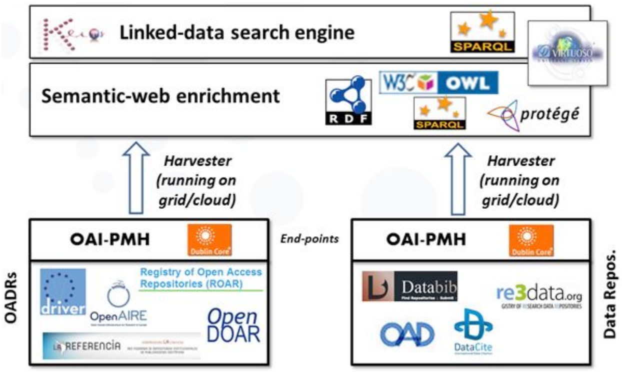

Figure 2 below shows first search results for the search term "bellis perennis":

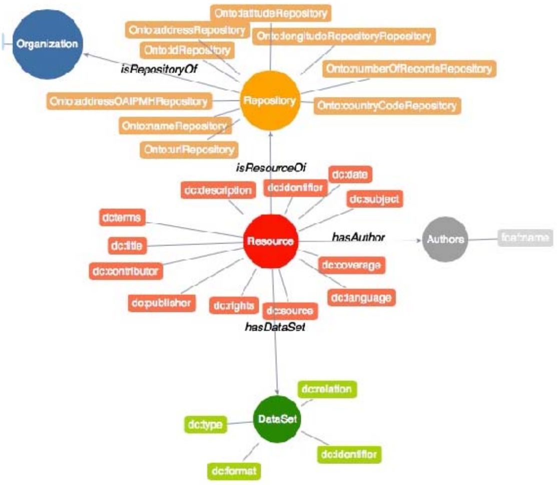
Figure 3 below introduces the SSE-schema:



Exploring cultural diversity and multilinguality: Supporting ALE and COST ENeL

The certain use case is developed to support Pan-European Lexicography and Lexicology and explore new methods of scholarship. The main use case partners are members of the two European initiatives in the fields, namely for Lexicography the COST action IS 1305 European network for electronic Lexicography (ENeL) and for Lexicology the Atlas Linguarum Europae (ALE).

Both of these initiatives aim to explore cultural diversity against the background of multilingual Europe. Europe, as "common space of knowledge" with a common background for lexicography and with shared lexicographical practices and methodological principles, was to this regards influenced by a common canon of dictionaries and other reference works rather than as independent works (Haß [2010]; Kirkness [2012]) .

Moreover, the purpose of these dictionaries was to contribute to nation-building, which explains their – usually strong – monolingual view. Yet, this does not adequately reflect the common Pan-European linguistic heritage (Munske / Kirkness [1996]; Habermann [1999]) of the languages of Europe, which have been in fact in permanent contact with each other (COST Memorandum of Understanding) .Possibilities to study the Pan-European commonal i ties are explored in the framework of COST ENeL and are to be supported by the science gateway and DARIAH Competenc eCentre.

The Use Case definitely meets user needs: The Memorandum of Understanding for the COST action ENeL [COST MoU, p: 6] refers directly to the lack of common approaches and lacking standards as well as the ambition to "fully explore the possibilities of the digital medium".

The developed Science Gateway is one of the solutions for some of the items aimed to be results of the COST ENeL action Working Group 4 "Lexicography and Lexicology from a Pan-European perspective" (COST / Wandl-Vogt / Nowak) , namely mainly 1) Developing ways in which already existing information from single language dictionaries can be displayed and interlinked to present more adequately their common European heritage – 2) Finding new applications for the very large amount of interconnected dictionary information from the European dictionary portal in the field of digital humanities [COST MoU: 14]. Main topics to be addressed in this paper are forms of scholarship and production of knowledge (Nowotny / Scott / Gibbons [2003]) – a) collaborative – b) explorative – c) interdisciplinary transdisiplinary / in the framework of Open S ci ence.

a) Collaborative: The proposers of the paper discuss how open online collaboration is furthering research on the examples of ALE and COST EneL.

b) Explorative: The authors of the paper introduce how their developed and adapted infrastructure supports explorative scholarship.

c) Interdisiplinary, transdisciplinary, towards Open Science: Finally, they reflect their transdisciplinary collaboration – with background in sciences as well as Humantities – and the added value of it on the one hand; on the other hand they reflect on transforming their workflows towards Open Science Commons.

Conclusion and Outlook: Beyond Digital Humanities?

This paper presents a collaboration beyond Digital Humanities: The contributors introduce into a new science gateway for the Digital Humanities, discuss the main technologies adopted and developed and point at the added value of a collaboration beyond Digital Humanities.

The GeoHumanities Special Interest Group: Fostering and facilitating the geospatial turn

Katherine Hart Weimer
kathy.weimer@rice.edu
Rice University, United States of America

Karl Grossner
karlg@stanford.edu
Stanford University, United States of America

Introduction

The GeoHumanities Special Interest Group (SIG) was formed in 2013, and in two and a half years, over 500 individuals have subscribed to the group's email and social media feeds. However, there remains considerable untapped potential for SIG activities informing and enabling humanities scholars' investigations of geospatial research methods and theory. This poster will publicize the SIG's mission and activities, and gather input from conference attendees on possible future endeavors.

Formation

The 2013 Digital Humanities conference program reflected an increasing interest in questions of place and space by scholars from various disciplines. Recognizing the need for cross-disciplinary collaborations and sharing of experience, the SIG co-founders responded to ADHO's call for proposals during that year's SIG slam. Our intent was to utilize ADHO's SIG structure to unite and support the disparate groups of scholars conducting research with a spatial or geographic context. In naming the SIG, we have emphasized geography's traditional attention to not only spatial, but spatial-temporal and 'placial' perspectives. Soon after DH2013, the GeoHumanities SIG proposal was approved.

Goals

The SIG's stated goals are

> "... to create a venue for pooling knowledge and best practices for relevant existing digital tools and methods, to foster the collaborative development of shared resources and new tools and extensions to geospatial software, and to keep humanist scholars at large informed about the possibilities and inherent pitfalls in their use."

Activities

The SIG uses various communication channels, including a web site (geohumanities.org), an email-list and twitter feed. Subscribers now number over 500, primarily from the US and Europe, and the group has had a few notable accomplishments during that time. SIG members have contributed to the expansion of the DiRT Directory by augmenting the TaDiRAH DH taxonomy and are contributing annotations to DiRT listings that are relevant to geospatial research, on an ongoing basis. Those listings are fed automatically to the SIG site in a feature called *GeoDiRT*. The web site also features a list of over 150 Humanities GIS projects from around the world. That resource was originally developed by one of our members several years ago, and transferred to our ADHO-hosted site to ensure its longevity and to facilitate contributions. The SIG website includes blog postings, announcements and a twitter feed.

In each of the past two years the GeoHumanities SIG has held pre-conference events. At Lausanne in 2014, a well-attended day-long meeting focused on "Place and Period in an Emerging Global Gazetteer," and at Sydney in 2015, the SIG promoted a workshop hosted by several of its members on the topic of peer review in GeoHumanities. In 2016, the SIG endorsed and promoted a member organized workshop, "A Place for Places: Current Trends and Challenges in the Development and Use of Geo-historical Gazetteers." Each of these sessions provided a venue to share expertise and shape research agendas.

Future

The GeoHumanities SIG's future initiatives may include:

- Enabling the enhancement of Humanities GIS project listings by their investigators.
- Improving browse and search capability for the Humanities GIS project list.
- Improving integration of DiRT and GeoDiRT.
- Coordinating the collaborative development of an online primer on geospatial analytic and mapping tools, data resources, and best practices.
- Engaging SIG members to enhance GeoDiRT by reviewing tool listings.
- Other ideas brought forward by members.

The DH conference poster venue is a great opportunity to increase awareness of the GeoHumanities SIG and its activities, expand the member base and gather input on current and future directions.

DH Bridge: Teaching Computational Thinking in the Humanities

Jeri Wieringa
jwiering@gmu.edu
George Mason University

Celeste Sharpe
csharpe2@masonlive.gmu.edu
University of Pennsylvania; George Mason University

This poster will introduce and demonstrate DH Bridge (http://dhbridge.org/), a pedagogical model and curriculum for one to two day workshops that provides intensive training in computational thinking in humanities contexts. There are an ever increasing number of opportunities for training in the digital humanities, from informal workshops held at THATCamps (http://thatcamp.org/) to multiple week training programs, such as the NEH Institutes for Advanced Topics (http://www.neh.gov/grants/apply-neh-funded-seminar-institute-or-workshop), Humanities Intensive Learning and Teaching (HILT) (http://www.dhtraining.org/hilt/), and the Digital Humanities Summer Institute (DHSI) (http://www.dhsi.org/). While these workshops provide excellent opportunities to gain exposure to new ideas or to dive deep into a particular subject area, they are also dependent upon the expertise of the particular instructors and, depending on the length of the workshop or institute, require substantial commitments of time and money.

Building on the examples of Rails Bridge (http://www.railsbridge.org/) and Rails Girls (http://railsgirls.com/), which focus on lowering the barriers to entry for underrepresented persons in code, DH Bridge offers an additional model for training in the digital humanities. Rather than relying on a single instructor, DH Bridge relies on a group of coaches to guide participants through a shared tutorial, troubleshoot technical problems, and provide additional contextual information for participants. Throughout the day of the workshop, technical work is interwoven with group activities aimed at helping participants develop useful mental models of computational processes and articulate research questions that would benefit from computational analysis. We have found that this combination of community supported learning, technical work, and group exercises creates a supportive environment where technical learning can take place.

DH Bridge started as a locally hosted Rails Girls workshop for humanities scholars (http://railsgirls.com/digitalhumanities_fairfax) held in early September 2013. The event was well-received and successful, highlighting for us the strength of the model of the short workshop with a central curriculum and small group coaching. It was clear, however, from the feedback we received that the Rails Girls curriculum was too focused on gaining technical skills for employment, as participants struggled to connect the skills they learned to their intellectual goals as humanities scholars. Thanks to an incubation grant from the Association for Computers and the Humanities (http://ach.org/2014/07/09/ach_microgrants_winners_2014/), we were able to develop a curriculum focused not on the mechanics of code, per se, but on the processes of computational thinking. This curriculum was used in a second workshop, held on November 1, 2014.

What is unique about this pedagogical approach in the current landscape of digital humanities training is that the workshops run from a central and open curriculum that can be adjusted and expanded for a particular community. Because the emphasis is on patterns of thinking, rather than use of particular tools, the workshop curriculum is flexible. Whether using the included text-mining tutorial, or adapting tutorials from outside sources such as The Programming Historian (http://programminghistorian.org/), workshop organizers can customize the day for the interests of their community. In addition, the central curriculum, together with the local focus and short timeframes of the events, helps to keep the costs of the workshops low for both participants and organizers. And, most importantly, the success of the curriculum is derived from the community—the participants and the coaches work together to solve problems, both at the level of the code and at the theoretical level of scholarly investigation through code.

We've taken this approach to help expand the community of scholars leveraging computational approaches in their research. Cultural and institutional barriers to learning computational methods are well documented, and organizational responses like FemTechNet (http://femtechnet.org/) and GO::DH (http://www.globaloutlookdh.org/) are doing valuable work in challenging the systemic barriers. DH Bridge aligns with this work, and seeks to provide a local means for groups of people underrepresented in the digital humanities to learn and engage with the concepts and skills of programming in a way that is meaningful to their interests.

This poster will address our lessons learned from running the two iterations of the workshop, as well as our plans for future workshops. We will discuss the model of the one to two day workshop as a way of lowering the costs for participants and organizers; our theoretical and pedagogical choices in developing the curriculum; the challenges we faced and some lessons learned; and the feedback we have received from participants. We invite and look forward to engagement with and collaboration on the curriculum and the model of DH Bridge.

Browsing, Sharing, Learning and Reviewing the Haine du théâtre Corpus through Insightful Island

Researchers of DH need visualizations to help them analyze and share their research results. Meanwhile, the users of the corpus are waiting for a tool (e.g. knowledge Map) to help them with learning and information seeking, and help them with knowledge understanding and memorizing tasks. The insightful island is one of the most promising tool for the perception of the corpus and its memorization.

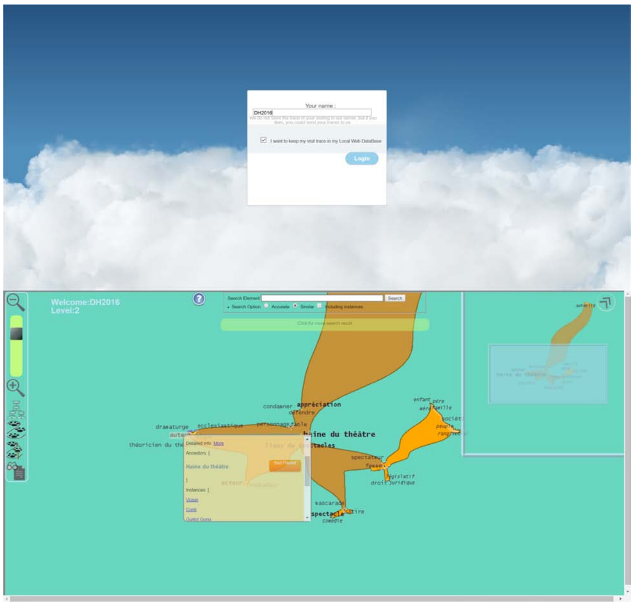

Figure 1. Visualize the HdT corpus as an insightful Island

Cartographic Visualizations (Gansner et al., 2013), have a lot of advantages: they propose to map contents onto two-dimensional knowledge maps that use cartographic metaphors and geographical analogies. These help users to understand the knowledge and allow them to show their own understanding on the visualization, then share it with other scholars. With knowledge maps, people from different domains can collaborate with each other, thus leading to additional benefits. For example, the famous Torrance's experiments (Torrance, 1970) show that working in pairs facilitates creativity.

Figure 2. Access, detail information and search with the HdT island

The Project *Haine du théâtre* (HdT) aims at analyzing theatre debates in Europe by using scientific approaches and critical editions of polemical texts. The reflections of the HdT team are mainly focused around the discovery of the circumstances and the arguments used in theatre controversies all across Europe, from the 16th century up to the 19th century.

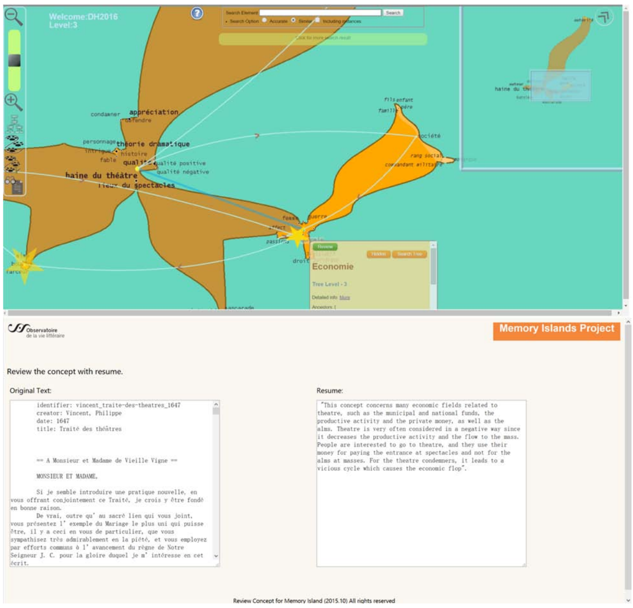
In this poster, we show how to use Memory Island (MI) technique (Yang, 2015) to help us creating an insightful island for the HdT corpus. MI is inspired by the "loci" method of the Art of Memory technique, and it consists of associating each entity of knowledge to a designated area on a created virtual island. We generated a 2D knowledge island (Figure 1) of an ontology built to access the HdT corpus by employing the MI technique.

This visual representation allows users to navigate through the corpus, based on the insights of experts. It uses distance measures, based on the perception of the literary field expressed by scholars specialized of the considered period. This is achieved in this same way that experts from the "Knowledge Cartography" field (Okada et al., 2008) manually craft their knowledge maps.

Users can circulate through the corpus and discover interesting documents that appear to be semantically close to the one they are viewing. The overall organization being based on the ontology skeleton (i.e. a hierarchical structure), the spatial proximity corresponds to a semantic proximity between documents that could arise unexpectedly to the eyes of the viewer, which should stimulate his/her curiosity. In addition, the users can get more information about the concepts by simply clicking their labels on the map: detailed information windows appear on demand. Moreover, the users can study the online corpus, together with the labels of instances and the supplementary information by clicking the chosen items in this window (Figure 2).

Then we designed two different actions: "Visit" and "Study". "Visit" is the action performed by the user that allows her to see a concept's detailed information; "study" is the action allowing users to examine concepts and learn from it at a deeper level. We developed techniques for helping the users to learn and memorize this knowledge based on these map representations. For example, the users can share visiting trace with others, which allows to collaboratively study the corpus (Figure 3). This is essential in the perspective of a participatory activity in DH. User can visually display her visiting trace and allow others to re-visit her trace.

The studied concepts of one user are also visually represented (Figure 3) by the novel review function which simulates our mind's memorization and learning mechanisms. The frequency of learning is also visually represented, using degrees of transparency (least transparent means most studied), in a technique analogous to that of the "heat-maps". If the user wants to review the studied concepts, it will show her a summary about the concept, prepared by the expert, also allowing the comparison with the original text in the corpus.



Review the concept with resume.

Original Text:

```
        identifier: vincent_traite-des-theatres_1647
        creator: Vincent, Philippe
        date: 1647
        title: Traité des théâtres

        == A Monsieur et Madame de Vieille Vigne ==

        MONSIEUR ET MADAME,

        Si je semble introduire une pratique nouvelle, en
vous offrant conjointement ce Traité, je crois y être fondé
en bonne raison.
        De vrai, outre qu' au sacré lien qui vous joint,
vous présentez l' exemple du Mariage le plus uni qui puisse
être, il y a ceci en vous de particulier, que vous
sympathisez très admirablement en la piété, et vous employez
par efforts communs à l' avancement du règne de Notre
Seigneur J. C. pour la gloire duquel je m' intéresse en cet
écrit.
```

Resume:

```
"This concept concerns many economic fields related to
theatre, such as the municipal and national funds, the
productive activity and the private money, as well as the
alms. Theatre is very often considered in a negative way since
it decreases the productive activity and the flow to the mass.
People are interested to go to theatre, and they use their
money for paying the entrance at spectacles and not for the
alms at masses. For the theatre condemners, it leads to a
vicious cycle which causes the economic flop".
```

Review Concept for Memory Island (2015.10) All rights reserved

Figure 3. Visualize the visiting trace and review the studied concepts (highlighting with the five-point stars). In this case, the user has studied "society", "quality" and "thematics" concepts, alighting on the concept "economy" and reading its summary

In the future, we envisage integrating Natural Language Processing and Artificial Intelligence techniques, such as Name Entities Recognition to rendering our technique fully automatic; this in turn will enable all scholars in DH to develop their own Memory Islands for sharing their knowledge more easily.

Mapping Kipnis

Sarah Ellen Zarrow
sarah.zarrow@gmail.com
New York University, United States of America

Hanna Kipnis King
Hannashimona@gmail.com
Harvard University Libraries

What did everyday life look like for a Polish Jew in Warsaw around the time of the First World War? We teach music history, musicology, Jewish history, and Slavic studies. Our students come to us with various pre-conceptions: either that Jews and Poles (conceived of as mutually exclusive categories) lived in open hostility to each other, or that they lived entirely separate from each other, their paths only crossing out of necessity. We want to create, together with our students, a digital tool that will challenge this pre-conception, and their broader ideas about history. We know that preconceptions often interfere with classroom instruction, and often remain much more salient than new knowledge (see, for example, Sam Wineburg, *Historical Thinking and Other Unnatural Acts*, 2001). We believe that hands-on digital tools may do more to interfere with preconceptions than traditional methodologies.

The work of Menachem Kipnis (1878-1942) belies those assumptions. For 16 years, between 1902 and 1918, he performed with the Warsaw Opera; he also sang at the a synagogue in downtown Warsaw. He wrote about these experiences in a variety of newspapers, including Poland's widest circulation Yiddish-language daily, *Haynt*. His accounts are full of rich details that mix the personal and the geographic—how he could run from Tłomackie Street to the Opera and arrive, out of breath, but with enough time to change, for example. Other archival records in which he appears demonstrate the difficulties that Jews faced in joining non-Jewish Polish society—Kipnis's obviously-Jewish first name was not always given in Opera programs, or is Slavicized.

We came to create *Mapping Kipnis* as a challenge to see what an interactive mapping project, one designed by historians and Jewish studies scholars, could do for students' (and our own) understandings of Kipnis's world. Using Omeka, we present Kipnis's Warsaw, with locations enhanced by his words and photographs. We plan a second phase of the project to look at Kipnis's tour through Eastern Europe; his writing from those years offers a warm and colorful picture of Jewish life before the Holocaust. This phase will help students form an understanding of the political and cultural geography of Europe during the period.

Virtually none of our students have been to Warsaw, and have only the vaguest understanding of what it looks like, and even less of an understanding of pre-World War Two Warsaw. For these students, we believe that using interactive tools can provide a layer of understanding about the social geography of Jewish life in Poland that a purely textual account cannot.

Mapping Kipnis is incomplete and we envision students being able to contribute to it, and to add adjacent projects to it as well. Thus, it is both an instructionally demonstrative tool, and an opportunity for our students to familiarize themselves with digital mapping and with the potential digital life of archival material. We are delighted to bring *Mapping Kipnis* to Krakow in 2016, for demonstration and feedback. We hope it sparks as many conversations among participants as it has among the three of us.

Towards a Cross-generation Social Network for Jewish Sages

Maayan Zhitomirsky-Geffet

Bar Ilan University, Israel

Introduction

Construction and analysis of social networks for historical figures has lately become a popular approach in History and Prosopography (Keats-Rohan, 2007), Sociology (Wetherell, 1998; Roldán Vera and Schupp, 2006) and digital humanities (Rochat, 2015; Yamada, 2015). This approach is especially beneficial for providing a global view and automatic mathematical and statistical analysis for large historical corpora (Rossi et al., 2013), for which researchers are unable to gain much knowledge by even an exhaustive manual exploration.

Jewish Biblical and Rabbinic literature is a great source of ancient wisdom and cultural heritage. It includes a large amount of people such as prophets, political and religious leaders, sages and other historical figures. Amazingly, although these people were spread over the world and through different time periods, they were united and connected by the same text - the Bible. Therefore, the aim of this research is to propose and implement a methodology for construction of a cross-generation social network for Jewish sages to explore their inter-relationships on a large scale, using modern computerized tools for text analysis and graph mining (Rossi et al., 2013; Yamada, 2015).

The proposed methodology

At the first stage we define the corpus of the study and a reliable digital resource for this corpus. We work with the text of Mishna (2nd century CE) and Talmud (4th-5th century CE). Next, the following information is retrieved from existing traditional research sources, such as encyclopedia of Jewish sages (as most of these sources have not been digitized, the person-related data is extracted manually and stored in the digital form):

1. A list of sages for the selected corpora. One of the biggest challenges with sages' names is their ambiguity and a large number of namesakes (Rochat, 2015; Keats-Rohan, 2007). To tackle this problem we add identifying discriminative features to each name (e.g. father's name or place of birth).

2. A list of basic relationships between sages, e.g. family relationships, teacher-student, time period, place, possessing a similar political/social/professional role, studying in the same institution, participation in the same event.

Finally, the above basic relationship list can be further extended with text-based relationships, such as sages who cite each other, disagree, or comment on the same section of the biblical text. This is achieved by automatically learning lexical patterns in which pairs of sages co-occur in texts and using them to extract the corresponding relations.

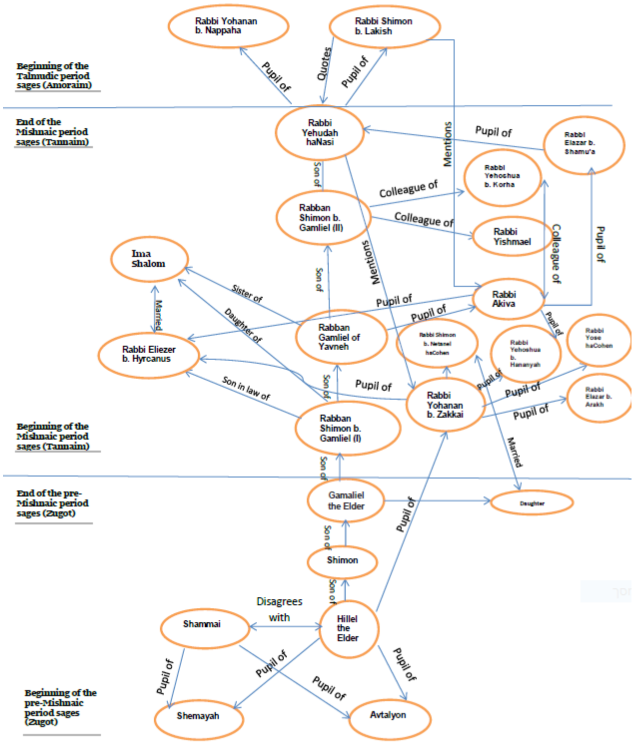

Figure 1: A fragment of the cross-generation social network for Jewish sages

All the extracted data from multiple independent resources are digitized and integrated in the single database and can be queried and visualized by the common tools (e.g. Gephi (Bastian et al., 2009)). Figure 1 illustrates a fragment of the proposed type of the cross-generation social network for Jewish sages. Complex queries can be further answered by mining the network, e.g. whether a given pair of sages are related and how? What are all the various direct and indirect relationships of a given sage? Whether the same text segment cites sages from different time periods (meaning that it has been edited at a later period)? At the global level the social network helps identify the central figures/communities of the sages in different places, times, schools, dynasties, philosophical approaches, text segments, and citations according to the number of network relationships and their density, centrality and coreness (Rochat, 2015; Keats-Rohan, 2007). The historical data in the built network becomes accessible to researchers from the humanities and will take their research capabilities to the next level.

Pre-conference workshops

RDA/ADHO Workshop: Evaluating Research Data Infrastructure Components and Engaging in their Development

Austrian Academy of Sciences, Austria

Summary

The purpose of this workshop is to conduct a meaningful examination of the data fabric and infrastructure components being defined by the Research Data Alliance (RDA), to test their relevance and applicability to the needs of the digital humanities community, and to discuss opportunities for humanities engagement in further standards development.

RDA is an international initiative to facilitate the development of effective data practices, standards and infrastructure in particular research domains, and across domains. It aims to enhance capacity to archive, preserve, analyze and share data, and for collaboration both within and across research communities. The humanities have an important presence in RDA, and can benefit from the opportunities RDA provides to learn across research communities working to develop digital infrastructure. RDA also brings together diverse types of technical expertise, which is organized to put forward (best practice) "adoption products." Some of these products are starting to be taken up in the humanities, such as the Practical Policy Recommendations mentioned below, and there is significant potential for further collaborative work between RDA and digital humanities developers in the future.

Much of the infrastructure needed to support data sharing is of great relevance to Digital Humanities projects, where we find ourselves too often developing and reinventing ad-hoc solutions for data management, draining resources that could be put to better use focusing on the domain-specific nature of our problems and driving new research. It's easy, especially when time and resources are constrained, to get locked into thinking that our problems are unique and that we need to design custom solutions, but when we examine the problem from other perspectives, the abstractions begin to rise to the surface. But in order to take advantage of the solutions as they are built, we must be part of the discussion about the requirements, push for our use cases to be considered in their design, and take part in testing, implementing and sustaining the solutions.

This will be a full day workshop in the format of a hands-on round-table and open discussion. Participants will be asked to come prepared to discuss details of their particular use cases, as well as solutions and needs relevant to two of the initial outputs of the RDA: the Persistent Identifier (PID) Types (Weigel, et. al., 2015) and Data Types Registry (DTR) (Lannom, et. al., 2015). In advance of the workshop, organizers will provide summaries of these outputs and detailed examples of their analysis for use cases in humanities and other relevant domains.

This workshop is a complement to the panel by Dr. Natalie Harrower et. al. entitled "Digital data sharing: the opportunities and challenges of opening research". The panel presents particular challenges in humanities research data management, and aims to generate a discussion around the uniqueness and challenges inherent in humanities research data. This workshop, on the other hand, is a hands-on effort to work with real humanities data use-cases, provided by participants, to understand how to best shape RDA outputs to enable better data sharing and management in the humanities.

Format of the Workshop

In the first two hours of the workshop, organizers will present a summary of humanities activities in RDA thus far, and describe current calls for participation by RDA working and interest groups.

These calls address an array of topics important in the digital humanities: Institutional Review Boards (IRB), access solutions and metadata standards that support data sharing; the need for institutional repositories for both live and archived digital projects; the need for a "data net" to connect globally distributed repositories, enabling discovery and access; the need for cultural and organizational changes in the humanities to research data sharing and open scholarship.

Specific RDA activities covered will include:

- The Digital Practices in History and Ethnography Interest Group (DPHE-IG) (https://rd-alliance.org/node/508), chaired by anthropologists Mike Fortun and Kim Fortun at Rensselaer, and Jason Jackson, Director of the Mathers Museum of World Cultures at the University of Indiana.
- The successful adoption by the Platform for Experimental and Collaborative Ethnography (PECE) (http://worldpece.org) of the RDA Practical Policies

Recommendations, a specification for best practices for data management.

- Two nascent RDA Working Groups: the Research Data Collections WG (https://rd-alliance.org/groups/pid-collections-wg.html) and the WG on Empirical Humanities Metadata.

We will wrap up the first half of the morning session with a group effort to identify the range of solutions and support needed for research data management and sharing in the digital humanities in coming years, and potential opportunities for RDA collaboration. The list generated will be taken back to the RDA community for their consideration and feedback.

The second half of the morning will be devoted to an in-depth presentation of the RDA PID Types and DTR outputs, including a demonstration of their implementation.

After lunch, each participant will be invited to present their use case/requirements and engage with workshop organizers and participants in a discussion of the relevance and gaps and cost/benefit of adopting the solutions being proposed by RDA. Prior to the workshop the organizers will issue a short survey for participants to answer directed questions about their requirements as well as a template for more detailed descriptions of their use cases. Specific focus will be on the PID Types and DTR solutions, but other relevant outputs or in-progress efforts may be considered as well. Workshop organizers will take notes and produce a summary report following the workshop to share with the RDA community for their consideration and feedback.

Target Audience

Members of the ADHO community who are interested in collaborating with a global multi-disciplinary community to define, develop, test and adopt infrastructure for supporting the management, preservation and sharing of humanities research data. Participants should have some experience with digital humanities projects for which general solutions for working with Persistent Identifiers and machine actionable Data Types are relevant.

Workshop Leaders

Bridget Almas is a Senior Software Developer for the Perseus Digital Library at Tufts University (http://www.perseus.tufts.edu) and co-PI of the Perseids Project (http://www.perseids.org), a collaborative online environment for creating and publishing datasets consisting of transcriptions, translations, linguistic annotations and commentaries of and on ancient source documents. She is a co-chair of the RDA Research Data Provenance Interest group, and a former member of the RDA Technical Advisory board.

Kim Fortun is a cultural anthropologist and Professor of Science & Technology Studies at Rensselaer Polytechnic Institute. From 2005-2010, Fortun co-edited the *Journal of Cultural Anthropology* (http://www.culanth.org/), as it was developing its original digital infrastructure. Fortun has played a lead role in the development of the Platform for Experimental and Collaborative Ethnography (PECE), an open source/access online work space for anthropological and historical research. Fortun co-chairs the RDA DPHE Interest Group.

Dr. Natalie Harrower is the Director of the Digital Repository of Ireland (DRI) (http://www.dri.ie/) - a publicly accessible online repository for the long-term preservation, sharing and reuse of humanities and social science data. In addition to building an open-source trusted digital repository to international standards, the DRI also influences policy and publishes reports and guidelines on data archiving, metadata standards, preservation infrastructures, Linked Data, digital preservation challenges unique to cultural data, and digital humanities. DRI is piloting a research data management project with diverse digital arts and humanities data, and their current flagship project is the award-winning digital cultural heritage site *Inspiring Ireland* (inspiring-ireland.ie).

Eveline Wandl-Vogt, research manager at the Austrian Academy of Sciences, Austrian Centre for digital Humanities and VCC1 Co-Chair eInfrastructures, COST ENeL; expert in several national and international committees – mainly focussing on standardisation, interoperability, Social Innovation and Open Science. Recently, she mainly focuses on supporting transformation processes from the Humanities towards Interdisciplinary Humanities and applied Humanities in the framework of Open Science, Citizen Science and Open Innovation.

A Place for Places: Current Trends and Challenges in the Development and Use of Geo-Historical Gazetteers

Carmen Brando
carmen.brando@ign.fr
Institut National de l'information géographique et forestière (IGN), France

Francesca Frontini
francesca.frontini@ilc.cnr.it
Istituto di Linguistica Computazionale "A.Zampolli", Italy

The implementation of geo-historical gazetteers increasingly depends upon the development of Natural Language Processing (NLP) and Corpus Linguistics as well as geographical analysis in disciplines such as History, Archaeology and Literary Studies. The application of these methods usually relies on the appropriate modelling of databases for performing the semantic enrichment of documents including geoparsing tasks. At the same time, even when performing a manual enrichment and referencing of place mentions in texts or in library or museum catalogues (e.g. when applying the CIDOC CRM model and its spatio-temporal extension), an adequate source of external information is crucial.

Today, geo-historical data are more and more often published following the Linked Data (LD) principles: i.e. using URIs and data format standards (RDF) and linking to other data sets to enable information discovery. Moreover, an implicit driving principle of LD, widespread in the Semantic Web community, is the reuse of vocabularies and ontologies already defined by others to avoid duplication. Keeping track of provenance is crucial. Pleiades is one of the best examples these days, but other generalistic sources such as DBpedia, Wikidata or GeoNames also provide interesting - albeit partial – geo-historical information and have proved to be useful in Digital Humanities (DH) projects. Linking texts to external sources using URIs enables the retrieval of additional information about the referenced places. Once this has been achieved, the information in the sources can be easily used to produce different views and aggregated analysis of corpora: i.e. visualizations (Jessop, 2008); this in turn is meant to help scholars to capture place perceptions and to analyse spatio-temporal phenomena described in corpora.

The choice of geo-historical datasets which are used as gazetteers depends on the domain of the texts under consideration. Pleiades is specifically suited to places in Mediterranean Ancient History texts. However, tasks such as referencing places from historical periods other than Antiquity, or identifying geographically vague or imaginary places in literary texts, if ever possible, might need the development of a different methodological approach, which would include the construction of conceptual mapping models and the creation of a completely different kind of gazetteer. In any case, the choice will have an important influence on the results of such visualizations as well as on the pertinence of the interpretation. Existing gazetteers vary widely in how they abstract the world. Important aspects – such as scale, the representation of time (and change over time), complex geometries, uncertainty and vagueness as to location and/or date, multiple points-of-view, representation of hierarchies of political-administrative units, their boundaries and their change over time, alternative names (rejected and standard forms, vernacular and multilingual), representation of fantastic places – are modelled in different ways, or are missing altogether. This limits their applicability in the Humanities. Moreover, interlinking between corresponding entities in different gazetteers is often lacking, although progress has been made in this regard, through community initiatives or by using GeoNames, or Wikidata as backbones (Simon et al., 2015). Finally, the ontologies used to link toponyms in texts to spatial references need to be further developed, especially when it comes to deal with fuzziness and uncertainty in mentions (Reuschel and Hurni, 2011).

Clearly, new models should conform to LD principles, and they should privilege the reuse of existing and consolidated ontologies, vocabularies and datasets whenever possible. Long term preservation and maintenance are also crucial problems in this sense because texts enriched with references to sources that have become obsolete or unavailable may have results that are unusable for the task for which they were tagged (Janowicz et al., 2012). In this sense, specialisation of efforts on the one hand (for pooling efforts) and coordination on the other, are crucial for such projects. Finally, geo-historical projects should also promote harmonization of their data with standards and practices of the broader DH community, and of the current research trends, in particular for what concerns the interoperability of resources within the framework of larger research infrastructures such as CLARIN or DARIAH.

In the proposed full-day workshop, we will focus on geo-historical gazetteers, and we will discuss their limits in supporting the needs of the Spatial Humanities (SH) community. The proposed workshop will be composed of nine presentations (abstracts are listed below), each of which concerns the production of geo-historical gazetteers as LD as well as the annotation, the recognition and the geoparsing of place names referenced in texts, library and museum catalogs, digitized maps, etc.

Christopher Donaldson (University of Birmingham), Extracting and visualizing the geographies in historical travel writing: This presentation will introduce a procedure for the automated extraction and resolution of geographical information from a corpus of historical writings about the English Lake District. The research on which the presentation is based is using the spatial analysis of geo-historical LD sets to achieve a more comprehensive and refined understanding of how the landscape of the Lake District was perceived, represented, and experienced in the past.

Karl Grossner (Stanford University), Joining Place and Period in Historical Gazetteers: Places referred to in historical documents and gazetteers have temporal as well as spatial extents. Likewise, historical periods have spatial extents. However existing data models and format standards and the mapping and timeline software that use them do not reflect this. I will discuss recent work on Topotime, an extension to the GeoJSON format adding temporal expressions, and allowing for some types of uncertainty encountered in historical data.

Katherine Hart Weimer (Rice University): A wealth of geographic information is included in library catalogs, with existing structures for name disambiguation, cross-referencing and inclusion of geographic coordinates. Recently, efforts are underway in libraries to convert this data into LD allowing for cross platform applications. The presentation describes an experiment in this sense.

Maurizio Lana (Università del Piemonte Orientale): Annotation of place mentions in Latin Literature. The annotation pipeline uses parsing+NER but later mentions are manually checked and referenced to external gazetteers such as Pleiades. The novelty of the project is the GeoLat GO! ontology that allows for a more complex annotation.

Bruno Martins (University of Lisbon): NLP and IR methods for handling geospatial information in textual documents. In my talk, I will present a brief survey of techniques for handling geospatial information within textual documents, including work at our team in the University of Lisbon, and other methods proposed within the Computational Linguistics and IR communities. I will discuss methods to address the problems of (i) document geocoding, (ii) toponym resolution, and (iii) selecting geographically relevant key-phrases. Applications within the broad field of DH, and SH in particular, will also be outlined.

Patricia Murrieta-Flores (University of Chester): So far, research in the SH has been mainly concerned with geographically precise information or what could be considered as 'real' places in historical and literary sources. Nevertheless, non-locational places play an important role in narratives of all sorts of sources from the fantastic, to geographically vague travel accounts. This is an important limitation in the analysis of place in the DH. Using Medieval Romances as an example, this presentation will discuss the challenges posed by literary narratives of place in terms not only of disambiguation, but also reference to fantastic and non-locational places.

Michael Page (Emory University): Atlanta Explorer: Historical Geocoding & the City: Atlanta Explorer focuses on building datasets and geospatial tools to explore the history of the city. Completed is a geodatabase and geocoder for circa 1930 and the pilot 3D virtual environment. The next phase includes producing geocoders for the remaining years (1868–1930) and therefore strategies and methods for developing historical geocoding datasets and tools for place discovery will be discussed. Our goal is to also share the underlying data with the community CityGML as how we would likely share and archive the model.

Rainer Simon (Austrian Institute of Technology), Pelagios project: an international community initiative concerned with the development of Linked Open Data methods, tools and services to better interconnect geo-historical datasets. In its most recent project phase ("Pelagios 3 - Early Geospatial Documents"), Pelagios has developed Recogito, a semi-automatic geo-annotation tool; Peripleo, a geotemporal search engine. Furthermore, Pelagios has annotated more than 300 historical sources from different cartographic traditions, collecting more than 120,000 place references in literary texts and early maps.

Humphrey Southall (University of Portsmouth): Engaging the wider public with historical gazetteers. Gazetteers are a powerful tool for humanities researchers, but are also of great fascination and utility for the general public. That interest enables academic projects to achieve wider "impact", enables popular web sites to be sustained by advertising income, and enables expansion through crowd-sourcing. This presentation covers three experiences: the established Vision of Britain site; PastPlace, our new LD gazetteer which uses Wikidata as a spine to which we are adding historical toponyms; and GB1900, a crowd-sourced gazetteer building project developed in collaboration with National Libraries in Great Britain.

The proposed workshop targets an audience of scholars, data designers, and software developers, and will also comprise a speed presenting session for participants, topic-based breakout discussions between experts and attendees, a panel to highlight research priorities and summarize the main contributions of the workshop and research directions.

Introduction

Modern infrastructures for the management and dissemination of humanities data face various challenges. On the one hand, sustainability and availability for long-term preservation have to be guaranteed. On the other hand, flexibility and the possibility of individual data usage play a major role in this field. The FEDORA based Asset Management System GAMS (Geisteswissenschaftliches Asset Management System – Humanities' Asset Management System) and the corresponding Cirilo client, developed by the Centre for Information Modelling - Austrian Centre for Digital Humanities (ZIM-ACDH), address both demands in combining long-term preservation with a presentation and management layer. This means that all of the mentioned challenges can be solved within one infrastructure.

GAMS

GAMS is an OAIS compliant infrastructure designed for the management, publication and long-term preservation of digital resources. It is based on the Open Source software FEDORA and focuses on the long-term availability and flexible use of digital content. Since 2014 it is a certified trusted digital repository in accordance with the guidelines of the Data Seal of Approval.

FEDORA offers content models for the aggregation of the digital content, metadata and processing instructions. An example for such an aggregation could be a TEI-document with XSL transformations for various dissemination formats (HTML, PDF, different views for analysis purposes etc.), an RDF datastream that handles the description of the object's semantic relations and images with their metadata (e.g. facsimiles of the data covered in the TEI). A functional view on FEDORA's object model includes program-controlled processes based on web services e.g. XSL transformations for dynamic outputs or automatic extraction of semantic relations within a TEI document.

Cirilo

Cirilo is a java application developed for content preservation and data curation in FEDORA-based repository systems. The client operates through FEDORA's Management API (API-M) and consequently offers functionalities, which are especially suited to be used as tools for mass operations on FEDORA objects, complementing FEDORA's inbuilt administrator's client. Cirilo exploits FEDORA's object model by providing a collection of predefined content models optimized for specific primary sources like TEI, LIDO, METS/MODS, OAI-Records, HTML, PDF, BibTeX or external resources that can be accessed via a URL.

Several possibilities to semantically enrich the digital objects during the ingest process through different customizable mapping methods are offered: Dublin Core for exposing the objects in harvesting environments (like Europeana), geographical information to present data in map applications (like the DARIAH-DE Geo-Browser), or RDF statements that are stored in triplestores. Furthermore, extraction of semantic information, automatic addition of picture references to the object or resolving text data in combination with underlying ontologies are possible.

Since 2014, the Cirilo client has been available as an open-source tool including a comprehensive documentation, representing one of the Austrian contributions to DARIAH-EU. Thus, the entire infrastructure including repository and client is accessible as an archive-in-a-box solution for a broad user community.

Application

In this context, the infrastructure was adopted by the Petőfi Literary Museum as a solution for their online editions. The project DigiPhil is an online knowledge base for publishing scholarly text editions, writers' bibliographies, aggregating philological metadata and semantic annotation of these sources. At the University of Graz, GAMS hosts numerous digital editions as well as image collections and source books from various disciplines: the literary analysis of the enlightened Spectator press of the 18th century, a postcard collection with topographical and historical views on Styria from 1900 to the present or the account books of Basel from 1535 to 1610.

The workshop offers the opportunity to learn more on the underlying principles of the infrastructure and to try the mentioned functionalities of the Cirilo client in a hands-on session with a provided data sample.

There is an abundance of biographical information online that begs to be analyzed with computational methods. Resources like Wiki- and DBpedia, Biographical Dictionaries, Historical Databases, Newsfeeds, Facebook and Twitter all provide information on individual's lives. 'Biographical data' is of particular interest to computer scientists, because it can be well structured and all people share common attributes such as place of birth, place of residence, parents, et cetera.

The analysis of `biographical data' with new techniques is a topic that is finding strong interest in research groups all over the world, demonstrated most recently by the first conference on Biographical Data, organized in Amsterdam in 2015. This conference brought researchers from various domains together including historians, librarians, computer scientists, data scientists, and computational linguists.

The purpose of this workshop is to take a next step in strengthening the community working with digital biographical data by exploring possibilities of turning shared interest into new international collaborations. A central theme in this next step will be connecting and linking data.

A strong international community working on biographical data and aiming for shared data representations can directly support other domains in the digital humanities: easily accessible background information on people involved in historical or contemporary events, on artists, researchers or groups of people with common professions can provide background information and therefore be of interest to digital humanities researchers working with topics beyond research on biographical data.

This workshop brings together researchers from various domains working on biographical data. In addition to sharing latest progress, it has the specific aim of initiating efforts to share (knowledge about) data and data models. The workshop directly contributes to the efforts of the DARIAH workgroup on biographical data and aims to involve new researchers in this collaboration. A call for organization will go out for the Biographical Data in a Digital World Conference in 2017 (2015 conference: http://ceur-ws.org/Vol-1399/).

The workshop consist of two main components: 1) a poster session where researchers can share their latest work on biographical data and computational analysis and 2) dedicated sessions about data and data models.

For our poster session, we explicitly invite researchers to the workshop who work with biographical data for historical research or data analysis (e.g. computational linguists, visualization experts) and are thus already very familiar with models for biographical data, but are not necessarily involved in designing them. This perspective is of great value during discussions on sharing and modeling data and can provide insights into what kind of data models are practical to work with or which links between various datasets are most valuable for research. These insights can in turn help to identify logical and practical first steps towards increasing international collaboration

Descriptions on data models and data samples will be distributed to participants in advance and studied by a panel. The panel will present their findings and support the discussion on sharing data. Direct involvement in several projects and strong relations with other international partners guarantees an interesting set of data and data models.

Digital Literary Stylistics Workshop

J. Berenike Herrmann
bherrma1@gwdg.de

Francesca Frontini
francesca.frontini@ilc.cnr.it
Instituto di Linguistica Computazionale “A. Zampolli”, CNR, Pisa, Italy

Marissa Gemma
marissa.gemma@aesthetics.mpg.de
Max Planck Institute for Empirical Aesthetics, Frankfurt, Germany

The study of textual style by computational means has a long tradition, but only quite recently have such approaches been able to leave the sphere of forensics to become an instrument of legitimate literary analysis of style.

This new line of research has already yielded a considerable range of digital style studies of epochs, genres, and authors (e.g., Egbert, 2012, Hoover, 2007, Houston, 2013, Mahlberg, 2012). At the same time, questions of conceptualization (e.g., Herrmann et al., 2015) and method (e.g., Jockers, 2013, Moretti, 2013 and 2005) have quickly arisen, and it has become clear that the use of software and computational means does not necessarily imply the adherence to a strictly experimental methodological approach (cf. Ramsay, 2011).

In this workshop, we shall explore novel empirical findings as well as methodological and epistemological questions connected with the computational study of style. In particular, we intend to address topics that fall within the following domains:

(A.) The technical domain. Tools/methods of analysis (computational stylistics, corpus stylistics, literary authorship attribution, NLP, digital hermeneutics); research infrastructures and corpus building;

(B.) The empirical domain. Style variation across factors such as genre, author, gender, epoch and period; narrative perspective and characterization; non-literary registers;

(C.) The conceptual domain. Notion(s) of style; style and aesthetics; typology of style indicators; style production and reception; research design (“close”, “scalable”, and “distant reading”); epistemological status of data; issues of representativeness.

First, the workshop will feature a set of papers focused on the technical side of digital literary stylistics. **Jean-Gabriel Ganascia** will present a tool for establishing stylistic distinctiveness on the basis of syntax (“Towards a computational and syntax-based stylistics”) and **Tomoji Tabata** will evaluate a series of Eder's (2015) “Rolling Stylometry” techniques (“Experimental Stylistics: A Meta-analysis to Evaluate Rolling Stylometry”).

Next, we turn our attention to empirical findings about style. Papers in this category include **Christof Schöch**’s computationally-informed revision of Spitzer’s take on Racine (“Spitzer on Racine, digitally revisited”); **Natalie Houston**’s discussion of period-specific styles in nineteenth-century British poetry (“Towards a Computational Poetics: Some Features of Nineteenth-Century Poetic Style”); **Anne Bandry-Scubbi**’s presentation of stylistic differences between male and female authors in a corpus of novels between 1750-1830 (“Women’s Novels 1750s-1830s and the Company They Keep: A Computational Stylistic Approach”); **Jan Rybicki**’s analysis of how most frequent word usage changes with time in the oeuvre of authors of various languages and literary periods (“Authorial chronology by most frequent words: do writers’ stylometric thumbprints evolve with age?”), and **Christine Knoop**’s analysis of the distribution of rhyme and cadence schemata in German lyrical poetry between 1700-1930 (“Rhyme and Cadence Distribution in Poetry”).

Finally, the workshop will address ‘style’ conceptually within the framework of computational analysis, with papers including a discussion by **Mike Kestemont** of different ways of understanding artistic authenticity in various humanistic disciplines (“The Matter of Art: Authenticity Criticism in the Humanities”); a paper by **Sarah Allison** on what the humanistic adoption of the statistics concept of a ‘proxy’ means for stylistic research (“A Proxy for Style”); and **Fotis Jannidis** on whether the concept of “historical period” is a meaningful notion in stylometry (“Period Styles”). Expanding this conceptual discussion, **Hugh Craig** will present some possible remedies to critiques of descriptive quantitative stylistics (“Beyond Authorship”), and **Mark Algee-Hewitt** will examine how two common assumptions in digital literary stylistics (that authors are individuals with identifiable mentalities, and, in the pragmatics of authorship attribution, that these individuals can be reduced to probabilities of word frequencies) affect our notion of the author (“The Author: Between Style and Substance”).

Insights from the three domains will be drawn together in a discussion panel. Here, we will identify current topics and trends, define the horizons of “Digital Literary Stylistics” and map out the avenues of collaboration between its different branches. Our aim is to define a shared roadmap for a Special Interest Group (SIG) within the ADHO for the field of Digital Literary Stylistics. A special issue of a DH journal will comprise the papers as well as a report of this discussion.

Multispectral imaging is a powerful tool to recover text from manuscripts affected by fading, palimpsesting, water, fire, or overpainting. Many scholars working in the digital humanities have some acquaintance with the technology, but practical experience will help them better understand the range of imaging modalities that comprise contemporary multispectral imaging and the potential of each to advance their research. Though this workshop, scholars will be equipped to identify good candidates for the technology, and thus contribute to the recovery and preservation of our cultural heritage.

The Lazarus Project, headquartered at the University of Mississippi and directed by Gregory Heyworth, operates such a state-of-the-art multispectral imaging system that can be transported to institutions and researchers around the world so that the technology can be made available at no cost. This is part of the educational mission of the Lazarus Project – as a teaching tool for undergraduate and graduate students in the humanities and the imaging sciences – and is the reason why the capability may be offered at no cost. The system has been transported to institutions in the USA, England, Wales, France, Italy, Germany, and the Republic of Georgia to image a number of important historical objects, among which are the Vercelli Book, the Black Book of Carmarthen, and the c. 1491 world map by Henricus Martellus. This mission and capability of the Lazarus Project enables mid-sized institutions with a few manuscripts to benefit from the technology of multispectral imaging without making a sizeable investment in imaging equipment and personnel training. In addition, the cultural heritage objects are imaged at their home institution, without the difficulty of traveling to a stationary system that may be thousands of miles distant. The availability of this portable system that provides multispectral imaging free of charge makes it even more important that scholars who visit libraries and archives be able to identify good candidates for the technology.

The Lazarus Project will offer a workshop for participants in DH2016 in which the portable multispectral imaging system and the subsequent spectral image processing will be demonstrated. These demonstrations will take place in the Jagiellonian Library, and manuscripts from the library will be imaged. Thus, participants in the workshop will have the opportunity to see how multispectral imaging works, from the imaging of the object to the processing of the images and results. Each session will include a description of the equipment and process (camera, lens, LED light system, PhotoShoot software, and processing software tools), a few cycles of imaging of leaves of a manuscript, and a look at what goes into processing the images—with time for questions.

There will be four 90-minute workshops at the following times:

Monday, 11 July 2016: 9:30am - 11:00am
Monday, 11 July 2016: 2:30pm - 4:00pm
Tuesday, 12 July 2016: 9:30am - 11:00am
Tuesday, 12 July 2016: 2:30pm - 4:00pm

A maximum of 17 participants will be permitted in each session due to space constraints in the room in the Jagiellonian Library.

We look forward to seeing you at the demonstration.

Visual Network Analysis with Gephi WorkshopCollective Interpretation of DH Communities Through Twitter Networks

Mathieu Jacomy
mathieu.jacomy@sciencespo.fr
Sciences Po, médialab, France

Martin Grandjean
martin.grandjean@unil.ch
University of Lausanne, Switzerland

Paul Girard
paul.girard@sciencespo.fr
Sciences Po, médialab, France

Gephi is a free and open source network analysis software used, among other things, in social network analysis. This workshop is intended for beginners as well as confirmed users. First, we offer an introduction to the basics of Gephi, then we explore through practice the question of visual network interpretation. We provide a dataset of both Twitter hashtags and Twitter followers graphs on various topics related to the DH community.

Why network interpretation matters

Reading a network visualization can sometimes be harder than simply producing it. Once the graph has been produced, what are we supposed to look at? Nowadays, it is common to learn how to use social network analysis software such as Gephi via online tutorials, but it is often difficult to learn how to interpret the results. Based on the experience of members of the software development team and Gephi power users, we offer this workshop to help users interpret their results.

Network visualizations are exploratory rather than explanatory. As a scholar, it is important to leverage network visualization in order to find interesting insights inside your data. Exploring a network requires mobilizing external knowledge on data's context. Exploration is about generating, and not validating, hypotheses. Networks do not carry a single, clear message, and it is as fruitful for analysis as it is bad for communication. Dispelling this misunderstanding is very important if you want to fully benefit from a tool like Gephi.

The idea that a tool can analyze things for you is another misunderstanding we can help tackle. Gephi allows you to explore multiple facets of your data, but the interpretation remains to be done by the user him/herself. Users have to spend time with their data, and a workshop is a good place to introduce this data-care principle.

Once you know what to look for in a network, you will capable of finding insight but you still have to excavate some evidence. Network metrics are more capable of doing so than the visualization itself. In this workshop we will also learn to match visual features with metrics so that you can provide evidence for what you have seen. For instance, observed clusters are proven to be modularity clusters in the sense of Newman (Noack, 2009).

Workshop schedule

Part 1: Visual network analysis in a nutshell

We start the workshop with a presentation about why and how we visualize networks (Jacomy et al., 2014) and how we interpret them (Venturini et al., 2015) through a Exploratory Data Analysis method (Tukey, 1977)

Part 2: Gephi practice

In this part we explain Gephi through examples. We manipulate Gephi on screen while participants execute the same operations on their computers, using the provided datasetsAckland, R. 2013. "Web social science: Concepts, data and tools for social scientists in the digital age." SageAckland, R. 2013. "Web social science: Concepts, data and tools for social scientists in the digital age." Sage (Grandjean, 2015). The complete chain of usage will be addressed by illustrating Gephi features from basics (software installation, layout, data table…) to advanced (computing statistics, filtering, exporting…).

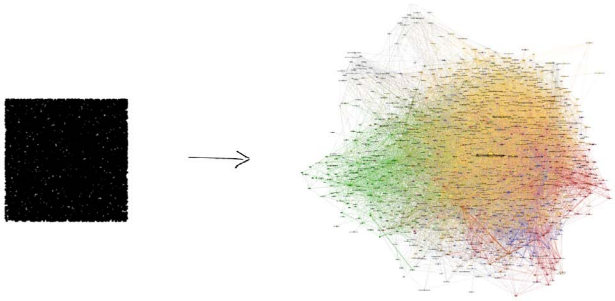

Figure 1: Participants will learn how to produce a readable Gephi map

Part 3: Guided practice

Each group makes a visualization and wraps it up in a few slides using screenshots (Girard et al., 2015). The trainers provide practical help to participants.

Part 4: Collective discussion

Each group presents its findings, and we leverage these live examples to discuss the interpretation process through networks and notably its robustness compared to the visualisation choices.

This workshop is supported by DIME-WEB part of DIME-SHS research equipment financed by the EQUIPEX program (ANR-10-EQPX-19-01).

Web Communities Mapping With HypheHow to use a curation-oriented web crawler to map communities?

Mathieu Jacomy
mathieu.jacomy@sciencespo.fr
Sciences Po, France

Paul Girard
paul.girard@sciencespo.fr
Sciences Po, France

Benjamin Ooghe-Tabanou
benjamin.ooghe@sciencespo.fr
Sciences Po, France

This workshop introduces a curation-oriented web crawler called Hyphe. This software, developed with and for Social Sciences and Humanities scholars, aims at providing a method and a tool to build a research corpus from web content (web pages and HTTP links). It provides a web mining tool wrapped with a User Interface and curation features (defining web pages aggregates, filtering contents, expansion method) required by Social Sciences and Humanities scholars.

We will focus on using the web crawler and will not take the time to present web studies, digital sociology or digital methods in general. Participants should have basic knowledge of the web and already consider it as a legitimate field for scientific investigation (Ackland, 2013). Participants are encouraged to come with ideas regarding which websites would be interesting to study for their personal research agenda (a list of entry points).

Hyphe, a curation-oriented approach to web crawling for the social sciences

The web is a field of investigation for social sciences, and platform-based studies have long proven their relevance. However the generic web is rarely studied in and of itself, though it contains crucial embodiments of social actors: personal blogs, institutional websites, hobby-specific media… We realized that some sociologists see existing web crawlers as "black boxes" unsuitable for research though they are willing to study the broad web. Hyphe is a crawler which was developed with and for social scientists, with an innovative "curation-oriented" approach meant to address two of the main social science problems when working with web mining: how to build a corpus and how to delineate an actor's presence (Jacomy et al., 2016).

Workshop schedule

The workshop will first introduce Hyphe's software and methodological principles through a guided case study. The participants will be guided through their first use of Hyphe to build their own web corpus.

Part 1: Presentation of methodological approaches with a case study

We will start the workshop with a presentation of our software Hyphe and its methodological principles. It will be done through its application on a case study. We offer to map the Digital Humanities communities through the many websites used to present and organise associations, conferences, research projects, research labs… We will build such a corpus live during this first part to introduce the participants to the main concepts and practical steps one should meet when building a web corpus. The teachers will have prepared the corpus before the workshop with a series of most common use cases and issues. The subject of digital humanities is proposed first because these communities use web communication a lot, and secondly to better engage the participants with a subject they are familiar with.

Part 2: Hyphe practice

After this extensive presentation of Hyphe, participants will be invited to engage in practice themselves. Individually or as groups of two, they will be given access to their own corpus on an online version of Hyphe and will be invited to map web communities on their subject of research following Hyphe's iterative curation process:

- define the first actors web "boundaries" and start crawling them
- observe the resulting network of actors (websites)
- prospect the web for other potentially interesting actors by exploring most linked actors, filtering out irrelevant ones such as Google or Youtube
- crawl these actors' websites as well
- adjust the "boundaries" of the new actors found to better represent their social reality
- iterate over and over until obtention of a reasonably complete corpus
- visualize as a network map and take a quick look at its structural properties (clusters, density…)

We will conclude this part with a discussion on methodologies to wrap-up the workshop.

This workshop is supported by DIME-WEB part of DIME-SHS research equipment financed by the EQUIPEX program (ANR-10-EQPX-19-01).

Data mining digital libraries

Lars Gunnarsønn Johnsen
yoonsen@gmail.com
National Library of Norway, Norway

Magnus Breder Birkenes
magnus.birkenes@nb.no
National Library of Norway, Norway

Arne Martinus Lindstad
arne.lindstad@nb.no
National Library of Norway, Norway

The central theme for this workshop is data mining and the connection between metadata and data in the context of digital libraries. Digital resources and search engines raise several questions about the relationship between metadata and the data they describe. For example, what is the relationship between metadata keywords and classification categories (e.g. Dewey)? How should topics found by topic modeling algorithms be labelled? With readily available search engine technology, using document relevance based on content words, is there a need for library classification systems at all, like Dewey or UDC?

While there may be overlap between metadata and the texts described contentwise, metadata typically contain information not found within the text, such as author, geolocation and time data. In addition, subject or topic words typically consist of carefully constructed language models in the form of thesauri dedicated specifically towards specialized literary collections within different fields. The question is then how search engines may benefit from such metadata with a language model, and for what kind of library user?

In this workshop, we invite colleagues to discuss the application of various methods related to digital library resources, including the structure of the metadata itself, as well as digital book collections. Many resources are available to libraries in digital form, like journals and new book titles, while some libraries also have launched digitization programs to create digital libraries, using scanners and OCR technology.

Both the text data and the metadata of digital libraries can be scrutinized with data mining techniques, opening up the material for large-scale, quantitative analysis. This makes such collections highly relevant for Digital Humanities studies.

Background

The ongoing trend towards increased digitization in society in general poses numerous challenges at many levels, but also opens up for vast opportunities within many fields, including the library sector.

At the National Library of Norway, a mass digitization project was initiated in 2006, with the goal of digitizing the entire collection of books, newspapers, movies, radio- and television-broadcasts, music etc., in sum everything published in the public domain in Norway of all media types, i.e. the entire cultural heritage of Norway. For books, the goal is to have the entire stock digitized by 2017. Thus far, some 435.000 of 450.000-500.000 books have been digitized. When all books and newspapers have been digitized, we estimate that our Norwegian text corpus will consist of some 80 - 100 billion tokens, which is big for a rather small language like Norwegian with approximately 5 million speakers. In comparison, the Google Books corpus contains approximately 500 billion tokens for English.

The National Library cooperates with scholars of literary studies and linguistics in developing and applying methods of data mining to the digital collection. We develop services that make the content available for quantitative research, without challenging intellectual property rights. One such service is NB N-gram for Norwegian (see http://www.nb.no/sp_tjenester/beta/ngram_1/), comparable to Google Ngram Viewer for English and other languages.

Workshop leaders

Lars G. Johnsen: Research librarian at the Nation Library of Norway, PhD in linguistics. Fields of interest: semantics, grammar, philosophy of language, probability theory and applications. Email: Lars.Johnsen@nb.no, Phone: +47 23 27 61 84

Arne Martinus Lindstad: Research librarian at the National Library of Norway, PhD in linguistics. Fields of interest: corpus linguistics, language change, comparative syntax, negation. Email: arne.lindstad@nb.no, Phone: +47 23 27 62 11

Magnus Breder Birkenes: Research librarian at the National Library of Norway, PhD in linguistics. Fields of interest: corpus linguistics, history and dialectology of the Germanic languages. Email: magnus.birkenes@nb.no, Phone: +47 23 27 60 54

Call for papers (cfp)

Are you interested in automatic classification of documents and what implications this has for libraries? How may search engines (like ElasticSearch) benefit from library metadata? Do you have any experience with developing public/academic web services on top of large amounts of library data? If these questions appeal to you, this workshop may be of interest. The central theme for this workshop is data mining and the connection between metadata and data in the context of digital libraries.

We invite papers on topics such as:

- The structure of subject headings and descriptors, used in book classification (e.g. in building thesauri)
- The relationship between topic words and library classification systems
- The relationship between content words and topic words (of existing metadata, or as output from topic modeling algorithms)
- Automatic classification of digital documents
- Authorship attribution
- Development of computational services for research and the general public
- Legal issues arising with different data mining practices

Please send us an abstract of max. 500 words that is situated within the above context.

Audiovisual Data And Digital Scholarship: Towards Multimodal Literacy

Martijn Kleppe
martijn.kleppe@kb.nl
National Library of the Netherlands, The Hague

Scagliola Stef
scagliola@eshcc.eur.nl
Erasmus University Rotterdam

Henderson Clara
clahende@indiana.edu
Indiana University, Bloomington

Oomen Johan
joomen@beeldengeluid.nl
Netherlands Institute for Sound and Vision

In many online platforms and websites, audio-visual data is gradually playing an equal or greater role than text. Similarly, in multiple disciplines such as anthropology, ethnomusicology, folklore, media studies, film studies, history, and English, scholars are relying more and more on audio-visual data for richer analysis of their research and for accessing information not available through textual analysis. Developing aural and visual literacy has therefore become increasingly essential for 21st century digital scholarship. While audiovisual data allows for research to be disseminated and displayed linearly, within one modality (e.g., reading a book from first to last page), it also allows for non-linear discovery and analysis, within multiple modalities (e.g., reading a webpage, browsing to a link with a sound clip, from there to a clip with film). This workshop will address both the challenges of *analyzing* audiovisual data in digital humanities scholarship, as well as the challenges of educating contemporary digital humanists on how to access, analyze, and disseminate an entire century of information generated with audiovisual media.

Other challenges to be addressed at this workshop concern issues surrounding copyright and sustainability and their impact on the dissemination and long-term access of audiovisual resources. One area of heated debate is whether certain copyright laws, which were originally instated to protect the development of new inventions, are in fact hampering the dissemination of new knowledge due to the restrictions they place on ways information may be displayed or disseminated. Some scholars contend that copyright laws will become obsolete over the next decades, while others argue that these laws will progressively restrict how scholars use audiovisual media in digital humanities research. Because of the complicated ways these copyright restrictions relate to audiovisual media, they affect films, television and sound more profoundly than digitized books with text and still images. Given these particular challenges faced by digital humanists working with audiovisual materials, a number of questions arise regarding how we might navigate these complex issues concerning copyright, sustainability and long-term storage and access. Can infrastructures essential for shepherding these digital transitions be made available for individual audiovisual digital humanities projects? Can digital humanists look to the university library as the place to support and sustain the websites, datasets and tools created by audiovisual DH research? How can digital humanists secure the massive server space needed to sustain the large-scale storage needs inherent in audiovisual DH projects? Who should oversee the recurring process of inevitable file migration and quality assurance needed for film, photo and sound formats? Are 'business-models' and their potential commercial benefit the way to go or are such arrangements overly optimistic? Are there encouraging examples of successfully sustained audiovisual DH projects that have effectively dealt with copyright issues? Will audiovisual DH scholars become increasingly dependent on philanthropic monopolistic corporations such as Google, Facebook, IBM and Microsoft to sustain their projects? What role should universities play as custodians and advocates of the knowledge produced by our audiovisual DH projects?

Workshop Overview

This full-day workshop will start with a keynote address on multimodal literacy by Dr. Claire Clivaz, Head of Digital Enhanced Learning at the Swiss Institute of Bioinformatics of Lausanne and active in #dariahTeach for which she is Head of dissemination and developer of the module Multimodal Literacies. This keynote will be followed by three sessions of paper presentations based around three themes:

- Models for training digital humanists in accessing and analyzing audiovisual collections
- Analysis and discovery models for audiovisual materials
- Copyright and sustainability

During the fourth session, workshop participants can give very short lightning talks/project pitches of max 5 minutes of ongoing work, projects or plans. Registration for this session will take place during the workshop so no submission is needed for part of the workshop. The workshop will be closed with a plenary & interactive session.

All papers will be selected by members of the Programme Committee, following a Call for Abstract which was published at https://avindhsig.wordpress.com/workshop-2016-krakowcfp/

Programme Committee

Prof. Franciska de Jong, Erasmus University Rotterdam / CLARIN ERIC (chair)

Big Data: Complex Systems and Text Analysis

William Kretzschmar
kretzsch@uga.edu
Department of English, University of Georgia, United States of America

Allison Burkette
burkette@olemiss.edu
Department of Modern Languages, University of Mississippi, United States of America

Jacqueline Hettel
jacqueline.hettel@asu.edu
Nexus Lab, Arizona State University, United States of America

A complex system (CS) is a system in which large networks of components with no central control and simple rules of operation give rise to complex collective behavior, sophisticated information processing, and adaptation via learning or evolution. The order that emerges in human language is simply the configuration of components, whether particular words, pronunciations, or constructions, that comes to occur in our communities and occasions for speech and writing. Nonlinear frequency profiles (A-curves) always emerge for linguistic features at every level of scale. Three recent books have embraced CS and developed ideas about it much more fully. Kretzschmar has demonstrated how complex systems do constitute speech in *The Linguistics of Speech* (2009), focusing on nonlinear distributions and scaling properties. Kretzschmar's *Language and Complex Systems* (2015) applies CS to a number of fields in linguistics, including a long chapter on sociolinguistics. Finally, Burkette 2016, *Language and Material Culture: Complex Systems in Human Behavior*, applies CS to both the study of language and the anthropological study of materiality. In this workshop we wish to introduce some basic ideas about complex systems, including A-curves and scaling; talk about corpus creation with either a whole population or with random sampling; and talk about quantitative methods, why "normal" statistics don't work and how to use the assumption of A-curves to talk about document identification and comparison of language in whole-to-whole or part-to-whole situations like authors or text types. A knowledge of emergent patterns in the CS of a language can cut through the problem of "noise" currently faced in NLP experiments that restrict findings to probabilities little more than chance.

We will start the workshop with a 60 minute (40 minute explanation and demonstration, 20 minute experiential learning) general introduction by Burkette to basic terms in CS such as "states" and "emergence," and also apply those principles to language in the form of nonlinear frequency distributions and scale-free networks (as from Kretzschmar 2009). The introductory section will acquaint the audience with how the operation of a CS leaves characteristic patterns in language as people use it. One feature of the introduction will be the use of a computer simulation (Kretzschmar) so that the audience can see the process in action, not just observe its end products.

We will then organize the workshop in two additional parts: 1) Hettel, CS and Corpus Creation; 2) Kretzschmar, CS and Quantitative Measurement. In each part, we will offer explanation and demonstrations for 40 minutes, and allow 20 minutes for experiential learning. Hettel will present a rationale for corpus creation using methods of random sampling. For work on language in texts, this means using either an entire population of texts (such as all the novels by one author) or, more usually, a rigorously sampled selection of texts from a population. Either an entire population of texts or a random sample is required in order to avoid undue influence from any subsection of texts, since CS distributions emerge in every subgroup of texts. Using the example of documents from the nuclear power industry, Hettel will illustrate how a random sample can be created using quotas for each variable to be investigated. Kretzschmar will discuss the problem that frequency patterns that emerge from a CS are always nonlinear, never "normal" in the sense required for use of typical Gaussian statistics. He will present a method to assess just how nonlinear a frequency profile is so that A-curves can be distinguished from normal distributions, and then will discuss how emergent frequency profiles from a CS can be usefully described and differentiated. The discussion will conclude with examples of whole-to-whole and part-to-whole comparisons that take advantage of emergent A-curve patterns.

The organizers will provide data for participants to use on their own laptops. Participants should have a spreadsheet program (Excel, or something that reads Excel files) in order to process the data.

TEI Processing Model Toolbox: Power To The Editor

Wolfgang Meier
wolfgang@existsolutions.com
eXist Solutions

Magdalena Turska
tuurma@gmail.com
eXist Solutions

Crossing the divide between encoded XML sources and tangible, published digital edition has always been a weak spot for TEI community. Recent efforts of the TEI Simple project aimed to bridge that gap with TEI Processing Model idea. TEI Processing Model Toolbox, an eXist-db based application brings the promises of TEI Simple (Rahtz et al., 2015) to life with its implementation of the processing model enhanced with an app generator, allowing to create standalone digital editions out of the box.

Publishing an edition from TEI sources so far involved tedious work on complex stylesheets and significant effort in building an application on top of it. Using the TEI Processing Model, customising the appearance of the text is all done in TEI ODD by mapping each TEI element to a limited set of well-defined behaviour functions, e.g. “paragraph” or “heading”. The TEI Processing Model specification includes a standard mapping, which can be tweaked by overwriting selected elements. Rendition styles are transparently translated into different output media types like HTML, XSL-FO, LaTeX, or ePUB. This approach easily saves thousands of lines of code for media specific stylesheets. The power of the eXist-db database and the application framework on the other hand take care of all the other core features like browsing, search and navigation.

The proposed workshop intends to introduce the concepts of the TEI Processing Model and provide a tutorial on how to use TEI Processing Model Toolbox (Meier et al, 2016) app to experiment and try out various ODDs containing processing model instructions, upload users’ own files and create a custom ODD, and, finally, generate their own, standalone edition using the App Generator. As an inspiration it will also present examples of real apps built with App Generator and other systems employing TEI Processing Model.

It is hoped that exposure to the concepts and technologies presented during the workshop will give its participants a point of exit in the task of publishing their own research data. The subject of the workshop is also strongly tied to a short paper on practical lessons from applying the TEI Processing Model that will be presented later at the DH2016, giving interested participants the opportunity to be introduced to the concept in a much more detailed manner than is possible during brief conference talk.

> Internet is a revolution that will not stop "until everything is digitized", Louis Gerstner, former Chairman of IBM, quoted in *the Economist*, June 4th 1998

Description

The goal of this workshop is twofold: First, to provide a venue for researchers to describe and discuss practical methods and tools used in the construction of semantically annotated text collections, the raw material necessary to build knowledge-rich applications. We expect such tools to include lexical and semantic resources with a focus on the interlinking of concepts and entities and their integration into corpora.

A second goal is to report on the on-going development of new tools for providing access to the rich information contained in large text collections. Semantic tools and resources, notably, are reaching a quality that makes them fit for building practical applications. They include ontologies, framenets, syntactic parsers, semantic parsers, entity linkers, etc. We are interested in examples of cases that make use of such advanced tools and their evaluation in the field of digital humanities, with a specific interest on multilingual and cross-lingual aspects of semantic processing of text.

Topics of interest

- Construction and use of ontologies for text collections
- Entity nomenclatures and bridging
- Integration of lexical knowledge in text collections
- Visualization, user interfaces
- Semantic repositories: Entities and propositions
- Interlinking of concepts and entities in multilingual text
- Representing inter-textual relations
- Semantic search and information retrieval
- Tools for semantic annotation
- Timeline-based approaches such as "culturomics"
- Technical infrastructures and standards
- Quality evaluation
- Applications in digital humanities

Invited speakers

The workshop will include one, possibly two, invited speakers of international reputation.

Motivation

One of the consequences of the digital revolution is the gradual, but inexorable availability of all kinds of text in a machine-readable format. Libraries around the world scan their collections. Newspapers offer their articles on the web. Governments put their archives and laws online. A large part of what the human mind has produced: Literature, essays, encyclopedias, biographies, etc., is, or will be, accessible in a computerized form in a wide variety of languages. Within a few years, we can predict that (nearly) all text ever produced by humanity will be available in digital form: Either born digital or digitized from books, newspapers, archives, etc.

While digitization is well underway, turning the information contained in these texts into exploitable knowledge in the information society has become a major challenge as well as a major opportunity. IBM Watson and Google's knowledge graph are recent and spectacular achievements that show the significance of knowledge extraction from text. IBM Watson is a system that can answer questions in the US Jeopardy quiz show better than any human being. One of its core components is the PRISMATIC knowledge base consisting of one billion semantic propositions extracted from the English version of Wikipedia and the New York Times, while Google's knowledge graph is based on a systematic extraction of millions of entities from a variety of sources. Such technologies are defining the information age, and they have the potential to bring a much higher degree of sophistication to "distant-reading" methodology in digital humanities, enabling large-scale access to text content.

Audience

The target audience is a mix of users that would like to apply semantic processing techniques to text and researchers in this area. Users, for instance, could be interested in the extraction of entities and their association with encyclopedic text or the extraction of relations from text: date and place of birth/death, profession, etc. Researchers would describe practical techniques and algorithms that could fit the needs of the users.

Mining Texts with the Extracted Features Dataset

Peter Organisciak
organis2@illinois.edu
University of Illinois at Urbana-Champaign, United States of America

J. Stephen Downie
jdownie@illinois.edu
University of Illinois at Urbana-Champaign, United States of America

The HathiTrust Digital Library holds digitized copies of nearly 15 million scanned volumes from libraries around the world. These volumes are a significant resource for large-scale research: with their scale and breadth of material, a digital humanities scholar can make new inferences on history, language use, cultural trends, or even the structure of the printed word. However, access is complicated by the complexities of navigating copyright laws around the world, while use of the materials is impeded by the effort and technical demands of a researcher. To address both of these issues, the Extracted Features (EF) dataset from the HathiTrust Research Center (HTRC) provides volumes in a format that has already been cleaned, extracted, and tagged for computation use.

In this hands-on tutorial, participants will learn to use the Extracted Features dataset for text analysis alongside the HTRC Feature Reader library, equipping them to perform research on millions of publicly-accessible volumes. Through the HTRC Feature Reader, participants will be make use of popular data science tools in Python for EF dataset analysis, and will be left with demonstrative materials to repurpose in their future work.

Data

The Extracted Features (EF) dataset from the HathiTrust Research Center (Capitanu et al., 2015) provides an open and permissive download of page-level extracted information for every page of 4.8 million volumes from the HathiTrust Digital Library. A "feature" refers broadly to a quantitative measure of some property in a dataset; for example, the number of times a word appear on a page. The EF data features include part-of-speech-tagged term counts, line and sentence counts, counts of the characters occurring on the far left and far right side of a page, and inferred language probabilities. Most notably, this information is provided *for every page*. Also, headers, body, and footer have been identified and features are provided separately for each part.

In the tutorial, participants will learn the significance of each feature, such as using line counts and character information to identify the type of content on a page, or using part-of-speech tags for improving topic models based on content.

Skills

This tutorial introduces participants to introductory text analysis in Python using the Extracted Features dataset with the HTRC Feature Reader. This includes accessing term counts and other raw information, slicing within that data, visualization trends within or across books, and leading into advanced techniques like topic modeling and sentiment tagging.

The skills taught in this tutorial are underpinned by programming in Python using a popular set of data science libraries. All code examples are provided, though they are most useful if participants are comfortable in tinkering and have a familiarity with Python's basic conventions. Our intention is to make the code examples transparent enough so as to be easily modifiable by beginner users.

A participant completing the workshop will understand:

- the structure and possibilities of the HTRC Extracted Features Dataset;
- how to access the EF dataset files, both for individual and bulk use;
- how to start a Jupyter notebook, an accessible browser-based approach to data science in Python;
- the fundamentals of reading volume files, accessing metadata, and slicing and grouping token lists;
- basic visualization of EF data; and
- an advanced analytic technique modeled on recent digital humanities methods, discussed below.

The first part of the tutorial teaches the fundamental skills for working with the HTRC Feature Reader. For the final exercise of the tutorial, participants have a choice from prepared advanced exercises, which instructors will assist individually. This structure accommodates more intensive approaches in the time given, while also leaving participants with more examples for practicing their newly-acquired skills in the future.

The advanced exercises to be provided are: classification of paratext, using features suggested by Underwood (2014); visualization of sentiment trends in books as a proxy for a plot arc as previously performed by Jockers (2015), and within-book topic modeling using the inference approach presented by Organisciak et al. (2015).

Summary

The EF dataset offers a diverse and incredibly large collections of works for analysis in an easily accessible way. By providing these works as already extracted data, the EF dataset covers a large part of the text analysis workflow for researchers and is thus particularly suited for learners. This tutorial will use EF to teach text analysis through Python, using new software called the HTRC Feature Reader. By the end, students will be able to slice, group, and manipulate individual volumes for their needs, and will be familiar with techniques for modeling texts, identifying pertinent pages, and plotting trends across books.

Reflectance Transformation Imaging (RTI) for Cultural Heritage Artefacts

Konstantinos Papadopoulos
cpapadopoulos84@gmail.com
An Foras Feasa, Maynooth University, Ireland

Introduction: Description of the Method

Reflectance Transformation Imaging (RTI) is a non-invasive/non-contact method that has its roots in the principles of raking light (light from a low angle) that has been extensively used in museums and other heritage contexts since the 1930s. RTI only requires regular photographic equipment (DSLR camera, tripod, and a portable flashlight) and freely available software developed by Hewlett Packard Labs (Malzbender et al., 2001) and the non-profit organisation Cultural Heritage Imaging (http://culturalheritageimaging.org/). Also, it can be used both indoors and outdoors and there is no limitation regarding the size or the material of the subject-matter. Using a digital camera and a light source (flash or other point light) RTI can enhance objects' subtle surface details and interactively relight them resulting in levels of information that would have been lost by using conventional photographic techniques. In addition, dynamic shading methods by a series of predefined computational algorithms can further enhance the perception of surface characteristics (Figure 1), therefore making the identification of minor details, such as flaking, scratches, and fingerprints, possible.

The method has been extensively used on a wide range of cultural objects, such as inscriptions, manuscripts, rock art, paintings, numismatics and any possible material including metal, stone, leather, paper, wax, bone, and clay (Earl et al., 2010; Kotoula and Kyranoudi, 2013; Newman, 2015; Díaz-Guardamino et al., 2015). Conservation practice has also benefitted from the capabilities of the method since it provides very high resolution and great level of detail that helps in the identification of conservation needs and the establishment of preventive conservation measures (Kotoula, 2014).

Relevance to the Digital Humanities

Many disciplines within the Humanities have a long tradition in using imaging methods for recording and investigating cultural heritage artefacts. Computational Imaging methods, such as photogrammetry, multispectral photography, and RTI provide a whole new way of extracting information from digital photographs and producing new interactive visualisations that enhance traditional modes of working with the photographed subjects. RTI is a method that has already proven its capabilities in a wide range of contexts. The use of low-cost equipment, the ease of use, the speed of capturing and processing datasets, and most importantly the results obtained, offer users many opportunities to approach artefacts in different ways beyond conventional digitisation practices. However, RTI has not been widely used in Humanities datasets, not only because text is the main source but also due to the fact that bibliographic resources about applications and technical developments of the method are relatively scattered in areas that humanists are not very familiar with, such as archaeology and computer science. In addition, such new methods of working with cultural heritage datasets bring to the front new challenges, such as the creation of interactive online repositories, different ways of sharing processes and results, community engagement (Beale and Beale, 2015), and digital preservation.

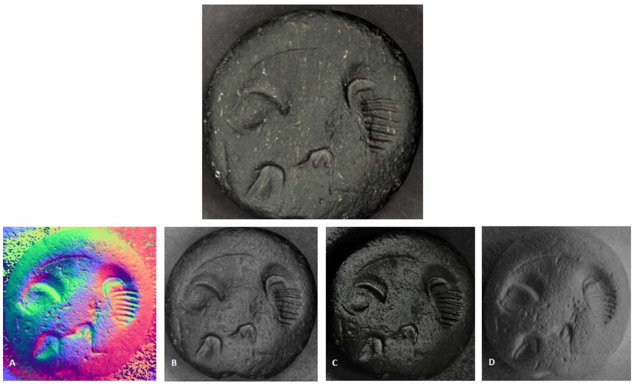

Figure 1: Reflectance Transformation Imaging on a steatite seal from Zominthos, Crete, Greece. Top: Conventional Digital Image. Bottom: Dynamic shading algorithms: A. Normal maps; B. CoefficientA5; C. Specular Enhancement; D. CoefficientA3

Method of Delivery

The tutorial will combine lecturing and hands-on practice. Participants will have the chance to learn and practice all the different stages involved in RTI - from capturing to processing and viewing as well as embedding results to webpages using the WebRTIViewer (http://vcg.isti.cnr.it/rti/webviewer.php). During the tutorial, they will capture new objects but they will also process and view pre-captured datasets. These datasets ensure that participants will work on material that has been properly captured and is of sufficient quality for all the different stages involved. Participants are also welcomed to bring artefacts that they would like to capture and process with the RTI method during the session.

Does your library or digital humanities center employ graduate students? Are you considering employing graduate students in digital scholarship work at your university? This full-day workshop will bring together institutions that do to discuss the variety of institutional arrangements for employing graduate students in digital scholarship labor. If graduate students can help build capacity for digital work on your campus, what are some best practices for structuring their employment? What are some current models in place, and what are the benefits and challenges of fellowships vs. part time employment or RAships? This workshop will present helpful practical advice on this topic, but also serve as a starting point for a broader discussion about the place of student labor in DH work.

Graduate students represent valuable members of digital humanities teams in a variety of institutional and library settings. They collaborate with scholars in labs, as members of project teams, as fellows, interns, instructors, research assistants, principal investigators, and everything in between. In her 2015 Office of Digital Humanities keynote presentation entitled "on capacity and care," Nowviskie argued that, as we continue to build individual, institutional, and even national capacity for digital scholarship in higher education, we should make an "ethic of care" the foundation upon which we work. This workshop will address how libraries and digital humanities organizations can make an ethic of care the foundation upon which their varied graduate student labor arrangements are built as they look to expand capacity within their institutions and beyond. Workshop participants will discuss the benefits, challenges, and best practices for the wide variety of institutional arrangements that result in graduate students doing DH work in libraries and DH organizations today.

Efforts to forge a global digital humanities community are continually hampered by linguistic divides. Fiormonte argues that non-Anglo American DH is largely ignored by the dominant Anglo-American hegemony in the field: "But from the point of view of the scientific results, research projects, and institutional presence, Informatica Umanistica, like most of the "other" DH practiced in the world, practically doesn't exist" (Fiormonte, 2012). Rockwell asserts that lack of access to this "other" DH diminishes DH as a whole: "...it is precisely when thinkers make strange what you thought you knew that you can think about it afresh. This would be thinking-through translation. This is the message Domenico Fiormonte returns us to when arguing for multiculturalism in the digital humanities" (Rockwell, 2016).

Even when many aspects of global DH practices are not dependent on language, especially within a scholarly community that has adopted a *lingua franca*, multilingual translation is a productive avenue to explore the situatedness and locality of global DH work. It is also an indispensable basis to interlink peripheral, border, global south DH practice with mainstream and canonical DH work (Ortega, 2016). Galina poses language as a potential mode of inclusiveness, given the dominance of a few countries/institutions and English language in DH, a dominance that is reflected from academia writ large. She suggests: "… there are some indicators that there is an interest by the main DH organizations of proposing alternative models that can, if not solve, at least alleviate this phenomenon. There are two approaches: the first is making more information available in other languages and the second is making English, used as the *lingua franca*, more accessible to non-native speakers" (Galina, 2014).

How can we move beyond a monolingual DH, and promote exchange of works among linguistic communities? And how can we ensure this exchange is ongoing and sustainable? This hack-a-thon brings together practitioners from two ADHO SIGs--Global Outlook::Digital

Humanities and the Libraries and DH SIGs--and a primarily monolingual dh community project--*dh+lib*-- in an attempt to hack a solution. The half-day hack-a-thon will work on a pilot that models a translation process for a particular publication, *dh+lib*, that could be applicable to other scholarly communication vehicles and venues. The group will think through existing infrastructure, address questions around translation, labor, and design, and perform hands-on translation of works nominated by the DH and libraries community. Translation is, of course, more art than science, and any attempt to build a multilingual dh/libraries exchange must acknowledge the complexity of the undertaking. Thus the hack-a-thon builds upon previous translation exercises put into practice by both SIGs and *dh+lib*, like DH Whisperers (Ortega et al., 2015) and simultaneousbilingual publication of blog posts (Galina et al., 2015).

Despite the clear need for and benefit of broader translation in the DH community, translation is shied away from, perhaps due to a perceived inability to deal with the associated costs or develop the necessary skills. By applying the Translation Toolkit developed by GO::DH, the hack-a-thon will position translation as achievable. The Translation Toolkit gathers a catalogue of readily available tools and suggested practices to approach the sometimes daunting task of translating and preparing multilingual resources, whether at conferences, in editorial and authorial journal work, and website and resource developments. During the hack-a-thon, participants will be able to explore and put into practice the materials available in the toolkit in order to launch the translation exercises and the design of sustainable multilingual workflows at the center of the session. Further, the Translation Toolkit proposes translation and multilingual exchanges based on distributed community efforts like those put into practice by *dh+lib*.

The focus on *dh+lib* as a pilot project is notable. A community publication project, *dh+lib* was launched in 2012 by a group of librarians to enable exchange at the intersection of digital humanities and librarianship. *dh+lib* has enjoyed support from the Association of College & Research Libraries and the ADHO Libraries and DH SIG. The project includes an active site, featuring original posts, a weekly *Review* round up (using the PressForward curation tool and a multi-tiered process of editorial review), and resource pages. More than 200 volunteers and 50 authors have contributed to the site; according to GoogleAnalytics, more than 38,000 users have accessed the site. Modeled on *DHNow*, the *Review* engages volunteer editors-at-large, who develop conversance with current scholarship in digital humanities while using their Library and Information Studies expertise to bring important work by libraries to a broader audience. Editors come from a variety of professions, disciplines, and institutions (both within and outside the United States), and form a distributed community of practice connected through the collaborative hub of this participatory project. This, then, provides an ideal use case to test out the mechanisms of collaborative translation: how would a multilingual *dh+lib* function? Could this editorial system of nomination and curatorial intervention be extended to operate as a translation hub?

Building in translation as a feature of aggregation and community-based distribution will benefit the global DH community by facilitating timely cross-linguistic exposure and dialogue. Since its approval as an ADHO SIG, GO::DH has sought to “leverage the complementary strengths, interests, abilities and experiences of participants through special projects and events, profile and publicity activity, and by encouraging collaboration among individual projects, institutions, and researchers” (Global Outlook::Digital Humanities, n.d.). The collaborative hack-a-thon seeks to take full advantage of both SIGs’ pre-existing communities, the multilingual and translations initiatives previously put into practice, and the content nomination practices of *dh+lib*. The convergence of expertise will allow us to investigate approaches for sharing the labor of translation and making use of existing channels.

This hack-a-thon will prepare attendees to engage in translation work and will continue conversations around translation practices and existing workflows. It will offer participants practical and adaptable approaches to developing comfort with and practices around translation in their own institutions and endeavors. Additionally, it will provide the workshop presenters with feedback from potential users, which will help guide development of both the Translation Toolkit and a more international *dh+lib*.

We anticipate that this event, situated as it is at the beginning of DH2016, will stimulate conversations on translation and linguistic diversity that will permeate other conference events. We further expect that it will connect participants in both SIGs and serve as the basis for an ongoing collaboration throughout the year on translation workflows. We envision hosting follow-up sessions in Montreal in 2017 and Mexico City in 2018 to regroup, report progress, and continue to articulate strategies for increasing translated material among our communities, publications, and projects.

Scheduled for 12 July 2016, this Digital Humanities 2016 workshop will explore the practice and influence of minimal computing from both a practical and theoretical perspective. We use "minimal computing" to refer to computing done under some set of significant constraints, including constraints of hardware, software, education, network capacity, infrastructure, and power. Minimal computing is also used to capture the maintenance, refurbishing, and use of machines to do work out of necessity, along with the choice to use streamlined computing hardware, such as Raspberry Pi or Arduino.

In essence, it calls for the reduction of the technical infrastructure required to produce, disseminate, and preserve digital scholarship. Put this way, it can reduce external dependencies (such as reliance on proprietary software, network infrastructure, or complex technology stacks), help communities to assert some control over their content, and facilitate sharing and preservation. This dichotomy of choice versus necessity underscores technology that is arguably not the high-performance computing of high-income economies. By operating within this tension between choice and necessity, minimal computing brings important concepts and practices within digital humanities to the fore. In this way it is also an intellectual concept, akin to environmentalism, asking for balance between gains and costs in areas including social justice, manufacturing, waste, and labor.

The workshop will engage questions such as (but not limited to):

- What are best practices for application construction in order to maximize access, decrease obsolescence, and reduce e-waste?
- How and in what ways does experience in mid- and low-income economies inform ongoing assumptions about how research and collaboration are conducted in high-income economies?
- In terms of computing and culture, what meaningful differences emerge across economical, infrastructural, and material conditions?
- In and beyond digital humanities, what is implied by minimalist design, and to what effects on practice?
- In digital humanities and other contexts, what research is being conducted with which physical computing technologies, how, and why?
- How do the different histories of minimalism in art, design, and industry form genealogies for minimalism in computers? Or what interesting work are people currently doing with minimal computing in areas such as art, design, and experimental media?

Despite its fundamental concerns, minimal computing still lacks a cogent research agenda within digital humanities. As such, this workshop aims to bring like-minded researchers from a variety of disciplines to the same space to share work in progress and collectively articulate lines of future inquiry.

Format

The workshop will blend delivery of short papers (or thought pieces) with seminar discussion, demonstrations, and prototype testing.

9:30am-12:30pm: The first half of the workshop will consist of 8-10 presentations, together with focused discussion of the presenters' minimal computing projects. Presentations and projects will be drawn from responses to a workshop CFP circulated in March 2016.

1:30pm-4:00pm: Participants will collectively develop a research agenda for minimal computing, with all participants collaborating to identify projects, build ideas, share and test prototypes, and articulate collective interests. Where applicable, participants will demonstrate workflows and projects involving physical computing platforms such as Raspberry Pi and Arduino.

Participation

Participation in the workshop may range from presenting a paper or sharing a prototype to responding to presentations, testing prototypes, or simply observing to learn more about minimal computing practice and theory.

Working with WissKI – A Virtual Research Environment for Object Documentation and Object-Based Research

Martin Scholz
martin.scholz@fau.de
University Erlangen-Nürnberg, Germany

Dorian Merz
dorian.merz@fau.de
University Erlangen-Nürnberg, Germany

Guenther Goerz
guenther.goerz@fau.de
University Erlangen-Nürnberg, Germany

In recent years semantic technologies have become increasingly popular to represent, manage and publish data in the humanities. Virtual research environments with semantic backends are used to build complex networks, data is exposed as triples using RDF, and important vocabularies and thesauri are available as linked data. Ontologies like the CIDOC Conceptual Reference Model (CRM) are the semantic backbone of this approach and provide interoperability and data exchange beyond pure linking.

WissKI (wiss-ki.eu) is a ready-to-be-used web-based virtual research environment and publishing framework that in its core relies on Semantic Web technologies to represent the curated knowledge. The user experience for data acquisition and presentation, however, intentionally borrows from traditional modes, while the user profits from the possibilities of linked and semantically enriched data. Thus, the system enables digital humanists to produce high-quality linked data, without having to cope with technical issues of the Semantic Web and ontologies in general or the often-quoted pecularities of CIDOC CRM in particular. This is achieved by defining a mapping between traditional index card or tabular style on the one hand and graph-based linked data on the other hand. The mapping may be opaque to the users and only be managed by an (ontological) administrator. Also, mappings may be shared between systems and projects, so that best practice patterns may evolve; this actually already has happened and still happens.

By default, data may be input and displayed either as free text or as structured data via forms. Free text may be input through a graphical editor and is semantically indexed in terms of named entity recognition results, calendar date specifications, mentioned events, and also technical terms as far as appropriate authority files are available (e.g. Getty's Art and Architecture Thesaurus). Form input provides mechanisms for error reduction like spelling variants, e.g. by showing autocompletion hints that are again backed by available authorities. From the textual annotations, RDF triples may be generated and be reused as structured data. Furthermore, the system allows the upload, derivation and display of images. Other, more application-specific ways of data acquisition like mass imports or 2D/3D annotation may be included through extensions.

From the technical perspective, WissKI is based on Drupal (drupal.org). Drupal is a widely used Web Content Management System with a big and active user and developer community. It has a modular architecture and there exists a vast variety of third party extension. Being such an extension, WissKI profits from a stable core system (security updates!) and also from these community contributions, providing all sorts of functionality.

As Drupal itself, WissKI is published as open source and can be downloaded from the project web site (wiss-ki.eu) or from github.

Although WissKI in its core is domain-agnostic, it is designed to best fit the needs of object centered documentation and research as it is typical for many memory institutions, but also for research projects from art history, biodiversity, architecture, epigraphy, etc. As such it naturally goes together with the CIDOC CRM, an ontology designed for the documentation of cultural heritage. It is used by several academic and memory institutions in Germany in national and international research projects; it is used for such diverse purposes as research environment, curated collection management, virtual exhibition, or in courses and seminars.

The tutorial aims at all researchers, archivists and curators who are interested in object documentation, in particular its semantic disclosure integrating data from (database and content management systems) form-based input and plain text fields. Furthermore it addresses people interested in applications of the CIDOC CRM.

This half-day tutorial

- gives a short introduction to the (technical) approach of WissKI,
- presents current use cases and modes of use,
- shows how to install, configure, and use WissKI, and
- includes a hands-on for semantic modelling and data acquisition with WissKI and CIDOC CRM.

Digital Archiving and Storytelling in the Classroom with Omeka and CurateScape

Victoria Szabo
ves4@duke.edu
Duke University, United States of America

Hannah Jacobs
hj24@duke.edu
Duke University, United States of America

Edward Triplett
edward.triplett@duke.edu
Duke University, United States of America

Digital Archives and Exhibitions are one of the most accessible ways to bring historical and cultural materials into public circulation. This tutorial is an intensive introduction to archive development and storytelling within the Omeka content management and exhibition system (http://omeka.org/), which was developed by George Mason University's Roy Rosenzweig Center for History and New Media. This tool has been tested in a variety of academic and cultural heritage settings and was developed with extensive input and revision from the academic community. Omeka enables users to input various types of digital media content using standardized metadata structures, to organize them into Collections, and to present them in multimedia digital narratives known as Exhibitions. The platform is easy to use, and can be installed as a package in many web hosting environments. We will also demonstrate the use of the CurateScape plugin, which allows users to create location-based itineraries drawn from Omeka items optimized for mobile devices. CurateScape (http://curatescape.org), developed by the Center for Public History and Digital Humanities at Cleveland State University, can be used in a wide variety of settings. They are freely available with the only cost to the scholar being web hosting. These advantages make both tools ideal for diverse classroom settings.

Over the course of the tutorial we will introduce participants to the principles of digital archive collection development using exercises developed for the Duke University Wired! Lab for Digital Art History and Visual Culture tutorials. Content types may include digital images, audio files, 3D models, video, text facsimiles, and other source materials. These Items may be annotated with descriptive elements, locations, and other metadata relevant to search and presentation. We will explore data input formats and techniques as part of the hands-on exercises. Items in Omeka may also be organized into location-based Tours using the CurateScape Framework, a set of freely available themes and plug-ins.

In addition to providing a technical, hands-on overview of the system, we will discuss data management and digital storytelling strategies for online archives and exhibitions that take advantage of these and other tools to support their successful use in a classroom setting. We will reflect on digital pedagogy by sharing examples of successful project-based seminars that have taken advantage of Omeka based systems to scaffold course assignments around topics including discovery and remediation of analog content into digital form; integration of secondary historical and critical sources into a dynamic archive; development of taxonomies and data structures; exploration of ways to collaborate on digital media project development; recontextualization of historical objects and locations; and presentation strategies for diverse audiences in academia and in the wider public. Participants in the session will come away with a solid understanding of the features of the Omeka system, the knowledge to create their own archives, strategies for teaching with these tools, and the ability to communicate their support needs to tech professionals in their local communities.

Our plan for the session is to provide a basic Omeka installation for each participant on our shared server in the Wired! Lab, and to provide instructions to users who wish to set up their own sites on Reclaim Hosting or another hosting platform. The mobile component of the tutorial will require users be able to access wifi or local data. We will bring a few devices for users to test their projects on.

Contact Info

Victoria Szabo, Associate Research Professor, Visual and Media Studies, Duke University, ves4@duke.edu

Szabo's primary research focus is on media history and the critical and practical affordances of database-driven spatial media such as digital maps, games, virtual worlds, and mobile applications for teaching, research, and public outreach. She is especially interested in theories and practice of augmented reality experience design for digital heritage and creative expression, and has worked on location-based urban AR projects in Durham, NC and Venice, Italy, among other places. Her NC Jukebox digital audio archive project relies on the Omeka platform. She also develops art-games with the Psychasthenia Studio. She holds a PhD in English from the University of Rochester and is the Director of Duke's Information Science + Information Studies Program and the Duke Digital Humanities Initiative. Before coming to Duke she worked as an Academic Technology Specialist and Manager at Stanford University.

Hannah L. Jacobs, Multimedia Analyst, Wired! Lab, Duke University, hj24@duke.edu

Hannah holds a MA in Digital Humanities from King's College London and a BA in English/Theatre from Warren Wilson College. As Multimedia Analyst for the Wired! Lab at Duke University, she teaching web technologies, mapping, and 3D modeling tools for art history courses, as well as concepts for digital storytelling, historic mapping, and reconstruction. She teaches Omeka in a variety of course and humanities research contexts. She also consults on student-led faculty research projects and collaborates with digital humanities specialists across the university to develop workshops and resources for digital research. Hannah's research interests include digital narrative, visual storytelling, digital pedagogies, and public digital humanities.

Edward Triplett, CLIR Fellow, Duke University, edward.triplett@duke.edu

Ed recently received his PhD in the history of art and architecture from the University of Virginia. He also holds masters' degrees in 3D Modeling and Animation and in Medieval History. He is experienced with photogrammetry, virtual reality, and various interactive online presentation systems, and has instructional experience as a Visualization Specialist at UVA. As a CLIR (Council of Library and Informational Resources) postdoctoral fellow at Duke University, Ed partners with the Duke Library and the Wired! Lab to form data curation and project management plans for born digital and digitized materials. His dissertation research combined 3D modeling and GIS techniques to reconsider the architectural history of military-religious orders in medieval Iberia. His research interests include computer vision, agent-based modeling, augmented reality and data visualization.

Description of Target Audience and Number of Participants

Anyone looking for ways to implement digital storytelling and archiving tools with students. Participant limit is fifteen.

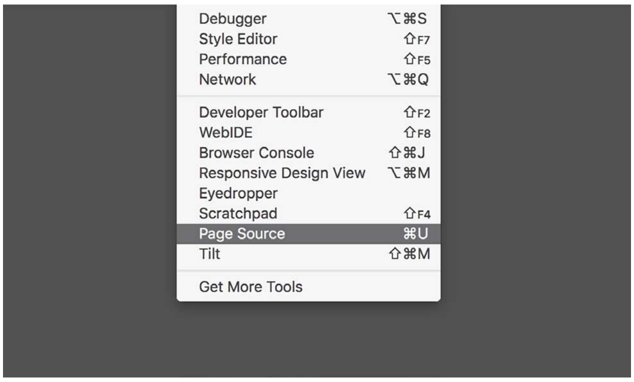
Tech Support Requirements

Participants must bring their laptops. Everyone will need internet access. Access to Omeka and CurateScape will be provided by the instructors.

View Source: Reading the Hidden Texts of the Web

Jeff Thompson
mail@jeffreythompson.org
Stevens Institute of Technology, United States of America

When discussing the web, the two layers of online experience we most often talk about are interactions and their underlying technology. We unpack the conversations and transactions happening online (anti-feminist rhetoric, how Twitter differs from Medium), and we discuss how algorithms shape those experiences (Facebook's decisions about what is in your feed, A/B testing). But at an intermediary level, an entire corpus is being written in Javascript variables and HTML comments , standardized but hidden files, and even the structure of websites themselves. This workshop will investigate these intermediary layers from a critical, exploratory point of view.



This workshop will use a hackathon-like methodology of play and exploration to maximize breadth and depth – the goal is creative and critical investigation rather than technical. After some short, fairly low-tech tutorials to introduce tools and methodologies, participants will spend the remainder of the workshop digging across the web and presenting their findings. All levels of technical expertise will be encouraged, as will ad hoc collaboration. Those with prior experience using the tools introduced are encouraged to dig deeper.

Workshop Leader

Jeff Thompson an artist, teacher, hacker, and writer whose work investigates the poetics of technology, how its functionality can provide access points for meaningful exploration, the agency of increasingly self-aware systems, and the physicalization of otherwise invisible processes. He is currently Assistant Professor and Program Director of Visual Arts and Technology at Stevens Institute of Technology.

Questions about this workshop: jeff.thompson@stevens.edu

Tech requirements

Participants should bring:

- A laptop with WiFi access
- An up-to-date version of Firefox installed (mozilla.org/firefox)
- Sublime Text text editor (free version is fine, sublimetext.com)
- If possible, please install wget (gnu.org/software/wget)
- Other text-mining/web tools of your choice

Introduction to Natural Language Processing

Lauren Tilton
lauren.tilton@yale.edu
Yale University, United States of America

Taylor Arnold
taylor.arnold@yale.edu
Yale University, United States of America

Brief Description

The application of computational tools to textual data is a growing area of inquiry in the humanities. From the culling of "Culturomics" via the 30 million document Google books collections, to the painstakingly detailed process of analyzing the text of Shakespeare's plays to ascertain their 'true' creator, a wide range of techniques and methods have been employed and developed. Text analysis in the humanities has also garnered an impressive level of interest in the mainstream media. For example, a study analyzing the relationship of a professor's gender to their teaching reviews and an overview of Franco Moretti's 'distant reading' both recently appeared in the New York Times. The Atlantic featured an historical critique of the language used in the period drama 'Mad Men', where textual analysis of the script revealed departures from the standard American English spoken in the 1960s. The majority of this work, however, relies on techniques such as n-grams and bag-of-word models. Recent developments in computational linguists, which have attempted to mimic the complex process by which humans parse and interpret language, are finding increased use within the humanities.

This workshop will introduce the basic components of modern natural language processing. Techniques include tokenization, lemmatization, part of speech tagging, and coreference detection. These will be introduced by way of examples on small snippets of text before being applied to a larger collection of short stories. Applications to stylometric analysis, document clustering, and topic detection will be briefly mentioned along the way. Our focus will be on a high-level, conceptual understanding of these techniques and the potential benefits of using them over models commonly employed for text analysis within humanities research. We will also introduce open-source software that is available for a wide range of programming languages (i.e., Java, R, Python, Ruby, Perl) and applicable for parsing an increasingly large number of natural languages (i.e., English, French, Spanish, Chinese, German, Turkish, Arabic). The workshop is based on a chapter from the instructor's book Humanities Data in R: Exploring Networks, Geospatial Data, Images, and Text (Spring, 2015).

Instructors

Taylor Arnold, is currently a lecturer in the department of statistics at Yale and senior scientist at ATandT Labs. His research focuses on the analysis of large, complex datasets and the resulting computational challenges. A particular area of focus is the sparse representation of highly structured objects such as text corpora and digital images. He is the technical co-director of the NEH funded project Photogrammar. Together with Lauren Tilton, he is the co-author of the text *Humanities Data in R: Exploring Networks, Geospatial Data, Images, and Text*.

Lauren Tilton, is a doctoral candidate in American Studies at Yale University. She is the Co-Director of Photogrammar (photogrammar.yale.edu) and Participatory Media (http://participatorymediaproject.org/). Research interests include 20th century U.S. history and visual culture as well as digital and public humanities. She is the co-author with Taylor Arnold of *Humanities Data in R: Exploring Networks, Geospatial Data, Images, and Text*. She will be joining the faculty at the University of Richmond as a Visiting Assistant Professor of Digital Humanities in Fall 2016.

Target Audience and Size

This workshop is accessible to participants from all backgrounds.

Brief Outline of Workshop

- Introduction to NLP
- Tokenization and Sentence Splitting
- Lemmatization
- Part of Speech Tagging
- Dependencies
- Named Entity Recognition
- Coreference resolution
- Overview and comparison of current software
- Stanford CoreNLPApache OpenNLPspaCy.io

Music Information Retrieval Algorithms for Oral History Collections

Sharon Webb

James Baker
james.baker@sussex.ac.uk
Sussex Humanities Lab, University of Sussex

Digital humanities, as a largely text based domain, often treats audio files as texts, retrieving semantic information in order to categorise, sort, and discover audio. This workshop will treat audio as audio. Taking oral history collections from the University of Sussex Archive of Resistance Testimony as a test case, participants will be lead through the use of Music Information Retrieval (MIR) approaches to categorise, sort, and support their discovery of an audio collection. Participants will also be supported in planning the extension of these approaches to explore audio collections that they know or work with.

All instructors for this workshop are from the new inter-disciplinary Sussex Humanities Lab at the University of Sussex. The workshop combines the diverse interests of the instructors to focus on the application of music technology to history and stems from this inherently collaborative environment.

Oral history best practice publications and resources often focus on the application and use of digital methods and tools to create, store and manage audio, audio-visual, and subsequent text files. They recommend, for example, standards for file formats, metadata and text encoding, software for audio to text conversion, and database and content management systems. However, while a number of projects provide innovative and useful tools that challenge the privilege of the text (i.e. Oral History Metadata Synchroniser), the majority of projects rely on the ability to encode an oral history interview to carry out further analysis using digital tools and methods. The analysis, therefore, is based on the text surrogate rather than the original audio source, but as Alessandro Portellii states this focus denies the 'orality of the oral source'.

Text encodings or transcripts of oral history interviews have their obvious advantages - they are easier to anonymise, distribute and store, and we have established techniques for text analysis. However, there are indications within the community that the privilege of this text based approach should be questioned given the ever increasing possibility for computational analysis of audio. This is evident in the Oral History Society's recent call for papers which remarks that the 'auditory dimension of oral history was for decades notoriously underused'.

In light of this loss of context and information this workshop will explore the original sources for the richer datasets which they afford. The field of MIR provides this opportunity. MIR draws from digital audio signal processing, pattern recognition, psychology of perception, software system design, and machine learning to develop algorithms that enable computers to 'listen' to and abstract high-level musical information from low-level audio data. Just as human listeners can recognize pitch, tempo, chords, genre, song structure etc, MIR algorithms are capable of recognizing and extracting this information, enabling systems to perform extensive sorting, searching, music recommendation, metadata generation, transcription on large data sets. Deployed initially in musicology research and more recently for automatic recommender systems, the research potential for MIR tools in non-musical audio data mining is being recognised (e.g. analysing bio-acoustic data for ecological purposes) but yet to be fully explored in the humanities.

The aim of this workshop is to help the digital humanities community explore the possibilities of MIR in a practical and methodological fashion within context of oral history collections. Our participatory design approach enables development for a broader scope of problems and support participants to challenge current methodologies for oral history analysis. We seek to apply an objective analysis based on the content of the source material in its entirety and complement or challenge human and text based analysis with computational methods. By applying MIR algorithms to a field that traditionally privileges text we hope to add new understandings and interpretations to rich audio resources.
